Business Rule API - ServiceNow Fluent

The Business Rule API defines server-sides scripts [sys_script] that run when a record is displayed, inserted, updated, or deleted, or when a table is queried.

For general information about business rules, see Classic Business rules.

Related topics

ServiceNow Fluent

BusinessRule object

Create a business rule [sys_script] that automatically changes values in form fields when certain server-side conditions are met.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A name for the business rule.
table	String	Required. The name of the table on which the business rule runs.
script	Script	A custom script runs when the defined conditions are true. This property supports a function from a JavaScript module, a reference to another file in the application that contains a script, or inline JavaScript. Format: • For functions, use the name of a function, function expression, or default function exported from a JavaScript module and import it into the `.now.ts` file. For information about JavaScript modules, see JavaScript modules and third-party libraries. • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or `Script``.
order	Number	A number indicating the sequence in which the business rule should run. If there are multiple rules on a particular activity, the rules run in the order specified, from lowest to highest. Default: 100
active	Boolean	Flag that indicates whether the business rule is enabled.

Properties (continued)

Name	Type	Description
		Valid values: • true: The business rule is enforced. • false: The business rule isn't enforced. Default: true
when	String	The time that the business rule should execute. For more information about when business rules run, see How business rules work. Valid values: • before • after • async • display Default: before
action	Array	The record options that the business rule applies to. For more information about business rule actions, see How business rules work. Valid values: • insert • update • delete • query
addMessage	Boolean	Flag that indicates whether to add a message that appears when the business rule runs. Valid values: • true: Displays a message. • false: Doesn't display a message. Default: false
abortAction	Boolean	Flag that indicates whether to abort the current database transaction. For example, on a before insert business rule, if the conditions are met, don't insert the record into the database. Valid values: • false: Doesn't abort the current database transaction. • true: Aborts the current database transaction. You can't perform additional actions on the record,

Properties (continued)

Name	Type	Description
		such as setting field values and running scripts. You can still display a message to users with the *addMessage* and *message* properties. Default: false
message	String	A message that appears when the business rule runs.
roleConditions	Array	A list of variable identifiers of *Role* objects that users who are modifying records in the table must have for the business rule to run. For more information, see Role API - ServiceNow Fluent.
condition	String	A JavaScript conditional statement that specifies the fields and values that must be true for the script to run. This property supports inline JavaScript or a reference to another file in the application that contains a script. **Note:** Don't use this property if you include the condition statement with the *filterCondition* or *script* properties. By specifying the condition statement with this property, the condition is evaluated separately, and the business rule runs only if the condition is true. To have the condition statement reevaluated a second time before running an async business rule, set the *glide.businessrule.async_condition_check* system property to true. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script'` or `` `Script` ``.
filterCondition	String	A filter query that specifies the fields and values that must be true for the business rule to run. For more information, see Operators available for filters and queries.
setFieldValue	String	The values to set for fields in the table. This can be provided as an encoded query, such as `setFieldValue: 'sec_created=false^EQ'`.
description	String	A description of what the business rule does.
protectionPolicy	String	A policy that determines whether someone can view or edit the script include after the application is installed

Properties (continued)

Name	Type	Description
		on their instance. If undefined, other application developers can customize the script include. Valid values: • read: Allows anyone to read values from this downloaded or installed script include. No one can change script values on the instance on which they download or install the script include. • protected: Provides intellectual property protection for application developers. Customers who download the script include cannot see the contents of the script field. The script is encrypted in memory to prevent unauthorized users from seeing it in plain text.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { BusinessRule } from '@servicenow/sdk/core'
import { FunctionExport, FunctionExpression } from '../server/scripts.js'
import DefaultExportFunction from '../server/scripts.js'

const BR1 = BusinessRule({
    name: 'exportedFunction',
    table: 'x_snc_table',
    when: 'after',
    action: ['update', 'delete', 'insert'],
    script: FunctionExport,
    order: 100,
    active: true,
    addMessage: false,
    message: '<p>message</p>',
    abortAction: false,
    $id: Now.ID[0],
})

const BR2 = BusinessRule({
```

```
    name: 'businessrule2',
    table: 'x_snc_table',
    script: FunctionExpression,
    when: 'after',
    action: ['update'],
    $id: Now.ID[1],
})

const BR3 = BusinessRule({
    name: 'businessrule3',
    table: 'x_snc_table',
    script: DefaultExportFunction,
    when: 'after',
    action: ['update'],
    filterCondition:
 `sys_updated_onSTARTSWITHb^sys_updated_bySTARTSWITHm^EQ
    <item goto="false" or="false" field="sys_updated_on" endquery="false"
 value="b" operator="STARTSWITH" newquery="false"/>
    <item goto="false" or="false" field="sys_updated_by" endquery="false"
 value="m" operator="STARTSWITH" newquery="false"/>
    <item goto="false" or="false" field="" endquery="true" value=""
 operator="=" newquery="false"/>`,
    $id: Now.ID[2],
})

const BR4 = BusinessRule({
    name: 'templateBR',
    action: ['insert'],
    when: 'after',
    table: 'x_snc_table',
    roleConditions: [admin],
    order: 100,
    active: true,
    addMessage: true,
    message: '<p>message</p>',
    script: `gs.info('info')`,
    abortAction: false,
    $id: Now.ID[3],
})
```

Client Script API - ServiceNow Fluent

The Client Script API defines client-side scripts [sys_script_client] that run JavaScript on the client (web browser) when client-based events occur, such as when a form loads, after form submission, or when a field changes value.

For general information about client scripts, see Client scripts.

Related topics

ServiceNow Fluent

ClientScript object

Create a client script [sys_script_client] to configure forms, form fields, and field values while the user is using the form.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
table	String	Required. The name of the table on which the client script runs.
name	String	Required. The name of the client script.
active	Boolean	Flag that indicates whether the client script is enabled. Valid values: • true: The script is enabled. • false: The script isn't enabled. Default: true
appliesExtended	Boolean	Flag that indicates whether the client script applies to tables extended from the specified table. Valid values: • true: The script applies to extended tables. • false: The script doesn't apply to extended tables. Default: false
uiType	String	The user interface to which the client script applies. Valid values: • desktop • mobile_or_service_portal • all Default: desktop
description	String	A description of the functionality and purpose of the client script.
messages	String	Text strings that are available to the client script as localized messages using `getmessage('[message]')`. For more information, see Translate a client script message.
isolateScript	Boolean	Flag that indicates whether the script runs in strict mode, with access to direct DOM, jQuery, prototype, and the window object turned off. Valid values:

Properties (continued)

Name	Type	Description
		• true: Isolate the script and don't run it in strict mode. • false: Run the script in strict mode. Default: false
script	Script	A client-side script that runs in the browser. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script'` or `` `Script` ``.
global	Boolean	Flag that indicates on which views of the table the client script runs. Valid values: • true: The script runs on all views. • false: The script runs only on the specified views. Default: true
view	String	The views of the table on which the client script runs. This property applies only when the *`global`* property is set to false.
type	String	The type of client script, which defines when it runs. For more information about the supported types, see Client scripts. Valid values: • onCellEdit: Runs when the list editor changes a cell value. • onChange: Runs when a particular field value changes on the form. • onLoad: Runs when the system first renders the form and before users can enter data. Typically, *`onLoad()`* client scripts perform client-side-manipulation of the current form or set default record values. • onSubmit: Runs when a form is submitted. Typically, *`onSubmit()`* scripts validate things on the form

Properties (continued)

Name	Type	Description
		and ensure that the submission makes sense. An *onSubmit()* client script can cancel form submission by returning a value of false.
field	String	A field on the table that the client script applies to. This property applies only when the *type* property is set to onChange or onCellEdit.
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { ClientScript } from '@servicenow/sdk/core'

export const cs = ClientScript({
    $id: Now.ID['my_scripts'],
    name: 'my_scripts',
    table: 'incident',
    active: true,
    appliesExtended: false,
    global: true,
    uiType: 'all',
    messages: '',
    isolateScript: false,
    type: 'onLoad',
    script: Now.include('../client/client-script.js'),
})
```

The client script is defined in the `client-script.js` file referenced from the *script* property. For example:

```
function onLoad() {
     const x = 'util' g_form.addInfoMessage(x)
}
```

Cross-Scope Privilege API - ServiceNow Fluent

The Cross-Scope Privilege API defines cross-scope privileges [sys_scope_privilege] for runtime access tracking.

Runtime access tracking allows administrators to manage script access to application resources by creating a list of script operations and targets that the system authorizes to run. For general information about cross-scope privileges, see Cross-scope privilege record.

Related topics

ServiceNow Fluent

CrossScopePrivilege object

Configure cross-scope privileges [sys_scope_privilege] that determine which script operations and targets the system allows to run in the application.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
status	String	Required. The authorization for this record. Valid values: • requested • allowed • denied
operation	String	Required. The operation that the script performs on the target. The target type determines the available operations. Tables [sys_db_object] support the read, write, create, and delete operations. Script includes [sys_script_include] and script objects [sys_db_object] only support the execute operation. Valid values: • create • delete • read • write • execute
targetName	String	Required. The name of the table, script include, or script object being requested.
targetScope	String	Required. The application scope from which resources are requested.
targetType	String	Required. The type of request: script include, script object, or table. Valid values:

Properties (continued)

Name	Type	Description
		• sys_script_include • scriptable • sys_db_object
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { CrossScopePrivilege } from '@servicenow/sdk/core'

CrossScopePrivilege({
   $id: Now.ID['cross_1'],
   status: 'allowed',
   operation: 'execute',
   targetName: 'Script type',
   targetScope: 'x_snc_example',
   targetType: 'scriptable',
})
```

Dashboard API - ServiceNow Fluent

The Dashboard API defines dashboards [par_dashboard] for organizing and sharing data visually.

A dashboard consists of tabs, widgets, visibilities, and permissions. Each tab contains widgets that display data visualizations, headings, rich text, and other components.

Dashboards can be used as the home page of a workspace by referring to one or more workspaces from the *visibilities* array of the *Dashboard* object. To create a workspace, see Workspace API - ServiceNow Fluent.

For general information about dashboards, see Dashboards in Platform Analytics.

Related topics

ServiceNow Fluent

Dashboard object

Create a shareable dashboard [par_dashboard] with data visualizations, filters, tabs, widgets, permissions, and visibility rules.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A name to display for the dashboard.
active	Boolean	Flag that indicates whether the dashboard is active. Default: true
tabs	Array	A list of tabs to display in the dashboard. For more information, see tabs array.
permissions	Array	A list of user permissions required to access the dashboard. For more information, see permissions array.
visibilities	Array	A list of visibility rules that control which UX experiences display the dashboard. For more information, see visibilities array. Default: A default visibility rule with sys_id 08c73d60537101100834ddeeff7b1287 is used.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { Dashboard } from '@servicenow/sdk/core'

Dashboard({
    $id: Now.ID['incident-dashboard'],
    name: 'Incident Management Dashboard',
    tabs: [
        {
```

```
            $id: Now.ID['overview'],
            name: 'Overview',
            widgets: [
                {
                    $id: Now.ID['incident-count-chart'],
                    component: 'vertical-bar', // Vertical bar chart
                    componentProps: {
                        title: 'Incident Count',
                        dataSource: 'incident',
                        aggregation: 'count'
                    },
                    height: 8,
                    width: 6,
                    position: { x: 0, y: 0 },
                },
                {
                    $id: Now.ID['recent-incidents-list'],
                    component: 'list', // List component
                    componentProps: {
                        table: 'incident',
                        filter: 'active=true',
                        limit: 10,
                        columns:
['number', 'short_description', 'priority', 'state']
                    },
                    height: 8,
                    width: 6,
                    position: { x: 6, y: 0 },
                }
            ],
        },
        {
            $id: Now.ID['analytics'],
            name: 'Analytics',
            widgets: [
                {
                    $id: Now.ID['metrics-widget'],
                    component: 'single-score', // Single score component
                    componentProps: {
                        title: 'Key Metrics',
                        scoreSize: 'large'
                    },
                    height: 12,
                    width: 12,
                    position: { x: 0, y: 0 },
                }
            ],
        }
    ],
    permissions: [
        {
            $id: Now.ID['admin-user-permission'],
            user: '6816f79cc0a8016401c5a33be04be441', // sys_id of admin user
            canRead: true,
            canWrite: true,
            canShare: true,
            owner: true,
```

```
        },
        {
            $id: Now.ID['itil-role-permission'],
            role: '2831a114c611228501d4ea6c309d626d', // sys_id of itil role
            canRead: true,
        },
        {
            $id: Now.ID['support-group-permission'],
            group: '287ebd7da9fe198100f92cc8d1d2154e', // sys_id of IT Support
group
            canRead: true,
        }
    ],
    visibilities: [
        {
            $id: Now.ID['workspace-visibility'],
            experience: myWorkspace,
        }
    ]
})
```

The workspace referenced is defined using the *Workspace* object:

```
export const myWorkspace = Workspace({
  $id: Now.ID["my_workspace"],
  title: "My Workspace",
  path: "my-workspace",
  tables: ["incident"],
  listConfig: myListConfig
})
```

tabs array

Create tabs [par_dashboard_tab] that contain widgets for a dashboard.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A name to display on the tab.
active	Boolean	Flag that indicates whether the tab is active. Default: true
widgets	Array	A list of widgets to display in the tab. For more information, see widgets array.

Within a dashboard, tabs are ordered using their position in the array.

```
tabs: [
        {
            $id: Now.ID['overview-tab'],
```

```
            name: 'Overview',
            widgets: [
                {
                    $id: Now.ID['chart-widget'],
                    component: 'line', // Line chart component
                    componentProps: {
                        selectedElements: [],
                        chartVariation: 'stacked',
                        yAxisPosition: 'bottom'
                    },
                    height: 12,
                    width: 12,
                    position: { x: 0, y: 0 },
                },
                {
                    $id: Now.ID['header-widget'],
                    component: 'heading', // Heading component
                    componentProps: {
                        variant: 'header-primary',
                        label: 'Dashboard Metrics',
                        level: '1'
                    },
                    height: 4,
                    width: 12,
                    position: { x: 0, y: 12 },
                }
            ],
        },
        {
            $id: Now.ID['details-tab'],
            name: 'Details',
            widgets: []
        }
]
```

widgets array

Create widgets [par_dashboard_widget] within a tab in a grid layout.

Dashboards use a 48-point grid system for positioning widgets.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
component	Reference or String	Required. The name of a component (such as line or single-score) or the sys_id of a component from the UX Macroponent Definition [sys_ux_macroponent] table to display as a widget. Component names aren't case sensitive and resolve to their sys_ids during the build process.

Properties (continued)

Name	Type	Description
height	Number	Required. The height of the widget in grid units.
width	Number	Required. The width of the widget in grid units. Maximum value: 48
position	Object	Required. The position of the widget in the grid layout with `x` and `y` properties. For example, a value of `{ x: 0, y: 0 }` positions the widget in the top-left corner of the grid.
componentProps	Object	The property configuration of a component. For more information, see componentProps object.

```
widgets: [
                {
                    $id: Now.ID['incident-count-chart'],
                    component: 'vertical-bar',  // Vertical bar chart
                    componentProps: {
                        title: 'Incident Count',
                        dataSource: 'incident',
                        aggregation: 'count'
                    },
                    height: 8,
                    width: 6,
                    position: { x: 0, y: 0 },
                },
                {
                    $id: Now.ID['recent-incidents-list'],
                    component: 'list',  // List component
                    componentProps: {
                        table: 'incident',
                        filter: 'active=true',
                        limit: 10,
                        columns:
 ['number', 'short_description', 'priority', 'state']
                    },
                    height: 8,
                    width: 6,
                    position: { x: 6, y: 0 },
                }
            ],
        },
        {
            $id: Now.ID['analytics'],
            name: 'Analytics',
            widgets: [
                {
                    $id: Now.ID['metrics-widget'],
                    component: 'single-score',  // Single score component
                    componentProps: {
                        title: 'Key Metrics',
                        scoreSize: 'large'
                    },
```

```
                height: 12,
                width: 12,
                position: { x: 0, y: 0 },
            }
]
```

componentProps object

Configure the properties of widgets [par_dashboard_widget].

The available properties are determined by the component specified with the *component* property of the *Dashboard* object.

- Trend data components require the *dataSources*, *metrics*, and *trendBy* properties. The *groupBy* property is optional.
- Group data components require the *dataSources*, *metrics*, and *groupBy* properties. The *trendBy* property isn't supported in these visualizations.
- Simple data components require the *dataSources* and *metrics* properties. The *groupBy* and *trendBy* properties aren't supported in these visualizations.

Properties

Name	Type	Description
dataSources	Array	A list of data sources for the component. For example: `dataSources: [ { label: "Incident", // Human-readable label sourceType: "table", // Type of data source tableOrViewName: "incident", // ServiceNow table name filterQuery: "", // Optional encoded query filter id: "data_source_1" // Unique data source ID }, ... ]`
headerTitle	String	A title to display with the widget.
metrics	Array	A list of metrics to measure for the data source. For example: `metrics: [{ dataSource: 'data_source_1', // Must match dataSource id id: 'metric_1', // Unique metric ID aggregateFunction: 'AVG', // COUNT, SUM, AVG, MIN, MAX, COUNT_DISTINCT aggregateField: 'business_duration' // Field to be used for aggregation. axisId: 'primary', // Which axis to display the series }, ...]`

Properties (continued)

Name	Type	Description
groupBy	Array	A list of configurations for grouping and organizing data by data source. For example: `groupBy: [ { groupBy: [ { dataSource: "data_source_1", // Must match dataSource id groupByField: "state" // Field to group by } ], maxNumberOfGroups: 10, // Maximum categories to show showOthers: false // Show "Others" category }, ... ]`
trendBy	Object	A configuration for trend charts. For example: `trendBy: { "trendByFrequency": "year", // Frequency of the trend (date, week, month, year) "trendByFields": [ { "field": "sys_created_on", // Field to trend on (from the table of the dataSource) "metric": "metric_1" // ID of the metric } ] }`
sortBy	String	The method of sorting data. Valid values: • value • label • field

In the following example, the `line` component, which is a trend data type visualization, is used to show how a metric changes over time.

```
{
    component: 'line',
    componentProps: {
        dataSources: [
            {
                label: 'Incident',
                sourceType: 'table',
                tableOrViewName: 'incident',
                filterQuery: '',
```

```
                id: 'data_source_1',
            },
        ],
        headerTitle: 'Incidents by State',
        metrics: [
            {
                dataSource: 'data_source_1',
                id: 'metric_1',
                aggregateFunction: 'COUNT',
                axisId: 'primary',
            },
        ],
        trendBy: {
            trendByFrequency: "year",
            trendByFields: [
                {
                    field: "sys_created_on",
                    metric: "metric_1"
                }
            ]
        },
    },
    height: 14,
    width: 17,
    position: { x: 0, y: 0 },
}
```

In the following example, the `single-score` component, which is a simple data type visualization, is used to show a single count metric.

```
{
    component: 'single-score',
    componentProps: {
        dataSources: [
            {
                label: 'Incident',
                sourceType: 'table',
                tableOrViewName: 'incident',
                filterQuery: '',
                id: 'data_source_1',
            },
        ],
        headerTitle: 'Open Incidents',
        metrics: [
            {
                dataSource: 'data_source_1',
                id: 'metric_1',
                aggregateFunction: 'COUNT',
                axisId: 'primary',
            },
        ]
    },
    height: 14,
    width: 14,
    position: { x: 0, y: 0 },
}
```

permissions array

Define permissions [par_dashboard_permission] to read, edit, and share a dashboard.

At least one of the *user*, *group*, or *role* properties must be specified for each permission in the array.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
user	Reference or String	The variable identifier or sys_id of a user [sys_user] to which to grant permissions. To define a user, use the Record API - ServiceNow Fluent.
group	Reference or String	The variable identifier or sys_id of a user group [sys_user_group] to which to grant permissions. To define a user, use the Record API - ServiceNow Fluent.
role	Reference or String	The variable identifier or sys_id of a role [sys_user_role] to which to grant permissions. To define a user, use the Role API - ServiceNow Fluent.
canRead	Boolean	Flag that indicates whether the user, group, or role can view the dashboard. Default: true
canWrite	Boolean	Flag that indicates whether the user, group, or role can edit the dashboard. Default: false
canShare	Boolean	Flag that indicates whether the user, group, or role can share the dashboard. Default: false
owner	Boolean	Flag that indicates whether the user, group, or role is the owner of the dashboard. For at least one user, the *owner* property should be set to true. Default: false

```
permissions: [
        {
            $id: Now.ID['manager-user-permission'],
            user: 'a8f98bb0eb32010045e1a5115206fe3a', // sys_id of manager
user
            canRead: true,
            canWrite: true,
            owner: true,
        },
```

```
        {
            $id: Now.ID['itil-role-permission'],
            role: '2831a114c611228501d4ea6c309d626d', // sys_id of itil role
            canRead: true,
            canWrite: false,
        },
        {
            $id: Now.ID['support-group-permission'],
            group: 'd625dccec0a8016700a222a0f7900d06', // sys_id of Service
Desk group
            canRead: true,
            canWrite: false,
        }
]
```

visibilities array

Define visibility rules [par_dashboard_visibility] for which UX experiences display the dashboard.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
experience	Reference or String	Required. The variable identifier of a *`Workspace`* object or sys_id of a UX application [sys_ux_page_registry]. For more information, see Workspace API - ServiceNow Fluent.

```
visibilities: [
  {
    $id: Now.ID["dashboard_visibility_1"],
    experience: myWorkspace // Reference to Workspace object
  }
]
```

Email Notification API - ServiceNow Fluent

The Email Notification API defines notifications [sysevent_email_action] that send automated emails based on database operations, custom events, or manual triggers.

For general information about email notifications, see Email and SMS notifications.

Related topics

ServiceNow Fluent

EmailNotification object

Create an email notification [sysevent_email_action] specifying when to send it, who receives it, what it contains, and if it can be delivered in an email digest.

For general information about creating email notifications, see Create an email notification.

Properties

Name	Type	Description
table	Reference or String	Required. The variable identifier or name of a table to which the notification applies. To define a table, use the Table API - ServiceNow Fluent. **Note:** Don't select the Task [task] table, which is for extending other tables. Notifications that run on the Task table directly aren't supported.
triggerConditions	Object	Required. The conditions that trigger the notification. For more information, see triggerConditions object.
name	String	A unique name for the email notification.
description	String	A description of the purpose of the email notification.
category	Reference or String	The variable identifier or name of a notification category for grouping notifications. To define a notification category, use the Record API - ServiceNow Fluent. Default: The default email category (c97d83137f4432005f58108c3ffa917a)
notificationType	String	The type of notification. Valid values: • email: A standard email. • vcalendar: A meeting invitation. Meeting invitations aren't supported with email digests. Default: email
active	Boolean	Flag that indicates whether the notification is active. Default: true
mandatory	Boolean	Flag that indicates whether the notification is required. Default: false
enableDynamicTranslation	Boolean	Flag that indicates whether to enable dynamic translation for the notification. Default: false
emailContent	Object	The email content and formatting. For more information, see emailContent object.
recipientDetails	Object	The email recipients. For more information, see recipientDetails object.
digest	Object	The email digest content and formatting. For more information, see digest object.
$meta	Object	Metadata for the application metadata.

Properties (continued)

Name	Type	Description
		With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { EmailNotification } from '@servicenow/sdk/core'

EmailNotification({
    table: 'incident',
    name: 'Custom Event Notification',
    description: 'Triggered by custom event',
    category: 'c97d83137f4432005f58108c3ffa917a',    // Default email category sys_id
    triggerConditions: {
        generationType: 'event',
        eventName: 'custom.incident.escalated',
        order: 100
    },
    recipientDetails: {
        recipientUsers: ['6816f79cc0a8016401c5a33be04be441'],    // Admin user sys_id
        eventParm1WithRecipient: true,    // Event param 1 contains recipient
        isSubscribableByAllUsers: true
    },
    emailContent: {
        contentType: 'text/html',
        subject: 'Incident Escalated',
        messageHtml: '<p>An incident has been escalated.</p>'
    }
})
```

triggerConditions object

Configure the conditions that must be met for the notification to be sent.

Note:
If the same trigger generates multiple notifications, the system sends only one notification. The system considers all other notifications, even if they have a different subject and body, as duplicates. The Ignore Duplicates business rule controls this functionality.

Properties

Name	Type	Description
generationType	String	Required. The method of triggering the email notification. Valid values: • engine: Sends the notification when a record is inserted or updated. • event: Sends the notification when custom events occur. • triggered: Manually triggered notifications. The following properties don't apply if this property is set to `triggered`.
onRecordInsert	Boolean	Flag that indicates whether to send the notification when a record is inserted. **Note:** Either this property or the *`onRecordUpdate`* property must be true. Default: false
onRecordUpdate	Boolean	Flag that indicates whether to send the notification when a record is updated. **Note:** Either this property or the *`onRecordInsert`* property must be true. Default: false
eventName	String	The name of a custom event to trigger sending the notification. This property is required if the value of the *`generationType`* property is `event`.
affectedFieldOnEvent	String	The event parameter that contains the affected field. This property applies only if the *`generationType`* property is set to `event`. Valid values: • parm1 • parm2
weight	Number	The notification priority relative to duplicate notifications. Notifications that have the same target table and recipients are considered duplicates if the weights are different. If weights are same, an additional evaluation is done to check if the subject and the body (excluding watermark) are the same to qualify as duplicate notification. When there are duplicate notifications, the system only sends the notification with the highest weight. All other notifications are moved from the Outbox to the Skipped mailbox. The default value of 0 causes the system to send the notification (assuming the conditions are met).

Properties (continued)

Name	Type	Description
		Maximum value: 1000 Default: 0
condition	String	A filter query that specifies the fields and values that must be true for users to access the object. For more information, see Operators available for filters and queries.
advancedCondition	String	A JavaScript conditional statement that must return true or set a global answer variable to true to send the notification. For more information, see Advanced conditions for email notifications. **Note:** This property is evaluated in addition to other conditions that you set on the notification. Both the condition and advanced condition must evaluate to true to send the notification.
itemTable	Reference or String	The variable identifier or name of the table to which the notification item refers. To define a table, use the Table API - ServiceNow Fluent.
item	String	The item to use for the notification context.
order	Number	The execution order of the notification. Maximum value: 9999 Default: 100

```
triggerConditions: {
    generationType: "engine",
    onRecordInsert: false,
    onRecordUpdate: true,
    weight: 100,
    condition: "priority=1^ORpriority=2^state!=6^state!=7",  // High/Critical priority,
not resolved/closed
    order: 100
}
```

emailContent object

Configure the contents of an email notification.

Properties

Name	Type	Description
contentType	String	The type of email content. Valid values:

Properties (continued)

Name	Type	Description
		• text/html • text/plain • multipart/mixed Default: text/html
template	Reference or String	The variable identifier or sys_id of an email template [sysevent_email_template]. To define an email template, use the Record API - ServiceNow Fluent. You can only specify an email template that meets one of the following conditions: • The template has the same scope and table as the notification. • The template has the same scope but has no specified table. • The template has the same table and is in the global scope.
style	Reference or String	The variable identifier or sys_id of an email style [sys_email_style]. To define an email style, use the Record API - ServiceNow Fluent.
subject	String	A subject line for the email. If empty, the system uses the Subject value from the email template. You can use the `\${variable}` format for variable references. Variables map to column names available from the notification table, its parent tables, and reference tables. Use variables to include values from a record in the table, such as the short description or comments and work notes.
smsAlternate	String	A notification message to send specifically to SMS devices. The SMS alternate message is limited to 140 characters. If empty, the system uses the SMS alternate value from the email template. You can use the `\${variable}` format for variable references. Variables map to column names available from the notification table, its parent tables, and reference tables. Use variables to include values from a record in the table, such as the short description or comments and work notes.
importance	String	The level of importance of the message. Valid values: • low • high
includeAttachments	Boolean	Flag that indicates whether to include attachments from the notification trigger record with the email.

Properties (continued)

Name	Type	Description
		Default: false
omitWatermark	Boolean	Flag that indicates whether to omit the watermark attached to each email. For more information, see Watermarks on notification emails. Default: false
from	String	The email address from which to send the notification.
replyTo	String	The email address to which recipients can reply.
pushMessageOnly	Boolean	Flag that indicates whether to send the notification only as a push notification to a mobile device. Default: false
pushMessageList	Array	A list of variable identifiers or sys_ids of push messages [sys_push_notif_msg] to associate with the notification. To define a push notification, use the Record API - ServiceNow Fluent. **Note:** The push message and notification must be for the same table.
forceDelivery	Boolean	Flag that indicates whether to bypass user notification preferences that would prevent a notification and send the notification anyway. Default: false
messageHtml	String	The HTML content of the notification message. If empty, the system uses the message HTML from the email template. You can use the `\${variable}` format for variable references. Variables map to column names available from the notification table, its parent tables, and reference tables. Use variables to include values from a record in the table, such as the short description or comments and work notes. This property is required if the value of the *`contentType`* property is `text/html` or `multipart/mixed`.
messageText	String	The plain text content of the notification message. If empty, the system uses the message text from the email template. You can use the `\${variable}` format for variable references. Variables map to column names available from the notification table, its parent tables, and reference tables. Use variables to include values from a record in the table, such as the short description or comments and work notes.

Properties (continued)

Name	Type	Description
		This property is required if the value of the *contentType* property is `text/plain` or `multipart/mixed`.
message	String	Deprecated. Message contents.

```
emailContent: {
    contentType: "text/html",
    subject: "CRITICAL: Incident \${number} - \${short_description}",
    messageHtml: `
            <div style="background-color: #ff4444; color: white; padding: 10px;
border-radius: 5px;">
                <h2>CRITICAL INCIDENT ALERT</h2>
                <p><strong>Incident:</strong> \${number}</p>
                <p><strong>Priority:</strong> \${priority}</p>
                <p><strong>Description:</strong>
 \${short_description}</p>
                <p><strong>Assigned To:</strong>
 \${assigned_to.name}</p>
                <p><strong>Created:</strong>
 \${sys_created_on}</p>
                <p><a href="\${instance_url}/incident.do?sys_id=\${sys_id}"
 style="color: #ffffff; text-decoration: underline;">View Incident</a></p>
            </div>
        `,
    smsAlternate:
      "CRITICAL: Incident \${number} - \${short_description}. Priority: \${priority}.
Assigned: \${assigned_to.name}",
    pushMessageList: ["mobile_push_notification_sys_id"],
    forceDelivery: true,
    importance: "high"
}
```

digest object

Configure the contents of an email digest that summarizes the activity for a selected notification and its target records during a specified time interval.

For general information about email digests, see Email digests.

Properties

Name	Type	Description
allow	Boolean	Flag that indicates whether users to receive this notification as a digest. If false, all other properties of the *digest* object are ignored. Default: false
default	Boolean	Flag that indicates whether digest mode is enabled by default for this notification. Default: false

Properties (continued)

Name	Type	Description
type	String	The type of digest. Valid values: • single: Sends the notification in an email digest when it's triggered multiple times during the selected interval for a single target record, for example INC001 only. • multiple: Sends the notification in an email digest when it's triggered multiple times during the selected interval for a multiple target record, for example INC001, INC002, and more.
defaultInterval	Reference or String	The variable identifier or sys_id of a digest interval [sys_email_digest_interval] to use as the default time interval for digest delivery. To define a digest interval, use the Record API - ServiceNow Fluent.
subject	String	A subject line for the email digest. If empty, the system uses the Subject value from the email template. You can use the `\${variable}` format for variable references. Variables map to column names available from the notification table, its parent tables, and reference tables. Use variables to include values from a record in the table, such as the short description or comments and work notes.
html	String	The HTML content of the email digest. You can use the `\${variable}` format for variable references. Variables map to column names available from the notification table, its parent tables, and reference tables. Use variables to include values from a record in the table, such as the short description or comments and work notes.
text	String	The plain text content of the email digest. You can use the `\${variable}` format for variable references. Variables map to column names available from the notification table, its parent tables, and reference tables. Use variables to include values from a record in the table, such as the short description or comments and work notes.
template	String	The variable identifier or sys_id of an email template [sysevent_email_template]. To define an email template, use the Record API - ServiceNow Fluent.
separatorHtml	String	An HTML separator that appears between each item summarized in the digest. You can use the `\${variable}` format for variable references. Variables map to column names available from the notification table, its parent tables, and reference tables. Use variables to include values from a record in the table, such as the short description or comments and work notes.

Properties (continued)

Name	Type	Description
		Default: `<p> </p>\n<hr>\n<p> </p>`
separatorText	String	A plain text separator that appears between each item summarized in the digest. You can use the `\${variable}` format for variable references. Variables map to column names available from the notification table, its parent tables, and reference tables. Use variables to include values from a record in the table, such as the short description or comments and work notes. Default: `----------` `\n`
from	String	The email address from which to send the notification.
replyTo	String	The email address to which recipients can reply.

```
digest: {
    allow: true,
    defaultInterval: hourlyDigest,
    template: escalationTemplate,
    subject: "Incident Escalation Digest - \${digest_count} incidents require attention",
    html: `<div>
           <div>Incident Escalation Digest</div>
           </div>`,
    separatorHtml: '<hr style="margin: 15px 0;">',
    from: "noreply@company.com",
    replyTo: "itsupport@company.com"
}
```

recipientDetails object

Configure who receives an email notification.

Notification recipients must be active users defined as active users in the User [sys_user] table. They must also have a valid email address defined for their primary channel (device) in the Notification Device [cmn_notif_device] table. Your notification recipients must also have the appropriate notification preferences enabled.

Properties

Name	Type	Description
recipientUsers	Array	A list of variable identifiers or sys_ids of users [sys_user] or a list of email addresses to receive the notification. To define a user, use the Record API - ServiceNow Fluent.
recipientFields	Array	A list of fields that reference the users or user groups to receive the notification. The fields must be reference fields. For example, if a notification uses the Incident [incident] table, you can specify the `opened_by` field to send the notification to users or groups who opened the incident. This

Properties (continued)

Name	Type	Description
		list of users or groups is variable and depends on the values of the associated task record. You can also select a field that includes an email address string to send a notification to that address.
recipientGroups	Array	A list of variable identifiers or sys_ids of user groups [sys_user_group] to receive the notification. To define a user group, use the Record API - ServiceNow Fluent. **Note:** Group members receive individual notifications only if **Include members** is selected in the group record.
excludeDelegates	Boolean	Flag that indicates whether to exclude delegated users. Set this property to true to help prevent the instance from sending email notifications to delegates of the users and members of the groups you selected. Default: false
isSubscribableByAllUsers	Boolean	Flag that indicates whether to allow all users to subscribe to the notification. For more information, see Subscription-based notifications. **Note:** If the record contains sensitive or protected data, consider restricting the recipient list only to those users and groups who normally have access to it, leaving the value of this property as false. You can also configure your notification content so that private or sensitive data isn't exposed. For example, you could insert a link back to the associated record, so that details aren't revealed in the notification. Default: false
sendToCreator	Boolean	Flag that indicates whether to send the notification to the person who performed the action that started the notification process, if the person is also a recipient. If the event creator isn't specified in one of the recipient fields, the event creator doesn't receive a notification regardless of the setting in this field. Default: false
eventParm1WithRecipient	Boolean	Flag that indicates whether the event parameter 1 contains one or more notification recipients. This property only applies to event-based notifications.
eventParm2WithRecipient	Boolean	Flag that indicates whether the event parameter 2 contains one or more notification recipients.

Properties (continued)

Name	Type	Description
		This property only applies to event-based notifications.

```
recipientDetails: {
    recipientGroups: ["d625dccec0a8016700a222a0f7900d06"], // IT Support
group sys_id
    recipientFields: ["assigned_to", "caller_id"],
    sendToCreator: false,
    isSubscribableByAllUsers: false
}
```

Flow API - ServiceNow Fluent

The Flow API defines flows and subflows [sys_hub_flow], which automate business processes with reusable multiple-step components.

Create a flow using the Flow object. For more information, see Flow object.

Create a subflow using the Subflow object. For more information, see Subflow object.

For general information about flows, see Exploring flows. For general information about subflows, see Exploring subflows.

ServiceNow Fluent

Flow object

Create a flow [sys_hub_flow] to run a sequence of actions and flow logic when a set of trigger conditions occur.

Flows only run when their trigger conditions are met. Use flows for event-driven automation that requires a consistent and predefined trigger.

A Flow object consists of these components.

- One configuration object that defines the flow configuration properties.
- One wfa.trigger function that defines when to run the flow.
- One Body function that defines what actions and flow logic to run.
  - Zero or more wfa.action functions
  - Zero or more wfa.flow_logic functions

Properties

Name	Type	Description
configuration	Object	Required. An object containing the metadata configuration properties for the Fluent object or function.
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs.

Properties (continued)

Name	Type	Description
		Format: `Now.ID['String' or Number]`
name	String	Required. Display name of the flow. The flow name should be meaningful and descriptive to easily identify its purpose.
description	String	Description of what the flow does.
runAs	String	Determines under which user context the flow actions are run. The system user setting runs as a privileged user that bypasses role-based ACLs. The user setting runs with the privileges and roles of the user who started the flow. Valid values: system, user Default: user
runWithRoles	String	Specify the roles that the flow uses while running. For more information about running a flow with roles, see Flow roles.
flowPriority	String	Defines the execution priority of the flow in the Flow Engine. Valid values: LOW, MEDIUM, HIGH Default: MEDIUM
protection	String	Defines whether the flow is read-only (read) or editable (empty string). Valid values: read, '' Default: ''
access	String	Defines whether a flow is public or private. Valid values: public, package_private Default: public
flowVariables	Object	Object defining data variables available to the flow using Column types. Use the get_table_schema function to fetch field definitions.
wfa.trigger	Function	Defines when to run the flow. When the trigger conditions are met, the system runs the flow using the data provided by the trigger. For more information about the *`wfa.trigger`* function, see wfa.trigger function.
Flow body	Function	*`Flow body`* is an *`Arrow function`* in TypeScript that represents the execution steps in the flow. The Flow Body receives the *`params`* parameter as its input, which contains the *`wfa.trigger`* and *`flowVariables`* objects.The steps in the *`Flow body`* consist of these function types:

Properties (continued)

Name	Type	Description
		• `wfa.action` function: Execute specific tasks and operations within a flow, such as creating records, sending emails, requesting approvals, or integrating with external systems. For more information about the `wfa.action` function, see wfa.action function. • `wfa.flow_logic` function: Control how flows execute, providing conditional branching, iteration, and flow structuring capabilities. For more information about `wfa.flow_logic` function, see wfa.flow_logic function. You can use these parameter values in the Flow body function. **params.trigger.current** Data type: Record. Parameter that stores the current record that started a create record, update record, or create or update record flow. **params.trigger.previous** Data type: Record. Parameter that stores the previous record values that started an update record flow. **params.trigger.table_name** Data type: String. Parameter that stores the table name of the current record that started the flow. **params.trigger.flowVariables** Data type: Object. Parameter that stores the flow variables defined in this flow.

This example creates a flow that runs when an incident is created with an empty origin field value. The flow alerts managers and team members based on the incident severity.

```
import { action, Flow, wfa, trigger } from '@servicenow/sdk/automation'

export const incidentSeverityAlertFlow = Flow(
    {
        $id: Now.ID['incident_severity_alert_flow'],
        name: 'Incident Severity Alert Flow',
        description: 'Alerts managers and team members based on incident severity
for incidents with empty origin',
    },
    wfa.trigger(
        trigger.record.created,
        { $id: Now.ID['empty_origin_incident_trigger'] },
        {
            table: 'incident',
            condition: 'origin=NULL',
            run_flow_in: 'background',
            run_on_extended: 'false',
            run_when_setting: 'both',
            run_when_user_setting: 'any',
```

```
            run_when_user_list: [],
        }
    ),
    (params) => {
        wfa.action(
            action.core.log,
            { $id: Now.ID['log_incident_short_description'] },
            {
                log_level: 'info',
                log_message: `Incident created:
 ${wfa.dataPill(params.trigger.current.short_description, 'string')
}`,
            }
        )

        wfa.flowLogic.if(
            {
                $id: Now.ID['check_severity_high'],
                condition:
 `${wfa.dataPill(params.trigger.current.severity, 'string')}=1`,
                annotation: 'High severity (1)',
            },
            () => {
                const assignmentGroup = wfa.action(
                    action.core.lookUpRecord,
                    { $id: Now.ID['lookup_assignment_group'] },
                    {
                        table: 'sys_user_group',
                        conditions:
 `sys_id=${wfa.dataPill(params.trigger.current.assignment_group,
 'reference')}`,
                        sort_type: 'sort_asc',

 if_multiple_records_are_found_action: 'use_first_record',
                    }
                )

            }
        )
    }
)
```

This example runs when a change request is approved and notifies the requester.

```
import { action, Flow, wfa, trigger } from '@servicenow/sdk/automation'

export const changeRequestApprovalNotificationFlow = Flow(
    {
        $id: Now.ID['change_request_approval_notification_flow'],
        name: 'Change Request Approval Notification Flow',
        description: 'Sends formatted notification to requester when change
 request is approved',
    },
    wfa.trigger(
        trigger.record.updated,
        { $id: Now.ID['change_request_approved_trigger'] },
        {
            table: 'change_request',
            condition: 'approval=approved',
            run_flow_in: 'background',
            trigger_strategy: 'unique_changes',
            run_when_user_list: [],
            run_when_setting: 'both',
            run_on_extended: 'false',
            run_when_user_setting: 'any',
        }
    ),
    (params) => {
        const requester = wfa.action(
            action.core.lookUpRecord,
            { $id: Now.ID['lookup_requester_details'] },
            {
                table: 'sys_user',
                conditions:
 `sys_id=${wfa.dataPill(params.trigger.current.requested_by, 'refer
ence')}`,
                sort_type: 'sort_asc',

 if_multiple_records_are_found_action: 'use_first_record',
            }
        )

        wfa.action(
            action.core.sendEmail,
            { $id: Now.ID['send_approval_notification_email'] },
            {
                table_name: 'change_request',
                watermark_email: true,
                ah_subject: `Change Request
 ${wfa.dataPill(params.trigger.current.number, 'string')} -
 Approved`,
```

```
                ah_body: `Your change request has been
approved.`,
                record:
wfa.dataPill(params.trigger.current.sys_id, 'reference'),
                ah_to:
wfa.dataPill(requester.Record.email, 'string'),
            }
        )

        wfa.action(
            action.core.updateRecord,
            { $id: Now.ID['update_work_notes_notification_sent'] },
            {
                table_name: 'change_request',
                record:
wfa.dataPill(params.trigger.current.sys_id, 'reference'),
                values: TemplateValue({
                    work_notes: `Approval notification
sent to ${wfa.dataPill(requester.Record.name, 'string')}
(${wfa.dataPill(requester.Record.email, 'string')})`,
                }),
            }
        )
    }
)
```

Subflow object

Create a subflow [sys_hub_flow] to run a reusbale sequence of actions and flow logic when called by a flow or API.

Subflows run when called by a flow or an API. Use subflows for on-demand automation that can be called by multiple flows.

Subflows consist of these components.

- One configuration object that defines the subflow configuration properties.
  - Zero or one inputs object that defines subflow inputs.
  - Zero or one outputs object that defines subflow outputs.
  - Zero or one flow variables object that defines flow variables.
- One Body function that defines what actions, flow logic, and subflows to run.
  - Zero or more wfa.action functions
  - Zero or more wfa.flow_logic functions

Properties

Name	Type	Description
configuration	Object	Required. An object containing the metadata configuration properties for the Fluent object or function.
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs.

Properties (continued)

Name	Type	Description
		Format: `Now.ID['String' or Number]`
name	String	Required. Display name of the subflow. The subflow name should be meaningful and descriptive to easily identify its purpose. This property is part of the Subflow configuration object.
description	String	Description of what the flow does. This property is part of the Subflow configuration object.
runAs	String	Determines under which user context the subflow actions are executed. Valid values: system, user Default: user This property is part of the Subflow configuration object.
runWithRoles	Array	Specify the roles that the subflow uses while running. This property is part of the Subflow configuration object.
flowPriority	String	Defines the execution priority of the subflow in the Flow Engine. Valid values: LOW, MEDIUM, HIGH Default: Medium This property is part of the Subflow configuration object.
protection	String	Defines whether the subflow is read-only (read) or editable (empty string). Valid values: read, `''` This property is part of the Subflow configuration object.
access	String	Defines the visibility/accessibility of the subflow to other subflow authors. Valid values: public, package_private Default: public This property is part of the Subflow configuration object.
category	String	Category for organizing the subflow. This property is part of the Subflow configuration object.
inputs	Object	Object defining input parameters using Column types. This property is part of the Subflow configuration object.

Properties (continued)

Name	Type	Description
outputs	Object	Object defining output parameters using Column types. This property is part of the Subflow configuration object.
flowVariables	Object	Object defining data variables available to the subflow using Column types. This property is part of the Subflow configuration object.
Flow body	Function	*`Flow body`* is an *`Arrow function`* in TypeScript that represents the execution steps in the flow. The Flow Body receives the *`_params`* parameter as its input, which contains the *`inputs`* and *`flowVariables`* objects.The steps in the *`Flow body`* consist of these function types: • *`wfa.action`* function: Execute specific tasks and operations within a flow, such as creating records, sending emails, requesting approvals, or integrating with external systems. For more information about the *`wfa.action`* function, see wfa.action function. • *`wfa.flow_logic`* function: Control how flows execute, providing conditional branching, iteration, and flow structuring capabilities. For more information about *`wfa.flow_logic`* function, see wfa.flow_logic function. You can use these parameter values in the Flow body function. **_params.trigger.current** Data type: Record. Parameter that stores the current record that started a create record, update record, or create or update record flow. **_params.trigger.previous** Data type: Record. Parameter that stores the previous record values that started an update record flow. **_params.trigger.table_name** Data type: String. Parameter that stores the table name of the current record that started the flow. **_params.trigger.flowVariables** Data type: Object. Parameter that stores the flow variables defined in this flow.

This example uses a new user's name and office location to look up a User record, send a welcome notification, and look up an unassigned hardware asset and an available office location. If there is an available laptop asset and office location, then each are assigned to the new user.

```
import { Subflow, action, wfa } from '@servicenow/sdk/automation'
import { BooleanColumn, ReferenceColumn, StringColumn }
 from '@servicenow/sdk/core'

export const newUserOnboardingSubflow = Subflow(
    {
```

```
        $id: Now.ID['new_user_onboarding_subflow'],
        name: 'New User Onboarding Subflow',
        description: 'Sends welcome notification, assigns laptop and desk, returns
assignment results',
        inputs: {
            user_sys_id: ReferenceColumn({
                label: 'User',
                referenceTable: 'sys_user',
                mandatory: true,
            }),
            office_location: ReferenceColumn({
                label: 'Office Location',

            }
        )
    }
)
```

wfa.trigger function

Run a flow when the start conditions of a specific trigger type are met. Triggers determine when a flow runs and what data is available from the flow start conditions.

Add a *wfa.trigger* function to the *Flow Body* function of a *Flow* object.

The following types of action instances are supported:

- *trigger.record.created*
- *trigger.record.updated*
- *trigger.record.createdOrUpdated*
- *trigger.scheduled.daily*
- *trigger.scheduled.weekly*
- *trigger.scheduled.monthly*
- *trigger.scheduled.repeat*
- *trigger.scheduled.runOnce*
- *trigger.application.inboundEmail*
- *trigger.application.slaTask*
- *trigger.application.knowledgeManagement*
- *trigger.application.remoteTableQuery*

.

For more information about available actions, see Workflow Studio flow trigger types.

Properties

Name	Type	Description
trigger	String	Name of the specific trigger to run. All action names use a dot notation that starts with `trigger`. For example, `trigger.record.created`, `trigger.scheduled.daily`, or `trigger.application.serviceCatalog`.
configuration	Object	Required. An object containing the metadata configuration properties for the Fluent object or function.
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
inputs	Object	An object containing any input parameters required by the trigger such as `table` or `condition`.

This example runs a flow when a high priority incident record is created.

```
// Trigger definition - defines when the flow starts
wfa.trigger(
    trigger.record.created,  // TriggerDefinition - record creation event
    {
        $id: Now.ID['incident_trigger'],  // string | guid, mandatory - unique identifier
        annotation: 'When high priority incident is created'  // string, optional -
describes trigger purpose
    },
    {
        table: 'incident',  // string, mandatory - table name to monitor
        condition: 'priority=1^ORpriority=2',  // string, optional - encoded query filter
        run_on_extended: 'false',  // string, optional, default: 'false' - run on child
tables
        run_flow_in: 'any',  // string, optional, default: 'any' - 'any', 'background', or
'foreground'
        run_when_setting: 'both',  // string, optional, default: 'both' - 'both',
'non_interactive', or 'interactive'
        run_when_user_list: [],  // Array, optional, default: [] - need to use
runQuery to get user sys_ids from sys_user table
        run_when_user_setting: 'any'  // string, optional, default: 'any' - 'any',
'one_of', or 'not_one_of'
    }
)
```

This examples starts a flow daily at 9 AM.

```
// # CORRECT - Daily trigger at specific time
wfa.trigger(
    trigger.scheduled.daily,
    {
        $id: Now.ID['daily_report_trigger'],
        annotation: 'Runs daily at 9 AM'
    },
    {
```

```
        time: Time({ hours: 9, minutes: 0, seconds: 0 })
    }
)
```

This examples starts a flow when there is an email reply to an incident record.

```
// Trigger when email arrives for incident table
wfa.trigger(
    trigger.application.inboundEmail, // TriggerDefinition - inbound email
event
    {
        $id: Now.ID['incident_email_trigger'], // string | guid, mandatory
        annotation: 'Process emails for incident table' // string, optional
    },
    {
        target_table: 'incident', // string, optional - table for email replies/forwards
        email_conditions: '', // string, optional - filter which emails trigger the flow
        order: 100, // number, optional - execution order when multiple email triggers
exist
        stop_condition_evaluation: true // boolean, optional - stop
evaluating other triggers if this one matches
    }
)

// Access email data in flow body:
(_params) => {
    const emailSubject = _params.trigger.email.subject // Email subject
    const emailBody = _params.trigger.email.body // Email body
    const emailFrom = _params.trigger.email.from // Sender email address
}
```

wfa.action function

Run a specific action instance from a flow or subflow. Actions determine what data is generated, updated, or retrieved.

Add *wfa.action* functions to the *Flow Body* function of a *Flow* or *Subflow* object.

The following types of action instances are supported:

- *action.core.createRecord*
- *action.core.createOrUpdateRecord*
- *action.core.deleteRecord*
- *action.core.lookUpRecord*
- *action.core.lookUpRecords*
- *action.core.updateRecord*
- *action.core.updateMultipleRecords*
- *action.core.sendNotification*
- *action.core.sendEmail*
- *action.core.sendSms*
- *action.core.askForApproval*
- *action.core.waitForApproval*
- *action.core.createTask*

- `action.core.log`
- `action.core.waitForCondition`
- `action.core.waitForMessage`
- `action.core.slaPercentageTimer`

.

For more information about available actions, see Workflow Studio actions.

Properties

Name	Type	Description
action	String	Name of the specific action to run. All action names use a dot notation that starts with `action.core`. For example, `action.core.lookUpRecord`, `action.core.lookUpRecords`, `action.core.createRecord`, or `action.core.updateRecord`.
configuration	Object	Required. An object containing the metadata configuration properties for the Fluent object or function.
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
inputs	Object	An object containing any input parameters required by the action such as `table_name` or `values`.

This example runs when a change request is approved and notifies the requester. The flow uses the Look Up Records, Send Email, and Update Record actions.

```
import { action, Flow, wfa, trigger } from '@servicenow/sdk/automation'

export const changeRequestApprovalNotificationFlow = Flow(
    {
        $id: Now.ID['change_request_approval_notification_flow'],
        name: 'Change Request Approval Notification Flow',
        description: 'Sends formatted notification to requester when change
request is approved',
    },
    wfa.trigger(
        trigger.record.updated,
        { $id: Now.ID['change_request_approved_trigger'] },
        {
            table: 'change_request',
            condition: 'approval=approved',
            run_flow_in: 'background',
            trigger_strategy: 'unique_changes',
            run_when_user_list: [],
            run_when_setting: 'both',
            run_on_extended: 'false',
            run_when_user_setting: 'any',
```

```
        }
    ),
    (params) => {
        const requester = wfa.action(
            action.core.lookUpRecord,
            { $id: Now.ID['lookup_requester_details'] },
            {
                table: 'sys_user',
                conditions:
 `sys_id=${wfa.dataPill(params.trigger.current.requested_by, 'refer
ence')}`,
                sort_type: 'sort_asc',

 if_multiple_records_are_found_action: 'use_first_record',
            }
        )

        wfa.action(
            action.core.sendEmail,
            { $id: Now.ID['send_approval_notification_email'] },
            {
                table_name: 'change_request',
                watermark_email: true,
                ah_subject: `Change Request
 ${wfa.dataPill(params.trigger.current.number, 'string')} -
 Approved`,
                ah_body: `Your change request has been
 approved.`,
                record:
 wfa.dataPill(params.trigger.current.sys_id, 'reference'),
                ah_to:
 wfa.dataPill(requester.Record.email, 'string'),
            }
        )

        wfa.action(
            action.core.updateRecord,
            { $id: Now.ID['update_work_notes_notification_sent'] },
            {
                table_name: 'change_request',
                record:
 wfa.dataPill(params.trigger.current.sys_id, 'reference'),
                values: TemplateValue({
                    work_notes: `Approval notification
 sent to ${wfa.dataPill(requester.Record.name, 'string')}
 (${wfa.dataPill(requester.Record.email, 'string')})`,
                }),
            }
        )
    }
)
```

This example runs a flow when a change request record is created or updated as high impact. The flow runs the Update Record to mark the change request as high risk, the Look Up Record to find the group with the name CAB, the Send Notification to send a high risk change notification to the CAB group, and the Log action to document both the record update and the notification sent.

```
import { action, Flow, wfa, trigger } from '@servicenow/sdk/automation'

export const changeRiskTaggingFlow = Flow(
    {
        $id: Now.ID['change_risk_tagging_flow'],
        name: 'Change Risk Tagging Flow',
        description: 'Tags change requests with high-risk label when created or
updated with high impact',
    },
    wfa.trigger(
        trigger.record.createdOrUpdated,
        { $id: Now.ID['change_risk_trigger'] },
        {
            table: 'change_request',
            condition: 'active=true^impact=1',
            run_flow_in: 'background',
            run_on_extended: 'false',
            run_when_setting: 'both',
            run_when_user_setting: 'any',
            run_when_user_list: [],
        }
    ),
    (params) => {
        wfa.action(
            action.core.updateRecord,
            { $id: Now.ID['tag_high_risk'] },
            {
                table_name: 'change_request',
                record:
wfa.dataPill(params.trigger.current.sys_id, 'reference'),
                values: TemplateValue({
                    risk: 'high',
                    work_notes: 'Automatically tagged as high-risk due to high
impact.',
                }),
            }
        )

        const cab = wfa.action(
            action.core.lookUpRecord,
            { $id: Now.ID['lookup_cab_group'] },
            {
                table: 'sys_user_group',
                conditions: 'name=CAB^active=true',
                sort_type: 'sort_asc',

if_multiple_records_are_found_action: 'use_first_record',
            }
        )

        wfa.action(
            action.core.sendNotification,
            { $id: Now.ID['notify_cab_high_risk'] },
            {
                table_name: 'change_request',
```

```
                record:
wfa.dataPill(params.trigger.current.sys_id, 'reference'),
                notification: 'high_risk_change_cab_notification',
            }
        )

        wfa.action(
            action.core.log,
            { $id: Now.ID['log_risk_tagged'] },
            {
                log_level: 'warn',
                log_message: `Change
${wfa.dataPill(params.trigger.current.number, 'string')} tagged
as high-risk. CAB group ${wfa.dataPill(cab.Record.name, 'string')}
notified.`,
            }
        )
    }
)
```

wfa.flow_logic function

Run a specific flow logic instance from a flow or subflow. Flow logic determines how and when data is used.

Add `wfa.flow_logic` functions to the `Flow Body` function of a `Flow` or `Subflow` object.

The following types of flow logic instances are supported:

- `if`
- `elseIf`
- `else`
- `forEach`
- `waitForADuration`
- `exitLoop`, `endFlow`, `skipIteration`, `setFlowVariables`, and `assignSubflowOutputs`

.

For more information about available flow logic, see Workflow Studio flow logic.

Properties

Name	Type	Description
configuration	Object	Required. An object containing the metadata configuration properties for the Fluent object or function.
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
annotation	String	Describe what this instance of flow logic does. For example, `annotation: 'Priority is critical'`.

Properties (continued)

Name	Type	Description
condition	String	Required in a *wfa.flow_logic.if* and *wfa.flow_logic.elseIf* function. Data values that must be true to run this flow logic. For example, `condition: `\${_params.trigger.current.priority}=1`,`.
item	Array	Required in a *wfa.flow_logic.forEach* function. An array or a collection of records to iterate over. Typically, this list of records is dynamically generated from a *wfa.action* function call to the *action.core.lookUpRecords* action. For example, a `problems.Records` array can be generated from an *action.core.lookUpRecords* action. `(_params) => { //Find all the newly created problem records for the past day const problems = wfa.action(action.core.lookUpRecords, { $id: Now.ID['daily_unassigned_new_problems_triage_flow_step1'], annotation: 'Find all the newly created problem records for the past day', }, { table: 'problem', conditions: 'sys_created_onONYesterday@javascript:gs.beginningOfYesterday()@javascript:gs.endOfYesterday()', }) //Iterate over the problems wfa.flow_logic.forEach(problems.Records, { ... }`
label	String	Display value describing this instance of flow logic. For example, `label: 'If Priority is critical',`.
variables	Schema	Required in a *wfa.flow_logic.assignSubflowOutputs* and *wfa.flow_logic.setFlowVariables* function. A schema produced by the FlowVariables API that defines the data structure of the flow variables. For example, the `flowVars` schema can be generated from FlowVariables. `import { FlowVariables } from '@servicenow/sdk/automation' // Define flow variables const flowVars = FlowVariables({`

Properties (continued)

Name	Type	Description
		<pre> status: StringColumn({ label: 'Status' }), count: IntegerColumn({ label: 'Count' }), isActive: BooleanColumn({ label: 'Is Active' }), }) // Flow body (_params) => { // Set flow variables with literal values wfa.flow_logic.setFlowVariables({ $id: Now.ID['initialize_variables'], annotation: 'Initialize flow variables with default values', }, _params.flowVariables, { ... }</pre> **Important:** Always use `_params.flowVariables` as the argument for this property. Passing the wrong schema will cause validation errors.
Flow logic body	Function	*Flow logic body* is an *Arrow function* in TypeScript that represents the execution steps in the flow logic. The Flow Body receives the *_params* parameter as its input, which contains the *wfa.trigger* and *flowVariables* objects. The steps in the *Flow logic body* consist of these functions calls: • *wfa.action* function: Run a specific action instance from a flow or subflow. Actions determine what data is generated, updated, or retrieved.. For more information about the *wfa.action* function, see wfa.action function. • *wfa.flow_logic* function: Run a specific flow logic instance from a flow or subflow. Flow logic determines how and when data is used. For more information about the wfa.flow_logic function, see wfa.flow_logic function.

This example shows checking for conditions in the trigger record. If the current record has a priority of 1, it assigns the record to a critical priority team. Else If the current record has a priority value of 2, it assigns the record to a high priority team. If neither condition is met, the record is assigned to a general team.

```
// Flow body showing if/elseIf/else usage
(_params) => {
    wfa.flow_logic.if(
        {
            $id: Now.ID['check_critical_priority'],
            condition: `\${_params.trigger.current.priority}=1`,
            annotation: 'Priority is critical',
```

```
        },
        () => {
            wfa.action(
                action.core.updateRecord,
                { $id: Now.ID['assign_critical_team'],
 annotation: 'Assign to critical team' },
                { record: _params.trigger.current,
 table_name: 'incident', values: 'assignment_group=critical_team' }
            )
        }
    )
    wfa.flow_logic.elseIf(
        { $id: Now.ID['check_high_priority'], condition:
 `\${_params.trigger.current.priority}=2`, annotation: 'Priority is
high' },
        () => {
            wfa.action(
                action.core.updateRecord,
                { $id: Now.ID['assign_high_team'], annotation: 'Assign
to high team' },
                { record: _params.trigger.current,
 table_name: 'incident', values: 'assignment_group=high_team' }
            )
        }
    )
    wfa.flow_logic.else(
        { $id: Now.ID['assign_default'], annotation: 'Default assignment' },
        () => {
            wfa.action(
                action.core.updateRecord,
                { $id: Now.ID['assign_general_team'],
 annotation: 'Assign to general team' },
                { record: _params.trigger.current,
 table_name: 'incident', values: 'assignment_group=general_team' }
            )
        }
    )
}
```

This example iterates through a list of problem records to find unassigned records, assign them to a problem triage group, and send an email to the group.

```
// Flow body showing forEach usage with lookUpRecords
(_params) => {
    //Find all the newly created problem records for the past day
    const problems = wfa.action(
        action.core.lookUpRecords,
        {
            $id: Now.ID['daily_unassigned_new_problems_triage_flow_step1'],
            annotation: 'Find all the newly created problem records for the past
day',
        },
        {
            table: 'problem',
            conditions:
```

```
  'sys_created_onONYesterday@javascript:gs.beginningOfYesterday()@javascript:gs.endOf
Yesterday()',
        }
    )

    //Iterate over the problems
    wfa.flow_logic.forEach(
        problems.Records,
        { $id: Now.ID['daily_unassigned_new_problems_triage_flow_step2'],
 annotation: 'Iterate each problem' },
        (item) => {
            //Check if the problem is not assigned
            wfa.flow_logic.if(
                {
                    $id:
 Now.ID['daily_unassigned_new_problems_triage_flow_step3'],
                    condition:
 `\${item.assignment_group}ISEMPTY`,
                    annotation: 'Check if problem is not assigned',
                },
                () => {
                    wfa.action(
                        action.core.updateRecord,
                        {
                            $id:
 Now.ID['daily_unassigned_new_problems_triage_flow_step4'],
                            annotation: 'Update the problem record state',
                        },
                        { table_name: 'problem', record: item,
 values: 'state=1' }
                    )

                    //Send notification to the group
                    wfa.action(
                        action.core.sendNotification,
                        {
                            $id:
 Now.ID['daily_unassigned_new_problems_triage_flow_step5'],
                            annotation: 'Send notification to the group',
                        },
                        {
                            table_name: 'problem',
                            record: item,
                            notification: '',
                        }
                    )
                }
            )
        }
    )
}
```

This example sets flow variables to dynamic values stored in data pills.

```
import { FlowVariables } from '@servicenow/sdk/automation'
```

```
const flowVars = FlowVariables({
    incidentPriority: IntegerColumn({ label: 'Incident Priority' }),
    assignedGroup: StringColumn({ label: 'Assigned Group' }),
    threshold: IntegerColumn({ label: 'Threshold' }),
    actionResult: StringColumn({ label: 'Action Result' }),
})

(_params) => {
    // Lookup action result
    const lookupResult = wfa.action(
        action.core.lookUpRecord,
        { $id: Now.ID['lookup_config'], annotation: 'Get configuration' },
        { table: 'sys_properties', conditions: 'name=incident.threshold' }
    )

    // Set flow variables using datapills from trigger, action outputs, and other flow variables
    wfa.flow_logic.setFlowVariables(
        {
            $id: Now.ID['set_variables_with_datapills'],
            annotation: 'Set variables from trigger and action outputs',
        },
        _params.flowVariables,
        {
            incidentPriority: _params.trigger.current.priority,
       // Trigger datapill
            assignedGroup:
 _params.trigger.current.assignment_group,    // Trigger datapill
            threshold: lookupResult.Record.value,
       // Action output datapill
            actionResult: _params.flowVariables.status,
       // Flow variable datapill
        }
    )
}
```

This exampe assign subflow Outputs using flow variables.

```
// Flow body showing assignSubflowOutputs usage with flow variables
import { FlowVariables } from '@servicenow/sdk/automation'

const flowVars = FlowVariables({
    userEmail: StringColumn({ label: 'User Email' }),
    userName: StringColumn({ label: 'User Name' }),
    isApproved: BooleanColumn({ label: 'Is Approved' }),
})

(_params) => {
    // Call a subflow that returns user information
    const subflowResult = wfa.subflow(
        userInfoSubflow,
        { $id: Now.ID['get_user_info'], annotation: 'Get user
information' },
        { userId: _params.trigger.current.caller_id }
    )

    // Assign subflow outputs to flow variables in one operation
    wfa.flow_logic.assignSubflowOutputs(
```

```
        { $id: Now.ID['assign_outputs'], annotation: 'Assign user info to flow
variables' },
        flowVars,
        {
            userEmail: subflowResult.email,
            userName: subflowResult.name,
            isApproved: subflowResult.approved,
        }
    )

    // Now flow variables can be used throughout the flow
    // Access via _params.flowVariables.userEmail, etc.
}
```

wfa.dataPill function

Reference a specific runtime data pill value from an action or flow logic input.

Add `wfa.dataPill` functions to the input parameters of a `action` or `flow_logic` function. Define a constant for each data pill you want to use. Typically, this constant stores the output of a wfa.action or wfa.flow_logic function.

Properties

Name	Type	Description
expression	String	Required. Dot notation reference to the runtime data that you want use as an input value. Commonly used runtime values include trigger data, action outputs, and subflow outputs. **Trigger record data** Field values from a trigger record. For example, `_params.trigger.current.fieldName`. **Trigger record table** Table name of the trigger record. For example, `_params.trigger.table_name`. **Action output values** Output values from previously run actions. For example, `actionResult.fieldName` **Subflow output values** Output values from previously run subflows. For example, `subflowResult.fieldName`
Type	String	Required. Data type of the data such as string, boolean, integer, or reference. For a list of available field data types, see Field types.

This example uses an unbound email record to create either an incident or a task based on the values of the inbound email. This example uses the params object to refer to data in the trigger. This example also defines the constants sender, senderManager, p3Incident, and attachments to store the output of actions and flow logic for use in later wfa.dataPill functions.

```
import { action, Flow, wfa, trigger } from '@servicenow/sdk/automation'

export const emailIncidentTaskFlow = Flow(
    {
```

```
        $id: Now.ID['email_incident_task_flow'],
        name: 'Email Incident/Task Creation Flow',
        description: 'Creates incidents or tasks based on email content with "raise
incident or task" in subject',
    },
    wfa.trigger(
        trigger.application.inboundEmail,
        { $id: Now.ID['inbound_email_trigger'] },
        {
            email_conditions: 'subjectLIKEraise incident or task',
            target_table: 'incident',
        }
    ),
    (params) => {
        wfa.action(
            action.core.log,
            { $id: Now.ID['log_email_received'] },
            {
                log_level: 'info',
                log_message: `Email received from:
 ${wfa.dataPill(params.trigger.from_address, 'string')}, Subject:
 ${wfa.dataPill(params.trigger.subject, 'string')}`,
            }
        )

        const sender = wfa.action(
            action.core.lookUpRecord,
            { $id: Now.ID['lookup_sender'] },
            {
                table: 'sys_user',
                conditions:
 `email=${wfa.dataPill(params.trigger.from_address, 'string')}`,
                sort_type: 'sort_asc',

 if_multiple_records_are_found_action: 'use_first_record',
            }
        )

        // Internal P1 path — two tasks
        wfa.flowLogic.if(
            {
                $id: Now.ID['check_internal_p1'],
                condition:
 `
${wfa.dataPill(sender.Record.email, 'string')}LIKEservicenow^${wfa.d
ataPill(params.trigger.subject, 'string')}LIKEP1`,
                annotation: 'Internal sender with P1 subject',
            },
            () => {
                const senderManager = wfa.action(
                    action.core.lookUpRecord,
                    { $id: Now.ID['lookup_sender_manager'] },
                    {
                        table: 'sys_user',
                        conditions:
 `sys_id=${wfa.dataPill(sender.Record.manager, 'reference')}`,
                        sort_type: 'sort_asc',
```

```
if_multiple_records_are_found_action: 'use_first_record',
                    }
                )

                wfa.action(
                    action.core.createTask,

                {
                    table_name: 'incident',
                    ah_to:
wfa.dataPill(params.trigger.from_address, 'string'),
                    ah_subject: `Incident Created:
${wfa.dataPill(params.trigger.subject, 'string')}`,
                    ah_body: `Your request has been received
and a P3 incident has been created. Our team will be in touch
shortly.`,
                    record:
wfa.dataPill(p3Incident.record, 'reference'),
                }
            )
        })
    }
)
```

Import Sets API - ServiceNow Fluent

The Import Sets API defines transform maps [sys_transform_map] that specify how to transform and map data from the import set staging table to target tables.

Every import operation to a production table requires at least one transform map associated with an import set. The transform map specifies the data relationships between the import set and the target table.

To create an import set in ServiceNow Fluent code, you must define the required metadata in the following order:

1. Define the staging table [sys_db_object] using the Table API. The table must extend the Import Set Row [sys_import_set_row] table. For more information, see Table API - ServiceNow Fluent.

   The staging table defines all columns that receive imported data.

2. Define the data source [sys_data_source] using the Record API. The data source must reference the staging table from its *`import_set_table_name`* property. For more information, see Record API - ServiceNow Fluent.

   The data source defines the connection to external systems (files, databases, APIs) and how to load data into import staging tables. For more information, see Data sources.

3. Define the transform map [sys_transform_map] using the Import Sets API. The transform map must reference the staging table from its *`sourceTable`* property.

Important:
The string `NULL` is a reserved word. It shouldn't be used as a field value in import set transform maps or anywhere in the **First name** or **Last name** fields. The reserved word is `NULL` in all capital letters. A field with the value `Null` or `null`, for example, is acceptable. `NULL` should be used only to clear out a particular field.

For general information about import sets, see Import sets.

Related topics

ServiceNow Fluent

ImportSet object

Create a transform map [sys_transform_map] to define the relationships between fields in an import set table and fields in an existing table.

For general information about creating transform maps, see Create a transform map.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. An internal name for the transform map.
targetTable	String	Required. The name of the table in which you want the transformed data to be inserted. You can specify only tables within the application scope or the global scope, or tables that grant write access to other applications.

Properties (continued)

Name	Type	Description
sourceTable	String	Required. The name of the table containing the raw import set data to transform. An import table is any table that extends the Import Set Row [sys_import_set_row] table. You can specify only tables within the application scope. **Note:** The value of this property must match the value of the *name* property in the staging table definition and the *import_set_table_name* property in the data source definition.
order	Number	The execution order in which to apply transform maps if more than one map fits the conditions. Default: 100
active	Boolean	Flag that indicates whether the transform map is active. Default: false
runBusinessRules	Boolean	Flag that indicates whether to run business rules, workflows, approval engines, auditing, and field normalization while the transformation inserts or updates data into the target table. If false, *GlideRecord.setWorkflow()* runs with a value of false. Default: true
enforceMandatoryFields	String	An option to enforce mandatory fields on the target table. Valid values: • no: Don't enforce mandatory fields. • onlyMappedFields: Enforce mandatory mapped fields only. • allFields: Enforce all mandatory fields. Default: no
copyEmptyFields	Boolean	Flag that indicates whether to copy empty fields from source and override existing target field values. Default: false
createOnEmptyCoalesce	Boolean	Flag that indicates whether to create a record when coalesce fields are empty, instead of ignoring the record or overwriting an existing record. If *createOnEmptyCoalesce* is true for any field in the record, the record is coalesced. Default: false

Properties (continued)

Name	Type	Description
runScript	Boolean	Flag that indicates whether to execute the transform map script. The system runs the transform map script in addition to any field maps. Default: false
script	Script	A script that transforms field values in the source table to the target table. This property supports a function from a JavaScript module, a reference to another file in the application that contains a script, or inline JavaScript. Expects a function of type `(source, target, map, log, isUpdate) => void`. Format: • For functions, use the name of a function, function expression, or default function exported from a JavaScript module and import it into the `.now.ts` file. For information about JavaScript modules, see JavaScript modules and third-party libraries. • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``.
fields	Object	Key and value pairs of field mappings where the key is target field name and the value is the source field name or the fields object. Each target field name (key) must be unique within the fields object to avoid mapping conflicts. Format: • To map a target field name to a source field object, see fields object. • To map a target field name to a source field name, use the following format: `fields: { targetFieldName: 'sourceFieldName', ... }`
scripts	Array	A list of transform scripts for additional processing. For more information, see scripts array.

```
import '@servicenow/sdk/global'
import { Table, Record, ImportSet } from '@servicenow/sdk/core'

// STEP 1: Create Staging Table Definition (REQUIRED - MUST BE FIRST)
// This creates the actual table structure to hold imported data
export const userStagingTable = Table({
```

```
    $id: Now.ID['user-staging-table'],
    name: 'u_user_import_staging',
    label: 'User Import Staging',
    extends: 'sys_import_set_row',  // All staging tables extend this
    columns: [
        {
            name: 'u_email_address',
            type: 'email',
            max_length: 100,
            label: 'Email Address'
        },
        {
            name: 'u_full_name',
            type: 'string',
            max_length: 100,
            label: 'Full Name'
        },
        {
            name: 'u_username',
            type: 'string',
            max_length: 40,
            label: 'Username'
        },
    ]
})

// STEP 2: Create Data Source (REQUIRED - MUST BE SECOND)
// The data source defines HOW to get data from external systems
export const userDataSource = Record({
    $id: Now.ID['user-csv-datasource'],
    table: 'sys_data_source',
    data: {
        name: 'User CSV Data Source',
        type: 'File',
        format: 'CSV',
        file_retrieval_method: 'Attachment',
        csv_delimiter: ',',
        header_row: 1,
        // CRITICAL: This must match the table name from STEP 1
        import_set_table_name: 'u_user_import_staging',
        import_set_table_label: 'User Import Staging',
        batch_size: 500,
        active: true,
    },
})

// STEP 3: Create Import Set (Transform Map) (REQUIRED - MUST BE THIRD)
// The import set defines HOW to transform data from staging to target table
export const userImportSet = ImportSet({
    $id: Now.ID['user-import-transform'],
    name: 'User Import Transform',
    targetTable: 'sys_user',
    // CRITICAL: This must match import_set_table_name in Data Source
    sourceTable: 'u_user_import_staging',
    active: true,
    runBusinessRules: true,
    fields: {
```

```
        email: {
            sourceField: 'u_email_address',
            coalesce: true,
        },
        name: 'u_full_name',
        user_name: 'u_username',
    }
})
```

fields object

Define field mappings [sys_transform_entry] from the source fields of an import set to the fields of the target table.

Use the `fields` object within the `ImportSet` object. In the `fields` object, each key for the target field name must be unique to avoid mapping conflicts.

For general information about creating field maps, see Create a field map.

Properties

Name	Type	Description
sourceField	String	The name of the source field from the import table to be transformed. This property is required unless you use the `sourceScript` property or a coalesce-only configuration. Field on the source table to be transformed. If the `sourceTable` contains only raw data, the value can be empty.
choiceAction	String	The action to take if the import set contains a reference or choice value other than those available. This property applies if the target field is a choice list or reference field. Valid values: • create: Create a choice or record in the reference table. • ignore: Ignore the new value from the source table. • reject: Skip the entire row (record) containing the new value and continue to the next row.
sourceScript	Script	A script that transforms field values in the source table to the target table. This property supports a function from a JavaScript module, a reference to another file in the application that contains a script, or inline JavaScript. Expects a function of type `(source) => any`. Format: • For functions, use the name of a function, function expression, or default function exported from a JavaScript module and import it into the `.now.ts` file. For information about JavaScript modules, see JavaScript modules and third-party libraries. • To use text content from another file, refer to a file in the application using the following format:

Properties (continued)

Name	Type	Description
		`Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``.
useSourceScript	Boolean	Flag that indicates whether to use the source script instead of the source field. Default: false
dateFormat	String	The format for transformations when the target field is a Date or Date/Time field. **Note:** To learn more about allowable date formats, see Global date and time field format. Format: `'dd-MM-yyyy'`, `'yyyy-MM-dd'`, `'yyyy-dd-MM'`, `'MM-dd-yyyy HH:mm:ss z'`, `'yyyy-MM-dd HH:mm:ss'`, `'HH:mm:ss'`, `'MM-dd-yyyy HH:mm:ss'`, `'dd-MM-yyyy HH:mm:ss z'`, `'MM-dd-yyyy'`, or `'dd-MM-yyyy HH:mm:ss'`
referenceValueField	String	The reference value field when the target field is a reference field. The transform map needs a way to match incoming source values to existing records in the reference field's source table. Because most imports don't provide a 32-character sys_id value, you must specify a column from the reference field's source table that contains values that match the incoming source values. For more information, see Create a field map.
coalesce	Boolean	Flag that indicates whether the field is used for record matching. Configuring a target field to coalesce causes the import set to treat the field as a unique key. For more information, see Create a field map. Default: false
coalesceCaseSensitive	Boolean	Flag that indicates whether to make case-sensitive coalesce values result in the creation of new records. By default, coalesce fields are used in a case-insensitive lookup for existing records. Case-insensitive records update existing records only and don't cause the creation of new records. Default: false
coalesceEmptyFields	Boolean	Flag that indicates whether to match an empty source field value to an empty target field value. The *`coalesce`* property must be set to true for this property to apply.

Properties (continued)

Name	Type	Description
		For example, the User transform map coalesces on the email field. If this property is set to true, a source record containing an empty email address coalesces to a target record containing an empty email address. Default: false

```
fields: {
        email: {
            sourceField: 'email_address',
            coalesce: true,
            useSourceScript: true,
            sourceScript: `answer = (function
 transformEntry(source) {
                return source.email_address.toLowerCase().trim();
            })(source);`
        },
        department: {
            sourceField: 'dept_code',
            choiceAction: 'create'
        }
}
```

scripts array

Define transform scripts [sys_transform_script] that run at different stages of the import process.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
active	Boolean	Flag that indicates whether the script is active and executes. Default: true
order	Number	The execution order in which scripts run if more than one script fits the conditions. Default: 100
when	String	The stage of the import process in which to execute the script. For more information, see Map with transformation event scripts. Valid values: onBefore, onAfter, onReject, onStart, onForeignInsert, onComplete, onChoiceCreate

Properties (continued)

Name	Type	Description
		Default: onAfter
script	Script	A script that modifies the transformation behavior at the stage specified with the *when* property. This property supports a function from a JavaScript module, a reference to another file in the application that contains a script, or inline JavaScript. Expects a function of type `(source, map, log, target) => void`. Format: • For functions, use the name of a function, function expression, or default function exported from a JavaScript module and import it into the `.now.ts` file. For information about JavaScript modules, see JavaScript modules and third-party libraries. • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``.

```
scripts: [
        {
            $id: Now.ID['validate-email'],
            active: true,
            order: 100,
            when: 'onBefore',
            script: `(function runTransformScript(source, map,
 log, target) {
                if (!source.email_address ||
 source.email_address.indexOf('@') === -1) {
                    log.error('Invalid email address: ' +
 source.email_address);
                    return;
                }
            })(source, map, log, target);`
        },
        {
            $id: Now.ID['validate-user-script'],
            active: true,
            order: 100,
            when: 'onBefore',
            // Using imported function for lifecycle script
            script: validateUserData
        }
    ]
```

List API - ServiceNow Fluent

The List API defines list views [sys_ui_list] for tables.

For general information about lists, see List administration.

Related topics

ServiceNow Fluent

List object

Configure lists [sys_ui_list] and their views.

Properties

Name	Type	Description
table	String	Required. The name of the table to which the list applies.
view	Reference or String	Required. The variable identifier or name of the UI view [sys_ui_view] which applies, or the default view. To define a UI view, use the Record API - ServiceNow Fluent. To use the default view (`default_view`), you must import it: `import { default_view } from '@servicenow/sdk/core'`
columns	Array	Required. A list of columns in the table to display in the list, specified using the column name and position in the list.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { List } from "@servicenow/sdk/core";

List({
    $id: Now.ID["app_task_view_list"],
    table: "cmdb_ci_server",
    view: app_task_view,
    columns: [
        { element: "name", position: 0 },
```

```
        { element: "business_unit", position: 1 },
        { element: "vendor", position: 2 },
        { element: "cpu_type", position: 3 },
    ],
});
```

The UI view definition referenced is defined using the *Record* object:

```
import { Record } from "@servicenow/sdk/core";

const app_task_view = Record({
   $id: Now.ID['app_task_view'],
   table: 'sys_ui_view',
   data: {
        name: 'app_task_view',
        title: 'app_task_view'
   }
})
```

Property API - ServiceNow Fluent

The Property API defines system properties [sys_properties] that control instance behavior.

For general information about system properties, see Add a system property.

Related topics

ServiceNow Fluent

Property object

Add a system property [sys_properties] for configuring an aspect of an application.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. The name of the property beginning with the application scope in the following format: `<scope>.<name>`.
value	Any	A value for the property. The value must be the correct data type. All property values are stored as strings. When retrieving properties via the *`gs.getProperty()`* method, treat the results as strings. For example, a true|false property returns 'true' or 'false' (strings), not the Boolean equivalent.
type	String	A data type for the property value.

Properties (continued)

Name	Type	Description
		Valid values: string, integer, boolean, choicelist, color, date_format, image, password, password2, short_string, time_format, timezone, uploaded_image
description	String	A description of what the property does.
choices	Array	A comma-separated list of choice values. This property only applies if the *`type`* property is set to `choicelist`. If you need a different choice label and value, use an equal sign (=) to separate the label from the value. For example, `['Blue=0000FF', 'Red=FF0000', 'Green=00FF00']` displays **Blue**, **Red**, and **Green** in the list, and saves the corresponding hex value in the property value field.
roles	Object	The variable identifiers of *`Role`* objects or names of roles that have read or write access to the property. For example: `roles: {` `  read: [activity_admin, 'app_user'],` `  write: [admin]` `}` For more information, see Role API - ServiceNow Fluent.
ignoreCache	Boolean	Flag that indicates whether to cache flush when the value of the property is set. The system stores system property values in server-side caches to avoid querying the database for configuration settings. When you change a system property value, the system flushes the cache for the System Properties [sys_properties] table. Use this field to determine whether to flush this property's value from all other server-side caches. Valid values: • true: The system ignores flushing some server-side caches, thus flushing only the cache for the System Properties [sys_properties] table and preserving the prior property value in all other caches. This option avoids the performance cost of flushing all caches and retrieving new property values. Generally, you should only set this property to `true` when you have a system property that changes more frequently than once a month, and the property value is only stored in the System Properties [sys_properties] table table.

Properties (continued)

Name	Type	Description
		• false: The system flushes all server-side caches and retrieves the current property value from the database. Set this property to `false` for all caches to have the current property value. Default: false
isPrivate	Boolean	Flag that indicates whether to exclude the property from being imported via update sets. Keeping system properties private helps prevent settings in one instance from overwriting values in another instance. For example, you might not want a system property in a development instance to use the same value as a production instance. Valid values: • true: The property isn't included in update sets. • false: The property is included in update sets. Default: false
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { Property } from '@servicenow/sdk/core'

Property({
   $id: Now.ID['1234'],
   name: 'x_snc_app.some.new.prop',
   type: 'string',
   value: 'hello',
   description: 'A new property',
   roles: {
      read: ['admin'],
```

```
      write: [adminRole, managerRole],
   },
   ignoreCache: false,
   isPrivate: false,
})
```

The roles referenced are defined using the *Role* object:

```
import { Role } from "@servicenow/sdk/core";

const managerRole = Role({
   $id: Now.ID['manager_role'],
   name: 'x_snc_example.manager'
})

const adminRole = Role({
   $id: Now.ID['admin_role'],
   name: 'x_snc_example.admin',
   containsRoles: [managerRole]
})
```

Record API - ServiceNow Fluent

The Record API defines records in any table. Use the Record API to define application metadata that doesn't have a dedicated ServiceNow Fluent API.

Related topics

ServiceNow Fluent

Record object

Add data to any table with a record.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
table	String	Required. The name of the table to which the record belongs.
data	Object	Fields and their values in the table. For example: `data: { state: 'Ready', task: 'Add demo data' }` To use text content from another file, refer to a file in the application using the `Now.include` syntax. For more information, see ServiceNow Fluent language constructs.

Properties (continued)

Name	Type	Description
		`data: { script: Now.include('./script-file.js'), html: Now.include('./html-file.html'), css: Now.include('./css-file.css') }`
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

In this example, a record defining a menu category is added to the Menu Category [sys_app_category] table. The menu category style is defined in the `css-file.css` file.

```
import { Record } from "@servicenow/sdk/core";

export const appCategory = Record({
    table: 'sys_app_category',
    $id: Now.ID[9],
    data: {
        name: 'example',
        style: Now.include('./css-file.css'),
    },
})
```

In this example, a record defining an incident is added to the Incident [incident] table.

```
import { Record } from '@servicenow/sdk/core';

export const incident1 = Record({
  $id: Now.ID['incident-1'],
  table: 'incident',
  data: {
    active: 'true',
    approval: 'not requested',
    description: 'Unable to send or receive emails.',
    incidentState: '1',
    shortDescription: 'Email server is down.',
    subcategory: 'email',
```

```
    callerId: '77ad8176731313005754660c4cf6a7de',
  }
})
```

In this example, a record defining a server is added to the Server [cmdb_ci_server] table.

```
import { Record } from '@servicenow/sdk/core';

export const ciserver1 = Record({
  $id: Now.ID['cmdb-ci-server-1'],
  table: 'cmdb_ci_server',
  data: {
    assetTag: 'P1000199',
    attested: 'false',
    canPrint: 'false',
    company: 'e7c1f3d53790200044e0bfc8bcbe5deb',
    cost: '2160',
    costCc: 'USD',
    cpuSpeed: '633',
    cpuType: 'GenuineIntel',
    diskSpace: '100',
    manufacturer: 'b7e7d7d8c0a8016900a5d7f291acce5c',
    name: 'DatabaseServer1',
    os: 'Linux Red Hat',
    shortDescription: 'DB Server',
    subcategory: 'Computer',
  }
})
```

Role API - ServiceNow Fluent

The Role API defines roles [sys_user_role] that grant specific permissions to users of an application.

For general information about user roles, see Managing roles.

Related topics

ServiceNow Fluent

Role object

Create a role [sys_user_role] to control access to applications and their features.

Properties

Name	Type	Description
name	String	A name for the role beginning with the application scope in the following format: `<scope>.<name>`.
assignableBy	String	Other roles that can assign this role to users.
canDelegate	Boolean	Flag that indicates if the role can be delegated to other users. For more information, see Delegating roles. Valid values: • true: The role can be delegated to other users. • false: The role can't be delegated to other users.

Properties (continued)

Name	Type	Description
		Default: true
description	String	A description of what the role can access.
elevatedPrivilege	Boolean	Flag that indicates whether manually accepting the responsibility of using the role before you can access the features of the role is required. For more information about elevated privileges, see Elevated privilege roles. Valid values: • true: You must manually accept the responsibility of using the role before you can access its features. • false: You don't need to manually accept the responsibility of using the role to access its features. Default: false
grantable	Boolean	Flag that indicates whether the role can be granted independently. Valid values: • true: The role can be granted independently. • false: The role can't be granted independently. Default: true
containsRoles	Array	The variable identifiers of other *Role* objects that this role contains.
scopedAdmin	Boolean	Flag that indicates whether the role is an Application Administrator role. For general information about application administration roles, see Application administration. Valid values: • true: The role is an Application Administrator. • false: The role isn't an Application Administrator. Default: false
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*:

Properties (continued)

Name	Type	Description
		• demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { Role } from "@servicenow/sdk/core";

const managerRole = Role({
   $id: Now.ID['manager_role'],
   name: 'x_snc_example.manager'
})

const adminRole = Role({
   $id: Now.ID['admin_role'],
   name: 'x_snc_example.admin',
   containsRoles: [managerRole]
})
```

Script Action API - ServiceNow Fluent

The Script Action API defines script actions [sysevent_script_action] that run when an event occurs.

For general information about scheduled script executions, see Script actions.

Related topics

ServiceNow Fluent

ScriptAction object

Create a script action [sysevent_script_action] that performs a task when triggered by an event.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A unique name for the script action.
script	Script	Required. A server-side script that runs when triggered by an event. This property supports a function from a JavaScript module, a reference to another file in the application that contains a script, or inline JavaScript. Format:

Properties (continued)

Name	Type	Description
		• For functions, use the name of a function, function expression, or default function exported from a JavaScript module and import it into the `.now.ts` file. For information about JavaScript modules, see JavaScript modules and third-party libraries. • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script'` or `` `Script` ``.
eventName	String	Required. The event that triggers the script action to run. For information about creating events, see Create an event.
active	Boolean	Flag that indicates whether the script action is enabled. Valid values: • true: The script action executes when triggered by the event. • false: The script action doesn't execute. Default: false
description	String	A description of the functionality and purpose of the script action.
order	Number	A number indicating the sequence in which the script action should run. If there are multiple script actions on a particular event, the script actions run in the order specified, from lowest to highest. Default: 100
conditionScript	String	A JavaScript conditional statement that specifies the fields and values that must be true for the script to run. **Note:** Don't use this property if you include the condition statement with the *`script`* property. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script'` or `` `Script` ``.
$meta	Object	Metadata for the application metadata.

Properties (continued)

Name	Type	Description
		With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { ScriptAction } from '@servicenow/sdk/core'
import { insertIncident } from '../server/scripts.js'

ScriptAction({
    $id: Now.ID['sample-script-action'],
    name: 'SampleScriptAction',
    active: true,
    description: 'Insert an incident',
    script: insertIncident,
    eventName: 'sample.event',
    order: 100,
    conditionScript: "gs.hasRole('my_role')"
})
```

The *script* property refers to a function from the `scripts.js` module. For example:

```
import { GlideRecord } from '@servicenow/glide'

export const insertIncident = () => {
    var gr = new GlideRecord('incident')
    gr.initialize()
    gr.setValue('short_description', 'New incident from event')
    gr.insert()
}
```

Script Include API - ServiceNow Fluent

The Script Include API defines script includes [sys_script_include] that store JavaScript functions and classes for use by server-side scripts.

Note:
For new scripts, use JavaScript modules instead of script includes when possible to support code reuse and using third-party libraries within a scoped application. For more information about JavaScript module support and limitations, see JavaScript modules and third-party libraries.

For general information about script includes, see Script includes.

Related topics

ServiceNow Fluent

ScriptInclude object

Create a script include [sys_script_include] to define a server-side script that runs when called from other scripts.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. The name of the script include. If you define a class, the name must match the name of the class, prototype, and type. If you use a classless (on demand) script include, the name must match the function name.
script	Script	Required. A server-side script to call from other scripts. The script must define a single JavaScript class or a global function. The class or function name must match the *`name`* property. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``.
apiName	String	An internal name for the script include, which is used to call the script include from out-of-scope applications. Default: <scope>.<name>
description	String	A description of the purpose and function of the script include.
clientCallable	Boolean	Flag that indicates whether client-side scripts can call the script include using GlideAjax. The script include is available to client scripts, list/report filters, reference qualifiers, or if specified as part of the URL. Client callable script includes are invoked from *`GlideAjax`* and require users to satisfy an ACL associated with the script include. Valid values:

Properties (continued)

Name	Type	Description
		• true: The script include is available to client-side scripts. • false: The script include isn't available to client-side scripts. Default: false
mobileCallable	Boolean	Flag that indicates whether the script include is available to client scripts called from mobile devices. Valid values: • true: The script include is available to client scripts called from mobile devices. • false: The script include isn't available to client scripts called from mobile devices. Default: false
sandboxCallable	Boolean	Flag that indicates whether the script include is available to scripts invoked from the script sandbox, such as a query condition. **Important:** Script includes should only be made available to the script sandbox if necessary. Valid values: • true: The script include is available to scripts invoked from the script sandbox. • false: The script include isn't available to scripts invoked from the script sandbox. Default: false
callerAccess	String	An option for how cross-scope access to the script include is permitted. For more information, see Restricted caller access privilege settings. Valid values: • restriction: Calls to the script include must be manually approved. Access requests are tracked in the Restricted Caller Access table with a status of Requested. • tracking: Calls to the script include are automatically approved. Calls are tracked in the Restricted Caller Access table with a status of Allowed.
accessibleFrom	String	Specifies which applications can access the script include. Valid values:

Properties (continued)

Name	Type	Description
		• public: All application scopes can call the script include. • package_private: The script include can only be called from the application scope that it's within. Default: package_private
active	Boolean	Flag that indicates whether the script include is enabled. Valid values: • true: The script include is callable. • false: The script include isn't callable. Default: true
protectionPolicy	String	A policy that determines whether someone can view or edit the script include after the application is installed on their instance. If undefined, other application developers can customize the script include. Valid values: • read: Allows anyone to read values from this downloaded or installed script include. No one can change script values on the instance on which they download or install the script include. • protected: Provides intellectual property protection for application developers. Customers who download the script include cannot see the contents of the script field. The script is encrypted in memory to prevent unauthorized users from seeing it in plain text.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

In the following example, the script include uses a script from the `SampleClass.server.js` file.

```
import { ScriptInclude } from '@servicenow/sdk/core';

ScriptInclude({
    $id: Now.ID['sample-script-include'],
    name: 'SampleScriptInclude',
    script: Now.include("./SampleClass.server.js"),
    description: 'some description',
    apiName: 'x_scope.SampleScriptInclude',
    callerAccess: 'tracking',
    clientCallable: true,
    mobileCallable: true,
    sandboxCallable: true,
    accessibleFrom: 'public',
    active: true,
})
```

Scripted REST API - ServiceNow Fluent

The Scripted REST API defines the endpoints, query parameters, and headers for a scripted REST service [sys_ws_definition].

For general information about scripted REST services, see Scripted REST APIs.

Related topics

ServiceNow Fluent

RestApi object

Create a scripted REST API [sys_ws_definition] to define web service endpoints.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. The name of the API, which is used in the API documentation.
serviceId	String	Required. The API identifier used to distinguish this API in URI paths. It must be unique within the API namespace.
active	Boolean	Flag that indicates whether the API can serve requests. Valid values: • true: The API can serve requests. • false: The API can't serve requests. Default: true
shortDescription	String	A brief description of the API, which is used in the API documentation.

Properties (continued)

Name	Type	Description
consumes	String	A list of media types that resources of the API can consume. Default: application/json,application/xml,text/xml
docLink	String	A URL that links to static documentation about the API.
enforceAcl	Array	A list of variable identifiers of *ACL* objects or sys_ids of ACLs to enforce when accessing resources [sys_security_acl]. For more information, see Access Control List API - ServiceNow Fluent. To not enforce ACLs, set this property to an empty array ([ ]). Default: Scripted REST External Default
produces	String	A list of media types that resources of the API can produce. Default: application/json,application/xml,text/xml
routes	Array	The resources [sys_ws_operation] for the API. For more information, see routes object.
policy	String	The policy for how application files are protected when downloaded or installed. Valid values: • read: Files are viewable only. • protected: Users with password permissions can edit the files.
versions	Array	A list of versions [sys_ws_version] for the API. For more information, see versions object. Specifying versions allows you to manage different versions of an API and their statuses, such as whether they are active, the default version, or deprecated.
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*:

Properties (continued)

Name	Type	Description
		• demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { RestApi } from '@servicenow/sdk/core'
import { process } from '../server/handler.js'

RestApi({
    $id: Now.ID['rest1'],
    name: 'customAPI',
    serviceId: 'custom_api',
    consumes: 'application/json',
    routes: [
        {
            $id: Now.ID['route1'],
            path: '/home/{id}',
            script: process,
            parameters: [{ $id: Now.ID['param1'],
 name: 'n_param' }],
            headers: [{ $id: Now.ID['header1'],  name: 'n_token' }],
            enforceAcl: [acl],
            version: 1,
        },
    ],
    enforceAcl: [acl],
    versions: [
        {
            $id: Now.ID['v1'],
            version: 1,
        },
    ],
})
```

The ACL referenced is defined using the *ACL* object:

```
import { Acl } from "@servicenow/sdk/core";

const acl = Acl({
    name: 'My random ACL',
    type: 'rest_endpoint',
    script: `answer = (Math.random() > 0.5)`,
    active: true,
    adminOverrides: false,
    operations: ['execute'],
})
```

routes object

Create a scripted REST resource [sys_ws_operation] to define the HTTP method, the processing script, and to override settings from the parent service.

Use the `routes` object within the `RestApi` object.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	The name of the API resource, which is used in the API documentation. Default: the value of the `path` property
script	Script	Required. The custom script defines how the operation parses and responds to requests. This property supports a function from a JavaScript module, a reference to another file in the application that contains a script, or inline JavaScript. Format: • For functions, use the name of a function, function expression, or default function exported from a JavaScript module and import it into the `.now.ts` file. For information about JavaScript modules, see JavaScript modules and third-party libraries. • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or `Script``.
parameters	Array	A list of query parameters [sys_ws_query_parameter] for the route. For more information, see parameters and headers objects.
headers	Array	A list of headers [sys_ws_header] for the route. For more information, see parameters and headers objects.
active	Boolean	Flag that indicates whether the resource is used. Valid values: • true: The resource is used. • false: The resource isn't used.

Properties (continued)

Name	Type	Description
		Default: true
path	String	The path of the resource relative to the base API path. The relative URI can contain path parameters such as `'/abc/{id}'`. Default: /
shortDescription	String	A brief description of the resource, which is used in the API documentation.
consumes	String	A list of media types that the resource can consume. This property can be overridden with the PUT, PATCH, or POST methods. Default: The value of the *`consumes`* property in the *`RestApi`* object
enforceAcl	Array	A list of variable identifiers of *`ACL`* objects or sys_ids of ACLs to enforce when accessing resources [sys_security_acl]. For more information, see Access Control List API - ServiceNow Fluent. To not enforce ACLs, set this property to an empty array ([ ]). Default: Scripted REST External Default
produces	String	A list of media types that the resource can produce. Default: The value of the *`produces`* property in the *`RestApi`* object
requestExample	String	A valid sample request body payload for the resource, which is used in the API documentation.
method	String	The HTTP method that the resource implements. Valid values: GET, POST, PUT, PATCH, DELETE Default: GET
authorization	Boolean	Flag that indicates whether users must be authenticated to access the resource. Valid values: • true: Users must be authenticated to access the resource. • false: Authentication isn't required to access the resource. Default: true

Properties (continued)

Name	Type	Description
authentication	Boolean	Flag that indicates whether ACLs are enforced when accessing the resource. Valid values: • true: ACLs are enforced when accessing the resource. • false: ACLs aren't enforced when accessing the resource. Default: true
internalRole	Boolean	Flag that indicates whether the route requires the snc_internal role. This property is supported only if the Explicit Roles plugin (com.glide.explicit_roles) is enabled. Valid values: • true: The route requires the snc_internal role. • false: The route doesn't require the snc_internal role. Default: true
policy	String	The policy for how application files are protected when downloaded or installed. Valid values: • read: Files are viewable only. • protected: Users with password permissions can edit the files.
version	Number	The version of the API. This property is required if the *versions* property is used in the *RestApi* object. The version specified with this property is used to automatically generate a URI with a version, such as `/api/management/v1/table/{tableName}`. Version numbers identify the endpoint version that a URI accesses. By specifying a version number, you can test and deploy changes without impacting existing integrations.
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }`

Properties (continued)

Name	Type	Description
		Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
routes: [
   {
      $id: Now.ID['route1'],
      path: '/home/{id}',
      script: process,
      parameters: [{ $id: Now.ID['param1'],  name: 'n_param' }],
      headers: [{ $id: Now.ID['header1'],  name: 'n_token' }],
      enforceAcl: [acl],
      version: 1,
   },
],
```

parameters and headers objects

Create query parameters [sys_ws_query_parameter] and headers [sys_ws_header] for routes in a scripted REST API. Query parameters control what values a requesting user can pass in the request URI. Headers specify what the API accepts and can respond with.

Use the *parameters* and *headers* objects within the *routes* object.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. The name of the parameter or header, which is used in the API documentation.
required	Boolean	Flag that indicates whether the parameter or header is required. Valid values: • true: The parameter or header is required. • false: The parameter or header isn't required. Default: false

Properties (continued)

Name	Type	Description
exampleValue	String	An example of a valid value for the parameter or header, which is used in the API documentation.
shortDescription	String	A brief description of the parameter or header, which is used in the API documentation.
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
parameters: [{ $id: Now.ID['param1'],  name: 'n_param' }],
headers: [{ $id: Now.ID['header1'],  name: 'n_token' }],
```

versions object

Create versions for a scripted REST API [sys_ws_version] to define web service endpoints.

Use the *versions* object within the *RestApi* object.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
version	Number	Required. A version of the REST API.
active	Boolean	Flag that indicates whether the version of the REST API can serve requests. Valid values: • true: The version of the API can serve requests. • false: The version of the API can't serve requests.

Properties (continued)

Name	Type	Description
		Default: true
deprecated	Boolean	Flag that indicates whether the version of the REST API is deprecated. Resources belonging to deprecated versions can serve requests, but are identified as deprecated in documentation. Valid values: • true: The version of the API is identified as deprecated. • false: The version of the API isn't identified as deprecated. Default: false
shortDescription	String	A brief description of the version of the REST API, which appears in the API documentation.
isDefault	Boolean	Flag that indicates whether the version of the REST API is the default version. Clients can access the default version using either the versioned or non-versioned URI path. Valid values: • true: The version of the API is the default version. • false: The version of the API isn't the default version. Default: false
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
versions: [
 {
   $id: Now.ID['v1'],
```

```
    version: 1,
  },
],
```

Service Catalog API - ServiceNow Fluent

The Service Catalog API defines catalog items [sc_cat_item], record producers [sc_cat_item_producer], and related aspects of service catalogs.

For general information about service catalogs, see Service Catalog.

Related topics

ServiceNow Fluent

CatalogItem object

Create a catalog item [sc_cat_item] that users can request from a service catalog.

A catalog item must reference a flow, workflow, or execution plan that defines how the item request is fulfilled.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A name for the item that appears in the catalog.
active	Boolean	Flag that indicates whether the item is active and available to be ordered. Default: true
availability	String	The type of device on which the item displays. Valid values: • desktopOnly: The item displays only on desktop devices. • mobileOnly: The item displays only on mobile devices. • both: The item displays on both desktop and mobile devices. Default: desktopOnly
checkedOut	Boolean	Flag that indicates whether the item is checked out for editing. Default: false
description	String	A detailed description of the item that displays in the catalog when a user selects the item or the associated **Preview** link. You can embed videos, images, links to internal knowledge base (KB) articles, and links to external sources of information and instruction documentation.

Properties (continued)

Name	Type	Description
meta	Array	A list of metadata tags used to aid in searches related to the item. **Note:** The *meta* property is used only for Zing text indexing and search engine and not for AI Search.
model	Reference or String	The variable identifier or sys_id of a product model [cmdb_model] associated with the item. To define a product model, use the Record API - ServiceNow Fluent.
order	Number	The order in which the item appears within its category. Default: 0
owner	Reference or String	The variable identifier or sys_id of a user [sys_user] who owns the item and has edit access to it. To define a user, use the Record API - ServiceNow Fluent.
roles	Array	A list of variable identifiers of *Role* objects or sys_ids of roles [sys_user_role] that can access the item. For more information, see Role API - ServiceNow Fluent.
shortDescription	String	A short description of the item that appears on the catalog home page, search results, and the title bar of the order form.
showVariableHelpOnLoad	Boolean	Flag that indicates whether the item displays variable help text by default. Default: false
startClosed	Boolean	Flag that indicates whether to start the item in a collapsed state. Default: false
state	String	The publication state of the item, such as draft or published.
variables	Object	The variable definitions for the item that provide options for requesting it. Each variable type has a specific function. For example: `variables: {` `  laptopType: SelectBoxVariable({` `  question: "Laptop Type",` `  choices: {` `  standard: { label: "Standard Laptop", sequence: 1 },` `  developer: { label: "Developer Workstation", sequence: 2 }` `  },` `  mandatory: true,` `  order: 100` `  }),`

Properties (continued)

Name	Type	Description
		justification: MultiLineTextVariable({ question: "Business Justification", mandatory: true, order: 200 }) } For general information about catalog variables, see Service catalog variables.
version	Number	A version of the item. Default: 1
image	String	Deprecated. An image for the item.
icon	String	An image file that displays as an icon beside the item name in the catalog. Use a 27x27 pixel image. If no image is uploaded, the default icon appears.
picture	String	An image file to display as a picture of the item.
mobilePicture	String	An image to display as a picture of the item on mobile devices. This property applies only if the value of the *mobilePictureType* is mobilePicture.
mobilePictureType	String	The type of picture to display for the item on mobile devices. Valid values: • desktopPicture: Use the image from the *picture* property. • mobilePicture: Use the image from the *mobilePicture* property. • noPicture: The item doesn't display a picture on mobile devices. Default: desktopPicture
hideAddToCart	Boolean	Flag that indicates whether to hide the **Add to Cart** button. Default: false
hideAddToWishlist	Boolean	Flag that indicates whether to hide the **Add to Wishlist** button. Default: false
hideDeliveryTime	Boolean	Flag that indicates whether to hide the delivery time. Default: false
hideQuantitySelector	Boolean	Flag that indicates whether to hide the **Quantity** field.

Properties (continued)

Name	Type	Description
		Default: false
hideSaveAsDraf	Boolean	Flag that indicates whether to hide the **Save as Draft** button. Default: false
hideSP	Boolean	Flag that indicates whether to hide an item on Service Portal. Default: false
mandatoryAttac	Boolean	Flag that indicates whether to require adding an attachment to submit a request. Default: false
hideAttachment	Boolean	Flag that indicates whether to hide the attachment section and not support adding attachments. Default: false
assignedTopics	Array	A list of sys_ids of existing taxonomy topics that control the visibility of the item in the Employee Center portal. For more information, see Associate a catalog item with a taxonomy topic in Employee Center. **Note:** This property is available only when the Employee Experience Taxonomy plugin (sn_ect) is active.
availableFor	Array	A list of sys_ids of user criteria [user_criteria] that define who can access the item.
notAvailableFor	Array	A list of sys_ids of user criteria [user_criteria] that define who can't access the item. This property overrides the *availableFor* property.
variableSets	Array	A list of variable identifiers of *VariableSet* objects or sys_ids of variable sets [item_option_new_set] to attach to the item. For more information, see VariableSet object. Format: `{ variableSet, order }`
flow	Reference or String	The variable identifier of a *Flow* object or sys_id of a flow [sys_hub_flow] that defines how the request is fulfilled. To define a flow, use the Flow API - ServiceNow Fluent. **Note:** You should use flows as the fulfillment method for catalog items. When *flow*, *workflow*, and *executionPlan* are all specified, the system uses the flow.
executionPlan	Reference or String	The variable identifier or sys_id of an execution plan [sc_cat_item_delivery_plan] that defines how the request is

Properties (continued)

Name	Type	Description
		fulfilled. To define an execution plan, use the Record API - ServiceNow Fluent.
workflow	String	The sys_id of a legacy workflow [wf_workflow] that defines how the item request is fulfilled. Use the `flow` property for new implementations.
accessType	String	The user access required to request the item. Valid values: • restricted: Only users who have access to the item can request the item. • delegated: Users who don't have access to the item can request the item on behalf of someone else using the delegated request experience. For more information, see Delegated request experience. **Note:** This functionality is only applicable when the item has a Requested For variable. Default: restricted
location	Reference or String	The variable identifier or sys_id of a location [cmn_location] where the item is provided. To define a location, use the Record API - ServiceNow Fluent.
vendor	Reference or String	The variable identifier or sys_id of a vendor associated with the item. To define a vendor, use the Record API - ServiceNow Fluent.
deliveryPlanScript	Script	Deprecated. Use the `executionPlan` property instead.
deliveryTime	Object	The estimated time to deliver the item. Format: `deliveryTime: { days: Number, hours: Number })`
entitlementScript	Script	A script that defines entitlement for the item.
makeItemNonConversational	Boolean	Flag that indicates whether to prevent the ability to request the item from a conversational experience such as Virtual Agent. If true, the item can be requested from a conversational experience. Default: false
visibleBundle	Boolean	Flag that indicates whether item is visible in saved bundles. Default: true
visibleGuide	Boolean	Flag that indicates whether item is visible in order guides. Default: true
visibleStandalone	Boolean	Flag that indicates whether the standalone view is visible.

Properties (continued)

Name	Type	Description
		Default: true
fulfillmentAutomationLevel	String	The level of fulfillment automation for requests. Valid values: • unspecified: Automation level of item isn't specified. • manual: Catalog item isn't automated. • semiAutomated: Catalog item is semi-automated. • fullyAutomated: Catalog item is automated completely.
fulfillmentGroup	Reference or String	The variable identifier or sys_id of the group [sys_user_group] responsible for delivering the item. To define a user group, use the Record API - ServiceNow Fluent.
catalogs	Array	A list of sys_ids of the catalogs [sc_catalog] in which the item appears.
categories	Array	A list of sys_ids of the categories [sc_category] to which the item belongs. A catalog must be specified in the `catalogs` property before categories can be assigned. In the Service Portal, catalog searches find only items that are assigned to a category. In Employee Center, catalog searches find only items that are associated with a taxonomy topic. For more information, see Associate a catalog item with a taxonomy topic in Employee Center.
cost	Number	A number indicating the one-time cost of the item. Default: 0
displayPriceProperty	String	The system property that controls how the item price is displayed.
ignorePrice	Boolean	Flag that indicates whether to hide the item price in the cart and in the catalog listing. Default: true
mobileHidePrice	Boolean	Flag that indicates whether to hide the item price on mobile devices. Default: false
omitPrice	Boolean	Flag that indicates whether to omit the price entirely from all views of the item. Default: false
billable	Boolean	Flag that indicates whether the item is billable. Default: false

Properties (continued)

Name	Type	Description
pricingDetails	Array	A list of pricing entries for the item. Valid values: • price: A one-time price for the item. • recurring_price: A price that recurs at a regular interval. When using this value, the *`recurringFrequency`* property is required. Format: `{ amount, currencyType, field }`
recurringFrequency	String	The time interval at which the recurring price repeats, such as monthly or yearly. This property is required when *`pricingDetails`* contains a `recurring_price` field entry.
requestMethod	String	The label for the submission button and the order submission experience. Valid values: • order: Displays an **Order Now** button. A confirmation dialog is shown and delivery information is editable. • request: Displays a **Request** button. A confirmation dialog is shown but delivery information isn't displayed. Use for scenarios where delivery information is pre-determined, such as a code access request. • submit: Displays a **Submit** button. No confirmation dialog or delivery information is displayed. Use for scenarios where no further request information is required, such as a password reset. Default: order
customCart	Reference or String	The variable identifier or sys_id of a custom UI macro to use for cart rendering. To define a custom cart, use the Record API - ServiceNow Fluent.
useScLayout	Boolean	Flag that indicates whether the item uses the Service Catalog layout for display. Default: true
noCart	Boolean	Deprecated. Flag that indicates whether to hide the shopping cart. Default: false
noOrder	Boolean	Deprecated. Flag that indicates whether to hide the **Order** option. Default: false

Properties (continued)

Name	Type	Description
noOrderNow	Boolean	Deprecated. Flag that indicates whether to hide the **Order Now** option. Default: false
noProceedCheckout	Boolean	Deprecated. Flag that indicates whether to hide the checkout process. Default: false
noQuantity	Boolean	Deprecated. Flag that indicates whether to hide the **Quantity** field. Default: false
noSearch	Boolean	Deprecated. Flag that indicates whether to hide search. Default: false
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { CatalogItem } from "@servicenow/sdk/core";

export const softwareLicenseRequest = CatalogItem({
  $id: Now.ID["software_license_request"],
  name: "Software License Request",
  shortDescription: "Request a software license",

  catalogs: [serviceCatalog],
  categories: [softwareCategory],

  // Attach reusable variable sets
  variableSets: [
    { variableSet: contactInfoSet, order: 100 },
    { variableSet: approvalInfoSet, order: 200 }
  ],
```

```
  // Item-specific variables
  variables: {
    software_name: SingleLineTextVariable({
      question: "Software Name",
      mandatory: true,
      order: 100
    }),
    license_type: SelectBoxVariable({
      question: "License Type",
      choices: {
        individual: { label: "Individual", sequence: 1 },
        team: { label: "Team (5 seats)", sequence: 2 },
        enterprise: { label: "Enterprise (unlimited)", sequence: 3 }
      },
      mandatory: true,
      order: 200
    }),
    number_of_licenses: SingleLineTextVariable({
      question: "Number of Licenses",
      defaultValue: "1",
      order: 300
    }),
    justification: MultiLineTextVariable({
      question: "Business Justification",
      mandatory: true,
      order: 400
    })
  },

  // Pricing with recurring charges
  pricingDetails: [
    { amount: 0, currencyType: "USD", field: "price" },
    { amount: 99, currencyType: "USD", field: "recurring_price" }
  ],
  recurringFrequency: "monthly",

  flow: "523da512c611228900811a37c97c2014",
  deliveryTime: { days: 3, hours: 0 }
})
```

CatalogItemRecordProducer object

Create a record producer [sc_cat_item_producer] for users to create task-based records, such as incident or change request records, from the service catalog.

You can create a record producer for tables and database views that are in the same scope as the record producer. You can also create a record producer for tables that allow create access from applications in other scopes.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs.

Properties (continued)

Name	Type	Description
		Format: `Now.ID['String' or Number]`
table	Reference or String	Required. The variable identifier of a *`Table`* object or name of a table in which the record producer creates records, such as incident or change_request.
name	String	Required. A name for the item that appears in the catalog.
active	Boolean	Flag that indicates whether the item is active and available to be ordered. Default: true
availability	String	The type of device on which the item displays. Valid values: • desktopOnly: The item displays only on desktop devices. • mobileOnly: The item displays only on mobile devices. • both: The item displays on both desktop and mobile devices. Default: desktopOnly
checkedOut	Boolean	Flag that indicates whether the item is checked out for editing. Default: false
description	String	A detailed description of the item that displays in the catalog when a user selects the item or the associated **Preview** link. You can embed videos, images, links to internal knowledge base (KB) articles, and links to external sources of information and instruction documentation.
meta	Array	A list of metadata tags used to aid in searches related to the item. **Note:** The *`meta`* property is used only for Zing text indexing and search engine and not for AI Search.
model	Reference or String	The variable identifier or sys_id of a product model [cmdb_model] associated with the item. To define a product model, use the Record API - ServiceNow Fluent.
order	Number	The order in which the item appears within its category. Default: 0
owner	Reference or String	The variable identifier or sys_id of a user [sys_user] who owns the item and has edit access to it. To define a user, use the Record API - ServiceNow Fluent.

Properties (continued)

Name	Type	Description
roles	Array	A list of variable identifiers of *Role* objects or sys_ids of roles [sys_user_role] that can access the item. For more information, see Role API - ServiceNow Fluent.
shortDescription	String	A short description of the item that appears on the catalog home page, search results, and the title bar of the order form.
showVariableHelpOnLoad	Boolean	Flag that indicates whether the item displays variable help text by default. Default: false
startClosed	Boolean	Flag that indicates whether to start the item in a collapsed state. Default: false
state	String	The publication state of the item, such as draft or published.
variables	Object	The variable definitions for the item that provide options for requesting it. Each variable type has a specific function. For example: `variables: { laptopType: SelectBoxVariable({ question: "Laptop Type", choices: { standard: { label: "Standard Laptop", sequence: 1 }, developer: { label: "Developer Workstation", sequence: 2 } }, mandatory: true, order: 100 }), justification: MultiLineTextVariable({ question: "Business Justification", mandatory: true, order: 200 }) }` For general information about catalog variables, see Service catalog variables.
version	Number	A version of the item. Default: 1
view	Reference or String	Required. The variable identifier or name of the UI view [sys_ui_view] which applies, or the default view. To define a UI view, use the Record API - ServiceNow Fluent. To use the default view (`default_view`), you must import it:

Properties (continued)

Name	Type	Description
		`import { default_view } from '@servicenow/sdk/core'`
icon	String	An image file that displays as an icon beside the item name in the catalog. Use a 27x27 pixel image. If no image is uploaded, the default icon appears.
picture	String	An image file to display as a picture of the item.
mobilePicture	String	An image to display as a picture of the item on mobile devices. This property applies only if the value of the *`mobilePictureType`* is `mobilePicture`.
mobilePictureType	String	The type of picture to display for the item on mobile devices. Valid values: • desktopPicture: Use the image from the *`picture`* property. • mobilePicture: Use the image from the *`mobilePicture`* property. • noPicture: The item doesn't display a picture on mobile devices. Default: desktopPicture
assignedTopics	Array	A list of sys_ids of existing taxonomy topics that control the visibility of the item in the Employee Center portal. For more information, see Associate a catalog item with a taxonomy topic in Employee Center. **Note:** This property is available only when the Employee Experience Taxonomy plugin (sn_ect) is active.
availableFor	Array	A list of sys_ids of user criteria [user_criteria] that define who can access the item.
notAvailableFor	Array	A list of sys_ids of user criteria [user_criteria] that define who can't access the item. This property overrides the *`availableFor`* property.
variableSets	Array	A list of variable identifiers of *`VariableSet`* objects or sys_ids of variable sets [item_option_new_set] to attach to the item. For more information, see VariableSet object. Format: `{ variableSet, order }`
hideAddToCart	Boolean	Flag that indicates whether to hide the **Add to Cart** button. Default: false

Properties (continued)

Name	Type	Description
hideAddToWishlist	Boolean	Flag that indicates whether to hide the **Add to Wishlist** button. Default: false
hideDeliveryTime	Boolean	Flag that indicates whether to hide the delivery time. Default: false
hideQuantitySelector	Boolean	Flag that indicates whether to hide the **Quantity** field. Default: false
hideSaveAsDraft	Boolean	Flag that indicates whether to hide the **Save as Draft** button. Default: false
hideSP	Boolean	Flag that indicates whether to hide an item on Service Portal. Default: false
mandatoryAttachment	Boolean	Flag that indicates whether to require adding an attachment to submit a request. Default: false
hideAttachment	Boolean	Flag that indicates whether to hide the attachment section and not support adding attachments. Default: false
allowEdit	Boolean	Flag that indicates whether users can edit the created record after submission. Default: false
canCancel	Boolean	Flag that indicates whether to display a Cancel button on the record producer form. Users can select Cancel to cancel the record producer and return to the last-viewed screen. Default: false
postInsertScript	Script	A server-side script that runs after the record is inserted in the associated table. You can call `current.update()` in this script. **Note:** This script overrides the target record values and record producer template values. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format:

Properties (continued)

Name	Type	Description
		• To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``. Default: `/**` `* This script is executed after the record is generated.` `* `current` Is the GlideRecord produced by Record Producer. Use `current.update()` to update the record` `* To access the variables, use `producer.var1` where var1 is the name of the variable` `* To access the Record Producer use `cat_item`` `*/`
redirectUrl	String	The redirect destination after the record is generated. Valid values: • generatedRecord: Redirects to the task record created by the record producer. • catalogHomePage: Redirects to the service catalog. Default: generatedRecord
saveOptions	String	Advanced configuration options for saving the record producer.
saveScript	Script	A script that runs at every step save in Catalog Builder. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``. Default: `/**` `* This script is executed at every step save in Catalog Builder.` `* This script is executed before `Script` is executed.` `* `current` Is the GlideRecord produced by Record Producer.`

Properties (continued)

Name	Type	Description
		* To access the variables, use `producer.var1` where var1 is the name of the variable * To access the Record Producer use `cat_item` */
script	Script	A server-side script that runs before the record is created. Use this script to assign values to fields on the record dynamically. Don't call `current.update()` or `current.insert()` in this script. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``. Default: /** This script is executed before the Record is generated * `current`- GlideRecord produced by Record Producer * Don't use `current.update()` or `current.insert()` as the record is generated by Record Producer * Don't use `current.setValue('sys_class_name', 'xxx')` as this will trigger reparent flow and can cause data loss * Avoid `current.setAbortAction()` and generate a separate record * Use `producer.var1` to access variables */
image	String	Deprecated. An image for the item.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*:

Properties (continued)

Name	Type	Description
		• demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { CatalogItemRecordProducer } from "@servicenow/sdk/core";

const serviceCatalog = "e0d08b13c3330100c8b837659bba8fb4";
const itServicesCategory = "d258b953c611227a0146101fb1be7c31";

export const comprehensiveIncidentProducer =
 CatalogItemRecordProducer({
  $id: Now.ID["comprehensive_incident_producer"],
  name: "Report Incident with Full Configuration",
  shortDescription: "Complete incident producer with variables and scripts",
  table: "incident",

  catalogs: [serviceCatalog],
  categories: [itServicesCategory],

  variables: {
    short_description: SingleLineTextVariable({
      question: "Brief Summary",
      mandatory: true,
      mapToField: true,
      field: "short_description",
      order: 100
    }),
    urgency: SelectBoxVariable({
      question: "Urgency",
      mandatory: true,
      mapToField: true,
      field: "urgency",
      choices: {
        "1": { label: "High", sequence: 1 },
        "2": { label: "Medium", sequence: 2 },
        "3": { label: "Low", sequence: 3 }
      },
      order: 200
    }),
    assignment_group: ReferenceVariable({
      question: "Assignment Group",
      mapToField: true,
      field: "assignment_group",
      referenceTable: "sys_user_group",
      order: 300
    })
  },

  script: Now.include("../../scripts/rp-pre-insert.js"),
```

```
  postInsertScript: Now.include("../../scripts/rp-post-insert.js"),

  redirectUrl: "generatedRecord",
  view: "ess",
  allowEdit: true
})
```

CatalogUiPolicy object

Configure a catalog UI policy [catalog_ui_policy] to control variable behavior on catalog item forms based on conditions.

Catalog UI policies can make variables mandatory, read-only, visible, or hidden when specified conditions are met. For validation, calculations, or asynchronous calls, use catalog client scripts instead.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
shortDescription	String	Required. A short description of what the catalog UI policy does.
catalogItem	Reference or String	Required only if the *`variableSet`* property isn't used. The variable identifier of a *`CatalogItem`* or *`CatalogItemRecordProducer`* object or sys_id of the catalog item [sc_cat_item] or record producer [sc_cat_item_producer] to which the UI policy applies. For more information, see CatalogItem object or CatalogItemRecordProducer object.
variableSet	Reference or String	Required only if the *`catalogItem`* property isn't used. The variable identifier of a *`VariableSet`* object or sys_id of the variable set [item_option_new_set] to which the UI policy applies. For more information, see VariableSet object.
appliesTo	String	The scope to which the UI policy applies. Valid values: • item: The policy applies to a catalog item. • set: The policy applies to a variable set. Default: item
active	Boolean	Flag that indicates whether the catalog UI policy is active. Default: true
global	Boolean	Flag that indicates on which views of the table the Catalog UI Policy runs. Default: true

Properties (continued)

Name	Type	Description
onLoad	Boolean	Flag that indicates whether the catalog UI policy runs when the form loads. If false, the policy applies only when variable values change. Default: true
reverseIfFalse	Boolean	Flag that indicates whether to reverse the UI policy actions when the catalog condition evaluates to false. Default: true
inherit	Boolean	Flag that indicates whether the Catalog UI Policy is inherited. Default: false
isolateScript	Boolean	Flag that indicates whether the policy scripts run in an isolated scope. Default: true
catalogCondition	String	The encoded query conditions based on catalog item variable values that trigger the UI policy. For example: `catalogCondition: ` `${catalogItem.variables.singleLineText}=catalogitem^${catalogItem.variables.reference}ISNOTEMPTY^EQ`
appliesOnCatalogItemView	Boolean	Flag that indicates whether the UI policy applies to catalog items displayed in the order screen. This view is available to requesters. Default: true
appliesOnTargetRecord	Boolean	Flag that indicates whether the UI policy applies to records created for task-extended tables via record producers. Default: false
appliesOnCatalogTasks	Boolean	Flag that indicates whether the UI policy applies to catalog task forms. This view is available to fulfillers. Default: false
appliesOnRequestedItems	Boolean	Flag that indicates whether the UI policy applies to requested item forms. This view is available to fulfillers. Default: false
runScripts	Boolean	Flag that indicates whether to run the *executeIfTrue* and *executeIfFalse* scripts for this UI policy. Use scripts to apply behaviors beyond read-only, mandatory, or visible, such as targeting a specific role.

Properties (continued)

Name	Type	Description
		Default: false
executeIfTrue	String	A client-side script that runs when the catalog condition evaluates to true. The script must be wrapped in a `function onCondition() {}` function.
executeIfFalse	String	A client-side script that runs when the catalog condition evaluates to false. The script must be wrapped in a `function onCondition() {}` function.
runScriptsInUiType	String	The UI type on which the policy scripts run. Valid values: • desktop: Scripts run on the desktop interface. • mobileOrServicePortal: Scripts run on the mobile and Service Portal interfaces. • all: Scripts run on all interfaces. Default: desktop
vaSupported	Boolean	Flag that indicates whether the UI policy is supported in Virtual Agent conversations. Default: false
actions	Array	A list of variable actions to perform when the catalog condition is met. For more information, see actions array.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { CatalogUiPolicy } from "@servicenow/sdk/core";
import { hardwareRequestItem } from "./catalog-items/HardwareRequest.now";

export const managerApprovalPolicy = CatalogUiPolicy({
  $id: Now.ID["manager_approval_policy"],
  shortDescription: "Show manager approval when high priority selected",
  catalogItem: hardwareRequestItem,
```

```
  catalogCondition:
 `${hardwareRequestItem.variables.priority}=high^EQ`,
  actions: [
    {
      variableName:
 hardwareRequestItem.variables.manager_approval,
      visible: true,
      mandatory: true
    }
  ]
})
```

actions array

Configure the variable actions [catalog_ui_policy_action] that a catalog UI policy performs on variables when its conditions are met.

Each action in the array specifies a variable and the property changes to apply to that variable when the UI policy condition evaluates to true.

Properties

Name	Type	Description
variableName	String	Required. The variable to which the action applies.
visible	Boolean	Flag that indicates whether to make the variable visible. Default: false
disabled	Boolean	Flag that indicates whether to turn off the variable. Default: false
mandatory	Boolean	Flag that indicates whether to make the variable required. Default: false
cleared	Boolean	Flag that indicates whether to clear the variable value when the condition is met. Default: false
variableMessage	String	A message to display on the variable when the condition is met. This property applies only if the *variableMessageType* property has a value.
variableMessageType	String	The type of field message. Valid values: • info • warning • error
value	String	The value to set on the variable when the condition is met.

Properties (continued)

Name	Type	Description
		This property applies only if the *valueAction* property is set to setValue.
valueAction	String	The action to take on the variable value when the condition is met. Valid values: • setValue: Sets the variable to the value specified in the *value* property. • clearValue: Clears the variable value.
order	Number	The order in which the action is evaluated relative to other actions. Default: 100
readOnly	Boolean	Flag that indicates whether to make the variable read only. Default: false

```
actions: [
    {
      variableName: laptopRequest.variables.justification,
      mandatory: true,
      variableMessage: "Justification required for urgent requests",
      variableMessageType: "info",
      order: 100
    },
    {
      variableName: laptopRequest.variables.manager_approval,
      visible: true,
      mandatory: true,
      order: 200
    },
    {
      variableName: laptopRequest.variables.delivery_date,
      visible: true,
      order: 300
    }
]
```

CatalogClientScript object

Configure a catalog client script [catalog_script_client] that runs on the client side to control the behavior of a catalog item form.

Use catalog client scripts to validate user input, auto-populate fields, or display alerts on catalog item forms. For simple show/hide, mandatory, and read-only logic, use catalog UI policies instead.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A unique name for the catalog client script.
script	Script	The client-side script to run on the catalog item form. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``.
type	String	The event that triggers the client script to run. Valid values: • onLoad: Runs when the form loads. Use for initial setup such as setting field states, default values, and visibility. • onChange: Runs when a specific variable changes. Include an `if (isLoading) return;` guard. • onSubmit: Runs when the form is submitted. Return `false` to block submission. Avoid using *`GlideAjax`* in this type because of asynchronous issues.
uiType	String	The UI type on which the client script runs. Valid values: • desktop: Applies to the desktop interface. • mobileOrServicePortal: Applies to the mobile and Service Portal interfaces. • all: Applies to all interfaces. Default: desktop
active	Boolean	Flag that indicates whether the client script is enabled. Default: true
appliesTo	String	Required if using the *`variableSet`* property. The scope to which the catalog client script applies. Valid values:

Properties (continued)

Name	Type	Description
		• item: The script applies to a catalog item. • set: The script applies to a variable set. Default: item
catalogItem	Reference or String	Required only if the *variableSet* property isn't used. The variable identifier of a *CatalogItem* or *CatalogItemRecordProducer* object or sys_id of the catalog item [sc_cat_item] or record producer [sc_cat_item_producer] to which the client script applies. For more information, see CatalogItem object or CatalogItemRecordProducer object.
variableSet	Reference or String	Required only if the *catalogItem* property isn't used. The variable identifier of a *VariableSet* object or sys_id of the variable set [item_option_new_set] to which the UI policy applies. For more information, see VariableSet object.
variableName	String	Required if the value of the *type* property is `onChange`. The name of the catalog variable that triggers the script when its value changes.
appliesOnCatalogItemView	Boolean	Flag that indicates whether the client script applies to catalog items displayed in the order screen of the service catalog. This view is available to requesters. Default: true
appliesOnRequestedItems	Boolean	Flag that indicates whether the client script applies to requested item forms after the item is requested. This view is available to fulfillers. Default: false
appliesOnCatalogTasks	Boolean	Flag that indicates whether the client script applies to catalog task forms for the item. This view is available to fulfillers. Default: false
appliesOnTargetTask	Boolean	Flag that indicates whether the client script applies to records created for task-extended tables via record producers. Default: false
global	Boolean	Flag that indicates whether the client script runs in the global scope. Default: true
vaSupported	Boolean	Flag that indicates whether the client script is supported in Virtual Agent conversations. Default: false

Properties (continued)

Name	Type	Description
publishedRef	String	The sys_id of a published catalog item [sc_cat_item] or record producer [sc_cat_item_producer] that this client script references.
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { CatalogClientScript } from "@servicenow/sdk/core";
import { laptopRequest } from "../catalog-items/laptop-request.now";

CatalogClientScript({
  $id: Now.ID["laptop_onload"],
  name: "Laptop Request - OnLoad",
  script: Now.include("../../client/laptop-onload.js"),
  type: "onLoad",
  catalogItem: laptopRequest,
  active: true,
  appliesOnCatalogItemView: true
});
```

The client script is defined in the `laptop-onload.js` file referenced from the *script* property. For example:

```
function onLoad() {
   // Set initial field states
   g_form.setReadOnly("estimated_cost", true);
   g_form.setValue("estimated_cost", "$0");
   g_form.setMandatory("justification", true);
}
```

VariableSet object

Create a variable set [item_option_new_set] that groups reusable variables for use across multiple catalog items and record producers.

Variable sets are reusable collections of variables that can be attached to catalog items and record producers. Catalog UI policies and client scripts can be scoped to a variable set by setting the `appliesTo` property to `set`.

Note:

- Variable sets within a catalog item can't have the same internal name.
- Within a catalog item, the name of a variable can't be the same as the title or internal name of a variable set.
- Catalog client scripts and catalog UI policy scripts must refer to the internal name of a variable set, not the title or display name.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
title	String	Required. The display title of the variable set. This title appears only if the the *`displayTitle`* property is set to true.
internalName	String	The internal name of the variable set used for programmatic access through the *`g_form`* API and server-side scripts. If not provided, the internal name is automatically generated from the *`title`* property.
description	String	A description of the variable set and its intended use.
type	String	The type of the variable set. Valid values: • singleRow: Variables are arranged in a single row. • multiRow: Variables are arranged in multiple rows that users can add or remove. Default: singleRow
layout	String	The column layout for the variable set. Valid values: • normal: Variables are displayed in a single column. • 2down: Variables are displayed in two columns, one side then the other. • 2across: Variables are displayed in two columns with alternating sides. Default: normal
order	Number	The order in which a variable set displays relative to other variable sets on the form. Default: 100
displayTitle	Boolean	Flag that indicates whether to display a collapsible section header for the variable set. If true, the value of the *`title`* property is displayed as a collapsible header.

Properties (continued)

Name	Type	Description
		Note: Check box variables are grouped under a default title of Options. To use a custom title, add a Label variable with an `order` value that places it directly above the check box variables. Default: false
setAttributes	String	Additional configuration attributes for the variable set as a comma-separated string, such as `max_rows=10,collapsible=true`. Use the `max_rows` attribute to set the maximum number of rows for a multi-row variable set. **Note:** `AttachmentVariable`, `ContainerVariable`, `HtmlVariable`, and `CustomVariable` types aren't supported in multi-row variable sets.
readRoles	Array	A list of variable identifiers of `Role` objects or sys_ids of roles [sys_user_role] that can view the variable set. For more information, see Role API - ServiceNow Fluent.
writeRoles	Array	A list of variable identifiers of `Role` objects or sys_ids of roles [sys_user_role] that can modify variable values in the set. For more information, see Role API - ServiceNow Fluent.
createRoles	Array	A list of variable identifiers of `Role` objects or sys_ids of roles [sys_user_role] that can create row instances. For more information, see Role API - ServiceNow Fluent. This property applies only if the value of the `type` property is `multiRow`.
variables	Object	The variable definitions for the item that provide options for requesting it. Each variable type has a specific function. For example: `variables: { laptopType: SelectBoxVariable({ question: "Laptop Type", choices: { standard: { label: "Standard Laptop", sequence: 1 }, developer: { label: "Developer Workstation", sequence: 2 } }, mandatory: true, order: 100 }), justification: MultiLineTextVariable({ question: "Business Justification", mandatory: true,`

Properties (continued)

Name	Type	Description
		<pre>order: 200 }) }</pre> For general information about catalog variables, see Service catalog variables.
name	String	An optional name for additional identification of the variable set.
version	Number	The version of the variable set. Default: 0
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. <pre>$meta: { installMethod: 'String' }</pre> Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import {
  VariableSet,
  EmailVariable,
  SingleLineTextVariable,
  ReferenceVariable
} from "@servicenow/sdk/core";

export const contactInfoSet = VariableSet({
  $id: Now.ID["contact_info_set"],
  title: "Contact Information",
  description: "Standard contact information fields",
  type: "singleRow",
  layout: "2across",
  order: 100,
  displayTitle: true,
  variables: {
    email: EmailVariable({
      question: "Email Address",
      mandatory: true,
      order: 100
    }),
```

```
    phone: SingleLineTextVariable({
      question: "Phone Number",
      mandatory: true,
      order: 200
    }),
    department: ReferenceVariable({
      question: "Department",
      referenceTable: "cmn_department",
      referenceQualCondition: "active=true",
      order: 300
    })
  }
})
```

Service Level Agreement API - ServiceNow Fluent

The Service Level Agreement API defines service level agreements [contract_sla] that set the amount of time for a task to reach a specified condition, ensuring that tasks are resolved according to the service levels agreed between a service provider and customer.

For general information about SLAs, see Service Level Management.

Related topics

ServiceNow Fluent

Sla object

Create an SLA definition [contract_sla] that controls the timing, conditions, workflows, and other information required to create and progress task SLAs.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A name for the SLA definition.
table	String	The name of the table to which the SLA applies. Default: incident
type	String	The type of service level agreement. The type is used for reporting purposes only. Valid values: • SLA: A service level agreement between a service provider and an external customer. • OLA: An operational level agreement between internal teams within the same organization. • Underpinning contract: A contract with an external vendor that underpins the service delivered to the customer.

Properties (continued)

Name	Type	Description
		Default: SLA
active	Boolean	Flag that indicates whether the SLA definition is active and can be matched against task records. Valid values: • true: The SLA definition is active. • false: The SLA definition is inactive and isn't matched against task records. Default: true
target	String	The stage of the task that the SLA measures. The target is used for filtering, searching, and reporting purposes only. Valid values: • response: The SLA measures the time to first respond to a task. • resolution: The SLA measures the time to resolve a task.
duration	Object	The time duration within which the task must reach the target condition. Use the `Duration()` function to specify the duration. This property is required if the value of the *`durationType`* property is empty. Format: `duration: Duration({ days: Number, hours: Number, minutes: Number, seconds: Number })`
durationType	Reference or String	The sys_id of a relative duration [cmn_relative_duration], such as Breach on Due Date or End of next business day, to use instead of a user-specified duration. To define a relative duration, use the Record API - ServiceNow Fluent.
relativeDurationWorks	String	The record type from which the relative duration is calculated. This property only applies if the value of the *`durationType`* property is set. Valid values: • Task record: The relative duration is calculated from the task record. • SLA record: The relative duration is calculated from the SLA record. Default: Task record

Properties (continued)

Name	Type	Description
schedule	Reference or String	The sys_id of a schedule [cmn_schedule] for the time periods during which the SLAs accumulate business time. To define a schedule, use the Record API - ServiceNow Fluent. This property is required if the value of the *`scheduleSource`* property is `sla_definition`.
scheduleSource	String	The source from which the schedule is obtained. Valid values: • sla_definition: The schedule is specified in the SLA definition using the *`schedule`* property. • task_field: The schedule is obtained from a field on the task record specified with the *`scheduleSourceField`* property. • no_schedule: No schedule is used, and the SLA runs continuously (24x7). Default: sla_definition
scheduleSourceField	String	The field from the task that provides the schedule. This property is required if the value of the *`scheduleSource`* property is `task_field`.
conditions	Object	Encoded query conditions that control the timing of an SLA. For example, `'priority=1^state!=6'` matches tasks with a priority of 1 that aren't in a closed state. For more information about SLA conditions, see Create an SLA definition. For information about filter queries, see Operators available for filters and queries. Format: `conditions: { start: 'String', stop: 'String', pause: 'String', resume: 'String', reset: 'String', cancel: 'String', }`
advancedConditionType	String	The type of advanced condition logic to apply. Valid values: • none: No advanced condition logic is applied. • advanced: A custom advanced condition script is used. • advanced_journal: Advanced condition logic based on journal entries is used.

Properties (continued)

Name	Type	Description
		• advanced_system: Advanced condition logic based on system events is used. • advanced_journal_and_system: Advanced condition logic based on both journal entries and system events is used. Default: none
conditionType	String	The sys_id of an SLA condition [sla_condition_class] that determines when transitions between different stages of each task SLA.
resetAction	String	The action to take on the current task SLA record when the reset condition is met. Valid values: • cancel: The current task SLA record is canceled and a new one is created. • complete: The current task SLA record is marked as complete and a new one is created. Default: cancel
whenTo	Object	Settings that control when a paused SLA resumes and when an SLA cancels. • `resume`: The behavior that controls when a paused SLA resumes timing. Valid values: ○ on_condition: The SLA resumes when the task record matches the condition defined with the `resume` property of the `conditions` object. ○ no_match: The SLA resumes when the task record no longer matches the pause condition defined with the `pause` property of the `conditions` object. Default: on_condition • `cancel`: The behavior that controls when an active SLA is canceled. Valid values:

Properties (continued)

Name	Type	Description
		○ on_condition: The SLA is canceled when the task record matches the condition defined with the *cancel* property of the *conditions* object. ○ no_match: The SLA is canceled when the task record no longer matches the start condition defined with the *start* property of the *conditions* object. ○ never: The SLA is never canceled regardless of task record state. Default: on_condition Format: `whenTo: { resume: 'String', cancel: 'String', }`
retroactive	Object	Settings that control whether the SLA start time is set to a point in the past based on a specified field value. • *start*: Flag that indicates whether retroactive start is enabled. When enabled, the SLA start time is set to the value of the field specified in *setStartTo* rather than the time when the start condition was first met. Default: false • *setStartTo*: The field on the task record whose value is used as the SLA start time when retroactive start is enabled. This property is required if the value of the *start* property is true. • *pause*: Flag that indicates whether retroactive pause is enabled when retroactive start is active. When enabled, any time that the task was in a paused state before the SLA was attached is subtracted from the elapsed time. Default: true Format: `retroactive: { start: Boolean, setStartTo: 'String', pause: Boolean, }`
timezoneSource	String	The source from which the time zone for SLA calculations is obtained. Valid values:

Properties (continued)

Name	Type	Description
		• task.caller_id.time_zone: The time zone of the caller on the task record. • task.caller_id.location.time_zone: The time zone of the caller's location on the task record. • task.cmdb_ci.location.time_zone: The time zone of the configuration item's location on the task record. • task.location.time_zone: The time zone of the location on the task record. • sla.timezone: The time zone specified with the *`timezone`* property. Default: task.caller_id.time_zone
timezone	String	The time zone to use for SLA calculations, such as `US/Pacific`. This property is required if the value of the *`timezoneSource`* property is `sla.timezone`.
overrides	Reference or String	The variable identifier or sys_id of another SLA definition [contract_sla] that this SLA definition overrides.
workflow	Reference or String	The variable identifier or sys_id of a workflow [wf_workflow] to run when the SLA reaches a milestone or breaches. To define a workflow, use the Record API - ServiceNow Fluent.
flow	Reference or String	The variable identifier or sys_id of a flow [sys_hub_flow] to run when the SLA reaches a milestone or breaches. To define a flow, use the Flow API - ServiceNow Fluent. Default: Default SLA flow (828f267973333300e289235f04f6a7a3)
vendor	Reference or String	The variable identifier or sys_id of a company [core_company] that is the vendor for an underpinning contract SLA. To define a company, use the Record API - ServiceNow Fluent.
domainPath	String	The domain path that determines which domain owns the SLA in a multi-domain environment. Default: The global domain (/)
enableLogging	Boolean	Flag that indicates whether debug logging is enabled for the SLA definition. Valid values: • true: Debug logging is enabled. • false: Debug logging is turned off. Default: false
$meta	Object	Metadata for the application metadata.

Properties (continued)

Name	Type	Description
		With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { Sla, Duration } from '@servicenow/sdk/core'

Sla({
    $id: Now.ID['incident-p1-resolution'],
    name: 'P1 Incident Resolution',
    table: 'incident',
    target: 'resolution',
    duration: Duration({ hours: 4 }),
    schedule: 'b1992362eb601100fcfb858ad106fe16',
    conditions: {
        start: 'priority=1',
        stop: 'state=6',
        pause: 'state=3',
        resume: 'state!=3',
    },
    whenTo: {
        resume: 'on_condition',
    },
    resetAction: 'cancel',
})
```

Service Portal API - ServiceNow Fluent

The Service Portal API defines custom widgets [sp_widget] for portal pages.

For general information about portals, see Service Portal.

Related topics

ServiceNow Fluent

SPWidget object

Create a custom widget [sp_widget] to include on a portal page.

For general information about creating custom widgets, see Developing custom widgets.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A name for the widget.
category	String	The type of widget. Valid values: • standard • otherApplications • custom • sample • knowledgeBase • servicePortal • serviceCatalog Default: custom
clientScript	Script	A client-side script that defines the AngularJS controller. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``. Default: `api.controller=function() { /* widget controller */ var c = this;};`
serverScript	Script	A server-side script that sets the initial widget state, sends data to the widget's client script using the `data` object, or runs server-side queries. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format:

Properties (continued)

Name	Type	Description
		• To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``. Default: `(function () { /* populate the 'data' object */ /* e.g., data.table = $sp.getValue('table'); */ })();`
controllerAs	String	A variable for a reference to the controller in the directive's scope. The client script accesses the server data object using the `c.data` variable by default. Default: c
htmlTemplate	String	The body HTML code that defines what is rendered when the page is shown. It can contain either static XHTML, dynamically generated content defined as Jelly, or call script includes and UI Macros. This property supports a reference to another file in the application that contains HTML or inline HTML. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide inline HTML, use string literals or template literals for multiple lines of code: `'HTML' or` `` `HTML` ``. Default: `<div><!-- your widget template --></div>`
customCss	String	The CSS or SCSS that defines the widget style. This property supports a reference to another file in the application that contains CSS or inline CSS. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide inline CSS, use string literals or template literals for multiple lines of code: `'CSS' or` `` `CSS` ``.
dataTable	String	The table in which to store widget instance options. To define a custom option schema, you can add fields to a table that extends the Widget Instance [sp_instance] table and set your

Properties (continued)

Name	Type	Description
		widget to use the extension table as a data source. For more information, see Store instance options in a table. Default: sp_instance
demoData	String or Object	Data that demonstrates the widget functionality. This property supports inline strings, a reference to another file in the application that contains JSON, or inline JSON serializable objects. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide inline JSON, use an object with key and value pairs: `{ key: value }`.
description	String	A description of the widget and its purpose.
docs	Reference	The variable identifier of the Service Portal documentation [sp_documentation] that provides additional information about the widget and its purpose. To define Service Portal documentation, see Record API - ServiceNow Fluent.
fields	Array	A list of column names from the data table to use in the widget option schema.
hasPreview	Boolean	Flag that indicates whether you can preview the widget from the Widget Editor. Valid values: • true: You can preview the widget from the Widget Editor. • false: You can't preview the widget from the Widget Editor. Default: false
id	String	A unique ID for the widget. The ID can't contain spaces.
linkScript	Script	A link function that uses AngularJS to directly manipulate the DOM. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``.

Properties (continued)

Name	Type	Description
		Default: `function link(scope, element, attrs, controller) { }`
roles	Array	A list of variable identifiers of *Role* objects or names of roles that can access the widget. For more information, see Role API - ServiceNow Fluent.
optionSchema	Array	A list of parameters that a Service Portal administrator (sp_admin) can configure for a widget instance. The widget option schema supports reusing a widget and uniquely configuring instances of the widget on different pages. For more information, see Widget option schema. `optionSchema: [ { name: 'String', label: 'String', section: 'String', type: 'String', defaultValue: 'String', hint: 'String' }, ... ]` • name: Required. The name of the parameter. • label: Required. A label for the parameter that appears in the widget instance options. • section: Required. The section of the widget instance options in which the parameter appears. Valid values: ○ data ○ behavior ○ documentation ○ presentation ○ other • type: Required. The data type of the parameter. Valid values: ○ string ○ boolean ○ integer ○ reference ○ choice ○ fieldList

Properties (continued)

Name	Type	Description
		○ fieldName ○ glideList ○ glyphIcon • defaultValue: The default value of the parameter. • hint: A short description of the parameter that displays as tooltip when hovering over it.
public	Boolean	Flag that indicates whether the widget is available to unauthenticated users. Valid values: • true: Unauthenticated users can access the widget. • false: Only authenticated users can access the widget. Default: false
dependencies	Array	A list of variable identifiers of *SPWidgetDependency* objects or names or sys_ids of dependencies for the widget. For more information, see SPWidgetDependency object.
angularProviders	Array	A list of variable identifiers of *SPAngularProvider* objects or names or sys_ids of Angular providers for the widget. For more information, see SPAngularProvider object.
templates	Array	A list of Angular ng-templates [sp_ng_template] to associate with the widget. Angular ng-templates contain content that is rendered only when you instruct it to render. `templates: [ { $id: Now.ID['String' or Number] id: 'String' htmlTemplate: 'HTML' or `HTML` }, ... ]` • $id: Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. Format: `Now.ID['String' or Number]` • id: Required. The ID of the Angular ng-template. • htmlTemplate: Required. The HTML template content. This property supports a reference to another file in the application that contains HTML or inline HTML.
$meta	Object	Metadata for the application metadata.

Properties (continued)

Name	Type	Description
		With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { SPWidget } from '@servicenow/sdk/core'

SPWidget({
    $id: 'my_simple_widget',
    name: 'My Simple Widget',
    category: 'knowledgeBase',
    clientScript: Now.include('./client.js'),
    serverScript: Now.include('./server.js'),
    controllerAs: '$ctrl',
    customCss: Now.include('./custom_css.css'),
    dataTable: 'sp_instance',
    demoData: { message: 'Hello, World!' },
    description: 'This is a test widget',
    docs: widgetDoc,
    htmlTemplate: Now.include('./template.html'),
    fields: ['color', 'class_name'],
    hasPreview: true,
    id: 'my-simple-widget',
    linkScript: Now.include('./link.client.js'),
    optionSchema: [
        {
            name: 'my_option',
            label: 'My Option',
            type: 'string',
            section: 'behavior'
        }
    ],
    roles: [manager, 'admin'],
})
```

SPAngularProvider object

Create an Angular Provider [sp_angular_provider] to reuse components in multiple widgets and improve portal performance.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A name for the Angular provider.
clientScript	Script	A client-side script to reuse in widgets.This property supports inline JavaScript or a reference to another file in the application that contains a script. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or `Script``.
type	String	The type of Angular provider. Valid values: • directive • factory • service Default: directive
requires	Array	A list of variable identifiers of other *`SPAngularProvider`* objects or names or sys_ids of Angular providers.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*:

Properties (continued)

Name	Type	Description
		• demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { SPAngularProvider } from '@servicenow/sdk/core'
const OTHER_ANGULAR_PROVIDER = 'd11f285fe069e1f119b44bd05c0770aa'

SPAngularProvider({
    $id: 'my_angular_provider',
    name: 'my_angular_provider',
    clientScript: Now.include('my_angular_provider.client.js'),
    type: 'directive',
    requires: [OTHER_ANGULAR_PROVIDER]
})
```

SPWidgetDependency object

Create a widget dependency [sp_dependency] to link JavaScript and CSS files to widgets and use third-party libraries, external style sheets, or Angular modules.

Dependencies are loaded asynchronously from the server when needed. Widgets can have as many or as few dependencies as needed. However, the more you add, the more content a widget must download to render on the page. Keep dependencies as small as possible for more efficient load times. For more information, see Create a widget dependency.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. The name of the widget dependency.
angularModuleName	String	The name of the Angular module to load if the JS include is an Angular module.
includeOnPageLoad	Boolean	Flag that indicates when the dependency loads on a page. Valid values: • true: The dependency loads with the initial page load. • false: The dependency loads only when the linked widget is loaded on a page.

Properties (continued)

Name	Type	Description
		Default: false
cssIncludes	Array	A list of variable identifiers of *`CssInclude`* objects or sys_ids of CSS includes and their order. For more information, see CssInclude object. `cssIncludes: [ { order: Number, include: 'String' or Reference, }, ... ]`
jsIncludes	Array	A list variable identifiers of *`JsInclude`* objects or sys_ids of JS includes and their order. For more information, see JsInclude object. `jsIncludes: [ { order: Number, include: 'String' or Reference, }, ... ]`
portalsForPageLoad	Array	A list of sys_ids of portals [sp_portal] that load the widget dependency. If empty, the dependency is included on the page load for all portals.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { SPWidgetDependency } from '@servicenow/sdk/core'

SPWidgetDependency({
    $id: 'samplejs',
```

```
    name: 'Sample',
    angularModuleName: 'samplejs',
    includeOnPageLoad: true,
    portalsForPageLoad:
['b4572a48262a16df3032b48cef75a853', 'fe12dbbed14bd3f712f0787141c2f656'],
    cssIncludes: [
        {
            order: 100,
            include: localCss,
        },
        {
            order: 200,
            include: '94112ccb0fb3c2ed072b01d3cb401196',
        },
    ],
    jsIncludes: [
        {
            order: 100,
            include: localJs,
        },
        {
            order: 200,
            include: 'f8af18a5e6c71a3702c4f2038b43cf62',
        },
    ],
})
```

CssInclude object

Create a CSS include [sp_css_include] to reference a style sheet or external CSS in a widget dependency.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. The name of the CSS include.
url	String	The URL to an external CSS file. This property is required if a style sheet isn't provided with the *`spCss`* property.
spCss	String	The sys_id of a style sheet [sp_css]. This property is required if an external CSS file isn't provided with the *`url`* property.
rtlCssUrl	String	The URL to an external right-to-left (RTL) CSS file for mirroring the direction of a widget when the session language is a right-to-left language, such as Hebrew. For more information, see Styling for right-to-left languages in portals.

Properties (continued)

Name	Type	Description
lazyLoad	Boolean	Flag that indicates how to load the CSS Include. This property applies only if you use the *spCSS* property to specify a style sheet. Valid values: • true: The CSS include loads asynchronously to improve page load time. • false: The CSS include doesn't load asynchronously. Default: false
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { CssInclude } from '@servicenow/sdk/core'

const localCss = CssInclude({
    $id: '22bcf16da81e2bc0340c53d50d531adf',
    name: 'Sample Styles',
    spCss: '50e3e32aa321b1c7d1945c5f423228bd',
})
```

JsInclude object

Create a JS include [sp_js_include] to reference a UI script or external JavaScript code in a widget dependency.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs.

Properties (continued)

Name	Type	Description
		Format: `Now.ID['String' or Number]`
name	String	Required. The name of the JS include.
url	String	The URL to an external JavaScript file. The URL should be an absolute path. This property is required if a UI script isn't provided with the *`sysUiScript`* property.
sysUiScript	String	The sys_id of a UI script [sys_ui_script]. This property is required if an external JavaScript file isn't provided with the *`url`* property.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { JsInclude } from '@servicenow/sdk/core'

const localJs = JsInclude({
    $id: '98239e4eadfac88b01cce7daa23b6fc3',
    name: 'Sample Framework',
    sysUiScript: 'b67af05645f738df1f286bb3e9ecd55f',
})
```

Table API - ServiceNow Fluent

The Table API defines tables [sys_db_object] to store data in an application.

Create a table using the *`Table`* object. From the *`schema`* property, add Column objects, such as *`StringColumn`* or *`IntegerColumn`*, to define the columns.

For general information about tables, see Table administration.

Related topics

ServiceNow Fluent

Table object

Create a table [sys_db_object] in an application.

Properties

Name	Type	Description
name	String	Required. A name for the table beginning with the application scope and in all lowercase letters in the following format: `<scope>_<name>`. The name should match the variable identifier of the *`Table`* object. **Note:** To add columns to an existing table in a different application scope, you can provide the name of the table without the application scope followed by `as any`. The column names must begin with the application scope instead. Maximum length: 80
schema	Array	Required. A list of *`Column`* objects. For more information, see Column object.
extends	String	The name of any other table on which the table is based. Extending a base table incorporates all the fields of the original table and creates system fields for the new table. If they are in the same scope or if they can be configured from other scopes, you can extend tables that are marked as extensible.
label	String or Array	A unique label for the table in list and form views. Field labels can be provided as a string or an array of *`label`* objects. For more information, see label object. Maximum length: 80 Default: the value of the *`name`* property
licensingConfig	Object	The licensing configuration [ua_table_licensing_config] for a table. For more information, see licensingConfig object.
display	String	The default display column. Use a column name from the *`schema`* property.
extensible	Boolean	Flag that indicates whether other tables can extend the table. Valid values: • true: Other tables can extend the table. • false: Other tables can't extend the table. Changing this property from true to false prevents the creation of additional child tables but existing child tables remain unchanged. Default: false

Properties (continued)

Name	Type	Description
liveFeed	Boolean	Flag that indicates if live feeds are available for records in the table. Valid values: • true: Live feeds are provided for records in the table. This option adds the **Show Live Feed** option () in the form header. • false: Live feeds aren't provided for records in the table. Default: false
accessibleFrom	String	The application scopes that can access the table. Valid values: • public: The table is accessible from all application scopes. • package_private: The table is accessible from only the application scope it's in. Default: public
callerAccess	String	The access level for cross-scope requests. Valid values: • restricted: Calls to the resource must be manually approved. Access requests are tracked in the Restricted Caller Access table with a status of Requested. • tracking: Calls to the resource are automatically approved. Calls are tracked in the Restricted Caller Access table with a status of Allowed. • none: Cross-scope calls to the resource are approved or denied based on the value of the `accessibleFrom` property. For more information, see Restricted caller access privilege settings. Default: none
actions	Array	A list of access options. Valid values: • read: Allow script objects from other application scopes to read records stored in this table. For example, a script in another application can query data on this table. Read access is required to grant any other API record operations.

Properties (continued)

Name	Type	Description
		• create: Allow script objects from other application scopes to create records in this table. For example, a script in another application can insert a new record in this table. • update: Allow script objects from other application scopes to modify records stored in this table. For example, a script in another application can modify a field value on this table. • delete: Allow script objects from other application scopes to delete records from this table. For example, a script in another application can remove a record from this table. Default: read
allowWebServiceAccess	Boolean	Flag that indicates whether web services can make calls to the table. Valid values: • true: Web services can make calls to the table. • false: Web services can't make calls to the table. Default: false
allowNewFields	Boolean	Flag that indicates whether to allow design time configuration of new fields on the table from other application scopes. Valid values: • true: Allow design time configuration of new fields on the table from other application scopes. • false: Don't allow design time configuration of new fields on the table from other application scopes. Default: false
allowUiActions	Boolean	Flag that indicates whether to allow design time configuration of UI actions on the table from other application scopes. Valid values: • true: Allow design time configuration of UI actions on the table from other application scopes. • false: Don't allow design time configuration of UI actions on the table from other application scopes. Default: false

Properties (continued)

Name	Type	Description
allowClientScripts	Boolean	Flag that indicates whether to allow design time configuration of client scripts on the table from other application scopes. Valid values: • true: Allow design time configuration of client scripts on the table from other application scopes. • false: Don't allow design time configuration of client scripts on the table from other application scopes. Default: false
audit	Boolean	Flag that indicates whether to track the creation, update, and deletion of all records in the table. Valid values: • true: Track the creation, update, and deletion of all records in the table • false: Don't track the creation, update, and deletion of all records in the table. Default: false
readOnly	Boolean	Flag that indicates whether users can edit fields in the table. Valid values: • true: Users can't edit fields in the table. • false: Users can edit fields in the table. Default: false
textIndex	Boolean	Flag that indicates whether search engines index the text in a table. Valid values: • true: The table's text is indexed. • false: The table's text isn't indexed. Default: false
attributes	Object	Key and value pairs of any supported dictionary attributes [sys_schema_attribute]. For example: `attributes:` `  {` `  updateSyncCustom: Boolean,` `  nativeRecordLock: Boolean` `  }`

Properties (continued)

Name	Type	Description
		For more information, see Dictionary Attributes.
index	Array	A list of column references to generate indexes in the metadata XML of the table. The value of the *element* property should match the object key used with the *Column* object. A database index increases the speed of accessing data from the table with the expense of using additional storage. `index: [ { name: 'String', element: 'String', unique: Boolean }, ... ]`
autoNumber	Object	The auto-numbering configuration [sys_number] for a table. For more information, see autoNumber object.
scriptableTable	Boolean	Flag that indicates whether the table is a remote table that uses data retrieved from an external source. For more information, see Remote tables. Valid values: • true: The table is a remote table. • false: The table isn't a remote table. Default: false

For typeahead support for columns, assign the *Table* object to an exported variable with the same name as the *name* property.

```
import { Table, StringColumn } from "@servicenow/sdk/core";
import { myFunction } from "../server/myFunction.js"

export const x_snc_example_to_do = Table({
    name: 'x_snc_example_to_do',
    label: 'My To Do Table',
    extends: 'task',
    schema: {
        status: StringColumn({ label: 'Status' }),
        deadline: StringColumn({
            label: 'Deadline',
            active: true,
            mandatory: false,
            readOnly: false,
            maxLength: 40,
            dropdown: 'none',
            attributes: {
```

```
            updateSync: false,
        },
        default: 'today',
        dynamicValueDefinitions: {
            type: 'calculated_value',
            calculatedValue: '',
        },
        choices: {
            choice1: {
                label: 'Choice1 Label',
                sequence: 0,
                inactiveOnUpdate: false,
                dependentValue: '5',
                hint: 'hint',
                inactive: false,
                language: 'en',
            },
            choice2: { label: 'Choice2 Label', sequence: 1 },
        },
    }),
    dynamic1: StringColumn({
        dynamicValueDefinitions: {
            type: 'calculated_value',
            calculatedValue: myFunction,
        },
    }),
    dynamic2: StringColumn({
        dynamicValueDefinitions: {
            type: 'dynamic_default',
            dynamicDefault: `gs.info()`,
        },
    }),
    dynamic3: StringColumn({
        dynamicValueDefinitions: {
            type: 'dependent_field',
            columnName: 'status',
        },
    }),
    dynamic4: StringColumn({
        dynamicValueDefinitions: {
            type: 'choices_from_other_table',
            table: 'sc_cat_item',
            field: 'display',
        },
    }),
},
actions: ['create', 'read'],
display: 'deadline',
accessibleFrom: 'package_private',
allowClientScripts: true,
allowNewFields: true,
allowUiActions: true,
allowWebServiceAccess: true,
extensible: true,
liveFeed: true,
callerAccess: 'none',
autoNumber: {
```

```
        number: 10,
        numberOfDigits: 2,
        prefix: 'abc',
    },
    audit: true,
    readOnly: true,
    textIndex: true,
    attributes: {
        updateSync: true,
    },
    index: [
        {
            name: 'idx',
            element: 'status',
            unique: true,
        },
    ],
})
```

Column object

Add a column [sys_dictionary] to a table.

Add *Column* objects in the *schema* property of the *Table* object.

There are many types of columns based on the field type. Column objects use the format *<Type>Column* where *<Type>* is the field type. For information about field types, see Field types.

The following types of columns are supported: *ListColumn*, *RadioColumn*, *StringColumn*, *ChoiceColumn*, *ScriptColumn*, *BooleanColumn*, *ConditionsColumn*, *DecimalColumn*, *IntegerColumn*, *VersionColumn*, *DomainIdColumn*, *FieldNameColumn*, *ReferenceColumn*, *TableNameColumn*, *UserRolesColumn*, *BasicImageColumn*, *DocumentIdColumn*, *DomainPathColumn*, *TranslatedTextColumn*, *SystemClassNameColumn*, *TranslatedFieldColumn*, *GenericColumn*, *DateColumn*, *DateTimeColumn*, *CalendarDateTime*, *BasicDateTimeColumn*, *DueDateColumn*, *CalendarDateTime*, *IntegerDateColumn*, *ScheduleDateTimeColumn*, *OtherDateColumn*, *Password2Column*, *GuidColumn*, *JsonColumn*, *NameValuePairsColumn*, *UrlColumn*, *EmailColumn*, *HTMLColumn*, *FloatColumn*, *MultiLineTextColumn*, *DurationColumn*, *TimeColumn*, *FieldListColumn*, *SlushBucketColumn*, *TemplateValueColumn*, and *ApprovalRulesColumn*.

Properties

Name	Type	Description
label	String or Array	A unique label for the column that appears on list headers and form fields. Field labels can be provided as a string or an array of *label* objects. For more information, see label object. Default: the key used for the column object
maxLength	Number	The maximum length of values in the column.

Properties (continued)

Name	Type	Description
		A length of under 254 appears as a single-line text field. Anything 255 characters or over appears as a multi-line text box. **Note:** To avoid data loss, only decrease the length of a string field when you're developing a new application and not when a field contains data. Default: varies depending on the column type
active	Boolean	Flag that indicates whether to display the field in lists and forms. Valid values: • true: Displays the field. • false: Hides the field. Default: true
mandatory	Boolean	Flag that indicates whether the field must contain a value to save a record. Valid values: • true: The field must contain a value. • false: The field isn't required. Default: false
readOnly	Boolean	Flag that indicates whether you can edit the field value. Valid values: • true: You can't change the value, and the system calculates and displays the data for the field. • false: You can change the field value. Default: false
default	Any	The default value of the field when creating a record. The value must use the correct type based on the column type.
choices	Object	A list of choices [sys_choice] for a column. For more information, see choices object. This property only applies to `ChoiceColumn` objects and column types that extend choice columns. It can include either an array of primitive values or a series of choice objects.

Properties (continued)

Name	Type	Description
attributes	Object	Key and value pairs of any supported dictionary attributes [sys_schema_attribute]. For example: `attributes: { updateSyncCustom: Boolean, nativeRecordLock: Boolean }` For more information, see Dictionary Attributes.
functionDefinition	String	The definition of a function that the field performs, such as a mathematical operation, field length computation, or day of the week calculation. Each definition begins with `glidefunction:`, followed by the operation to be performed (such as, `concat`), followed by function parameters. Constants must be enclosed in single quotes. For example, the following function definition creates a field that shows the short description, followed by a space, followed by the caller name: `functionDefinition: 'glidefunction:concat(short_description, ' ', caller_id.name)'` For more information about function definitions, see Function field.
dynamicValueDefinitions	Object	Default values that are generated dynamically based on dynamic filters. Provide a combination of a type and a related behavior key to specify dynamic defaults. The following types are supported: • dynamic_default: Provide a function from the Dynamic Filter Options [sys_filter_option_dynamic] table. For more information, see Create a dynamic filter option. For example: `dynamicValueDefinitions: { type: 'dynamic_default', dynamicDefault: `gs.info()`, },` • dependent_field: Provide another column name from the same table. For example: `dynamicValueDefinitions: { type: 'dependent_field', columnName: 'status', },` • calculated_value: Provide a function for calculating the value. The function can be imported from a JavaScript module or be defined inline. For example:

Properties (continued)

Name	Type	Description
		`` dynamicValueDefinitions: { type: 'calculated_value', calculatedValue: function, }, ``` • choices_from_other_table: Provide choices from a column on another table. For example: ``` dynamicValueDefinitions: { type: 'choices_from_other_table', table: 'sc_cat_item', field: 'display', }, ```
dropdown	String	An option for how a list of choices displays for list and form views of the table. This property only applies to *`ChoiceColumn`* objects and column types that extend choice columns. Valid values: • none: The choices aren't enforced. • dropdown_without_none: A menu without the **-- None --** option. If you select this option, you must configure the *`default`* property for the column. • dropdown_with_none: A menu with the **-- None --** option. The default value is **-- None --**. • suggestion: Choices are displayed in a list of suggested values. Default: none

Column names are provided as object keys paired with the column definitions.

```
schema: {
   deadline: DateColumn({ label: 'Deadline' }),
   state: StringColumn({
      label: 'State',
      choices: {
         ready: { label: 'Ready' },
         completed: { label: 'Completed' },
         inProgress: { label: 'In Progress' },
      }
   }),
   task: StringColumn({ label: 'Task', maxLength: 120 }),
}
```

If the table name doesn't include the application scope, column names must be prefixed with the application scope instead.

```
schema: {
   x_scope_myColumn: StringColumn({...})
}
```

choices object

Configure choices [sys_choice] for a column in a table.

The `choices` object is a property within the `Column` object. Use the `choices` object with supported column types in the `schema` property of a `Table` object. Only certain column types extend the choice column type (`ChoiceColumn`) and can include choices.

Properties

Name	Type	Description
label	String	Required. The text to display for the choice in the list.
dependentValue	String	A value that you map to the `dependentField` in the `dynamicValueDefinitions` property of the `Column` object.
hint	String	A short description of the choice that displays as tooltip when hovering over it.
language	String	The BCP 47 code of the language for the translated choice. Default: en
sequence	Integer	The order in the list of choices that a choice occurs.
inactive	Boolean	Flag that indicates whether to show the choice in the list. Valid values: • true: The choice is hidden from the list. • false: The choice appears in the list. Default: false

The `choices` object includes a series of choice objects, where the names of the choices are provided as object keys paired with the choices definitions.

```
choices: {
   choice1: {
      label: 'Choice1 Label',
      sequence: 0,
      inactiveOnUpdate: false,
      dependentValue: '5',
      hint: 'hint',
      inactive: false,
      language: 'en',
   },
   choice2: { label: 'Choice2 Label', sequence: 1 },
}
```

label object

Configure a field label [sys_documentation] for a table or column.

The *label* object is a property within the *Table* and *Column* objects.

Properties

Name	Type	Description
language	String	The BCP 47 code of the language for the field label. A language can have only one label, so each language must be unique within an array of *label* objects.
label	String	The text of the field label in the specified language.
hint	String	A short description that displays as a tooltip when hovering over the field label.
help	String	Additional information about the field. Help text isn't displayed in form or list views of the table.
plural	String	The plural form of the field label.
url	String	A URL for a web page that provides information about the field. When a URL is provided, the label displays as a hyperlink.
urlTarget	String	Not used (deprecated).

```
label: [
   {
      label: 'English description',
      language: 'en',
      hint: 'Provide a short description'
   },
   {
      label: 'Description de español',
      language: 'es'
   },
]
```

licensingConfig object

Create a licensing configuration [ua_table_licensing_config] to track subscription counts for a table.

The *licensingConfig* object is a property within the *Table* object. If this property isn't specified, a default licensing configuration with *licenseModel* set to none is generated for the table on the instance.

Note:
Specifying a licensing model is not applicable for ServiceNow customers who build custom applications for their own use. Licensing models are used only by partners who sell and monitor the usage of resellable applications on the ServiceNow Store.

Properties

Name	Type	Description
licenseModel	String	The model for tracking subscription usage.

Properties (continued)

Name	Type	Description
		Valid values: • none: Licensing isn't used for the table. • fulfiller: Fulfiller/requester operations are tracked. This model applies to applications in which users open requests and fulfillers address them. Fulfillment is determined by insert, update, and delete operations on records in one or more key tables in the application under a set of specified conditions. For more information, see Fulfillment tables. • producer: Producer operations are tracked. This model applies to applications in which users can perform insert, update, and delete operations on a table without identifying requesters and fulfillers. Default: none
licenseRoles	Array	A list of roles for which any operations on records in the table count toward the subscription.
opDelete	Boolean	Flag that indicates whether a subscription is required to delete records for tables with the producer model. Valid values: • true: A subscription is required to delete records in the table. • false: A subscription isn't required to delete records in the table. Default: true
opInsert	Boolean	Flag that indicates whether a subscription is required to insert records for tables with the producer model. Valid values: • true: A subscription is required to insert records in the table. • false: A subscription isn't required to insert records in the table. Default: true
opUpdate	Boolean	Flag that indicates whether a subscription is required to update records for tables with the producer model. • true: A subscription is required to update records in the table. • false: A subscription isn't required to update records in the table.

Properties (continued)

Name	Type	Description
		Default: true
licenseCondition	String	A filter query that determines conditions for counting operations toward a subscription. For the fulfiller model, specify the set of conditions that determine whether the logged-in user is the fulfiller of the record. For the producer model, specify the set of conditions that determine whether records count toward the subscription.
ownerCondition	String	A filter query that determines whether a user owns a record for the fulfiller model.
isFulfillment	Boolean	Not used (deprecated). Flag that indicates whether to disallow updates by users who aren't subscribed to the application. Valid values: • true: Users who aren't subscribed to the application can't make updates to the table. • false: Users who aren't subscribed to the application can make updates to the table. Default: false

```
licensingConfig: {
  licenseModel: 'fulfiller',
  opInsert: false,
  licenseRoles: ['admin'],
}
```

autoNumber object

Configure auto-numbering [sys_number] for a table.

The *autoNumber* object is a property within the *Table* object.

Properties

Name	Type	Description
prefix	String	A prefix for every record number in the table. For example, INC for Incident. Default: pre
number	Integer	The base record number for this table. Record numbers are automatically incremented, and the next number is maintained in the Counter [sys_number_counter] table.

Properties (continued)

Name	Type	Description
		If you set the base number to a value higher than the current counter, the next record number uses the new base number. Otherwise the next record number uses the current counter. The counter doesn't reset to a base number lower than itself. Default: 1000
numberOfDigits	Integer	The minimum number of digits to use after the prefix. Leading zeros are added to auto-numbers, if necessary. For example, INC0001001 contains three leading zeros. The number of digits can exceed the minimum length. For example, if *numberOfDigits* is 2 and more than 99 records are created on the table, the numbers continue past 100 (such as INC101). **Warning:** Changing this field can update all number values for existing records on a table. Take care when changing this field on a production instance. Default: 7

```
autoNumber: {
   prefix: 'TODO',
   number: 2000,
   numberOfDigits: 9,
}
```

To use the number in a table, you need to create a number column that uses the number as the default value. For example:

```
number: IntegerColumn({
   default: 'javascript:getNextObjNumberPadded();'
})
```

UI Action API - ServiceNow Fluent

The UI Action API defines custom user interface (UI) actions [sys_ui_action], such as buttons, links, and context menu items on forms and lists.

For general information about UI actions, see Create a UI action.

Related topics

ServiceNow Fluent

UiAction object

Create a UI action [sys_ui_action] to display on a form.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
table	String	Required. The name of the table on which the UI action is available. By default, the UI action also appears on tables that extend the selected table. For example, Task actions appear on the Incident table. Set the value to `global` to make the action available on all tables.
name	String	Required. The text that appears on the button, link, or context menu item. The name must be unique within the table specified.
actionName	String	A unique name to use when referencing the UI action in scripts.
active	Boolean	Flag that indicates whether the UI action is enabled. Valid values: • true: The UI action appears and executes. • false: The UI action is hidden. Default: true
form	Object	Options for how UI actions appear on forms. For more information, see form object.
list	Object	Options for how UI actions appear on the list view. For more information, see list object.
client	Object	Options to execute the script in the browser. For more information, see client object.
workspace	Object	Options for how UI actions function and appear in workspaces. For more information, see workspace object.
overrides	Reference or String	The name or variable identifier of another UI action that the UI action overrides.
showInsert	Boolean	Flag that indicates whether to show a button on new records before they're inserted. Valid values: • true: The button appears on records before they're inserted. • false: The button doesn't appear on records that haven't been inserted.

Properties (continued)

Name	Type	Description
		Default: false
showUpdate	Boolean	Flag that indicates whether to show a button on existing records. Valid values: • true: The button appears on existing records. • false: The button doesn't appear on existing records. Default: true
showQuery	Boolean	Flag that indicates whether the UI action is visible on a list when a filter query is applied. Valid values: • true: The UI action appears when a filter query is applied. • false: The UI action doesn't appear a filter query is applied. Default: false
showMultipleUpdate	Boolean	Flag that indicates whether to show a button when multiple records are selected. Valid values: • true: The button appears when multiple records are selected. • false: The button doesn't appear when multiple records are selected. Default: false
condition	String	A JavaScript conditional statement that specifies the fields and values that must be true for the script to run.

Properties (continued)

Name	Type	Description
		Note: • Don't use this property if you include the condition statement with the *`script`* property. • The current object isn't available for conditions on a list context menu. If the list's *`showContextMenu`* property is true, any use of `current` on these actions is ignored. • You can reference the parent record for the UI action conditions on a related list button. For example, to disable the **New** and **Edit** buttons on the Affected CIs related list for closed changes, copy the global m2m UI actions to the task_ci table and add a condition of *`parent.active`*. • If you leave one of the fields that you specify in your condition statement empty, that condition defaults to true. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or `Script``.
script	Script	A client-side or server-side script that runs when the UI action is executed. Function names must be unique. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or `Script``.
comments	String	Internal notes about the UI action.
messages	String	Text strings that the UI action can use as a key to look up a localized message alternative from the Message [sys_ui_message] table. Each message key is on a separate line in the Messages field. The instance looks for a localized message string anytime the UI action makes a

Properties (continued)

Name	Type	Description
		`getmessage('[message]')` call where the message string matches a key in the Messages field. For more information, see Translate a client script message.
hint	String	A short description of the UI action that displays as tooltip when hovering over it.
order	Number	The order in which the UI action appears. The order applies to buttons from left to right and to menu actions from top to bottom. Default: 100
isolateScript	Boolean	Flag that indicates whether the script runs in strict mode, with access to direct DOM, jQuery, prototype, and the window object turned off. Valid values: • true: Isolate the script and don't run it in strict mode. • false: Run the script in strict mode. Default: false
roles	Array	A list of variable identifiers of *`Role`* objects or names of roles required for the UI action to apply. For more information, see Role API - ServiceNow Fluent.
includeInViews	Array	A list of names of views in which the UI action is included.
excludeFromViews	Array	A list of names of views from which the UI action is excluded.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { UiAction } from '@servicenow/sdk/core'

UiAction({
    $id: Now.ID['car_info'],
    table: 'x_snc_ts_custom_cars',
    actionName: 'Car Information',
    name: 'View car info',
    active: true,
    showInsert: true,
    showUpdate: true,
    hint: 'View car info',
    condition: "current.type == 'SUV'",
    form: {
        showButton: true,
        showLink: true,
        showContextMenu: false,
        style: 'destructive',
    },
    list: {
        showLink: true,
        style: 'primary',
        showButton: true,
        showContextMenu: false,
        showListChoice: false,
        showBannerButton: true,
        showSaveWithFormButton: true,
    },
    workspace: {
        isConfigurableWorkspace: true,
        showFormButtonV2: true,
        showFormMenuButtonV2: true,
        clientScriptV2: `function onClick(g_form) {
                        }`,
    },
    script: `current.name =  "updated by script";
                current.update();`,
    roles: ['u_requestor'],
    client: {
        isClient: true,
        isUi11Compatible: true,
        isUi16Compatible: true,
        },
    order: 100,
    showQuery: false,
    showMultipleUpdate: false,
    isolateScript: false,
    includeInViews: ['specialView'],
    excludeFromViews: [],
})
```

form object

Configure how a UI action appears on a form.

The *form* object is a property within the *UiAction* object.

Properties

Name	Type	Description
showButton	Boolean	Flag that indicates whether to include a button on a form. Valid values: • true: A button appears on forms. • false: A button doesn't appear on forms. Default: false
showLink	Boolean	Flag that indicates whether to include a link in the Related Links section of a form. Valid values: • true: A link appears in the Related Links section. • false: A link doesn't appear in the Related Links section. Default: false
showContextMenu	Boolean	Flag that indicates whether to include an item in the context menu of a form. Valid values: • true: An item appears in the context menu. • false: An item doesn't appear in the context menu. Default: false
style	String	A style that defines how UI action buttons appear on a form. Valid values: • primary: Colors the UI action blue. • destructive: Colors the UI action red. • unstyled: The UI action isn’t styled.
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*:

Properties (continued)

Name	Type	Description
		• demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
form: {
  showButton: true,
  showLink: true,
  showContextMenu: false,
  style: 'destructive',
}
```

list object

Configure how a UI action appears on the list view.

The *`list`* object is a property within the *`UiAction`* object.

Properties

Name	Type	Description
showButton	Boolean	Flag that indicates whether to include a button at the bottom of a list. **Note:** Buttons at the bottom of a list appear regardless of condition and are evaluated per record on execution. Valid values: • true: A button appears at the bottom of lists. • false: A button doesn't appear at the bottom of lists. Default: false
showLink	Boolean	Flag that indicates whether to include a link in the Related Links section of a list. Valid values: • true: A link appears in the Related Links section. • false: A link doesn't appear in the Related Links section. Default: false
showContextMenu	Boolean	Flag that indicates whether to include an item in the context menu of a list.

Properties (continued)

Name	Type	Description
		Valid values: • true: An item appears in the context menu. • false: An item doesn't appear in the context menu. Default: false
style	String	A style that defines how UI action buttons appear on the list view. Valid values: • primary: Colors the UI action blue. • destructive: Colors the UI action red. • unstyled: The UI action isn't styled.
showListChoice	Boolean	Flag that indicates whether to include a choice in the Actions list of a list. **Note:** Choices in the Actions list appear regardless of condition and are evaluated per record on execution. Valid values: • true: A choice appears in the Actions list. • false: A choice doesn't appear in the Actions list. Default: false
showBannerButton	Boolean	Flag that indicates whether to include a button on the banner of a list. **Note:** Buttons on the banner of a list aren't intended to support record-specific conditions. Only the first row is considered when the condition is evaluated to determine whether the button appears for the list. Don't use record-specific conditions, such as `current.getValue('state') === 'closed'`. Valid values: • true: A button appears on the banner of lists. • false: A button doesn't appear on the banner of lists. Default: false
showSaveWithFormButton	Boolean	Flag that indicates whether the form is saved when accessed from a list before executing the UI action button.

Properties (continued)

Name	Type	Description
		Valid values: • true: The form must be saved before the UI action executes. • false: The form doesn't have to be saved before the UI action executes. Default: false
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
list: {
  showButton: true,
  showLink: true,
  showContextMenu: false,
  style: 'primary',
  showListChoice: false,
  showBannerButton: true,
  showSaveWithFormButton: true,
}
```

client object

Configure options to execute the UI action script in the browser.

The *client* object is a property within the *UiAction* object.

Properties

Name	Type	Description
isClient	Boolean	Flag that indicates where the UI action script runs. Valid values:

Properties (continued)

Name	Type	Description
		• true: The script runs on the client (the user's browser). • false: The script runs on the server. Default: false
isUi11Compatible	Boolean	Flag that indicates whether the UI action is supported in the legacy UI 11. Valid values: • true: The UI action is supported in the legacy UI 11. • false: The UI action isn't supported in the legacy UI 11. Default: false
isUi16Compatible	Boolean	Flag that indicates whether the UI action is supported in the Core UI. Valid values: • true: The UI action is supported in the Core UI. • false: The UI action isn't supported in the Core UI. Default: false
onClick	String	The name of the JavaScript function to run when the UI action is executed. The function is defined with the *`script`* property.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
client: {
  isClient: true,
  isUi11Compatible: true,
  isUi16Compatible: true,
```

```
  onClick: 'reopenIncident()'
}
```

workspace object

Configure how a UI action functions and appears in workspaces.

The *workspace* object is a property within the *UiAction* object.

Properties

Name	Type	Description
isConfigurableWorkspace	Boolean	Flag that indicates the type of workspace in which a UI action applies. Valid values: • true: The UI action applies to Configurable Workspaces. • false: The UI action applies to Legacy Workspaces. Default: false
showFormButtonV2	Boolean	Flag that indicates whether to include a button on forms in a workspace. Valid values: • true: A button appears on forms. • false: A button doesn't appear on forms. Default: false
showFormMenuButtonV2	Boolean	Flag that indicates whether to include an item in the More Actions menu in a workspace. Valid values: • true: An item appears in the More Actions menu. • false: An item doesn't appear in the More Actions menu. Default: false
clientScriptV2	String	A script that runs when the UI action is executed in workspaces. This property supports inline JavaScript or a reference to another file in the application that contains a script. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more

Properties (continued)

Name	Type	Description
		information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or `Script``.
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
workspace: {
  isConfigurableWorkspace: true,
  showFormButtonV2: true,
  showFormMenuButtonV2: true,
  clientScriptV2: `function onClick(g_form) {
  }`,
}
```

UI Page API - ServiceNow Fluent

The UI Page API defines custom user interface (UI) pages [sys_ui_page] that display forms, dialogs, lists, and other UI components.

A UI page displays as a web page and can be added to a widget for use in dashboards. For general information about UI pages, see UI pages.

You can develop a simple React application with the UI Page API. In the `src/client` directory, add static content files that define the HTML, client script, and styling of the page. From the *UiPage* object, refer to the page's HTML entry point (`index.html`). For more information, see User interface development with React.

Related topics

ServiceNow Fluent

UiPage object

Create a UI page [sys_ui_page] for a custom user interface.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
endpoint	String	Required. The endpoint to access the web page. The endpoint value can't contain spaces. Format: `<scope>_<ui_page_name>.do`
description	String	A description of the user interface and its purpose.
direct	Boolean	Flag that indicates whether to omit the standard HTML, CSS, and JavaScript for a UI page. For React UI pages, set this property to `true`. Valid values: • true: Omit the standard HTML, CSS, and JavaScript and provide custom CSS and JavaScript for the page. • false: Include the standard HTML, CSS, and JavaScript. Default: false
html	String	The body HTML code that defines what is rendered when the page is shown. It can contain either static XHTML, dynamically generated content defined as Jelly, or call script includes and UI Macros. This property supports an alias to import an `index.html` file for React development, a reference to another file in the application that contains HTML, or inline JavaScript. **Note:** With React development and imported HTML, the *`html`* property of the *`UiPage`* object supports only one-way synchronization. After defining the HTML of a UI page in source code, if the HTML is modified outside of the source code, those changes aren't synchronized and reflected in the source code. Format: • An alias to import the `index.html` file from the previous build for UI development with React. The alias can be any value and must also be imported in the `now.ts` file that contains the *`UiPage`* object: `import <alias> from 'path/to/index.html'`. • To use text content from another file, refer to a file in the application using the following format:

Properties (continued)

Name	Type	Description
		`Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide inline HTML, use string literals or template literals for multiple lines of code: `'HTML' or` `` `HTML` ``.
category	String	The type of UI page. Valid values: • general: The page is general purpose. • homepages: The page is used as a home page. • htmleditor: The page is used to insert HTML content. • kb: The page is used with a Knowledge Base. • cms: The page is used with the Content Management System (CMS). • catalog: The page is used with Service Catalog.
clientScript	Script	A script that runs in the browser, such as functions called by buttons. This script handles any required client-side processing needed, like setting focus to a field or other interactive DHTML features after a page is loaded. This property supports inline JavaScript or a reference to another file in the application that contains a script. Client scripts for the UI page are deployed to the browser within a `<script>` tag, so the content can similarly be defined within the HTML field. The *`clientScript`* property can be used instead to define these scripts concisely to maintain the Jelly and HTML manageability. Format: • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script' or` `` `Script` ``.
processingScript	Script	A script that runs on the server when the page is submitted, which is useful if your page has a form defined with the `<g:ui_form/>` or `<g:form/>` tags. This property supports a function from a JavaScript module, a reference to another file in the application that contains a script, or inline JavaScript. Format:

Properties (continued)

Name	Type	Description
		• For functions, use the name of a function, function expression, or default function exported from a JavaScript module and import it into the `.now.ts` file. For information about JavaScript modules, see JavaScript modules and third-party libraries. • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script'` or `` `Script` ``.
$meta	Object	Metadata for the application metadata. With the *`installMethod`* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

In this example of UI development with React, the HTML of the page is imported from the `index.html` file in the `src/client` directory.

```
//incident-manager.now.ts
import '@servicenow/sdk/global'
import { UiPage } from '@servicenow/sdk/core'
import incidentPage from '../../client/index.html'

UiPage({
    $id: Now.ID['incident-manager-page'],
    endpoint: '<scope>_incident_manager.do',
    description: 'Incident Response Manager UI Page',
    category: 'general',
    html: incidentPage,
    direct: true,
})
```

In the `index.html` file, the `<script>` tag refers to the `main.jsx` file in the `src/client` directory, which contains the component code.

```
//index.html
<html>
<head>
  <title>Incident Response Manager</title>

  <!-- Initialize globals and Include ServiceNow's required scripts -->
  <sdk:now-ux-globals></sdk:now-ux-globals>

  <!-- Include your React entry point -->
  <script src="./main.jsx" type="module"></script>
</head>
<body>
  <div id="root"></div>
</body>
</html>
```

UI Policy API - ServiceNow Fluent

The UI Policy API defines user interface (UI) policies [sys_ui_policy] that dynamically change the behavior of information on a form and control custom process flows for tasks.

UI Policies can make fields mandatory, read-only, visible, hidden, or cleared when certain conditions are met. You can also use client scripts to perform all of these actions, but for faster load times use UI policies when possible.

For general information about UI policies, see UI policies.

Related topics

ServiceNow Fluent

UiPolicy object

Create a UI policy sys_ui_policy to configure form behavior.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
table	String	Required. The table of the form to modify.
shortDescription	String	Required. A description of the policy and its purpose.
active	Boolean	Flag that indicates whether the policy is applied to the form. Default: true
global	Boolean	Flag that indicates whether to which form views the policy applies. If true, the policy applies to all views of the table. If false, the policy is specific to the form view specified with the *`view`* property. Default: true

Properties (continued)

Name	Type	Description
onLoad	Boolean	Flag that indicates when the policy executes. If true, the policy runs every time a form is loaded if the conditions are satisfied. Default: true
reverseIfFalse	Boolean	Flag that indicates whether to invert the policy behavior when the condition evaluates to false. If true, the policy action is undone when the conditions of its policy evaluate to false. Default: true
inherit	Boolean	Flag that indicates whether tables that extend the current table inherit the policy. If true, extended tables inherit the policy. When a child table has an inherited policy from its parent table, the policy on the child table runs first. This event is true regardless of the order of the policies. Default: false
isolateScript	Boolean	Flag that indicates whether to run scripts in isolated scope. If true, the script runs in isolated scope. This property only applies if the *runScripts* is set to true. Default: false
conditions	String	A filter query that specifies the fields and values that must be true for users to access the object. For more information, see Operators available for filters and queries. To set conditions using a script, use a client script instead. Conditions are only rechecked if a user manually changes a field on a form. If the change is made by a UI action, context menu action, or through the list editor, it isn't evaluated.
runScripts	Boolean	Flag that indicates whether advanced behavior can be scripted for both true and false conditions. If true, scripts defined with the *scriptTrue*, *scriptFalse*, *uiType*, and *isolateScript* properties run when applicable. Default: false
scriptTrue	String	Client-side script that runs if the conditions of the policy are met. This property is required if the *runScripts* property is set to true. Format: `function onCondition() {}` Default: `function onCondition() {\n\n}`
scriptFalse	String	Client-side script that runs if the conditions of the policy aren't met and the *reverseIfFalse* property is set to true. This property is required if the *runScripts* property is set to true. Format: `function onCondition() {}`

Properties (continued)

Name	Type	Description
		Default: `function onCondition() {\n\n}`
uiType	String	The type of user interface to which the policy applies. This property is required if the *`runScripts`* property is set to true. Valid values: • desktop: The policy applies to desktop interfaces. • mobile-or-service-portal: The policy applies to mobile and Service Portal interfaces. • all: The policy applies to all interfaces. Default: desktop
actions	Array	A list of field actions to apply if the conditions are met. For more information, see actions array.
relatedListActions	Array	A list of visibility controls for related lists. For more information, see relatedListActions array.
description	String	Additional information about the policy.
modelId	String	The sys_id of the parent UI policy to which the policy applies when this policy is inherited. This property works in conjunction with *`model_table`* property.
modelTable	String	The name of the parent table to which the policy applies when a UI policy is inherited from a parent table. This property works in conjunction with the *`model_id`* property.
order	Number	The execution order in which to apply policies if more than one policy fits the conditions. For inherited UI policies, the extended table's policies are executed first. Then the base table policies are executed. Default: 100
setValues	String	(Deprecated) The field values to set using an encoded string format. Use UI policy actions [sys_ui_policy_action] instead.
view	Reference or String	Required. The variable identifier or name of the UI view [sys_ui_view] which applies, or the default view. To define a UI view, use the Record API - ServiceNow Fluent. To use the default view (`default_view`), you must import it: `import { default_view } from '@servicenow/sdk/core'`

```
import { UiPolicy } from '@servicenow/sdk/core';

export const securityIncidentPolicy = UiPolicy({
  $id: Now.ID['security_incident_policy'],
  table: 'incident',
  shortDescription: 'Lock critical fields for security incidents',
```

```
  active: true,
  onLoad: true,
  conditions: 'category="security"',
  actions: [
    {
      field: 'security_notes',
      mandatory: true,
      visible: true
    },
    {
      field: 'caller_id',
      readOnly: true   // Lock caller field when category is security
    },
    {
      field: 'assignment_group',
      readOnly: true   // Lock assignment group when category is security
    },
    {
      field: 'priority',
      readOnly: true   // Lock priority when category is security
    }
  ],
  relatedListActions: [
    {
      // Using plain GUID for system relationships
      list: 'b9edf0ca0a0a0b010035de2d6b579a03',  // Attachments
      visible: false
    },
    {
      // Using table.field format for reference fields
      list: 'x_snc_17sepapp1_expenseitem.expensereport',  // Example reference field
      visible: true
    }
  ]
})
```

actions array

Configure the actions [sys_ui_policy_action] that the UI policy performs on fields.

Use the *`actions`* array within the *`UiPolicy`* object. Actions are processed in the order that they appear in the array. At least one of the `visible`, `readOnly`, `mandatory`, or `cleared` properties must be specified for each action in the array.

Properties

Name	Type	Description
field	String	Required. The name of the field to which the action applies. **Note:** If the specified field isn't found on the form, the UI policy performs the action on the variable with the same name.
visible	Boolean or String	An option to control the visibility of the field. Valid values:

Properties (continued)

Name	Type	Description
		• true: The field is visible. • false: The field is hidden. • 'ignore': The field isn't changed. Default: ignore
readOnly	Boolean or String	An option to control access to edit the field. Valid values: • true: The field is read-only. • false: The field is editable. • 'ignore': The field isn't changed. Default: ignore
mandatory	Boolean or String	An option to control whether the field is required. Valid values: • true: The field is required. • false: The field is optional. • 'ignore': The field isn't changed. Default: ignore
cleared	Boolean	Flag that indicates whether the field should be cleared if the conditions of the policy are met. Default: false
table	String	The table to which the action applies, which overrides the table specified by the policy. If empty, the table specified by the policy applies.
value	String	The value to set the field to if the policy conditions are met.
fieldMessage	String	A message to display about the field if the policy conditions are met.
fieldMessageType	String	A message type that determines how the field message is presented. Valid values: • error • info • warning • none Default: none

Properties (continued)

Name	Type	Description
valueAction	String	An action to perform on the field value. Valid values: • set_value • clear_value • ignore Default: ignore

```
actions: [
        {
            field: 'assignment_group',
            mandatory: true,
            value: 'Critical Response Team',  // Set default value
            fieldMessage: 'This incident requires immediate attention from the
Critical Response Team',
            fieldMessageType: 'error'  // Show as error message
        },
        {
            field: 'urgency',
            value: '1',  // Set to High urgency
            fieldMessage: 'Urgency has been automatically set to High',
            fieldMessageType: 'info'
        },
        {
            field: 'impact',
            value: '1',  // Set to High impact
            fieldMessage: 'Impact has been automatically set to High',
            fieldMessageType: 'warning'
        }
    ]
```

relatedListActions array

Configure the visibility of related lists [sys_ui_policy_rl_action] on a form for a UI policy.

Use the *relatedListActions* array within the *UiPolicy* object. Related list actions are processed in the order that they appear in the array. Either the *list* or *visible* property must be specified for each related list action in the array.

Properties

Name	Type	Description
list	String	A reference to a related list on the form. If empty, the action applies to all related lists. This property is required if the *visible* property is not set. Format:

Properties (continued)

Name	Type	Description
		• sys_ID: The sys_ID for the list. Use this format for custom queries, attachments, and system-defined related lists. • table.field: The table and field name associated for the list, such as `'incident.caller_id'`. Use this format for reference field-based relationships.
visible	Boolean or String	An option to control the visibility of the related list. This property is required if the *`list`* property is not set. Valid values: • true: The related list is visible. • false: The related list is hidden. • 'ignore': The related list isn't changed. Default: ignore

```
relatedListActions: [
    {
      // Using plain GUID for system relationships
      list: 'b9edf0ca0a0a0b010035de2d6b579a03',  // Attachments
      visible: false
    },
    {
      // Using table.field format for reference fields
      list: 'x_snc_17sepapp1_expenseitem.expensereport',  // Example reference field
      visible: true
    }
  ]
```

Workspace API - ServiceNow Fluent

The Workspace API defines configurable workspace experiences for organizing and sharing data visually.

The Workspace API creates application metadata in the following tables depending on the workspace definition: UX Application [sys_ux_page_registry], UX App Configuration [sys_ux_app_config], UX Application Category M2M [sys_ux_registry_m2m_category], UX Page Property [sys_ux_page_property], UX Screen Collection [sys_ux_screen_type], UX App Route [sys_ux_app_route], UX Screen [sys_ux_screen], and UX Macroponent Definition [sys_ux_macroponent].

Dashboards can be used as the home page of a workspace by referring to one or more workspaces from the *`visibilities`* array of the *`Dashboard`* object. To create a dashboard, see Dashboard API - ServiceNow Fluent.

For general information about workspaces, see Configurable Workspace UI.

ServiceNow Fluent

Workspace object

Create a workspace for managing business entities in a single focused working area that enables users to complete an entire job.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
title	String	Required. A name for the workspace that appears in navigation and headers.
path	String	Required. The URL path segment of the workspace. Workspace URLs follow the pattern `/now/<path>/<landingPath>` and use kebab case. Workspaces require access control lists (ACLs) to secure the workspace routes. The *`field`* property of an *`Acl`* object must match the value of this property with a wildcard pattern: `{workspace.path}.*`.
tables	Array	Required. A list of table names to manage in the workspace.
listConfig	Reference	Required. The variable identifier of a *`UxListMenuConfig`* object that defines the navigation structure of the workspace. For more information, see UxListMenuConfig object.
landingPath	String	The URL path segment of the landing page. Workspace URLs follow the pattern `/now/<path>/<landingPath>` and use kebab case. Default: home
active	Boolean	Flag that indicates whether the workspace is accessible to users. Default: true

```
import { Workspace } from '@servicenow/sdk/core';

const itsmWorkspace = Workspace({
    $id: Now.ID['itsm_workspace'],
    title: 'IT Service Management',
    path: 'itsm',
    tables: ['incident', 'problem', 'change_request', 'user', 'sys_user_group'],
    listConfig: incidentListConfig
})
```

The UX List Menu Configuration referenced is defined using the *`UxListMenuConfig`* object.

UxListMenuConfig object

Define a UX list menu configuration [sys_ux_list_menu_config] for the navigation structure and list views of a workspace.

A UX list menu configuration organizes data into categories and lists, enabling users to access different views of business data with filtering, column selection, and role-based visibility. This structure appears in the workspace's navigation panel, providing organized access to different data views.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A name for the list configuration.
description	String	A description of the list configuration.
active	Boolean	Flag that indicates whether the list configuration is active. Default: true
categories	Array	A list of top-level groupings in the list configuration. For more information, see categories array.

```
import { UxListMenuConfig } from '@servicenow/sdk/core';

const incidentListConfig = UxListMenuConfig({
    $id: Now.ID['incident_list_config'],
    name: 'Incident List Configuration',
    description: 'Navigation for Incident Workspace',
    categories: [
        {
            $id: Now.ID['incidents_category'],
            title: 'Incidents',
            order: 10,
            lists: [
                {
                    $id: Now.ID['incidents_open'],
                    title: 'Open',
                    order: 10,
                    condition: 'active=true^EQ',
                    table: 'incident',
                    columns: 'number,short_description,priority,state',
                    applicabilities: [
                        {
                            $id: Now.ID['incidents_open_applicability'],
                            applicability: applicability
                        }
                    ]
                }
            ]
        }
    ]
})
```

categories array

Define categories of related lists [sys_ux_list_category] for a UX list menu configuration.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
title	String	Required. A title for the category to display in the navigation menu.
lists	Array	Required. A list of list views in the category. For more information, see lists array.
order	Number	A number indicating the position of the category in the navigation menu. Categories with lower numbers appear first.
active	Boolean	Flag that indicates whether the category is visible in the navigation menu. Default: true
description	String	A description of the category.

```
categories: [
    {
      $id: Now.ID["incidents_category"],
      title: "Incidents",
      order: 10,
      lists: [
        {
          $id: Now.ID["incidents_open"],
          title: "Open",
          order: 10,
          condition: "active=true^EQ",
          table: "incident",
          columns: "number,short_description,priority,state",
          applicabilities: [
            {
              $id: Now.ID["incidents_open_applicability"],
              applicability: applicability
            }
          ]
        },
        {
          $id: Now.ID["incidents_all"],
          title: "All",
          order: 20,
          condition: "",
          table: "incident",
          columns: "number,short_description,priority,state",
          applicabilities: [
            {
```

```
            $id: Now.ID["incidents_all_applicability"],
            applicability: applicability
          }
        ]
      }
]
```

lists array

Define list views of table data [sys_ux_list] with filtering and column configurations for a UX list menu configuration.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
title	String	Required. A title for the list to display in the navigation menu.
table	String	Required. The name of a table to use for the list.
columns	String	A comma-separated list of column names to display in the list.
condition	String	An encoded query string to filter the records displayed in the list.
order	Number	A number indicating the position of the list within its category. Lists with lower numbers appear first.
active	Boolean	Flag that indicates whether the list is visible to users. Default: true
applicabilities	Array	A list of variable identifiers of *`Applicability`* objects that control which roles can view the list. For more information, see Applicability object.

```
lists: [
        {
          $id: Now.ID["assets_active"],
          title: "Active",
          order: 10,
          condition: "install_status=1",
          table: "alm_asset",
          columns: "asset_tag,display_name,model_category,assigned_to",
          applicabilities: [
            {
              $id: Now.ID["assets_active_applicability"],
              applicability: assetApplicability
            }
          ]
        },
        {
          $id: Now.ID["assets_all"],
          title: "All",
```

```
            order: 20,
            condition: "",
            table: "alm_asset",
            columns: "asset_tag,display_name,model_category,assigned_to",
            applicabilities: [
              {
                $id: Now.ID["assets_all_applicability"],
                applicability: assetApplicability
              }
            ]
  }
]
```

Applicability object

Define the audience [sys_ux_applicability] that can view a list in the UX list menu configuration.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	Required. A name for the applicability rule.
description	String	A description of the audience.
active	Boolean	Flag that indicates whether the applicability rule is applied. Default: true
roles	Array	A list of variable identifiers of *`Role`* objects or sys_ids of roles that a user must have to view the list. For more information, see Role API - ServiceNow Fluent.
roleNames	String	A comma-separated list of role names that a user must have to view the list. This property is an alternative to the *`roles`* property.

```
import { Applicability } from '@servicenow/sdk/core';

const managerApplicability = Applicability({
    $id: Now.ID['manager_applicability'],
    name: 'Managers Only',
    roles: [managerRole]
})
```

The role referenced is defined using the *`Role`* object:

```
import { Role } from '@servicenow/sdk/core';

const managerRole = Role({
    $id: Now.ID['manager_user_role'],
    name: 'x_snc_manager.user',
```

```
    containsRoles: ['canvas_user']
})
```

Guided Application Creator

Guided Application Creator is an intuitive development interface for building applications on the ServiceNow AI Platform®. It provides a step-by-step process to guide you through your initial application construction.

Important:
You've landed at a legacy app creation tool that will be supported until the Australia release in Q1 2026. Try building and editing apps in the new version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Explains how to use Guided Application Creator to create a new application for workspace, mobile, and classic with an imported spreadsheet.

Watch this four-minute video to learn about getting started with Guided Application Creator.

Note:
Although the video describes creating a workspace in Guided Application Creator, this feature is no longer supported. Instead, you can create a workspace using App Engine Studio. For more information, see Building applications in App Engine Studio.

Using Guided Application Creator

Setting up an application in Guided Application Creator involves:

- Creating an application record
- Defining user roles
- Designating data tables
- Designing the application for different user experiences

You can also use Guided Application Creator to create an application record and then configure it in Studio later. For more information, see Create an application record in Guided Application Creator.

User experiences

When you set up an application in Guided Application Creator, you can make your application available in the following user experiences.

User experience	Description
Mobile	ServiceNow Agent mobile app. Select this user experience to support users who work from a mobile device.
Classic	Classic ServiceNow AI Platform experience. Select this user experience to let your users work on your application via lists and forms.

Guided Application Creator and the application creation process

Setting up an application in Guided Application Creator does not capture the entire process of creating an application. It is just one step of the process. Before you set up an application

in Guided Application Creator, plan what kind of application you need for your business requirements before you build it.

After you set up an application in Guided Application Creator, you can further develop the application using ServiceNow Studio, Flows in Workflow Studio, and Team Development. After the application is fully built, you can test the application and then share the application with your users.

For more information on the application creation process, see Building applications.

Activation information

Guided Application Creator is enabled via the Guided Application Creator (com.glide.sn-guided-app-creator) plugin, which is active by default in the ServiceNow AI Platform.

To work in Guided Application Creator, use a different browser. For more detail on Internet Explorer 11 support, see KB0683275.

Setting up an application in Guided Application Creator

Set up an application in Guided Application Creator to store information and manage business processes.

Shows how to create a no-code application on the ServiceNow platform quickly and easily through Guided Application Creator.

Note:
Although the video describes creating a workspace in Guided Application Creator, this feature is no longer supported. Instead, you can create a workspace using App Engine Studio. For more information, see Building applications in App Engine Studio.

Requirements

Plan your application before you build it. Define the business requirements of your organization, and then identify what information you want the application to track. For more information on the application development process, see Building applications.

To work in Guided Application Creator, use a different browser. For more detail on Internet Explorer 11 support, see KB0683275.

You must have the sn_g_app_creator.app_creator or admin role to access Guided Application Creator.

What to do

1. Create an application record in Guided Application Creator.

   Create an application record in Guided Application Creator to identify a custom application.

2. Define roles in Guided Application Creator.

   Create or select roles in Guided Application Creator for the members of your organization who use your custom application.

3. Select user experiences in Guided Application Creator.

   Let users access your application via the ServiceNow Agent mobile app or lists and forms.

4. Designate data tables in Guided Application Creator.

Select an existing table or create a custom table in Guided Application Creator to store data for your custom business application.

5. Customize user experiences in Guided Application Creator.

   Customize how the application appears in each user experience that you select.

Tip:
Complete the entire process of setting up an application in Guided Application Creator. If you exit, you have to continue setting up your application in Studio and across various forms. You can't pick up where you left off in Guided Application Creator.

Next steps

Although your application is ready to use, you may need to customize your application to fit the needs of your organization.

In ServiceNow Studio, configure:

- System notifications
- Form layouts
- UI policy
- Reports

You can also learn how to automate your processes and create business logic for your application in Flows in Workflow Studio.

Create an application record in Guided Application Creator

Create an application record in Guided Application Creator to identify a custom application.

Before you begin

By default, developers can't create applications in the global scope in Guided Application Creator. You can limit global application development to certain developers by assigning them an additional role. For more information, see Allow global application development in Guided Application Creator.

Role required: sn_g_app_creator.app_creator or admin

Procedure

1. Navigate to **All** > **System Applications** > **Studio**, and then select **Create Application**.
   If you are launching Guided Application Creator for the first time, select **Let's get started** on the welcome screen.
2. On the screen, fill in the fields.

Field	Description
Name	Name of your application.
Description	Description of your application.
Scope	Scope of your application. The application scope is set automatically when you name your application.

Field	Description
	If available, you can also select to create your application in the global scope. For more information on application scopes, see Application scope.

3. **Optional:** Give your application a logo image.
   You can drag and drop an image on the logo field, or you can select **Drag and drop or browse to upload logo**.

4. Select **Create** to assign roles for your application.

   To continue building your application in Guided Application Creator, follow the steps in Define roles in Guided Application Creator.

   You can optionally exit Guided Application Creator on the **Let's create some roles for this app** screen to save the application and add more functions to it later. To exit, select **X** to close the screen and then select **Yes, close**.

   Tip:
   Complete the entire process of setting up an application in Guided Application Creator. If you exit, you have to continue setting up your application in Studio and across various forms. You can't pick up where you left off in Guided Application Creator.

Result

Your application record is saved in the Custom Application [sys_app] table. You are added as a delegated developer for the application. To view your application later, navigate to **System Applications** > **My Company Applications**.

Define roles in Guided Application Creator

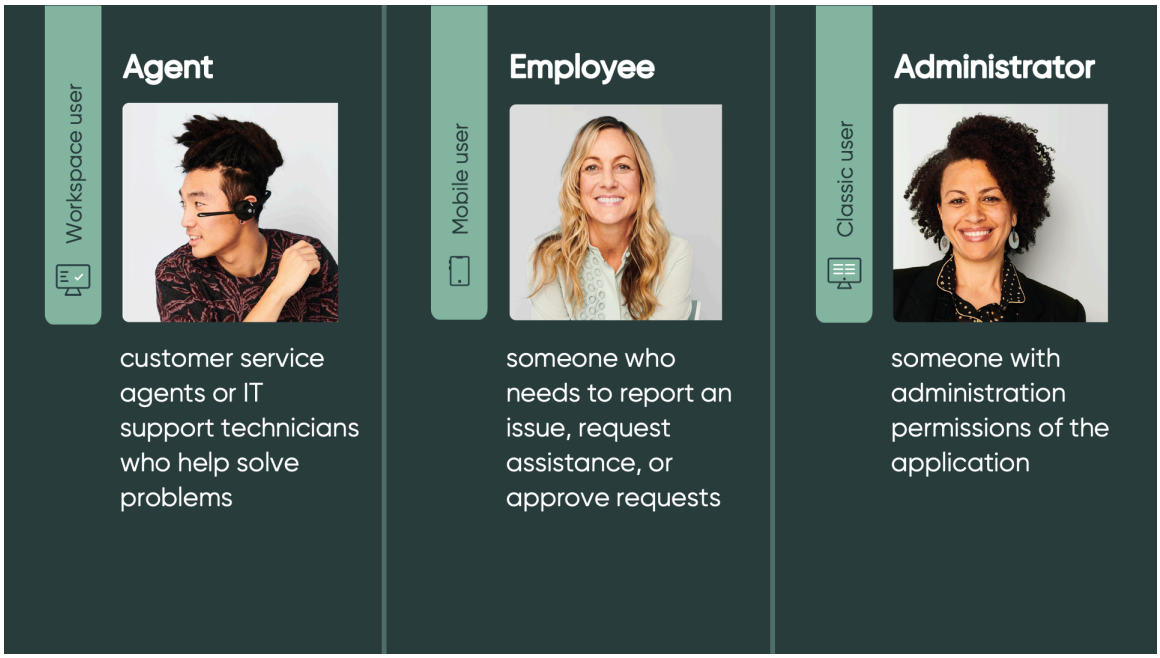
Create or select roles in Guided Application Creator for the members of your organization who use your custom application.

Before you begin

Complete the steps in Create an application record in Guided Application Creator.

Role required: sn_g_app_creator.app_creator or admin

About this task



Procedure

1. Define roles for your application.

   You can select existing roles or create roles.

2. Select **Continue**.

   You are taken to the screen in which you select user experiences for your application.

   Note:
   If you created any roles, you must select **Continue** to save the roles to your instance. If you exit Guided Application Creator before selecting **Continue**, the roles that you created are not saved.

What to do next

Continue building your application by following the steps in Select user experiences in Guided Application Creator.

Select user experiences in Guided Application Creator

Let users access your application via the ServiceNow Agent mobile app or lists and forms.

Before you begin

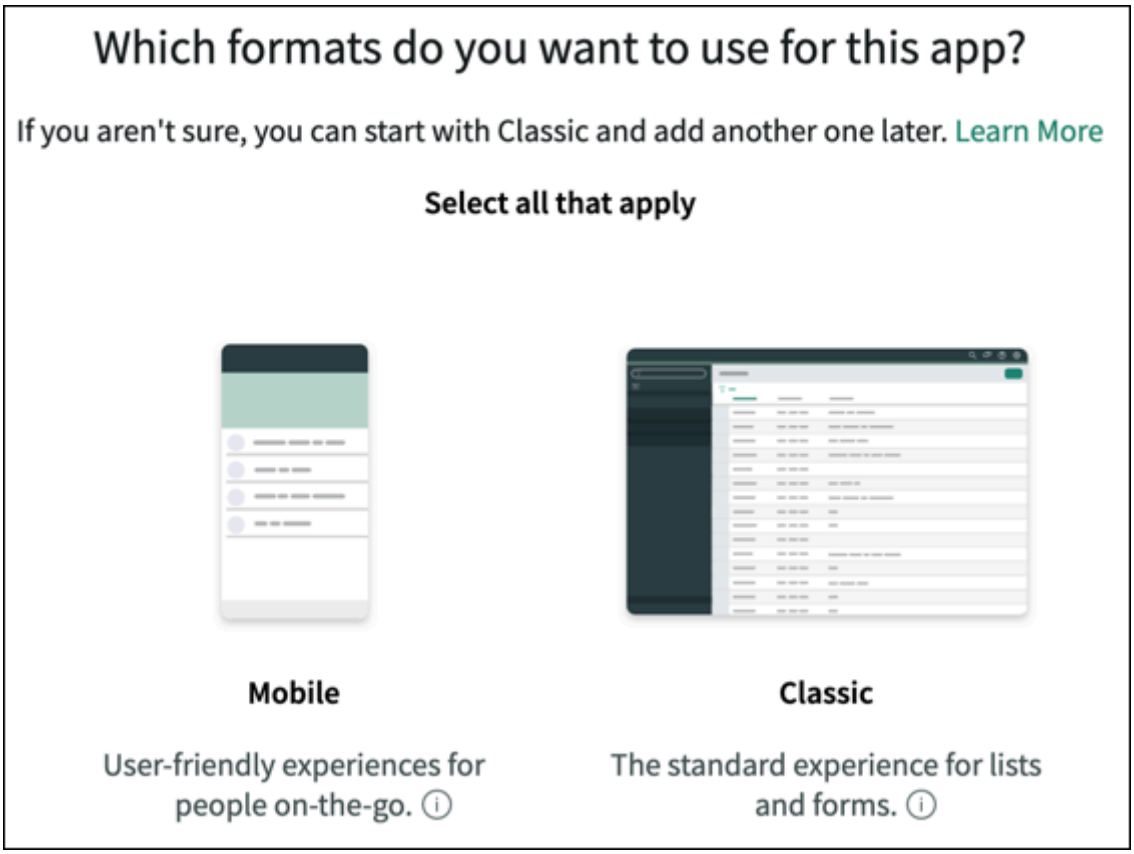
Complete:

1. Create an application record in Guided Application Creator
2. Define roles in Guided Application Creator

Role required: sn_g_app_creator.app_creator or admin

Procedure

1. Select user experiences in which to make your application available.



User experience	Description
Mobile	ServiceNow Agent mobile app. Select this user experience to support users who work from a mobile device.
Classic	Classic ServiceNow AI Platform experience. Select this user experience to let your users work on your application via lists and forms.

There is no option to create a workspace in Guided Application Creator. Instead, you can create a workspace using App Engine Studio. For more information, see Building applications in App Engine Studio.

2. Select **Continue** to designate a data table for your application.

What to do next

Continue building your application by following the steps in Designate data tables in Guided Application Creator. If you exit Guided Application Creator, the user experiences that you selected are not saved to your application.

Designate data tables in Guided Application Creator

Select an existing table or create a custom table in Guided Application Creator to store data for your custom business application.

Before you begin

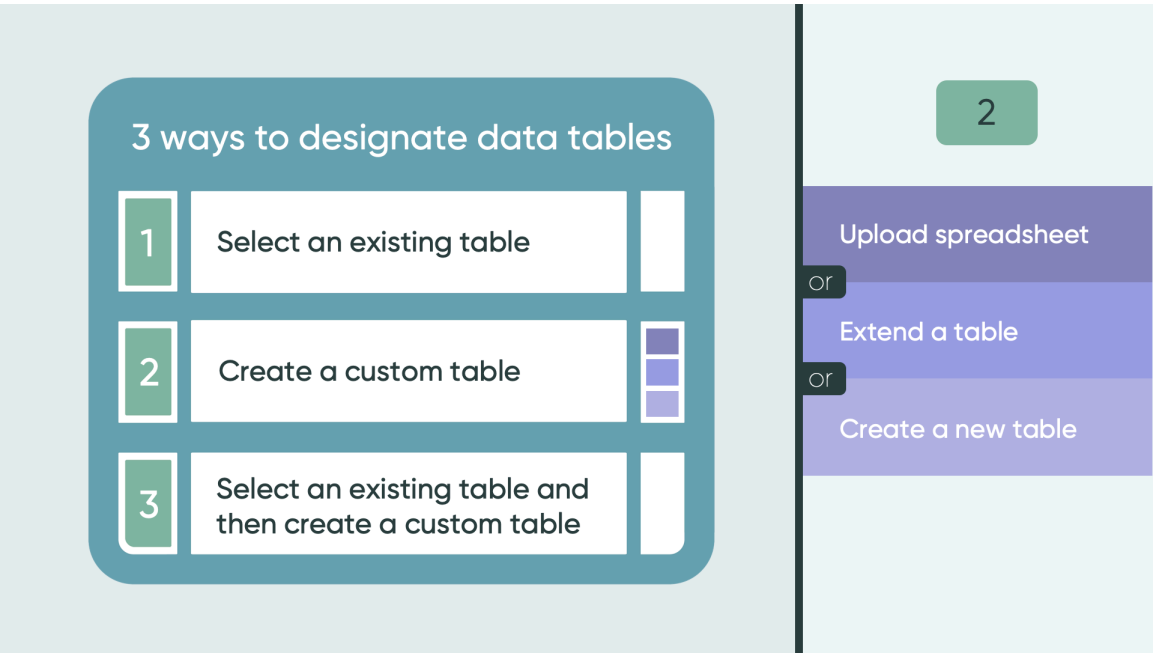
Complete:

1. Create an application record in Guided Application Creator
2. Define roles in Guided Application Creator
3. Select user experiences in Guided Application Creator

If you plan to create a custom data table, review the Data table guidelines for Guided Application Creator to ensure that your system performs as expected after you create a table.

Role required: sn_g_app_creator.app_creator or admin

About this task



Procedure

Designate data tables for your application.
You can select existing tables or create custom tables.

What to do next

Continue building your application by following the steps in Customize user experiences in Guided Application Creator. If you exit Guided Application Creator, the data tables that you designated are not saved to your application.

Upload a spreadsheet in Guided Application Creator

Turn your spreadsheet into a custom table in Guided Application Creator to store data for your custom application.

Before you begin

Complete:

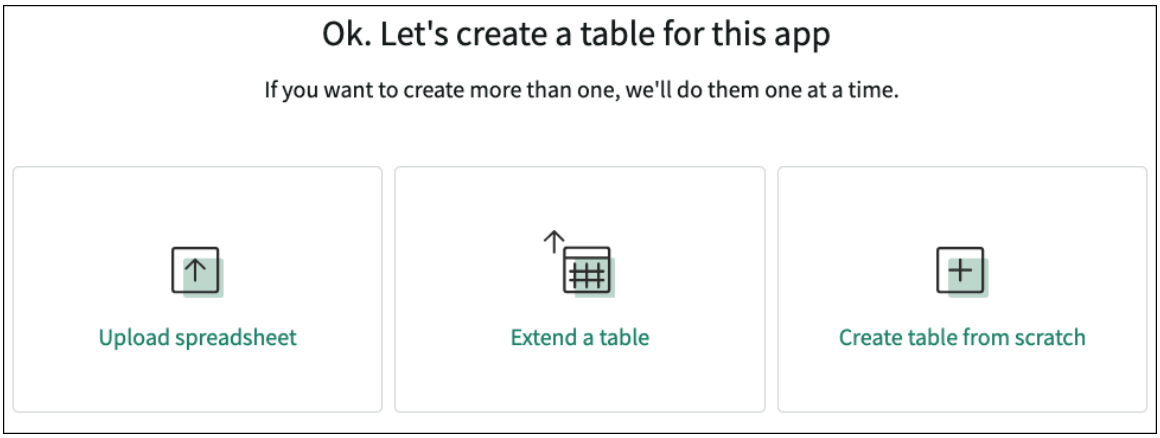
1. Create an application record in Guided Application Creator
2. Define roles in Guided Application Creator
3. Select user experiences in Guided Application Creator
4. Designate data tables in Guided Application Creator

Review the spreadsheet guidelines to ensure that your data uploads as expected.

Role required: sn_g_app_creator.app_creator or admin

Procedure

1. To select a table creation method, on the screen, select **Upload spreadsheet** and then select **Continue**.



2. Upload your spreadsheet.

   You can drag and drop the spreadsheet file or browse your system to select the spreadsheet file.

3. In **Enter a row for the table header**, enter the number of the header row on your spreadsheet.

   For example, if your spreadsheet has two columns in which the headers are in the second row (such as in the following image), you would enter 2.

	A	B
1		
2	**Client name**	**Phone number**
3	Beth Anglin	555-555-5551
4	Fred Luddy	555-555-5552
5	David Loo	555-555-5553
6	John Jason	555-555-5554
7	David Miller	555-555-5555
8		

4. Select the **Import spreadsheet data** option.
5. Select **Continue**.

   Your spreadsheet content is parsed into fields for your custom table.

6. On the form, fill in the fields.

Field	Description
Field Label	Unique label for the field.
Field Name	Name of the field in the database.
Field Type	Type of field. For more information on the different field types, see Field types. By default, there are only 18 field types to choose from. You can add a property to include more field types in Guided Application Creator. For more information, see Add field types in Guided Application Creator.
Display	When used as a reference field, the field is used as the display value for the table. Only one field can be defined as the display value for a table.
Mandatory	Requires that the field must contain a value before the record can be saved.

7. Select **Continue** to define properties and permissions for your custom table.
8. On the form, fill in the fields.

Field	Description
Table label	Unique label for the table (such as **Laptops** or **Thin clients**). The label appears on list and form views for the table. See Field Labels in Data dictionary tables.
Table name	Name of the table in the database. The table name is automatically populated based on the table label and the application scope that you defined earlier.
Make extensible	Option to enable other tables to extend this table. For more information on table extension, see Table extension and classes.
Auto-number	Option to add a number field to the table and automatically increment the ID numbers as they get added.
Manage access	User permissions for your application. For each role that you selected earlier, you can select to give your different levels of access. **Create** Enables users to insert new records (rows) into a table. **Read** Enables users to display records from a table. **Write** Enables users to update records in a table. **Delete** Enables users to remove records from a table or drop a table.

9. Select **Continue**.
10. On the confirmation screen, select **Continue**.
11. To add more tables to your application, follow the steps in Designate data tables in Guided Application Creator.
12. To finish designating tables, select **Done with tables**.

What to do next

Continue building your application by following the steps in Customize user experiences in Guided Application Creator. If you exit Guided Application Creator, the tables that you configured are not saved to the system.

Extend a table in Guided Application Creator

Extend a table in Guided Application Creator to create a custom table that copies an existing table. You can add more fields to your child table.

Before you begin

Complete:

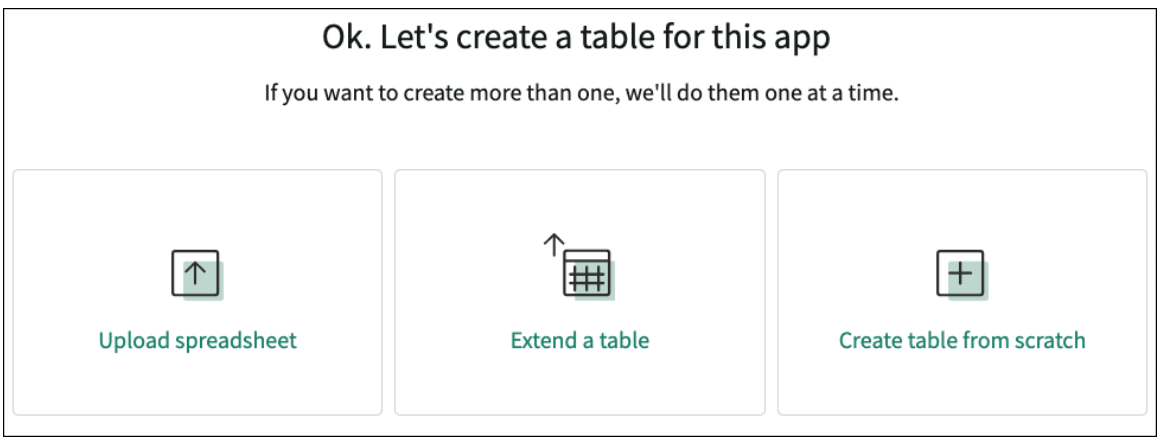
1. Create an application record in Guided Application Creator
2. Define roles in Guided Application Creator
3. Select user experiences in Guided Application Creator
4. Designate data tables in Guided Application Creator

Plan which table to extend. Review the extension model so that you can track which database tables are created after you extend your table.

Role required: sn_g_app_creator.app_creator or admin

Procedure

1. To select a table creation method, on the screen, select **Extend a table**.



2. In the **Table** field, select a table to extend.
3. Select **Continue**.

   The fields from the parent table are copied over to your custom table. You can't change the copied fields.

4. To add a field to your child table, select **+ Add a new field** and then fill in the fields.

Field	Description
Field Label	Unique label for the field.
Field Name	Name of the field in the database.
Field Type	Type of field. For more information on the different field types, see Field types. By default, there are only 18 field types to choose from. You can add a property to include more field types in Guided Application Creator. For more information, see Add field types in Guided Application Creator.
Display	When used as a reference field, the field is used as the display value for the table. Only one field can be defined as the display value for a table. **Note:** Extended tables inherit the display value of the parent table. Setting a separate display value for the extended table overrides the parent table's display value.
Mandatory	Requires that the field must contain a value before the record can be saved.

5. Select **Continue** to define properties and permissions for your custom table.
6. On the form, fill in the fields.

Field	Description
Table label	Unique label for the table (such as **Laptops** or **Thin clients**). The label appears on list and form views for the table. See Field Labels in Data dictionary tables.
Table name	Name of the table in the database. The table name is automatically populated based on the table label and the application scope that you defined earlier.
Make extensible	Option to enable other tables to extend this table. For more information on table extension, see Table extension and classes.
Auto-number	Option to add a number field to the table and automatically increment the ID numbers as they get added.
Manage access	User permissions for your application. For each role that you selected earlier, you can give different levels of access. **Create** Enables users to insert new records (rows) into a table. **Read** Enables users to display records from a table.

Field	Description
	Write Enables users to update records in a table. **Delete** Enables users to remove records from a table or drop a table.

7. Select **Continue**.
8. On the confirmation screen, select **Continue**.
9. To add more tables to your application, follow the steps in Designate data tables in Guided Application Creator.
10. To finish designating tables, select **Done with tables**.

What to do next

Continue building your application by following the steps in Customize user experiences in Guided Application Creator. If you exit Guided Application Creator, the tables that you configured are not saved to the system.

Create a table in Guided Application Creator

Create a table in Guided Application Creator to customize your application to fit your business needs.

Before you begin

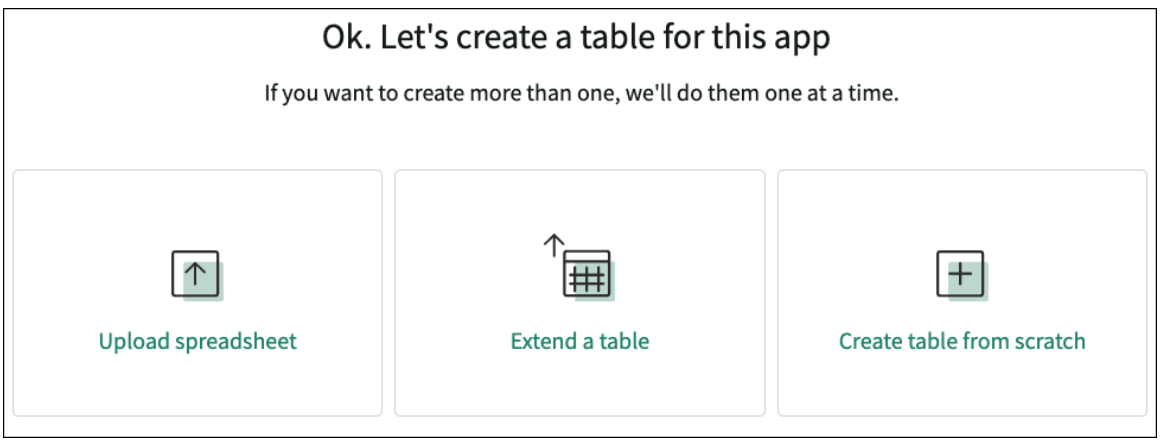
Complete:

1. Create an application record in Guided Application Creator
2. Define roles in Guided Application Creator
3. Select user experiences in Guided Application Creator
4. Designate data tables in Guided Application Creator

Role required: sn_g_app_creator.app_creator or admin

Procedure

1. To select a table creation method, on the screen, select **Create table from scratch** and then select **Continue**.



2. Add fields to your custom table.

a. Select **+ Add a new field**.

b. On the form, fill in the fields.

Field	Description
Field Label	Unique label for the field.
Field Name	Name of the field in the database.
Field Type	Type of field. For more information on the different field types, see Field types. By default, there are only 18 field types to choose from. You can add a property to include more field types in Guided Application Creator. For more information, see Add field types in Guided Application Creator.
Display	When used as a reference field, the field is used as the display value for the table. Only one field can be defined as the display value for a table.
Mandatory	Option to require that the field must contain a value before the record can be saved.

3. Select **Continue** to define properties and permissions for your custom table.

4. On the form, fill in the fields.

Field	Description
Table label	Unique label for the table (such as **Laptops** or **Thin clients**). The label appears on list and form views for the table. See Field Labels in Data dictionary tables.
Table name	Name of the table in the database. The table name is automatically populated based on the table label and the application scope that you defined earlier.
Make extensible	Option to enable other tables to extend this table. For more information on table extension, see Table extension and classes.
Auto-number	Option to add a number field to the table and automatically increment the ID numbers as they get added.
Manage access	User permissions for your application. For each role that you selected earlier, you can give different levels of access. **Create** Enables users to insert new records (rows) into a table. **Read** Enables users to display records from a table.

Field	Description
	Write Enables users to update records in a table. **Delete** Enables users to remove records from a table or drop a table.

5. Select **Continue**.
6. On the confirmation screen, select **Continue**.
7. To add more tables to your application, follow the steps in Designate data tables in Guided Application Creator.
8. To finish designating tables, select **Done with tables**.

What to do next

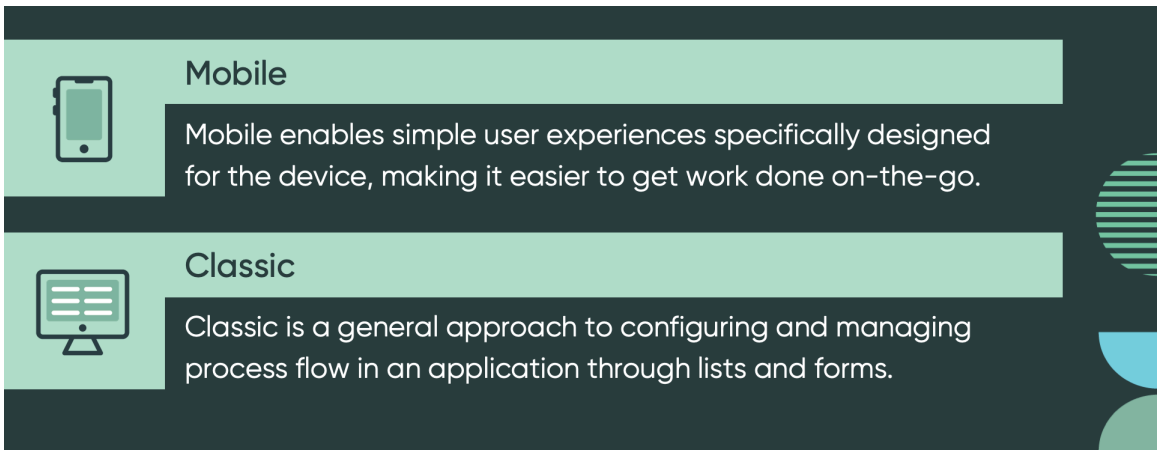
Continue building your application by following the steps in Customize user experiences in Guided Application Creator. If you exit Guided Application Creator, the tables that you configured are not saved to the system.

Customize user experiences in Guided Application Creator

Customize how the application appears in each user experience that you select.

Before you begin:

1. Create an application record in Guided Application Creator
2. Define roles in Guided Application Creator
3. Select user experiences in Guided Application Creator
4. Designate data tables in Guided Application Creator



Customize your application for the Mobile Agent mobile app

If you selected the Mobile Agent mobile app as a user experience for your application, you can customize how the application appears in the mobile app.

Before you begin

Role required: sn_g_app_creator.app_creator or admin

Note:
To edit application properties, a user must have at least one of the following:

- admin role
- sn_g_app_creator.app_creator role (this role is automatically assigned when the sn_app_eng_studio.user role is granted)
- delegated developer with delete permissions
- delegated admin

Procedure

1. Next to **Mobile**, select **Start** to configure application details.
2. On the form, fill in the fields.

Field	Description
App icon	Icon that appears on the application home page in the mobile app.
Available offline	Option to enable users to update application records while in offline mode. This option is available only if the SG Offline Support (com.glide.sg.offline) plugin is activated. For information on offline mode, see Updating records without an internet connection.
Name	Name of your application as it appears on the application home page. By default, this value is the application name that you created earlier.
Description	Description of your application. By default, this value is the application description that you created earlier.
Tables	Tables that appear as applets in the mobile app. Applets are subsections under your application that categorize the information and business processes in your application.
Roles	User roles that can access your application in the mobile app. By default, these values are the roles that you defined earlier.

3. Select **Create**.

What to do next

You've finished customizing your application for the Mobile Agent mobile app. If you selected another user experience, customize that user experience next. If you have no more user experiences left to customize, select **Done with apps**.

Customize your application for the classic ServiceNow AI Platform experience

If you selected the classic ServiceNow AI Platform experience for your application, you can customize how the application appears in the application navigator.

Before you begin

Role required: sn_g_app_creator.app_creator or admin

Note:
To edit application properties, a user must have at least one of the following:

- admin role
- sn_g_app_creator.app_creator role (this role is automatically assigned when the sn_app_eng_studio.user role is granted)
- delegated developer with delete permissions
- delegated admin

Procedure

1. Next to **Classic**, select **Start** to configure application details.
2. On the form, fill in the fields.

Field	Description
Name	Name of your application as it appears on the application navigator. By default, this value is the application name that you created earlier.
Description	Description of your application. By default, this value is the application description that you created earlier.
Tables	Tables in your application. Application modules are created for each table. By default, these values are the data tables that you designated earlier.
Roles	User roles that can access your application. By default, these values are the roles that you defined earlier.

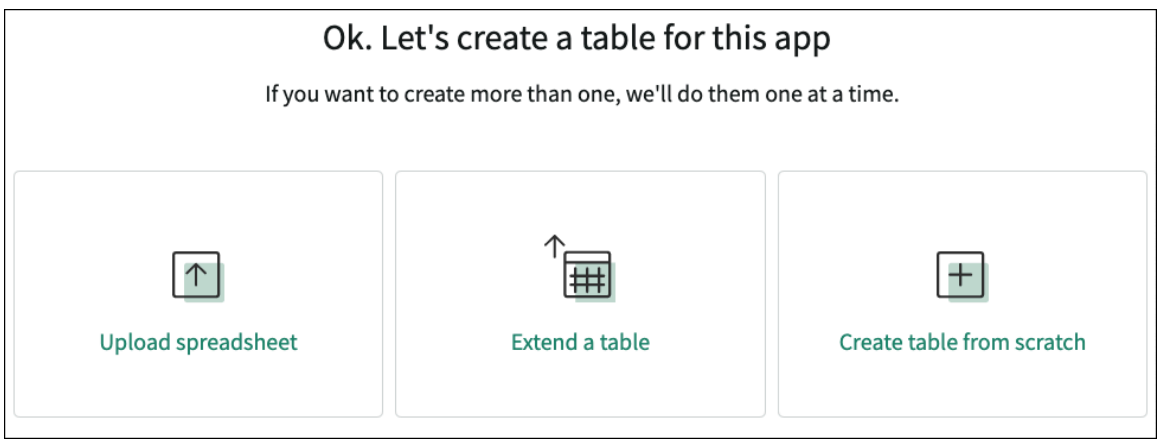
3. Select **Create**.

What to do next

You've finished customizing your application for the classic ServiceNow AI Platform experience. If you selected another user experience, customize that user experience next. If you have no more user experiences left to customize, select **Done with apps**.

Data table guidelines for Guided Application Creator

When you create an application in Guided Application Creator, you can optionally create a data table for your application. To ensure that you are within the limits of your subscription and that your application performs as expected, consult the data table guidelines before you create a data table.



Note:

ServiceNow AI Platform application subscriptions include custom table entitlements. You can create custom tables for any purpose, up to the entitlement limit in the subscription. To learn more about how your usage administrator maps the custom tables that you create to subscriptions, see Map custom tables to a product subscription in Subscription Management.

Spreadsheet guidelines

One way to create a new data table in Guided Application Creator is to upload an external spreadsheet. Prepare your spreadsheet beforehand so that you can transfer your data seamlessly and build custom applications faster.

Ensure your spreadsheet is:

- Formatted with horizontal columns and a header label for each
- Saved as an XLSX file type

For example, format your spreadsheet as follows.

	A	B
1		
2	**Client name**	**Phone number**
3	Beth Anglin	555-555-5551
4	Fred Luddy	555-555-5552
5	David Loo	555-555-5553
6	John Jason	555-555-5554
7	David Miller	555-555-5555
8		

In Guided Application Creator, you would designate the second row as the header row so that **Client name** and **Phone number** are uploaded as table fields.

Table extension guidelines

One option for creating a data table in Guided Application Creator is to copy an existing data table and then add more fields to the newly created table. Before you extend a data table, review the extension model for the table so that you can track which database tables are created after extension.

Extending a base table incorporates all the fields of the original table and creates system fields for the new table. If they are in the same scope or if they can be configured from other scopes, you can extend tables that are marked as extensible.

For more information on extension models, see Table extension and classes.

Table creation guidelines

You can optionally create a new table in Guided Application Creator, but it's possible to create more custom tables than your subscription permits. To ensure that you remain within the limits of your subscription, review the custom table entitlements for your organization.

Allow global application development in Guided Application Creator

By default, developers can't create applications in the global scope in Guided Application Creator. You can limit global application development to certain developers by assigning them an additional role.

Before you begin

Important:
Applications that you create in the global scope bypass scope protections and may cause licensing issues. For information on what to expect when you create an application in the global scope, see Application scope.

Role required: admin

About this task

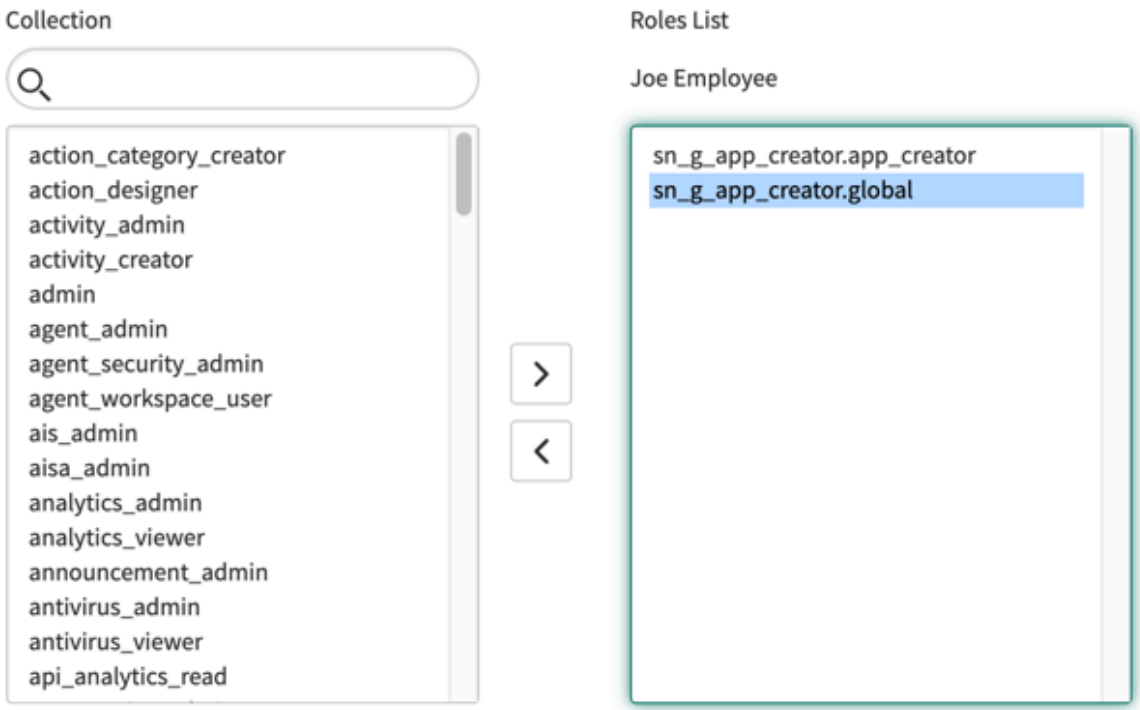
You designate someone to use Guided Application Creator by assigning them the sn_g_app_creator.app_creator role. You can allow this user to create applications in the global scope by also assigning the sn_g_app_creator.global role.

Alternatively, to allow all users with the sn_g_app_creator.app_creator role to create applications in the global scope, add the *sn_g_app_creator.allow_global* system property and set it to **true**. For more information on adding a property, see Add a system property.

Note:
Users with the admin role can create applications in the global scope, regardless of whether or not they have the sn_g_app_creator.global role.

Procedure

1. Navigate to **All** > **User Administration** > **Users** and open the user record of the developer.
2. On the Roles related list, select **Edit...**.
3. On the Edit Members page, move the sn_g_app_creator.global role from **Collection** to **Roles List**.



Ensure that the sn_g_app_creator.app_creator role is also selected. The developer needs both the sn_g_app_creator.app_creator and sn_g_app_creator.global roles to create applications in the global scope in Guided Application Creator.

4. Select **Save**.
5. On the user record, select **Update**.

Result

The option to create an application in the global scope is available to developers with the sn_g_app_creator.global role. Developers can use, for example, ServiceNow Studio, to create an app.

Add field types in Guided Application Creator

When you add fields to a custom table in Guided Application Creator, there are only 18 field types available by default. You can add a property to include more field types.

Before you begin

Role required: admin

About this task

For a list of field types that are available in the ServiceNow AI Platform, see Field types.

Procedure

1. Add a system property with the following settings:
   - Name: *sn_g_app_creator.field_types*
   - Type: string
2. In the **Value** field, enter a comma-separated list of field type names.
   For example, to add the Image and Document ID field types, enter `user_image,document_id`.
3. Select **Submit**.

Scripting

Use scripts to extend your instance beyond standard configurations. With scripts, you may automate processes, add functionality, integrate your instance with an outside application and more.

APIs (Application Programming Interfaces) provide classes and methods that you can use in scripts to define functionality. ServiceNow provides APIs as JavaScript classes, web services, and other points of connection for integrations. Note that you cannot access commonly used JavaScript objects (such as DOM or Window). Jelly scripts are also used in some modules. Jelly is used to turn XML into HTML and may include both client-side and server-side scripts.

Scripts may be server-side (run on the server or database), client-side (run in the user's browser), or run on the MID server.

Note:
When you are writing scripts, you cannot use reserved words.

Understand JavaScript before you begin customizing your instance, and with Jelly if you intend to deploy Jelly scripts.

Server-side scripts

Perform database operations. For example, use a server-side script to update a record. Create a script in a scoped application or in the global scope. Each execution context includes a set of available APIs.

Scoped environment

Use scoped APIs when scripting in a scoped application. Scoped `Glide` APIs do not include all the methods included in the global `Glide` APIs, and you cannot call a global `Glide` API in a scoped application.

Global environment

The global scope is a special application scope that identifies applications developed prior to application scoping, or applications intended to be accessible to all other global applications. Use global APIs when scripting in the global scope.

To learn more about server-side scripting, see Server-side scripting. To learn more about application scope, see Application scope.

Client-side scripts

Make changes to the appearance of forms, display different fields based on values that are entered, or change other custom display options.

- onLoad client scripts run when the form or page is loaded
- onChange client scripts run when something specific gets changed AND also when the form or page loads
- onSubmit client scripts run when the form is submitted

Client Scripts can also be called by other scripts or modules, including UI policies. To learn more about client-side scripting, see Client-side scripting.

Available script types

Scripts can be used in many places. The most important detail is whether the script runs on the client or the server.

Script types and where they run

Script	Description	Runs on
Access Control	Determines whether access will be granted for a specified operation to a specific entity. • type of entity being secured • operation being secured • unique identifier describing the object Can be defined by roles, conditional expressions or scripts.	server - script and any condition run on the server

Script types and where they run (continued)

Script	Description	Runs on
Ajax Scripts	Enables the client to get data from the server to dynamically incorporate into a page without reloading the whole page. • Ajax Client Scripts request that information be returned, or that action be taken, or sometimes both • Ajax Server Scripts fulfill Ajax Client Script requests	• client - Ajax Client Scripts run on the client • server - Ajax Server Scripts run on the server
Business Rules	Customizes system behavior • runs when a database action occurs (query, insert, update or delete) • the script may run ○ before or after the database action is performed (runs as part of the database operation) ○ asynchronously (at some point after the database operation) ○ on display (when displaying the data in a form)	server - script and any condition run on the server
Service Catalog UI policies	Defines the display of a variable set or a catalog item (from the service catalog).	• client - scripts in the "execute if true" field or "execute if false" field run on the client • server - all conditions run on the server
Client Scripts	Used for making changes to the appearance of forms, displaying different fields based on values that are entered or other custom display options. • onLoad means the Client Script runs when the form or page is loaded • onChange means the Client Script runs when something specific gets changed AND also when the form or page loads • onSubmit means the Client Script runs when the form is submitted Client Scripts can also be called by other scripts or modules, including UI policies.	client
Script actions	Contains scripts which run when an event occurs, for example	server - script and any condition run on the server

Script types and where they run (continued)

Script	Description	Runs on
	• approval is cancelled • change is approved • problem is assigned Can have a condition which must be true for the script to run. Commonly used to call a Script Include.	
Script Includes	Contains scripts which can be functions or classes. These scripts run only when called by other scripts (often Business Rules). Any server script which is complicated or reusable should be a Script Include (especially complicated Business Rules).	server
Transform maps	Used for importing data. • defines mapping relationships between tables • can use Business Rules, other scripts and/or other options to import that data Do not always include scripts.	server
UI actions	Creates the ability to choose a specific action such as clicking a button or a link. UI Actions put these items on forms and lists: • buttons • links • context menu items • list choices	• client - when the "Client" box is checked, the script in the script field runs on the client • server - when the "Client" box is unchecked, the script in the script field runs on the server • client - when the "Client" box is checked, the onClick script is available, which can contain any JavaScript but normally calls a function which is specified in the script field • server - all conditions run on the server
UI Context Menus	Defines which "right-click menu" will pop-up in which area, and the menu choices that will be available	• client - onShow scripts run on the client • client - action scripts run on the client

Script types and where they run (continued)

Script	Description	Runs on
	 **Note:** If you use a left-handed mouse configuration, right-click means "click the other button."	• server - dynamic action scripts run on the server • server - all conditions run on the server
UI macros	Contains modular, reusable components that can contain Jelly and are called by UI pages. They also contain different types of scripts and may be called multiple times on the same page. **Note:** Jelly turns XML into HTML.	• server - the UI Macro itself executes on the Server • server - may contain content that runs on the server (Jelly expressions or JavaScript inside Jelly constructs) • client - may generate output that runs on the client (embedded JavaScript within <script> tags)
UI Pages	Used to create and display pages, forms, dialogs, lists and other UI components. Can be displayed on a standalone basis, or called as a usable component, as part of a larger page.  Can contain • Client Scripts, • processing scripts (which are server scripts), • HTML,	• server - Jelly XML runs on the server to produce HTML • client - HTML may contain embedded JavaScript that runs on the client • client - client scripts run on the client • server - processing scripts run on the server

Script types and where they run (continued)

Script	Description	Runs on
	• Jelly, • UI Macros, • and also can call other scripts. **Note:** Jelly turns XML into HTML.	
UI Policies	Defines the behavior and visibility of fields on a form. • mandatory • visible • read only Use UI Policies rather than client scripts whenever possible. • UI Policies are always attached to one table • UI Policies often have a condition which must be true in order for them to run	• client - scripts in the "execute if true" field or "execute if false" field run on the client • server - all conditions run on the server
UI Properties	Designates what the instance will look like.	• server - properties set on the server • client - the results get rendered on the client no scripts
UI Scripts	Contains client scripts stored for re-use. Only used when called from other scripts. Not recommended for use.	client
Validation Scripts	Validates that values are in a specified format. For example, a validation script can verify that the only value allowed in a specific field is an integer.	client
Workflow editor	Used to create or change a workflow. Scripts can be run at any point in a workflow, or different scripts can be run at different points. Scripts also can be found inside every workflow activity and can be modified (although do so with extreme caution).	server - script and any conditions run on the server

Glide class overview

The ServiceNow Glide classes expose JavaScript APIs that enable you to conveniently work with tables using scripts.

Using the Glide APIs, you can perform database operations without writing SQL queries, display UI pages, and define UI actions. The following tables provide brief descriptions of the Glide classes and links to detailed information.

Server-side Glide classes

Class	Description
GlideRecord	Use this class for database operations instead of writing SQL queries. GlideRecord is a special Java class that can be used in JavaScript exactly as if it were a native JavaScript class. A GlideRecord is an object that contains records from a single table. See GlideRecord.
GlideElement	Use this class to operate on the fields of the current GlideRecord. See GlideElement.
GlideSystem	Use this class to get information about the system. See GlideSystem.
GlideAggregate	Use this class to perform database aggregation queries, such COUNT, SUM, MIN, MAX, and AVG, for creating customized reports or calculations in calculated fields. See GlideAggregate.
GlideDateTime	Use this class to perform date-time operations, such as date-time calculations, formatting a date-time, or converting between date-time formats. See GlideDateTime.

Client-side Glide Classes

Class	Description
GlideAjax	Use this class to execute server-side code from the client. See GlideAjax.
GlideDialogWindow	Use this class to display a dialog window. See GlideDialogWindow.
GlideForm	Use this class to customize forms. See GlideForm.
GlideList2	Use this class to customize (v2) lists, including normal lists and related lists. See GlideList2.
GlideMenu	Use this class to customize UI Context Menu items. See GlideMenu.
GlideUser	Use this class to get session information about the current user and current user roles. See GlideUser.

Glide stack

Glide is an extensible Web 2.0 development platform written in Java that facilitates rapid development of forms-based workflow applications (work orders, trouble ticketing, and project management, for example).

User interface stack technology map

Java packages		Technologies used
	User Interface (Browser)	• AngularJS • HTML • CSS • JavaScript
com.glide.ui com.glide.jelly	GlideServlet	Apache Jelly
com.glide.script	Business Rules	Mozilla Rhino
com.glide.db	Persistence	JDBC

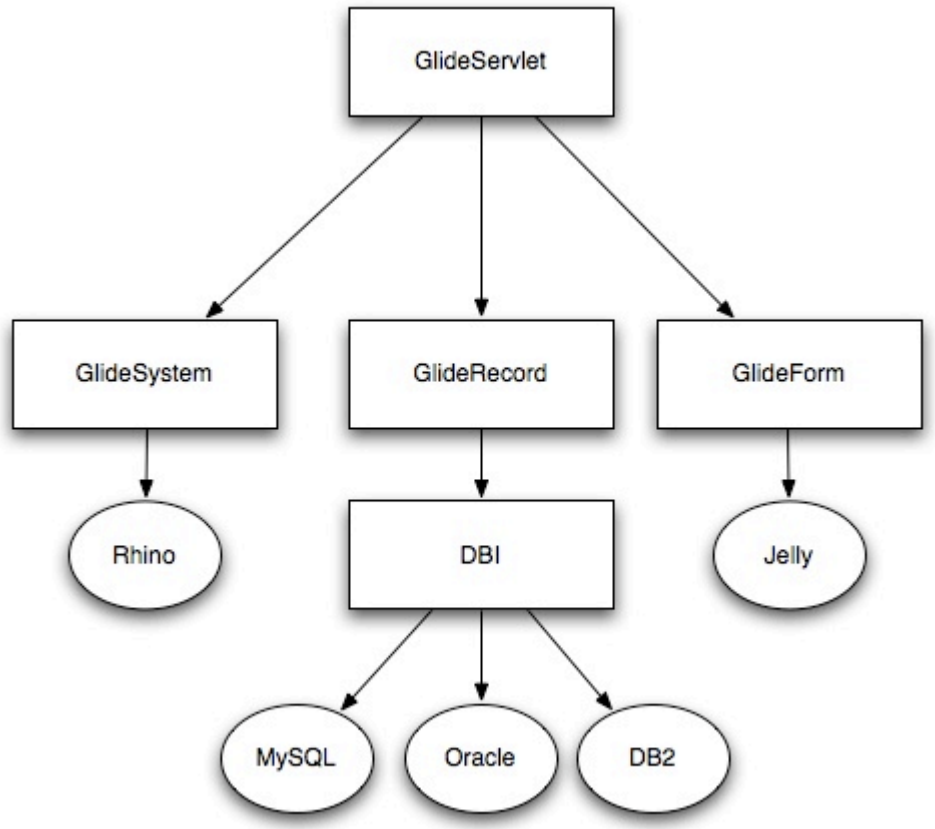
User interface stack technology map descriptions

Name	Description	Attributes
GlideServlet	The primary driver of Glide, and the only servlet in the system, is found in GlideServlet.java. The GlideServlet:	• Handles inbound action requests • Renders pages • Merges data with forms • Presents to user • Interfaces with script layer
Business Rules		• ECMA / JavaScript implementation based on Mozilla Rhino • Interfaces with persistence layer using JDBC recordset interface • Merges persistence layer meta-data with data for easy correlation
Persistence		• Persistence means any store ○ RDBMS ○ LDAP ○ File system • Uniform access regardless of store type

User interface stack technology map descriptions (continued)

Name	Description	Attributes
		• Provides QUID and meta-data capabilities • Interfaces presented to callers ○ RecordSet ○ TableDescriptor ○ ElementDescriptor

Glide servlet



Execution order of scripts and engines

Scripts, assignment rules, business rules, workflows, escalations, and engines all take effect in relation to a database operation, such as insert or update. In many cases, the order of these events is important.

Note:
Client-based code that executes in the browser, using Ajax or running as JavaScript, will always execute before the form submission to the server.

The order of execution is as follows:

1. Before business rules: Scripts configured to execute before the database operation with an order less than 1000.
2. Before engines. The following are not executed in any specific order:

- Approval engine (for task and sys_approval_approver tables)
- Assignment rules engine (for task tables)
- Escalation engine
- Data policy engine
- Field normalization engine
- Role engine - keeps role changes in sync with sys_user_has_role table (for sys_user, sys_user_group, sys_user_grmember, and sys_user_role tables)
- Execution plan engine (for task tables)
- Update version engine - creates version entry when sys_update_xml entry is written (for sys_update_xml table)
- Data lookup engine inserts or updates
- Workflow engine (for default workflows)

3. Before business rules: Scripts configured to execute before the database operation with an order greater than or equal to 1000.
4. The data base operation (insert, update, delete).
5. After business rules: Scripts configured to execute after the database operation with an order less than 1000.
6. After engines. The following are not executed in any specific order:
   - Label engine
   - Listener engine
   - Table notifications engine
   - Role engine - keeps role changes in sync with sys_user_has_role table (for sys_user, sys_user_group, sys_user_grmember and sys_user_role tables)
   - Text indexing engine
   - Update sync engine
   - Workflow engine (for deferred workflows)
   - Trigger engine (for all Workflow Studio flows)
7. Email notifications. The following are executed based on the weight of the notification record:
   - Notifications sent on an insert, update, or delete
   - Event-based notifications
8. After business rules (Only active records). Scripts configured to execute after the database operation with an order greater than or equal to 1000.

Note:
Like After business rules, Async business rules execute their logic after a database operation occurs. Unlike After business rules, Async business rules execute asynchronously, running in the background simultaneously with other processes. Async business rules run after the user submits the form and after the scheduler runs the scheduled job created from the business rule. The system creates a scheduled job from the business rule after the user submits the form but before any action is taken on the record in the database.

Script evaluation of fields by data type

Script fields evaluate data based on the field type of the input.

Evaluation of fields by data types

Type	Evaluates to in script	Example
String	The string	"dog" > "dog"
Decimal	A number with up to two decimal points	12.34 > 12.34
Integer	A number with zero decimal points	12 > 12
True / False	true or false	 > true  > false
Date	A date formatted as yyyy-mm-dd	2008-11-04
Date-time	A day and time formatted as yyyy-mm-dd hh:mm:ss	2008-11-04 06:46:20
Duration	A date that is equal to January 1st 1970 00:00:00 + the amount of time of the duration being stored **Note:** This date corresponds to the system time zone. If a different user time zone has been specified, the date and time value may appear different for that user.	> "1970-01-01 00:00:00" > "1970-01-02 02:03:04"
Choice	Returns the contents of the value field for the `sys_choice` record associated	> "2" (Note that this value is is a string)

Evaluation of fields by data types (continued)

Type	Evaluates to in script	Example
	with that choice. See: Choice List for more information on returning the value associated with a particular item in a choice list.	
Journal	Returns a string of all entries made to that journal field. See Journal Fields for scripting of journal type fields	The web server is down > The web server is down
Reference	Returns the `sys_id` of the record that is referenced	> "287ee6fea9fe198100ada7950d0b1b73"
Image	Returns the path to the image	> images/icons/image_name.gif
URL	Returns a string	> "http://www.service-now.com"
Glide Lists	Returns a string of comma-separated Sys IDs	> 5137153cc611227c000bbd1bd8cd2007,46d14f04a9fe19810142e40c6b071512

Scripting alert, info, and error messages

You can send messages to customers as alerts, informational messages, or error messages.

Business rule and other general use scripts

Script	Result
`current.field_name.setError("Hello World");`	Adds `Hello World` below the specified field in a red error message.
`gs.addInfoMessage("Hello World");`	Adds `Hello World` at the top of the browser window in a blue info message.
`gs.addErrorMessage("Hello World");`	Adds `Hello World` at the top of the browser window in a red error message.
`gs.print("Hello World");`	Writes `Hello World` to the text log on the file system but not to the sys_log table in the database.
`gs.log("Hello World");`	Writes `Hello World` to the database and the log file.

Business rule and other general use scripts (continued)

Script	Result
	Note: gs.log can adversely affect performance if used too frequently.

Client side scripts

Script	Result
`alert("Hello World");`	Displays a window with `Hello World` and an **OK** button. **Note:** Rather than use JavaScript *`alert()`*, for a cleaner look, you can display an error on the form itself with thee *`showFieldMsg()`* and *`hideFieldMsg()`* methods. For more information, see Display field messages.
`confirm("Hello World");`	Displays a window with `Hello World?` and **OK** and **Cancel** buttons.
`g_form.showFieldMsg("field_name", "Hello World", "error");`	Adds `Hello World` below the specified field in a red error message.
`g_form.hideFieldMsg("field_name");`	Hides the most recent message for the specified field.

Important: The methods in this table are only for use in client scripts.

It is also possible to add other custom messages to your forms if necessary using client scripting.

The text size of info and error messages at the top of the screen is customizable. Two properties control this. If you configured your forms, you may need to add these properties.

Note: The client script alert option is not available for use with Automated Test Framework (ATF).

Error and alert text size properties

Property	Description
`css.outputmsg.info.text.font-size`	Sets the size for info messages. Default is 11pt.
`css.outputmsg.error.text.font-size`	Sets the size for error messages. Default is 11pt.

Now Assist for code generation

Use ServiceNow® Now Assist for code generation for help writing scripts quickly with AI-generated code based on text or code prompts.

https://player.vimeo.com/video/1022256119?h=444ebb1578&badge=0&autopause=0&player_id=0&app_id=58479

AI limitations

This application uses artificial intelligence (AI) and machine learning, which are rapidly evolving fields of study that generate predictions based on patterns in data. As a result, this application may not always produce accurate, complete, or appropriate information. Further, there is no guarantee that this application has been fully trained or tested for your use case. To mitigate these issues, it is your responsibility to test and evaluate your use of this application for accuracy, harm, and appropriateness for your use case, employ human oversight of output, and refrain from relying solely on AI-generated outputs for decision-making purposes. This is especially important if you choose to deploy this application in areas with consequential impacts such as healthcare, finance, legal, employment, security, or infrastructure. You agree to abide by ServiceNow's AI Acceptable Use Policy, which may be updated by ServiceNow.

Data processing

This application requires data to be transferred from ServiceNow customers' individual instances to a centralized ServiceNow environment, which may be located in a different data center region from the one where your instance is, and potentially to a third-party cloud provider, such as Microsoft Azure. This data is handled per ServiceNow's internal policies and procedures, including our policies available through our CORE Compliance Portal.

Data collection

ServiceNow collects and uses the inputs, outputs, and edits to outputs of this application to develop and improve ServiceNow technologies including ServiceNow models and AI products. In addition, this application will collect information about scripts (and associated script records) in which Now Assist for code generation is called. Customers can opt out of future data collection at any time, as described in the Now Assist Opt-Out page.

For more information, see the Now Assist documentation.

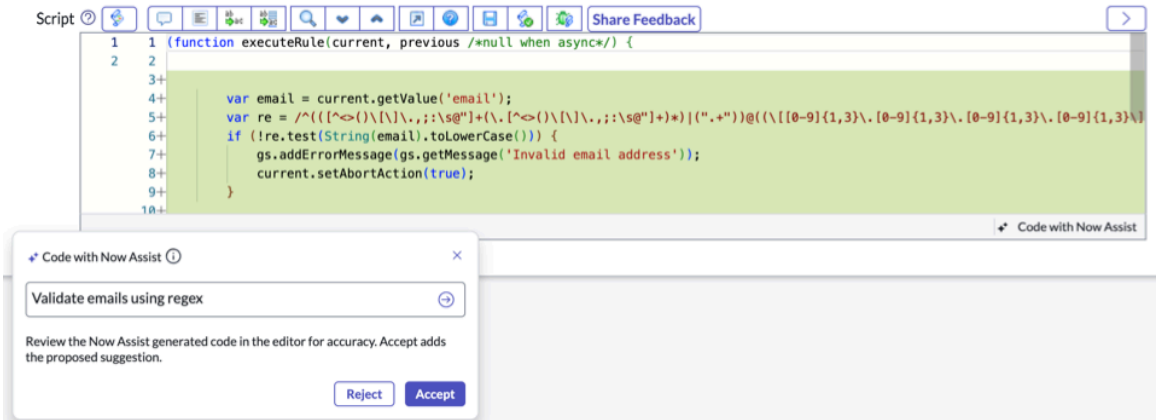
Exploring code generation

Learn about how AI-generated code can empower developers scripting on the ServiceNow AI Platform.

Code generation overview

Now Assist for Creator activates the code generation skill. With code generation, you provide text describing the code to generate and get code suggestions in the JavaScript editor on forms in the ServiceNow AI Platform and in Script steps in Workflow Studio. Developers with varying levels of experience in scripting on the ServiceNow AI Platform can benefit from using code generation to get started writing custom scripts or iterate on scripts more efficiently.

To generate code suggestions, you describe the goal of the code to generate in the Code with Now Assist dialog box. The code suggestion appears in the lines following your prompt but isn't added to your script until it's accepted.

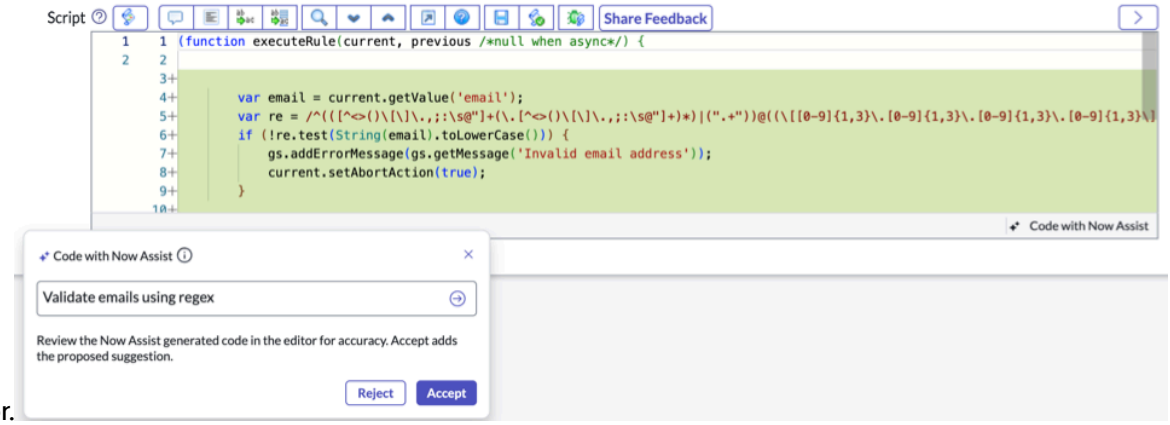


Note:
Developers must be assigned the now.assist.creator role to use code generation. For more information about using code generation, see Generate scripts with AI-powered code generation.

Code generation workflow

1. From the script editor, a developer opens the Code with Now Assist dialog box and describes the code they want to generate.
2. The developer triggers generating a code suggestion.

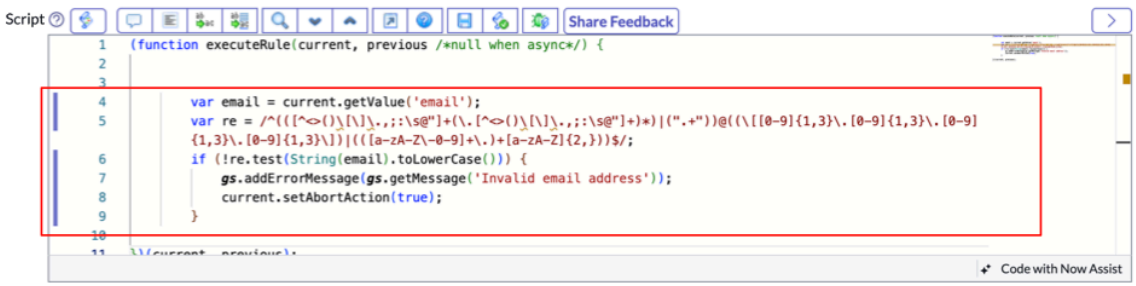
In the following example, a developer describes what they want the script to do in the Code with Now Assist dialog box. The code suggestion appears highlighted in the script editor.



3. The developer reviews the AI-generated code suggestion and either accepts or rejects it.
   - If they accept it, the code is added to the script, and they can make any necessary edits based on their review.
   - If they reject it, the code isn't added to the script, and they can rephrase their prompt to generate a new code suggestion.

   In the following example, a line next to the line numbers indicates which code was created by AI and hasn't been edited. If you edit AI-generated code, the line indicator doesn't appear for those lines of code.

   AI-generated code lines



Optionally, you can turn on code completion functionality to use code or single-shot prompts in script editors with Now Assist for code generation.

Code generation benefits

Benefit	Feature	Users
Improve quality of scripts, automate repetitive coding tasks, and reduce time spent searching for or recalling code	Text-to-code and code complete	Developers
Iterate on scripts efficiently	Code editing	Developers
Identify code generated by AI	Tracking AI-generated code	Developers, administrators

General guidelines for code generation

Use these general guidelines for code generation to get better code suggestions and create useful and accurate scripts.

Writing prompts

Write clear and specific but concise prompts

Specify the expected outcome and context, including necessary details like task requirements, specific APIs if you know them, and any constraints.

Experiment with different prompts

As you refine and experiment, the Now LLM Service uses this feedback to learn and improve.

- Try adjusting task instructions and incorporating examples, and then observe how code suggestions differ with different prompt styles and levels of detail.
- Try including a short code snippet as an example of how to start the script with a single-shot prompt.
- Keep track of your prompts, including any modifications, and instructions for generating prompts to meet your specifications. This tracking enables easy regeneration of past results for comparative analysis.

Example prompts for code generation

Strong prompt	Weak prompt	Notes
Get incidents with related tasks	Get incidents with tasks	Includes sufficient detail.
Use glide aggregate to count number of P1 incidents closed between 3rd March to 13 April assigned to admin	Count P1 incidents between 3-3 and 4-13	Includes the API name and more specific language.
If open change request is P1, do not allow reducing the severity unless it's the creator	Don’t allow changing P1 change requests	Includes more specific instructions on what shouldn't change.
Gliderecord of the most recent change	Latest change	Includes the API name and more specific language.

Reviewing code

Review code

Implement strict and detailed reviews of the AI-generated code to determine its accuracy, efficiency, and how well it adheres to your coding standards.

Test code

Validate the code by running it against test cases in controlled environments to ensure that it functions according to your requirements.

Configuring code generation

Configure how developers can use code generation on an instance.

Install Now Assist for code generation

Install the ServiceNow® Now Assist for Creator application from the ServiceNow® Store to get Now Assist for code generation.

Before you begin

- Review the Now Assist for Creator application listing in the ServiceNow Store for information on dependencies, licensing or subscription requirements, and release compatibility. Now Assist for Creator installs the Now Assist for code generation application (sn_now_assist_code).

Role required: admin

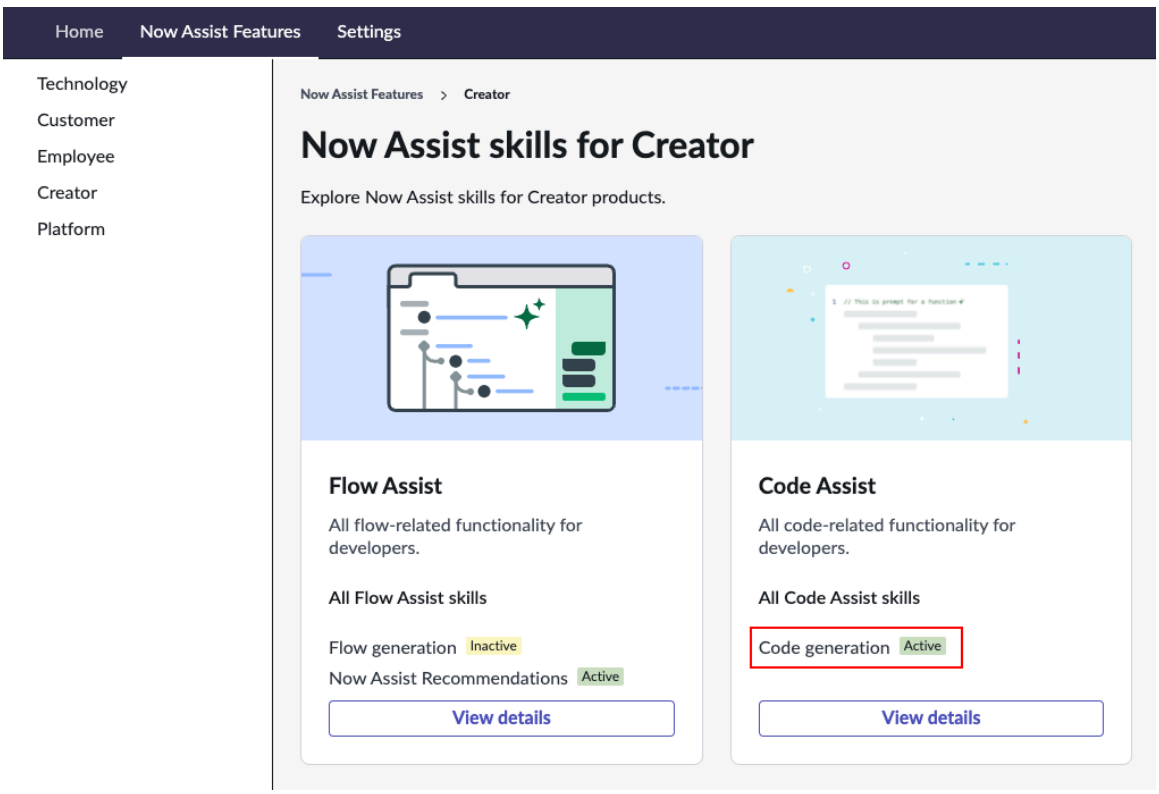
Procedure

1. From the Now Assist for Creator application page on the ServiceNow Store, select **Request App**.
2. After approval has been granted, on your instance, navigate to **All** > **System Applications** > **All Available Applications** > **All**.
3. Using the search bar, search for the Now Assist for Creator application (sn_now_creator).
4. Select **Install**.
5. Verify that Now Assist for Creator is installed:

   a. Navigate to **All** > *Now Assist Admin* > **Features**.

   b. In the workflow list, select **Creator**.

   c. On the Code Assist card, verify that the code generation skill is active.



For more information about Now Assist Admin, see Now Assist.

What to do next
Grant the now.assist.creator role to each user you want to use code generation.

Install Now Assist for Creator

Tracking AI-generated code
Control when to track and indicate that code is AI-generated.

When you accept a code suggestion, the lines of code that are AI-generated are tracked and indicated by a line next to the line numbers in script editors. If you edit AI-generated code, the line indicator doesn't appear for those lines of code.

You can turn on and off tracking of AI-generated code and configure how long to record and indicate AI-generated code in script editors. By default, AI-generated code is recorded and indicated for six months.

Configure how long to indicate AI-generated code
Show that code was generated by AI in script editors for a specified duration after accepting code suggestions.

Before you begin
Role required: admin

Procedure
1. In the navigation filter, enter `sys_auto_flush.list`.
2. Filter the Auto Flushes [sys_auto_flush] list by entering *`sn_now_assist_code_ai_generated_lines`* in the **Tablename** column filter.
3. Select *`sn_now_assist_code_ai_generated_lines`* to open the record.
4. In the **Age in seconds** field, enter the duration to record and indicate AI-generated code after its creation in seconds.
5. Select **Update**.

Result
AI-generated code created before the configured duration isn't recorded or indicated in script editors.

Turn off tracking AI-generated code
Turn off tracking and indicating which code is AI-generated.

Before you begin
Role required: admin

About this task
Tracking and indicating which code is AI-generated involves changes that are included in update sets. If you don't want to include changes related to this in update sets, you can turn off tracking and indicating AI-generated code.

Procedure
1. In the navigation filter, enter `sys_properties.list`.
2. Filter the System Properties [sys_properties] list by entering *`sn_now_assist_code.show_ai_code_line_marker`* in the **Name** column filter.

3. Select *sn_now_assist_code.show_ai_code_line_marker* to open the property record.
4. In the **Value** field, enter `false`.
5. Select **Update**.

Result
AI-generated code isn't recorded or indicated in script editors.

Generate scripts with AI-powered code generation

Generate scripts from text, code, or a combination of both with AI-powered code generation.

When code generation is enabled on an instance, a Now Assist icon (✨) appears in the script editor.

Developers must be assigned the now.assist.creator role to use code generation.

Generate scripts from text

Write scripts quickly with AI-generated code by telling Now Assist what you want the script to do.

Before you begin
Learn how to write prompts to generate better code suggestions. For more information, see General guidelines for code generation.

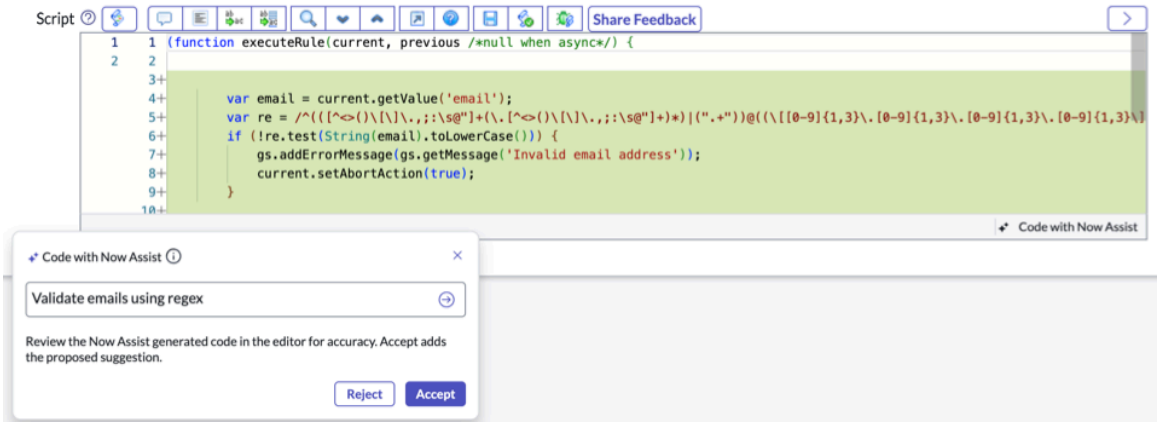
Role required: now.assist.creator

Procedure
1. Navigate to a form with a script field.

   Example
   For example, to open a script include form, navigate to **All** > **System Definition** > **Script Includes** and select **New** or enter `sys_script_include.do` in the navigation filter.
2. In the script editor, place your cursor where you want to add code.
3. Right-click and select **Open Code with Now Assist** or use one of the following keyboard shortcuts:
   - Windows: Ctrl-Enter
   - Mac: Cmd-Enter

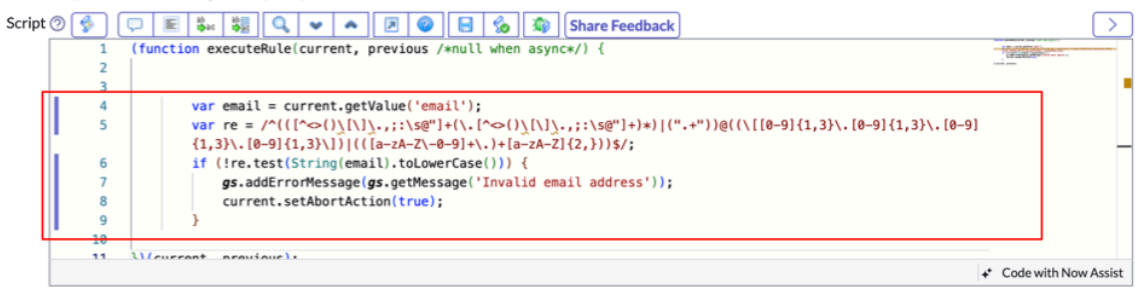
   Tip:
   Select the Help icon (🔵) to access the list of relevant keyboard shortcuts.
4. In the **Code with Now Assist** dialog box, enter text that describes the desired goal of the code to generate.

   The text you enter must be fewer than 1,000 characters.
5. Press Enter to generate a code suggestion.
   The code suggestion appears highlighted in the script editor.



6. Review the code suggestion and complete one of the following steps:
   - To include it in your script and make any edits, select **Accept**.
   - To regenerate a suggestion, revise the text in the dialog box and select the arrow icon ( ).
   - To remove it from the script, select **Reject**.

   When you accept a code suggestion, a line next to the line numbers indicates which code was created by AI and hasn't been edited. If you edit AI-generated code, the line indicator doesn't appear for those lines of code.



Trouble?
If the code suggestion doesn't meet your requirements, try rephrasing your prompt according to the prompt guidance and generating another code suggestion.

7. Select **Submit** or **Update** to save your changes.

Generate scripts from code

Write scripts quickly with AI-generated code completion.

Before you begin

Code completion must be turned on for the instance.

Role required: now.assist.creator

Procedure

1. Navigate to a form with a script field.

   Example
   For example, to open a script include form, navigate to **All** > **System Definition** > **Script Includes** and select **New** or enter `sys_script_include.do` in the navigation filter.

2. In a script field, enter code or a combination of text and code:

Example

- Enter the beginning of a function or other code to be automatically completed. For example:

```
var email = current.getValue('email');
var regex =
```

- Enter a combination of text in a code comment that describes the desired goal of the code to generate followed by an example of how you want the code to start. For example:

```
// Validate emails using regex
var email = current.getValue('email');
var regex =
```

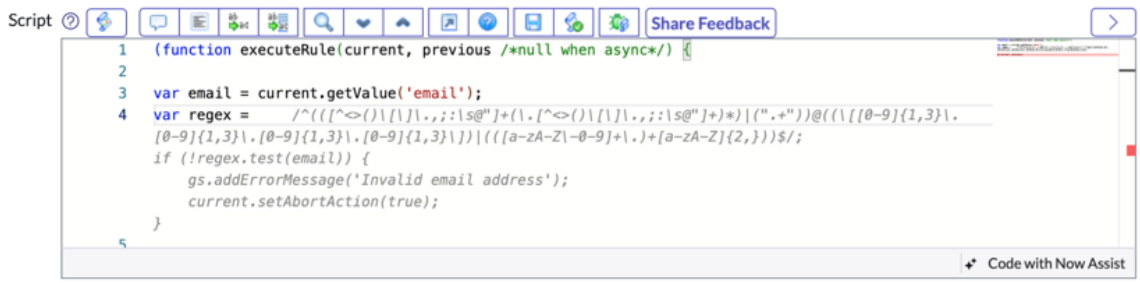
3. Right-click and select **Auto-generate code completion** or use one of the following keyboard shortcuts to generate a code suggestion:
   - Windows: Ctrl-Windows logo key-Enter
   - Mac: Ctrl-Cmd-Enter

   Tip:
   Select the Help icon ( ) to access the list of relevant keyboard shortcuts.

   The code preceding your cursor must be fewer than 1,000 characters when triggering code generation.

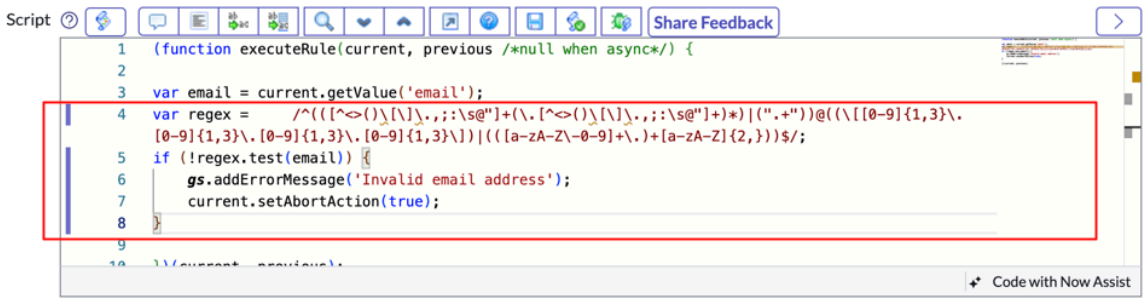
   You can't edit the prompt after triggering the code generation. If you need to edit your prompt before the code suggestion is returned, you can cancel the code generation by pressing the Backspace key.

   The spinner icon ( ) appears while generating a suggestion. The code suggestion appears in the lines following your prompt but isn't added to your script until you accept it.



4. Accept the code to include it in your script or reject it to remove it from the script.
   - Accept: Press the Tab key or the right arrow key. Selecting within the suggested code also accepts the suggestion.
   - Reject: Press the Escape key, left arrow key, or up arrow key. Typing or selecting anywhere outside of the suggested code within the script also removes the suggestion.

   When you accept a code suggestion, a line next to the line numbers indicates which code was created by AI and hasn't been edited. If you edit AI-generated code, the line indicator doesn't appear for those lines of code.



Trouble?
If the code suggestion doesn't meet your requirements, try modifying your code and generating another code suggestion.

5. Select **Submit** or **Update** to save your changes.

Edit code with Now Assist

Edit scripts quickly by telling Now Assist how to improve the code.

Before you begin

Role required: now.assist.creator

About this task

When code generation is enabled on an instance, a Now Assist icon (✨) appears in the script editor.

Procedure

1. Navigate to a script.

   Example
   For example, to open a script include form, navigate to **All** > **System Definition** > **Script Includes** and select a script include.

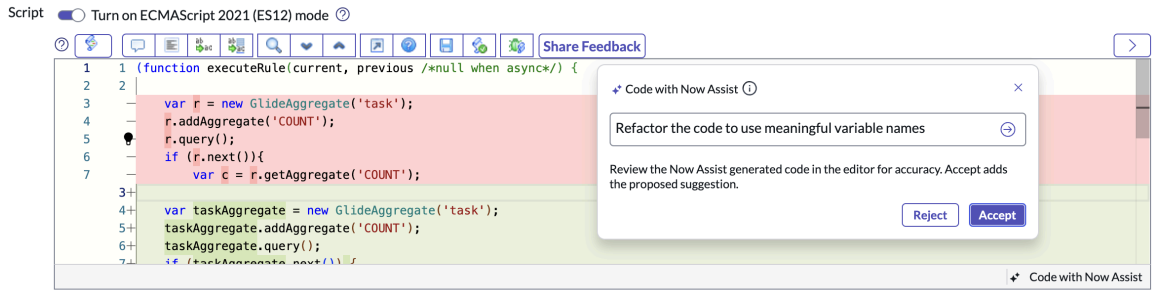
2. In the script editor, highlight the code to edit.
3. Right-click and select **Open Code with Now Assist** or use one of the following keyboard shortcuts:
   - Windows: Ctrl-Enter
   - Mac: Cmd-Enter

   Tip:
   Select the Help icon (?) to access the list of relevant keyboard shortcuts.

4. In the **Edit code with Now Assist** dialog box, enter text that describes how you want to refactor the code.

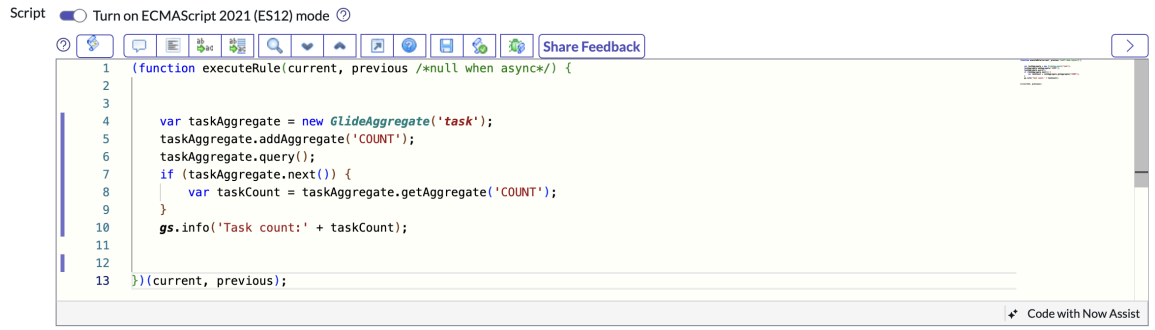
   The text you enter must be fewer than 1,000 characters.

5. Press Enter to generate an edited code suggestion.
   A view comparing the original code and the edited code suggestion appears in the script editor.



6. Review the edited code suggestion and complete one of the following steps:
   - To overwrite the original code with the edited code suggestion, select **Accept**.
   - To regenerate a suggestion, revise the text in the dialog box and select the arrow icon ( ).
   - To remove the edited code from the script and keep only the original code, select **Reject**.

   When you accept a code suggestion, a line next to the line numbers indicates which code was created by AI and hasn't been edited. If you edit AI-generated code, the line indicator doesn't appear for those lines of code.



Trouble?
If the code suggestion doesn't meet your requirements, try rephrasing your prompt according to the prompt guidance and generating another code suggestion.

7. Select **Submit** or **Update** to save your changes.

Code generation reference

Reference topics provide additional information about configuration properties, roles, and more.

Code generation properties

You can adjust how code generation functions on an instance using several advanced properties.

Note:
To open the System Properties [sys_properties] table, enter `sys_properties.list` in the navigation filter.

Properties for code generation

Property	Description
sn_now_assist_code.enable_code_assist	Enables using code generation in supported script editors.

Properties for code generation (continued)

Property	Description
	• Type: true | false • Default value: true • Location: System Property [sys_properties] table • Learn more: You can also enable code generation from Now Assist Admin. For more information, see Activate a Now Assist skill.
sn_now_assist_code.enable_prompt_modal	Enables using the Code with Now Assist dialog box to provide text prompts. • Type: true | false • Default value: true • Location: System Property [sys_properties] table • Learn more: Generate scripts from text
sn_now_assist_code.enable_code_edit	Enables editing code with Now Assist. • Type: true | false • Default value: true • Location: System Property [sys_properties] table • Learn more: Edit code with Now Assist
sn_now_assist_code.show_ai_code_line_marker	Enables tracking which lines of code are AI-generated. This code is indicated by a line next to the lines of code in a script editor. If you edit AI-generated code, the line indicator doesn't appear for those lines of code. • Type: true | false • Default value: true • Location: System Property [sys_properties] table • Learn more: Tracking AI-generated code

Properties for code generation (continued)

Property	Description
sn_now_assist_code.collect_schema_for_code_assist	Specifies whether to collect the data schema of the table a business rule or client script runs on when using code generation. If you set this property to false, you can receive code suggestions quicker but may get less contextual suggestions. • Type: true | false • Default value: true • Location: System Property [sys_properties] table

Code generation roles

The following roles are installed for use with code generation.

To learn more about managing per-user subscriptions, see Managing per-user subscriptions in Subscription Management and contact your account representative.

Now Assist Creator [now.assist.creator]

Write scripts using AI-powered code generation.

Groups

This role is assigned to no groups by default.

Contains Roles

This role contains no roles.

Elevated

This role is not an elevated role.

Special considerations

None

JavaScript syntax editor

The syntax editor provides support for editing JavaScript scripts.

The syntax editor has these features.

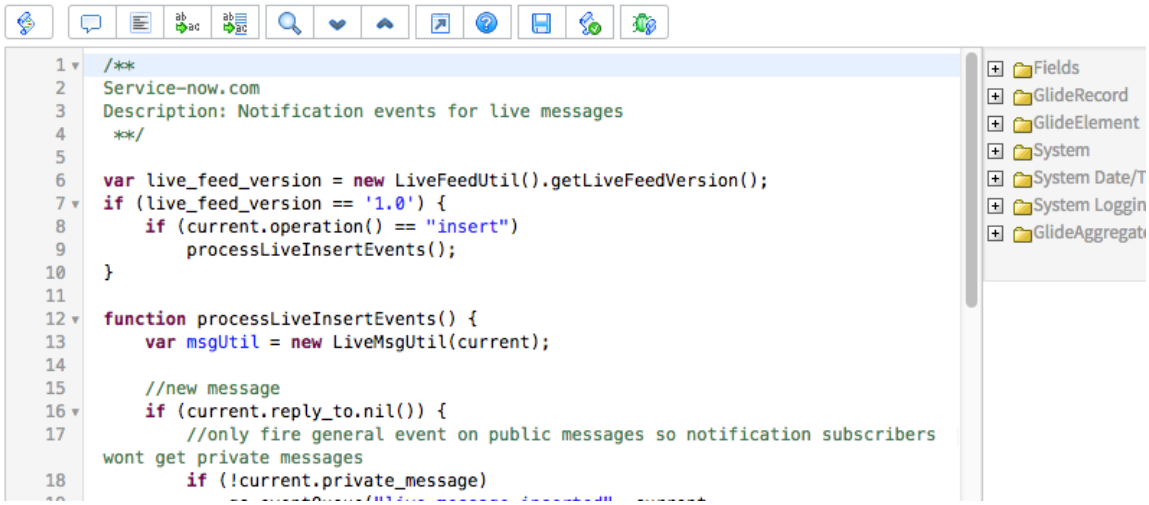
- JavaScript syntax coloring, indentation, line numbers, and automatic creation of closing braces and quotes
- JavaScript support
- Linting using the ESLint utility

Note:
Modify or view default linting configurations by accessing the *glide.ui.syntax_editor.linter.eslint_config* property in the System Property [sys_properties] table. See Available system properties for more information.

- Context menu for script includes, API, and tables
- Script macros for common code shortcuts

This feature requires the Syntax Editor (com.glide.syntax_editor) plugin.

JavaScript editor



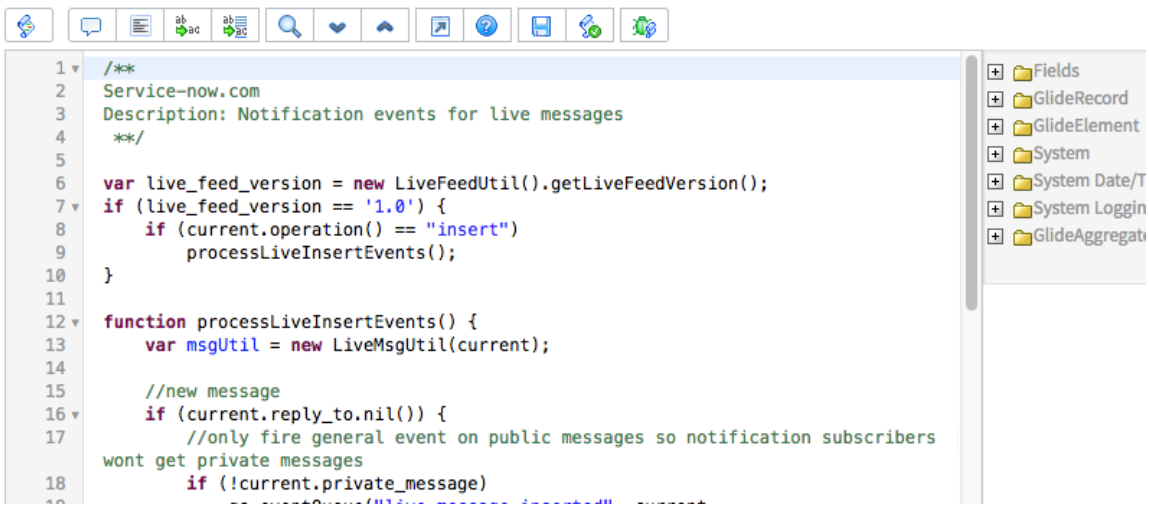
Syntax editor plugin

Enable the syntax editor plugin to use the syntax editor.

The syntax editor enables the following features for all script fields:

- JavaScript syntax coloring, indentation, line numbers, and automatic creation of closing braces and quotes
- Code editing functions
- Code syntax checking
- Script macros for common code shortcuts

JavaScript syntax editor



The syntax editor can be disabled or enabled by modifying the *glide.ui.javascript_editor* property in the sys_properties.list. In addition, administrators can configure the syntax editor to show error and warning indicators next to a line of code that contains an error by modifying the

glide.ui.syntax_editor.show_warnings_errors property. For information on the sys_properties.list, refer to Available system properties.

Note:
Administrators can disable or enable the syntax editor for all users, regardless of user preference.

Syntax editor JavaScript support

The syntax editor provides editing functions to support editing JavaScript scripts.

JavaScript editing functions

Icon	Keyboard Shortcut	Name	Description
	N/A	Toggle Syntax Editor	Disables the syntax editor. Click the button again to enable the syntax editor.
	Access Key + R	Format Code	Applies the proper indentation to the script.
	Access Key + C	Comment Selected Code	Comments out the selected code.
	Access Key + U	Uncomment Selected Code	Removes comment codes from the selected code.
	N/A	Check Syntax	Checks the code for syntax errors. By default, the system automatically checks for syntax errors as you type in a script field. If an error or warning is found, the syntax editor displays a bullet beside the script line containing the error or warning. This check occurs on all script fields.
	Access Key + \	Start Searching	Highlights all occurrences of a search term in the script field and locates the first occurrence. Click the icon, then enter the search term and press **Enter**. You can use regular expressions enclosed in slashes to define the search term. For example, the term */a{3}/* locates *aaa*.
	Access Key + [	Find Next	Locates the next occurrence of the current search term in the script field. Use *Start Searching* to change the current search term.
	Access Key +]	Find Previous	Locates the previous occurrence of the current search term in the script field. Use *Start Searching* to change the current search term.
	Access Key + W	Replace	Replaces the next occurrence of a text string in the script field. **1.** Click the icon, then enter the string to replace and press **Enter**. You can use regular expressions enclosed in slashes to define the string to replace. For example, the term */a{3}/* locates *aaa*. **2.** Enter the replacement string and press **Enter**.
	Access Key + ;	Replace All	Replaces all occurrences of a text string in the script field.

Icon	Keyboard Shortcut	Name	Description
			1. Click the icon, then enter the string to replace and press **Enter**. You can use regular expressions enclosed in slashes to define the string to replace. For example, the term */a{3}/* locates *aaa*. 2. Enter the replacement string and press **Enter**.
	N/A	Save	Saves changes without leaving the current view. Use this button in full screen mode to save without returning to standard form view.
	Access Key + L	Toggle Full Screen Mode	Expands the script field to use the full form view for easier editing. Click the button again to return to standard form view. This feature is not available for Internet Explorer.
	Access Key + P	Help	Displays the keyboard shortcuts help screen.

JavaScript editing tips

- To fold a code block, click the minus sign beside the first line of the block. The minus sign only appears beside blocks that can be folded. To unfold the code block, click the plus sign.
- To insert a fixed space anywhere in your code, press Tab.
- To indent a single line of code, click in the leading white space of the line and then press Tab.
- To indent one or more lines of code, select the code and then press Tab. To decrease the indentation, press Shift + Tab.
- To remove one tab from the start of a line of code, click in the line and press Shift + Tab.

JavaScript resources

Scripts use ECMA 262 standard JavaScript. Helpful resources include:

Syntax editor keyboard shortcuts and actions

The syntax editor offers keyboard shortcuts and actions to assist in writing code.

Syntax editor keyboard shortcuts and actions for writing code

Keyboard shortcut or action	Description	Example
Write code		

Syntax editor keyboard shortcuts and actions for writing code (continued)

Keyboard shortcut or action	Description	Example
Scripting assistance Control +Spacebar	Displays a list of valid elements at the insertion point such as: • Class names • Function names • Object names • Variable names Double-click an entry to add it to the script. **Note:** The elements are based on server or client type of script. However, these elements are available based on the UI type you select. For example, spUtil is available for Service Portal client scripts and g_navigation is available for Desktop scripts.	Enter a period character after a valid class name.	Displays a list methods for the class. Double-click an entry to add it to the script.	Enter an open parenthesis character after a valid class, function, or method name.	Displays the expected parameters for the class or method. Enter the expected parameters as needed.	Toggle full screen mode Control+M	Switches between displaying the form with the full screen and displaying it normally.	

Syntax editor keyboard shortcuts and actions for writing code (continued)

Keyboard shortcut or action	Description	Example
Format code • Windows: Control +Shift+B • Mac: Command +Shift+B	Formats the selected lines to improve readability.	
Toggle comment • Windows: Control+/ • Mac: Command +/	Adds or removes the comment characters `//` from the selected lines.	Insert macro text **1.** In the **Script** field, type the macro keyword text. For example `help`. **2.** Press Tab.	Inserts macro text at the current position.	Search		
Start search • Windows: Control+F • Mac: Command +F	Highlights all occurrences of a search term in the script field and locates the first occurrence. You can create regular expressions by enclosing the search terms between slash characters . For example, the search term `/a{3}/` locates the string `aaa` .	

Syntax editor keyboard shortcuts and actions for writing code (continued)

Keyboard shortcut or action	Description	Example
Find next • Windows: Control+G • Mac: Command +G	Locates the next occurrence of the current search term in the script field. Use **Start Searching** to change the current search term.	Find previous • Windows: Control +Shift+G • Mac: Command +Shift+G	Locates the previous occurrence of the current search term in the script field. Use **Start Searching** to change the current search term.	Replace • Windows: Control+E • Mac: Command +E	Replaces the next occurrence of a text string in the script field.	Replace all • Windows: Control+; • Mac: Command +;	Replaces all occurrences of a text string in the script field.	Help		
Help • Windows: Control+H • Mac: Command +H	Displays the list of syntax editor keyboard shortcuts.	
Syntax editor keyboard shortcuts and actions for writing code (continued)

Keyboard shortcut or action	Description	Example
Show description • Windows: Control+J • Mac: Command +J	Displays API documentation for the scripting element at the cursor's current location.	Show macros **1.** In the **Script** field, type `help`. **2.** Press Tab.	Displays the list of available syntax editor macros as text within the script field.	
Syntax editor macros

Script macros provide shortcuts for typing commonly used code. To insert macro text into a script field, enter the macro keyword followed by the Tab.

Syntax editor macros are defined in the Editor Macros [syntax_editor_macro] table. To create or modify a script macro, see Create or modify a script macro.

vargr

- Inserts a standard *GlideRecord* query for a single value.
- Output:

```
var gr = new GlideRecord("$0");
gr.addQuery("name", "value");
gr.query();
if (gr.next()) {

}
```

vargror

- Inserts a *GlideRecord* query for two values with an OR condition.
- Output:

```
var gr = new GlideRecord('$0');

var qc = gr.addQuery('field', 'value1');

qc.addOrCondition('field', 'value2');
gr.query();
```

```
while (gr.next()) {

}
```

for

- Inserts a standard recursive loop with an array.
- Output:

```
for (var i=0; i< myArray.length; i++) {
 //myArray[i];

}
```

info

- Inserts a *GlideSystem* information message.
- Output:

```
gs.addInfoMessage("");
```

method

- Inserts a blank JavaScript function template.
- Output:

```
/*~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
~~~~~~~~~~~~~
   * Description:
   * Parameters:
   * Returns:

 ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
~~~~~~~~~~~*/
: function() {

},
```

doc

- Inserts a comment block for describing a function or parameters.
- Output:

```
/**

 * Description:

 * Parameters:

 * Returns:
*/
```

Create or modify a script macro

Administrators can define new script macros or modify existing script macros.

Before you begin
Role required: admin

About this task
Script macros provide shortcuts for typing commonly used code. Several script macros are available by default. Administrators can define new or modify existing script macros.

Procedure
1. Navigate to **All** > **System Definition** > **Syntax Editor Macros**.
2. Click **New** or select the macro to edit.
3. Define the macro details with the fields listed in the table below.

Editor macro fields

Field	Description
Name	Macro keyword text users type to insert macro text.
Comments	Description of the macro. This text appears when the user types *help*.
Text	Full macro text that replaces the name in the editor.

Context menu in the syntax editor
View the context menu for script includes, Glide APIs, and tables in the JavaScript syntax editor.

With the context menu options, your users can navigate to:

- Script include definitions
- Glide API documentation
- System and custom table definitions and data

In the syntax editor, bold font is used for tokens that have a context menu. Right-click the token to view context menu options. If you use a Mac, you can use the Command-click shortcut.

Context menu options

Token type	Context menu option	Description
Script include	Open Definition	Definition of the script include in a new window.
	Find References	List of files referencing the script include.

Context menu options (continued)

Token type	Context menu option	Description
		Note: • To view the preview of the file, click the preview script icon. To open the file in a new window, click **Open File**. • To view all files that reference the script include, click **Show All Files**.
Glide API	Show Documentation	Documentation page of the Glide API.
Table	Show Definition	Definition of the system or custom table in a new window.
	Show Data	Records in the table that are based on the role of the current user.

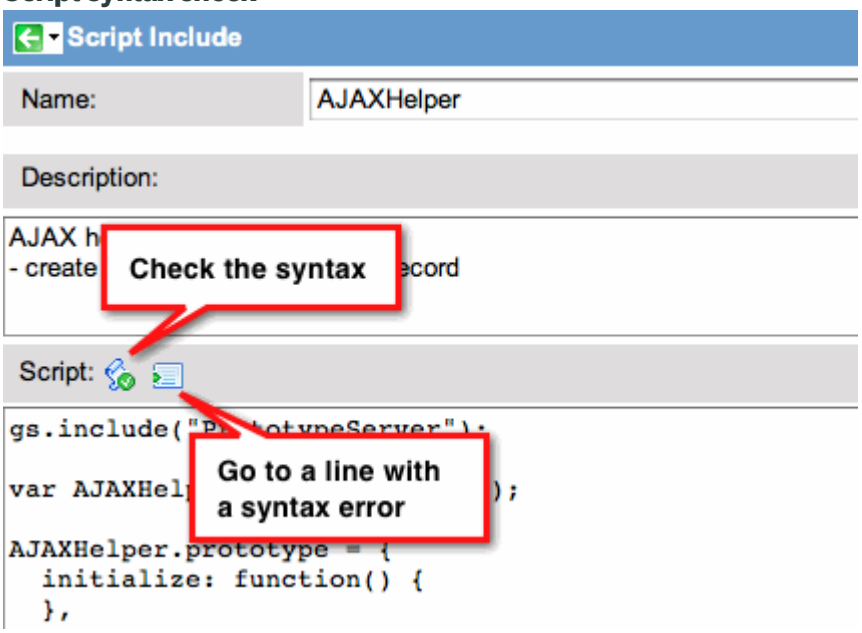
Enable or disable the context menu in the script editor using the *glide.ui.syntax_editor.context_menu* property in the System Property [sys_properties] table. See Available system properties for more information.

Note:
Context menu options can be accessed only if the browser supports SharedWorker. For example, Google Chrome and Mozilla Firefox.

Script syntax error checking

All script fields provide controls for checking the syntax for errors and for locating the error easily when one occurs. The script editor places the cursor at the site of a syntax error and lets you search for errors in scripts by line number.

Script syntax check



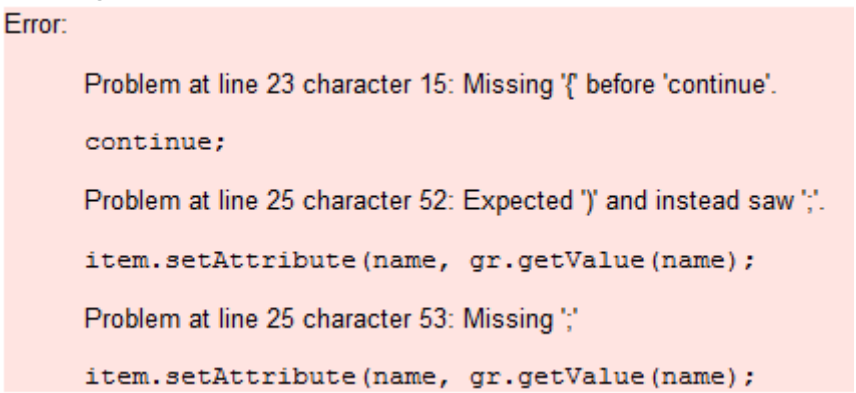
The script editor notifies you of syntax errors in your scripts in the following situations.

- Save a new record or update an existing record. A banner appears at the bottom of the editor showing the location of the first error (line number and column number), and the cursor appears at the site of the error. Warnings presented at **Save** or **Update** show only one error at a time.

  Script syntax error (short)

  
- Click the syntax checking icon before saving or updating a record. A banner appears at the bottom of the editor showing the location of all errors in the script, and the cursor appears at the site of the first error.

  Script syntax error

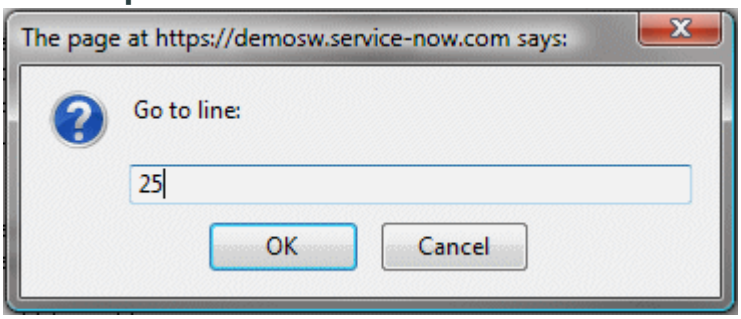
Searching for errors by line

To locate the exact position of the error in a large script, click the **Go to line** icon.

This feature is particularly useful when you are encounter a syntax error in a log file rather than in the ServiceNow record itself. In this case, you can navigate to the record and search for errors by line number. In the dialog box that appears, enter the line number of an error, and then click **OK**. Your view moves to the site of the error, and the cursor marks the correct line and column.

Note:
For this feature to function, you must disable the Syntax Editor.

Go to script error



Navigate to a line number

When the syntax editor is disabled, users can navigate to a specific line in the code using the Go to line icon ( ).

Before you begin

Disable the Syntax Editor.

Role required: admin

Procedure

1. Click the Go to line icon ( ).

   Note:
   This icon is not available when the editor is enabled.

2. Enter a number in the field and then press **Enter**.

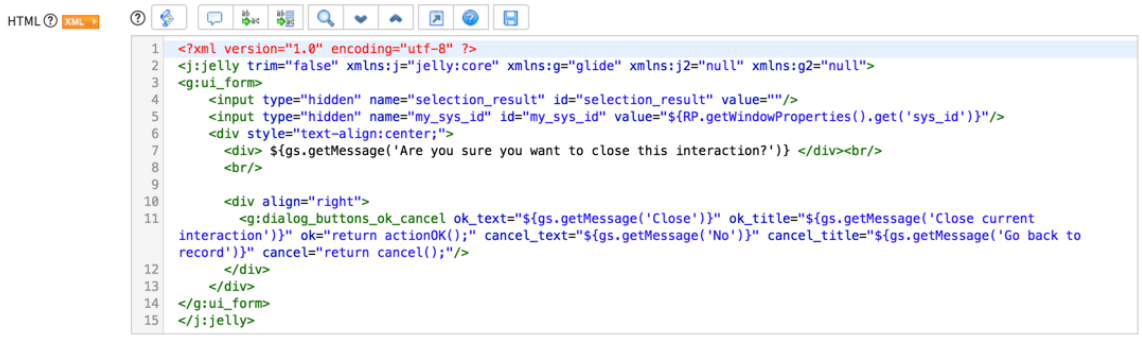
HTML syntax editor

The HTML syntax editor provides support for editing HTML and Jelly scripts and defines what's rendered when the page is displayed. The HTML syntax editor can contain either static XHTML or dynamically generated content defined as Jelly, and can call script includes and UI Macros.

The syntax editor has these features.

- HTML and Jelly script support
- HTML and Jelly syntax coloring, indentation, line numbers, and automatic creation of closing braces and quotes
- Auto-suggestions for HTML and Jelly tags
- Script macros for common code shortcuts

HTML syntax editor



HTML and Jelly editing functions

Icon	Keyboard shortcut	Name	Description
	N/A	Toggle syntax editor	Disables the syntax editor. Click the Toggle syntax editor icon ( ) again to enable the syntax editor.
	Cmd+/	Toggle comment	Comments the selected code.
	Cmd+E	Replace	Replaces the next occurrence of a text string in the script field. **1.** Click the Replace icon ( ), then enter the string to replace, and press#Enter. You can use regular expressions enclosed in slashes to define the string to replace. For example, the term `/a{3}/` locates `aaa`. **2.** Enter the replacement string and press#Enter.
	Cmd	Replace All	Replaces all occurrences of a text string in the script field. **1.** Click the Replace all icon ( ), then enter the string to replace and press#Enter. You can use regular expressions enclosed in slashes to define the string to replace. For example, the term `/a{3}/` locates `aaa`. **2.** Enter the replacement string and press#Enter.
	Cmd+F	Start Searching	Highlights all occurrences of a search term in the script field and locates the first occurrence. Click the Start searching icon ( ), then enter the search term and press Enter.
	Cmd+G	Find Next	Locates the next occurrence of the current search term in the script field. Click the Start searching icon ( ) to change the current search term.
	Cmd +Shift +G	Find Previous	Locates the previous occurrence of the current search term in the script field. Click the Start searching icon ( ) to change the current search term.

HTML and Jelly editing functions (continued)

Icon	Keyboard shortcut	Name	Description
	Ctrl+M	Toggle Full Screen	Expands the script field to use the full form view for easier editing. Click the Toggle full screen icon ( ) again to return to standard form view. This feature is not available for Internet Explorer.
	Cmd+H	Help	Displays the keyboard shortcuts help screen.
	N/A	Save	Saves changes without leaving the current view. Click the Save icon ( ) in full screen mode to save without returning to standard form view.

Editing tips

- To insert a fixed space anywhere in your code, press Tab.
- To indent a single line of code, click in the leading white space of the line and then press Tab.
- To indent one or more lines of code, select the code and then press Tab. To decrease the indentation, press Shift+Tab.
- To remove one tab from the start of a line of code, click in the line and press Shift+Tab.

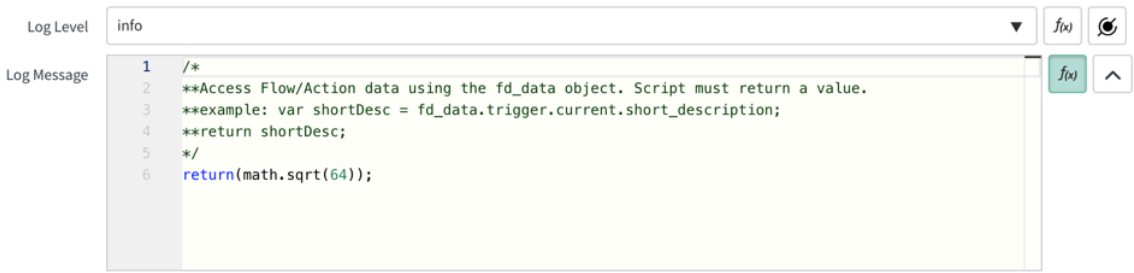
Code editor

The code editor provides support to use programming language services in a text editor and is used in scripts.

The code editor has these features for the supported language services and Inline scripts.

- Syntax coloring, indentation, line numbers, and automatic creation of closing braces and quotes
- Auto-suggestions and auto-completions

Code editor



Editing tips

- To insert a fixed space anywhere in your code, press Tab.
- To indent a single line of code, click in the leading white space of the line and then press Tab.
- To indent one or more lines of code, select the code and then press Tab. To decrease the indentation, press Shift+Tab.

- To remove one tab from the start of a line of code, click in the line and press Shift+Tab.
- To declare variables, use the `var` keyword so that they remain within the proper JavaScript scope.

Server-side scripting

Server scripts run on the server or database. They can change the appearance or behavior of ServiceNow or run as business rules when records and tables are accessed or modified.

Server-side Glide APIs (Application Programming Interfaces) provide classes and methods that you can use in scripts to perform server-side tasks.

Immediately invoked function expressions

The system uses immediately invoked function expressions when a script runs in a single context, such as in a Create a transform map. Functions that run from multiple contexts use Script includes instead.

By enclosing a script in an immediately invoked function expression, you can:

- Ensure that the script does not impact other areas of the product, such as by overwriting global variables.
- Pass useful variables or objects as parameters.
- Identify function names in stack traces.
- Eliminate having to make separate function calls.

An immediately invoked function expression follows this format:

```
(function functionName(parameter){

  //The script you want to run

})('value');//Note the parenthesis indicating this function
 should run.
```

You can declare functions within the immediately invoked function expression. These inner functions are accessible only from within the immediately invoked function expression.

```
(function functionName(parameter){

  function helperFunction(parameter){//return some value}

  var value = helperFunction(parameter);//Valid function call.

  //perform any other script actions

})('value');

var value2 = helperFunction(parameter);//Invalid. This function
 is not accessible from outside the self-executing function.
```

Glide Server APIs

ServiceNow provides APIs for the Glide Server.

GlideAggregate

The *GlideAggregate* class is an extension of *GlideRecord* and allows database aggregation (COUNT, SUM, MIN, MAX, AVG) queries to be done. This can be helpful in creating customized reports or in calculations for calculated fields.

Note:
This functionality requires a knowledge of JavaScript.

For additional information, refer to GlideAggregate API.

GlideAggregate examples

GlideAggregate is an extension of *GlideRecord* and its use is probably best shown through a series of examples.

Note:
This functionality requires a knowledge of JavaScript.

Here is an example that simply gets a count of the number of records in a table:

```
var count = new GlideAggregate('incident');
count.addAggregate('COUNT');
count.query();
var incidents = 0;
if(count.next())
   incidents = count.getAggregate('COUNT');
```

There is no query associated with the preceding example. If you want to get a count of the incidents that were open, simply add a query as is done with *GlideRecord*. Here is an example to get a count of the number of active incidents.

```
var count = new GlideAggregate('incident');
count.addQuery('active','true');
count.addAggregate('COUNT');
count.query();
var incidents = 0;
if(count.next())
   incidents = count.getAggregate('COUNT');
```

To get a count of all the open incidents by category the code is:

```
var count = new GlideAggregate('incident');
count.addQuery('active','true');
count.addAggregate('COUNT','category');
count.query();
while(count.next()){
  var category = count.category;
  var categoryCount = count.getAggregate('COUNT','category');
  gs.log("The are currently "+ categoryCount +" incidents with a
 category of "+ category);}
```

The output is:

```
 *** Script: The are currently 1.0 incidents with a category of
 Data
       *** Script: The are currently 11.0 incidents with a
 category of Enhancement
```

```
      *** Script: The are currently 1.0 incidents with a
 category of Implementation
      *** Script: The are currently 197.0 incidents with a
 category of inquiry
      *** Script: The are currently 13.0 incidents with a
 category of Issue
      *** Script: The are currently 1.0 incidents with a
 category of
      *** Script: The are currently 47.0 incidents with a
 category of request
```

The following is an example that uses multiple aggregations to see how many times records have been modified using the *MIN*, *MAX*, and *AVG* values.

```
var count = new GlideAggregate('incident');
count.addAggregate('MIN','sys_mod_count');
count.addAggregate('MAX','sys_mod_count');
count.addAggregate('AVG','sys_mod_count');
count.groupBy('category');
count.query();
while(count.next()){
  var min = count.getAggregate('MIN','sys_mod_count');
  var max = count.getAggregate('MAX','sys_mod_count');
  var avg = count.getAggregate('AVG','sys_mod_count');
  var category = count.category.getDisplayValue();
  gs.log(category +" Update counts: MIN = "+ min +" MAX = "+ max
 +" AVG = "+ avg);}
```

The output is:

```
      *** Script: Data Import Update counts: MIN = 4.0 MAX =
 21.0 AVG = 9.3333
      *** Script: Enhancement Update counts: MIN = 1.0 MAX =
 44.0 AVG = 9.6711
      *** Script: Implementation Update counts: MIN = 4.0 MAX =
 8.0 AVG = 6.0
      *** Script: inquiry Update counts: MIN = 0.0 MAX = 60.0
 AVG = 5.9715
      *** Script: Inquiry / Help Update counts: MIN = 1.0 MAX =
 3.0 AVG = 2.0
      *** Script: Issue Update counts: MIN = 0.0 MAX = 63.0 AVG
 = 14.9459
      *** Script: Monitor Update counts: MIN = 0.0 MAX = 63.0
 AVG = 3.6561
      *** Script: request Update counts: MIN = 0.0 MAX = 53.0
 AVG = 5.0987
```

The following is a more complex example that shows how to compare activity from one month to the next.

```
var agg = new GlideAggregate('incident');
agg.addAggregate('count','category');
agg.orderByAggregate('count','category');
agg.orderBy('category');
agg.addQuery('opened_at','>=','javascript:gs.monthsAgoStart(2)
');
agg.addQuery('opened_at','<=','javascript:gs.monthsAgoEnd(2)');
```

```
agg.query();
while(agg.next()){
  var category = agg.category;
  var count = agg.getAggregate('count','category');
  var query = agg.getQuery();
  var agg2 = new GlideAggregate('incident');
  agg2.addAggregate('count','category');
  agg2.orderByAggregate('count','category');
  agg2.orderBy('category');

 agg2.addQuery('opened_at','>=','javascript:gs.monthsAgoStart(3)
');

 agg2.addQuery('opened_at','<=','javascript:gs.monthsAgoEnd(3)
');
  agg2.addEncodedQuery(query);
  agg2.query();
  var last ="";
  while(agg2.next()){
     last = agg2.getAggregate('count','category');}
  gs.log(category +": Last month:"+ count +" Previous Month:"+
 last);

}
```

The output is:

```
 *** Script: Monitor: Last month:6866.0 Previous Month:4468.0
 *** Script: inquiry: Last month:142.0 Previous Month:177.0
 *** Script: request: Last month:105.0 Previous Month:26.0
 *** Script: Issue: Last month:8.0 Previous Month:7.0
 *** Script: Enhancement: Last month:5.0 Previous Month:5.0
 *** Script: Implementation: Last month:1.0 Previous Month:0
```

The following is an example to obtain distinct count of a field on a group query.

```
var agg = new GlideAggregate('incident');
agg.addAggregate('count');
agg.addAggregate('count(distinct','category');
agg.addQuery('opened_at', '>=',
 'javascript:gs.monthsAgoStart(2)');
agg.addQuery('opened_at', '<=',
 'javascript:gs.monthsAgoEnd(2)');
//
agg.groupBy('priority');
agg.query();
while (agg.next()) {
// Expected count of incidents and count of categories within
 each priority value (group)
  gs.info('Incidents in priority ' + agg.priority + ' = ' +
 agg.getAggregate('count') +
            ' (' + agg.getAggregate('count(distinct','category')
 + ' categories)');
}
```

The output is:

```
*** Script: Incidents in priority 1 = 13 (3 categories)
*** Script: Incidents in priority 2 = 10 (5 categories)
*** Script: Incidents in priority 3 = 5 (3 categories)
*** Script: Incidents in priority 4 = 22 (6 categories)
```

You can implement the SUM aggregate with or without the use of the *groupBy()* method. If you do not use the *groupBy()* method, the result of the SUM is the cumulative value for each different value of the field for which you request the SUM. For example, if you SUM the total_cost field in the Fixed Asset table, and the Fixed Asset table contains 12 total records:

- Three records with a total_cost of $12
- Four records with a total_cost of $10
- Five records with a total_cost of $5

When you SUM the record set, the *getAggregate()* method returns three different sums: $36, $40, and $25.

The following code illustrates implementing the SUM aggregate without using the *groupBy()* method:

```
var totalCostSum = new GlideAggregate('fixed_asset');
totalCostSum.addAggregate('SUM', 'total_cost');
totalCostSum.query();

while (totalCostSum.next()) {
  var allTotalCost = 0;
  allTotalCost = totalCostSum.getAggregate('SUM', 'total_cost');
  aTotalCost = totalCostSum.getValue('total_cost');
  gs.print('Unique field value: ' + aTotalCost + ', SUM = ' +
 allTotalCost + ', ' + allTotalCost/aTotalCost + ' records');
}
```

The output for this example is:

```
*** Script: Unique field value: 12, SUM = 36, 3 records
*** Script: Unique field value: 10, SUM = 40, 4 records
*** Script: Unique field value: 5, SUM = 25, 5 records
```

Using the same data points as the prior example, if you use the *groupBy()* method, the SUM aggregate returns the sum of all values for the specified field.

The following example illustrates implementing the SUM aggregate using the *groupBy()* method:

```
var totalCostSum = new GlideAggregate('fixed_asset');
totalCostSum.addAggregate('SUM', 'total_cost');
totalCostSum.groupBy('total_cost');
totalCostSum.query();
if(totalCostSum.next()){  // in case there is no result
   var allTotalCost = 0;
   allTotalCost = totalCostSum.getAggregate('SUM',
 'total_cost');
   gs.print('SUM of total_cost: = ' + allTotalCost);
}
```

The output for this example is:

```
*** Script: SUM of total_cost: 101
```

GlideRecord

GlideRecord is a special Java class (*GlideRecord.java*) that can be used in JavaScript exactly as if it was a native JavaScript class.

GlideRecord:

- is used for database operations instead of writing SQL queries.
- is an object that contains zero or more records from one table. Another way to say this is that a GlideRecord is an ordered list.

A GlideRecord contains both records (rows) and fields (columns). The field names are the same as the underlying database column names. For additional information, refer to GlideRecord - Scoped.

Note:
Use of `gs.sql())` scripting syntax was discontinued in Geneva. Use standard *GlideRecord* syntax in its place.

Using GlideRecordSecure

GlideRecordSecure is a class inherited from *GlideRecord* that performs the same functions as *GlideRecord*, and also enforces ACLs.

Non-writable fields

Be aware that, when using *GlideRecordSecure*, non-writable fields are set to NULL when trying to write to the database. By default, *canCreate()* on the column is replaced with *canWrite()* on the column. If that returns false, the column value is set to NULL.

Getting the object type

You can check if an object type is ScopedGlideRecordSecure by calling the *toString()* method.

Checking the returned GlideRecord real type

The current object can be passed as *ScopedGlideRecordSecure*. In most cases, you can call *current.toString()* to return the current object type.

The following line returns `[object ScopedGlideRecordSecure]` for a *ScopedGlideRecordSecure* object:

```
gs.info(current.toString());
```

If the returned object type is different than expected

Calling a scoped function that returns a GlideRecord object as its type returns different results depending on the scope it's called from.

- Calling the scoped function within application scope returns the expected object type of `GlideRecord` or `GlideRecordSecure`.
- Calling the scoped function within global scope returns the object type is `ScopedGlideRecord` or `ScopedGlideRecordSecure`.

Checking for NULL values

If an element cannot be read because an ACL restricts access, a NULL value is created in memory for that record. With GlideRecord, you must explicitly check for any ACLs that might restrict read access to the record. To do so, an if statement such as the following is required to check if the record can be read:

```
if ( !grs.canRead() ) continue;
```

With *GlideRecordSecure*, you do not need to explicitly check for read access using *canRead()*. Instead, you can use *next()* by itself to move to the next record. The following example provides a comparison between *GlideRecord* and *GlideRecordSecure*.

```
var count  = 0;
var now_GR  = new GlideRecord('mytable');
now_GR. query();
while (now_GR. next()) {
    if (!now_GR. canRead()) continue;
    if (!now_GR. canWrite()) continue;
    if (!now_GR. val. canRead() || !now_GR. val. canWrite())
        now_GR. val = null;
    else
        now_GR. val = "val-" + now_GR. id;
    if (now_GR. update())
        count ++;
}
```

```
var count  = 0;
var grs  = new GlideRecordSecure('mytable');
grs. query();
while (grs. next()) {
    grs. val = "val-" + grs. id;
    if (grs. update())
        count ++;
}
```

Examples

These are two simple examples using *GlideRecordSecure*.

```
var att  = new GlideRecordSecure('sys_attachment');
att. get('$[sys_attachment.sys_id]');
var sm  = GlideSecurityManager.get();
var checkMe  = 'record/sys_attachment/delete';
var canDelete  = sm.hasRightsTo(checkMe,att);
gs. log('canDelete: ' + canDelete);
canDelete;
```

```
var grs = new GlideRecordSecure('task_ci');
grs.addQuery();
grs.query();
var count  = grs. getRowCount();
if (count  > 0 ) {
    var allocation  = parseInt(10000/count) / 100;
    while (grs.next()) {
      grs.u_allocation = allocation;
      grs.update();
```

```
    }
}
```

GlideSystem

The `GlideSystem` API provides methods for retrieving information.

The `GlideSystem` (referred to by the variable name '`gs`' in business rules) provides a number of convenient methods to get information about the system, the current logged in user, etc. For example, the method `addInfoMessage()` permits communication with the user.

```
gs.addInfoMessage('Email address added for notification');
```

Many of the `GlideSystem` methods facilitate the easy inclusion of dates in query ranges and are most often used in filters and reporting.

For additional information, see GlideSystem.

GlideDateTime

The `GlideDateTime` class provides methods for performing operations on `GlideDateTime` objects, such as instantiating `GlideDateTime` objects or working with `glide_date_time` fields.

In addition to the instantiation methods described below, a GlideDateTime object can be instantiated from a `glide_date_time` field using the `getGlideObject()` method (for example, `var gdt = gr.my_datetime_field.getGlideObject();`).

Some methods use the Java Virtual Machine time zone when retrieving or modifying a date and time value. Using these methods may result in unexpected behavior. Use equivalent local time and UTC methods whenever possible.

GlideDate and GlideDateTime examples

The `GlideDate` and `GlideDateTime` APIs are used to manipulate date and time values.

Note:
This functionality requires a knowledge of JavaScript.

For additional information, refer to GlideDate API and GlideDateTime API.

You can create a `GlideDateTime` object from a `GlideDate` object by passing in the `GlideDate` object as a parameter to the `GlideDateTime` constructor. By default, the `GlideDateTime` object is expressed in the internal format, yyyy-MM-dd HH:mm:ss and the system time zone UTC.

```
var gDate = new GlideDate();
gDate.setValue('2015-01-01');
gs.info(gDate);

var gDT = new GlideDateTime(gDate);
gs.info(gDT);
```

Output:

```
2015-01-01
2015-01-01 00:00:00
```

See also Modify a GlideDateTime field value.

Set a duration field value in script

Examples of JavaScript that can be used to set the value of a duration field.

Note:
Negative duration values are not supported.

Using the GlideDateTime.subtract() method

The *subtract(GlideDateTime start, GlideDateTime end)* method in GlideDateTime enables you to set the duration value using a given start date/time and end date/time. An example on how to set the duration for the time a task was opened is:

```
var duration = GlideDateTime.subtract(start, end);
```

If you want to work with the value returned as a number to use in date or duration arithmetic, convert the return to milliseconds:

```
var time = GlideDateTime.subtract(start,end).getNumericValue();
```

If you want to set a duration to the amount of time between some event and the current date/time:

```
<duration_field> = GlideDateTime.subtract(new
 GlideDateTime(<start_time>.getValue()),gs.nowDateTime());
```

The time values presented to *GlideDateTime.subtract* are expected to be in the user's time zone and in the user's format.

Setting a default value of a duration field

Setting the default value for a duration field is similar to the method used in the previous topic.

Setting the duration field value in a client script

This script sets a *duration_field* value in a client script. Replace *duration_field* with the field name from your instance.

```
g_form.setValue('<duration_field>','11 01:02:03');
```

Calculating and setting a duration using a client script

Here is an example of how to return a value and populate it using a client script.

Create an `onChange` client script that includes the following code. You can modify this script if you need the calculation to happen in an `onLoad` script or some other way.

```
function onChange(control, oldValue, newValue, isLoading){
var strt = g_form.getValue('<start_field>');
var end = g_form.getValue('<end_field>');
var ajax = new GlideAjax('AjaxDurCalc');
  ajax.addParam('sysparm_name','durCalc');
  ajax.addParam('sysparm_strt',strt);
  ajax.addParam('sysparm_end',end);
  ajax.getXMLWait();
  var answer = ajax.getAnswer();
  g_form.setValue('<duration_field>', answer);}
```

Create a system script include file called *AjaxDurCalc* that handles the request. It may be reused for other functions as well.

```
var AjaxDurCalc = Class.create();
AjaxDurCalc.prototype =
 Object.extendsObject(AbstractAjaxProcessor,{
 durCalc:function(){return
 GlideDuration.subtract(this.getParameter('sysparm_strt'),this.g
etParameter('sysparm_end'));}});
```

Changing the duration field value

If you manipulate a duration value with addition/subtraction of some amount of time, use the functions that allow you to get and set the numeric value of the duration. A unit of measure for a duration numeric value is milliseconds. The following is an example that adds 11 seconds to the *duration* field in the current record.

```
var timems = current.duration.dateNumericValue();
timems = timems + 11*1000;
current.duration.setDateNumericValue(timems);
```

Formatting the Resolve Time

To format the **Resolve Time** or the **Business Resolve Time** fields as durations, which displays them as a duration instead of a large integer, add the following attribute to those fields:

```
format=glide_duration
```

Modify the dictionary entry for the field and add the attribute. If there is an existing attribute, separate multiple attributes with commas.

Setting the maximum unit of measurement

The *max_unit* dictionary attribute defines the maximum unit of time used in a duration. For example, if `max_unit=minutes`, a duration of 3 hours 5 minutes 15 seconds appears as 185 minutes 15 seconds. To set the maximum unit of duration measurement, add the following dictionary attribute to the *duration* field:

```
max_unit=<unit>
```

Date and time format guidelines

You can specify a date format with a sequence of specific date and time pattern strings. A pattern string consists of one or more uppercase and lowercase letters from A to Z. Any text within quotation marks is ignored and is instead copied into the date output.

String	Description	Output Format	Example
G	Era designator	Text	AD
y	Year	Year	2019; 19
Y	Week in year	Year	2019; 19
M	Month in year (within date)	Month	July; Jul; 07
L	Month in year (standalone value)	Month	July; Jul; 07
w	Week in year	Number	52
W	Week in month	Number	1
D	Day in year	Number	365

String	Description	Output Format	Example
d	Day in month	Number	2
F	Day of week in month	Number	3
E	Day name in week	Text	Wednesday; Wed
u	Day number of week	Number	3
a	a.m. or p.m.	Text	p.m.
H	Hour in day from 0 through 23	Number	0
k	Hour in day from 1 through 24	Number	24
K	Hour in a.m. or p.m. from 0 through 11	Number	0
h	Hour in a.m. or p.m. from 1 through 12	Number	12
m	Minute in hour	Number	59
s	Second in minute	Number	1
S	Millisecond	Number	500
z	Time zone in default format	Time zone in default format	Pacific Standard Time; PST
Z	Time zone in RFC 822 format	Time zone in RFC 822 format	-0800
X	Time zone in ISO 8601 format	Time zone in ISO 8601 format	-08; -0800; -08:00

Classic Business rules

A business rule is a server-side script that runs when a record is displayed, inserted, updated, or deleted, or when a table is queried.

Business rules are scripts that run when certain server-side conditions are met. Business rule conditions include when to run a business rule in relation to a database operation, and what record operations the business rule applies to. There are other scripting options available on the platform for client-side conditions, such as client scripts and UI actions.

Note:
Business rules are a classic automation solution that rely on scripting. Use Workflow Studio for any new process automation to create automations that are easier to extend, reuse, understand, and upgrade. As many organizations have business rules in production, use this documentation to learn how to work with existing business rules.

How business rules work

To configure business rules, you first need to determine when the business rule should run and what action it should take.

When business rules run

Business rules run based on two sets of criteria.

- When to run the business rule in relation to a database operation.
- What record operation the business rule applies to.

The following options are provided to determine when the business rule should run.

When the business rule should run

Option	When the rule runs
Before	After the user submits the form but before any action is taken on the record in the database.
After	After the user submits the form and after any action is taken on the record in the database.
Async	After the user submits the form and after the scheduler runs the scheduled job created from the business rule. The system creates a scheduled job from the business rule after the user submits the form but before any action is taken on the record in the database. **Note:** Newly created business rules will run during upgrades. If a record has an asynchronous business rule that makes decisions based on the data in the record, multiple updates to the record in quick succession can cause the business rule to execute out of order or incorrectly. If multiple async business rules update the same record, the updates performed by one script could be overwritten by another script or made in an unexpected sequence because the order of execution isn't guaranteed. You can use the After option for business rules or System Events as an alternative in these situations.
Display	Before the form is presented to the user, just after the data is read from the database.

Note:

- Asynchronous business rules do not have access to the previous version of a record. Therefore, the `changes()`, `changesTo()`, and `changesFrom()` `GlideElement` methods do not work with async rule script. However, the condition builder and condition field (advanced view) both support the `changes()`, `changesTo()`, and `changesFrom()` methods.
- Business rules do not honor ACLs until you want them to be honored. For more information, see Relationship between Business Rules and Access Control Rules (ACLs)

The following options are provided to determine what record operations the business rule applies to.

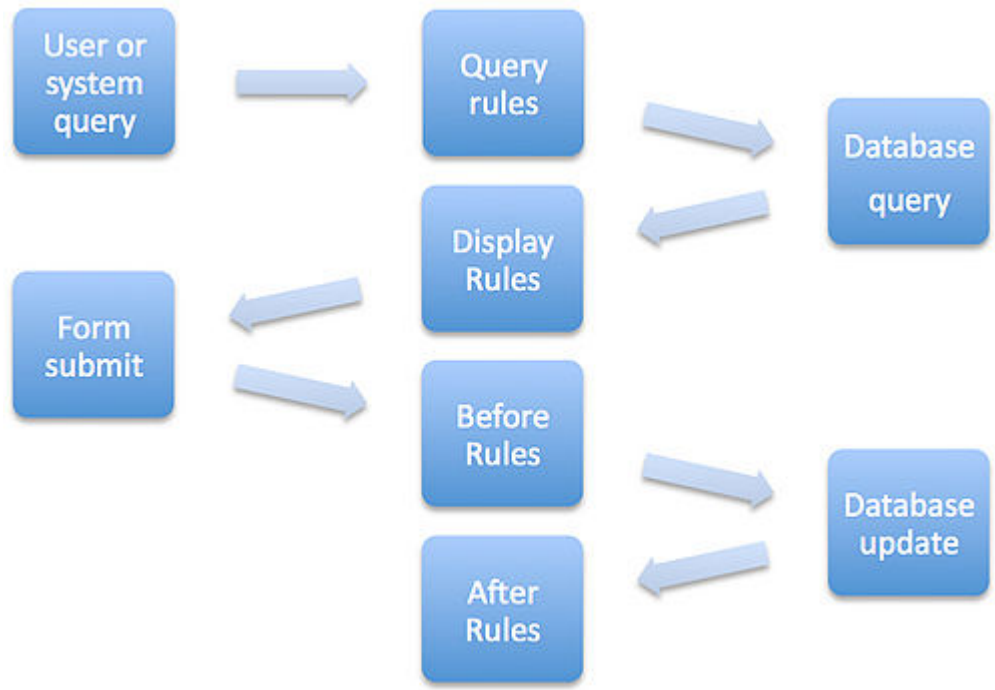
What record operation the business rule applies to

Option	When the rule runs
Insert	When the user creates a new record and the system inserts it into the database.
Update	When the user modifies an existing record.
Query	When the user sends a query for a record or list of records to the database. Typically you should use query operation for before business rules.
Delete	When the user deletes a record.

Note:
Business rules only run record operations when called from the GlideRecord API. Some applications intentionally bypass business rule processing to perform record operations directly. In addition, business rules ignore API calls run with the setWorkflow() method set to false.

This image shows when different types of business rules run:

Business rule processing flow



Note:
Business rules apply consistently to records regardless of whether they are accessed through forms, lists, or web services. This is one major difference between business rules and client scripts, which apply only when the form is edited.

Business rule actions

Business rules can perform a variety of actions. Common types of actions are:

- Changing field values on a form that the user is updating. Field values can be set to specific values available for that field, values copied from other fields, and relative values determined by the user's role.
- Displaying information messages to the user.
- Changing values of child tasks based on changes to parent tasks.
- Preventing users from accessing or modifying certain fields on a form.
- Aborting the current database transaction. For example, if certain conditions are met, prevent the user from saving the record in the database.

Administrators can set field values, create information messages, and abort transactions without writing a script.

Prevent recursive business rules

Avoid using `current.update()` in a business rule script. The `update()` method triggers business rules to run on the same table for insert and update operations, leading to a business rule calling itself over and over. Changes made in before business rules are automatically saved when all before business rules are complete, and after business rules are best used for updating related, not current, objects. When a recursive business rule is detected, the system stops it and logs the error in the system log. However, `current.update()` causes system performance issues and is never necessary.

You can prevent recursive business rules by using the `setWorkflow()` method with the false parameter. The combination of the `update()` and `setWorkflow()` methods is only recommended in special circumstances where the normal before and after guidelines mentioned above don't meet your requirements.

Business rules in scoped applications

Every business rule is assigned to either a private application scope or to the global scope.

The types of business rules you can create and how you can access those rules varies depending on the scope of the business rule and the scope of the table it runs on.

Note:
The term global can refer to two different aspects of a business rule: the table it runs on and the scope it runs in. Business rules can either run on specific tables or be global. In addition, they can be in the global scope or in a private application scope.

Business rules on specific tables

Most business rules run on a specific table, which is defined in the **Table** field. You can create business rules on tables in the same scope and on tables that allow configuration records from another application scope.

For tables that are in a different scope than the business rule record, the types of rules are limited.

- You can create a rule where **When is async** with any of the following options:
  - **Insert**, **Update**, and **Delete** database operations. You cannot select **Query**.
  - **Set field values** actions and scripts (the **Script** field).
- You can create a rule where When is before with any of the following options:
  - **Insert**, **Update**, and **Delete** database operations. You cannot select **Query**.
  - **Set field values** actions only. You cannot write scripts and you cannot abort the database transaction.
- You cannot create any other types of business rules on tables in a different scope.

Business rules on specific tables cannot be accessed by other business rules or scripts.

Global business rules

Warning:
Consider using script includes instead of global business rules. Script includes load only on request while global business rules load on every page in the system.

Global business rules are business rules where the **Table** field is set to **Global**. Global business rules may be accessible on multiple tables and from other scripts, depending on their scope

protection. For a global business rule, define the scope protection by setting the **Accessible from** field:

- **This application scope only**: prevents applications in a different scope than the business rule from calling this business rule.
- **All application scopes**: allows any application to call this business rule.

Note:
Global business rules do not support domain separation.

Scripts in scoped business rules

When you write a script in a business rule, you can access:

- Any script includes and global business rules in the same scope as the business rule.
- Script includes and global business rules that allow applications in a different scope to call them. To call functions from another scope, you must specify the scope of the function.
- For business rules in a unique scope, you can access the scoped system APIs only.

Create a business rule

You can create any type of business rule to run when a record is displayed, inserted, updated, or deleted, or when a table is queried.

About this task

Note:
These instructions and examples provide general guidance for how to implement this functionality. For help with unique use cases, refer to the Developer Community Forum, where you can ask questions, interact with other developers, and search for existing solutions.

Procedure

1. Navigate to **All** > **System Definition** > **Business Rules**.
2. Click **New**.
3. Fill in the fields, as appropriate.

Note:
You might need to configure the form to see all fields.

Business Rule fields

Field	Description
Name	Enter a name for the business rule.
Table	Select the table that the business rule runs on. **Note:** The list shows only tables and database views that meet the scope protections for business rules. Business rules defined for a database view can run only on **Query**. A business rule for a database view cannot run on insert, update, or delete.
Application	Application that contains this business rule.

Field	Description
Accessible from	Scope protection for a global business rule. **Note:** This field is visible only when the **Table** field is set to **Global**. It does not apply to rules that run on specific tables.
Active	Select this check box to enable the business rule.
Advanced	Select this check box to see the advanced version of the form.
When to run	
When	[Advanced] Select when this business rule should execute: **display**, **before**, **async**, or **after** the database operation is complete. **Note:** Consider setting the **Order** for **async** business rules as the system uses this value when creating the associated scheduled job. Newly created **async** business rules run automatically on upgrade. Existing **async** business rules can be migrated to use the new async behavior.
Order	[Advanced] Enter a number indicating the sequence in which this business rule should run. If there are multiple rules on a particular activity, the rules run in the order specified here, from lowest to highest.
Insert	Select this check box to execute the business rule when a record is inserted into the database.
Update	Select this check box to execute the business rule when a record is update.
Delete	[Advanced] Select this check box to execute the business rule when a record is deleted from the database.
Query	[Advanced] Select this check box to execute the business rule when a table is queried.
Filter Conditions	Use the condition builder to determine when the business rule should run based on the field values in the selected Table. If you select the **Advanced** option, you can also use the **Condition** field to build a condition with a script. Conditions defined with the **Filter Conditions** field and advanced **Conditions** field are evaluated at the same time. **Note:** Filters based on string compares are case-sensitive.
Role Conditions	Select the roles that users who are modifying records in the table must have for this business rule to run.
Actions	
Set field values	Set values for fields in the selected Table using the choice lists: ○ The field ○ The assignment operator:

Field	Description
	▪ **To:** An exact value ▪ **Same as:** The value of another field ▪ **To (dynamic):** A value relative to the user configuring the business rule or a user with a specific role ○ The value
Add message	Select this check box and enter a message that appears when this business rule is run
Abort action	Select this check box to abort the current database transaction. For example, on a before insert business rule, if the conditions are met, do not insert the record into the database. If you select this option, you cannot perform additional actions on the record, such as setting field values and running scripts. You can still display a message to users by selecting the **Add message** check box and composing the message.
Advanced	
Condition	Create a JavaScript conditional statement to specify when the business rule should run. By adding the condition statement to this field, you tell the system to evaluate the condition separately and run the business rule only if the condition is true. If you decide to include the condition statement in the **Script** field or the **Filter Conditions** field, leave this field blank. Conditions defined with the **Filter Conditions** field and advanced **Conditions** field are evaluated at the same time. To have the instance reevaluate the condition statement a second time before running an async business rule, add the system property *glide.businessrule.async_condition_check* and set the value to true.
Script	[Advanced] Create a script that runs when the defined condition is true. ○ onAfter ○ onAsync ○ onBefore ○ onDisplay For more information and examples, see Example business rule scripts.
Related list: Versions	
Versions	Shows all versions of the business rule. Use this list to compare versions or to revert to a previous version.

4. Click **Submit**.

Trouble?
If you run into issues with your business rule, see the Business Rule FAQ [KB0965707] article in the Now Support Knowledge Base.

Global variables in business rules

Predefined global variables are available for use in business rules.

Use the following predefined global variables to reference the system in a business rule script.

Global variable	Description
current	Current state of the record being referenced. See "Prevent null pointer exceptions" below to check for nulls before using this variable.
previous	State of the referenced record prior to any updates made during the execution context, where the execution context begins with the first update or delete operation and ends after the script and any referenced business rules are executed. If multiple updates are made to the record within one execution context, *previous* will continue to hold the state of the record before the first update or delete operation. Available on update and delete operations only. Not available on async operations. See "Prevent null pointer exceptions" below to check for nulls before using this variable.
g_scratchpad	Scratchpad object is available on display rules, and is used to pass information to the client to be accessed from client scripts.
gs	References to GlideSystem functions.

The variables *current*, *previous*, and *g_scratchpad* are global across all business rules that run for a transaction.

Prevent null pointer exceptions

In some cases, there may not be a *current* or *previous* state for the record when a business rule runs, which means that the variables will be null. To check for null before using a variable, add the following code to your business rule:

```
if (current == null) // to prevent null pointer exceptions.
return;
```

Define variables

User-defined variables are globally scoped by default. If a new variable is declared in an order 100 business rule, the business rule that runs next at order 200 also has access to the variable. This may introduce unexpected behavior.

To prevent such unexpected behavior, always wrap your code in a function. This protects your variables from conflicting with system variables or global variables in other business rules that are not wrapped in a function. Additionally, variables such as *current* must be available when a function is invoked in order to be used.

The following script is vulnerable to conflicts with other code. If the variable *now_GR* is used in other rules, the value of the variable may unexpectedly change.

```
var now_GR = new GlideRecord('incident');
now_GR.query();
while(now_GR.next()) {

   //do something

}
```

When this script is wrapped in a function, the variable is available only within the function and does not conflict with other functions using a variable named *now_GR*.

```
myFunction();

function myFunction() {
  var now_GR = new GlideRecord('incident');
  now_GR.query();
  while(now_GR.next()) {
    //do something
} }
```

Use business rules and client scripts to control field values

Implement both business rules and client scripts for a field to enable users to set record values properly using both forms and lists, and to see immediate changes to the values in forms as edits are made.

The problem with using only a client script or a business rule to control updates to a field is that fields can be changed on either a form or a list. Client scripts and UI policies run on forms only (client-side) and do not apply to list editing. Allowing list editing with client scripts running on fields in a form can result in incorrect data being saved to the record. For systems in which client scripts or UI policies apply to forms, either disable list editing or create appropriate business rules or access control to control the setting of values in the list editor. A side effect of this is that security measures implemented in client scripts are easy to circumvent. The user only needs to edit the field in a list.

Business rules on a form are not dynamic, the user must update the record for the change to be seen. This makes using client scripts the preferred method for controlling field values on forms.

When using both a business rule and client script to control field values, the update behavior is the same across the system. This means that updated values are not different depending on whether a list of form is used to make the change. This means that the same functionality must be implemented twice, once in a client script and once in a business rule or access control.

Example: Use a business rule to create email addresses during user record import

An organization has a client script that sets the email address for a user to `first.last@company.com`. Administrators do this so they can see the email address immediately when they enter the user's information. The administrator then performs a bulk import of users from a spreadsheet containing the users' first and last names. The expectation is that each user's email address will be set automatically, as they are when they edit the form. Since the client script runs only on the form (the interface to the record), it has no effect on data imported into the record from outside that interface, and no email addresses are created. To solve this problem, the administrator implements a business rule that runs when the import occurs and creates the email addresses.

Example: Prevent list edit for a field that is not editable in the form

An organization wants to hide the **Priority** field on an incident form if the assignment group is **Development**. They create a UI policy on the incident form to do this, but their users can still see and edit the **Priority** field using the list editor. To rectify this, apply an access control to prevent read access to the **Priority** field when the assignment group is **Development**.

Using NULL as a field value

The string NULL has a particular role in scripts and is a reserved word.

The reserved word is NULL in all capital letters. A field with the value **Null** or **null**, for example, is acceptable. Only use NULL to clear out a particular field.

Any NULL field values obtained from an import set data source are inserted into the staging table as empty field values. You should not use the term NULL as a field value in import set transform maps or anywhere in the **First name** or **Last name** fields. Also, do not use NULL in reference fields as the system interprets the value as a string containing the word NULL, not as a reserved word.

Display business-rules

Display rules are processed when a user requests a record form.

The data is read from the database, display rules are executed, and the form is presented to the user. The current object is available and represents the record retrieved from the database. Any field changes are temporary since they are not yet submitted to the database. To the client, the form values appear to be the values from the database; there is no indication that the values were modified from a display rule. This is a similar concept to calculated fields.

The primary objective of display rules is to use a shared scratchpad object, *g_scratchpad*, which is also sent to the client as part of the form. This can be useful when you need to build client scripts that require server data that is not typically part of the record being displayed. In most cases, this would require a client script making a call back to the server. If the data can be determined prior to the form being displayed, it is more efficient to provide the data to the client on the initial load. The form scratchpad object is an empty object by default, and used only to store name:value pairs of data.

To populate the form scratchpad with data from a display rule:

```
// From display business rule
g_scratchpad.someName = "someValue";
g_scratchpad.anotherName = "anotherValue";

// If you want the client to have access to record fields not
 being displayed on the form
g_scratchpad.created_by = current.sys_created_by;

// These are simple examples, in most cases you will probably
 perform some other
// queries to test or get data
```

To access the form scratchpad data from a client script:

```
// From client script
if(g_scratchpad.someName == "someValue") {
  //do something special
}
```

Task Active State Management business rule

This business rule determines whether the active field value needs to change based on changes to the **State** field.

The Task Active State Management business rule is executed when the **State** is changed for a task record. Its execution order is 50, and it runs before most other task business rules.

If the current task table has the *close_states* attribute defined on its table, or if it is inherited from a higher-level table, then the rule determines whether the active field needs to change. This is done by comparing the previous and current state values.

- If the state changes from an active state to an inactive state, the **Active** field is set to false.
- If the state changes from an inactive state to an active state, the **Active** field is set to true, effectively re-activating or re-opening the task.

It is recommended that you leverage the *(current.active.changesTo([true/false])* action in your business rule, as opposed to creating rules on each task table that mark tasks as inactive or active.

Example business rule scripts

Find an example business rule script that helps you with a requirement of your organization.

Note:
These instructions and examples provide general guidance for how to implement this functionality. For help with unique use cases, refer to the Developer Community Forum, where you can ask questions, interact with other developers, and search for existing solutions.

Compare date fields in a business rule

It is possible to compare two date fields or two date and time fields in a business rule, and abort a record insert or update if they are not correct.

For example, you may want a start date to be before an end date. The following is an example script:

```
if ((!current.u_date1.nil()) && (!current.u_date2.nil())) {
  var start =
 current.u_date1.getGlideObject().getNumericValue();
  var end = current.u_date2.getGlideObject().getNumericValue();
  if (start > end) {
    gs.addInfoMessage('start must be before end');
    current.u_date1.setError('start must be before end') ;
    current.setAbortAction(true);
 } }
```

This example has been tested in global scripts, and may need changes to work in scoped scripts. In addition to possibly needing API changes, security is more strict in scoped scripts.

As a good practice, make the business rule a before rule for insert and update actions. In the example script:

- *u_date1* and *u_date2* are the names of the two date fields. Replace these names with your own field names.
- The first line checks that both fields actually have a value.
- The next two lines create variables that have the dates' numerical values.
- The next two lines create different alert messages for the end user: one at the top of the form and one by the *u_date1* field in the form.
- The last line aborts the insert or update if the date fields are not correct.

Here is a more complex example of the above comparison. If you have more than one pair of start and end dates, you can use arrays as shown. Additionally, this script requires the input dates to be within a certain range, in this case, no fewer than 30 days in the past and no more than 365 days in the future.

```
// Enter all start and end date fields you wish to check, as
 well as the previous values
```

```
// Make sure that you keep the placement in the sequence the
 same for all pairs
var startDate = new
 Array(current.start_date,current.work_start);
var prevStartDate = new
 Array(previous.start_date,previous.work_start);
var endDate = new Array(current.end_date,current.work_end);
var prevEndDate = new
 Array(previous.end_date,previous.work_end);

// The text string below is added to the front of ' start must
 be before end'
var userAlert = new Array('Planned','Work');

// Set the number of Previous Days you want to check
var pd = 30;
// Set the number of Future Days you want to check
var fd = 365;

// You shouldn't have to modify anything below this line

var nowdt = new GlideDateTime();
nowdt.setDisplayValue(gs.nowDateTime());
var nowMs = nowdt.getNumericValue();
var pdms = nowMs;

// Subtract the product of previous days to get value in
 milliseconds
pdms -= pd * 24 * 60 * 60 * 1000;
var fdms = nowMs;

// Add the product of future days to get value in miliseconds
fdms += fd * 24 * 60 * 60 * 1000;
var badDate = false;

 // Iterate through all start and end date / time fields
for (x = 0; x < startDate.length; x ++) {
  if ((!startDate[x].nil()) && (!endDate[x].nil())) {
    var start = startDate[x].getGlideObject().getNumericValue();
    var end = endDate[x].getGlideObject().getNumericValue();
    if (start > end) {
      gs.addInfoMessage(userAlert[x] + ' start must be before
 end');
      startDate[x].setError(userAlert[x] + ' start must be
 before end');
      badDate = true; }
    else if ((prevStartDate[x]) != (startDate[x])) {
      if (start < pdms) {
         gs.addInfoMessage(userAlert[x] + ' start must be fewer
 than ' + pd + ' days ago');
         startDate[x].setError(userAlert[x] + ' start must be
 fewer than ' + pd  + ' days ago');
         badDate = true; } }
    else if ((prevEndDate[x]) != (endDate[x])) {
      if (end > fdms) {
         gs.addInfoMessage(userAlert[x] + ' end must be fewer
 than ' + fd + ' days ahead');
```

```
        endDate[x].setError(userAlert[x] + ' end must be fewer
 than ' + fd + ' days ahead');
        badDate  = true ;
} } } }
if (badDate == true ) {
  current. setAbortAction ( true ) ; }
```

Parse XML payloads

Fields in XML format can be parsed with the system's *getXMLText* function.

Fields that get inserted into the database in XML format, such as the payload of an `ecc_event` row, can be parsed with the system's *getXMLText* function. The *getXMLText* function takes a string and an XPATH expression. For example:

```
var name = gs.getXMLText("<name>joe</name>", "//name");
```

returns the string 'joe'.

Assuming that the field "payload" contains XML, the function call might look like:

```
var name = gs.getXMLText(current.payload, "//name");
```

For information on XPATH, visit w3schools.

Abort a database action in a before business-rule

In a before business rule script, you can cancel or abort the current database action using the *setAbortAction()* method.

For example, if the before business rule is executed during an insert action, and you have a condition in the script that calls `current.setAbortAction(true)`, the new record stored in current is not created in the database. The business rule continues to run after calling *setAbortAction()* and all subsequent business rules will execute normally. Calling this method only prevents the database action on current object from occurring.

You can use the *isActionAborted()* method to determine if the current database action (insert, update, delete) is going to be aborted. *isActionAborted()* is initialized for new threads and the *next()* method explicitly sets its value to false.

Note:
setAbortAction() can only be executed from the same scope as the record whose action is being aborted. `current.setAbortAction` is not honored if executed in a business rule that is defined in a different scope.

Determine the operation that triggered the business rule

You can write a script for a business rule that is triggered on more than one database action.

If you want the business rule script to dynamically branch depending on the action that triggered the event, you can use the *operation()* function. For example:

```
if(current.operation() == "update") {
  current.updates ++; }
  if(current.operation() == "insert") {
    current.updates = 0; }
```

Use an OR condition in a business rule

An **OR** condition can be added to any query part within a business rule.

An **OR** condition can be added to any query part within a business rule with the *addOrCondition()* method. The example below shows a query for finding all the incidents that have either a 1 or a 2 priority. The first *addQuery()* condition is defined as a variable and is used in the **OR** condition.

```
var inc = new GlideRecord('incident');
var qc = inc.addQuery('priority','1');
qc.addOrCondition('priority','2');
inc.query();
while(inc.next()) {
  // processing for the incident goes here
}
```

The following script is a more complex example, using two query condition variables doing the equivalent of `(priority = 1 OR priority = 2) AND (impact = 2 OR impact = 3)`. The results of the **OR** condition are run with two variables, *qc1* and *qc2*. This allows you to manipulate the query condition object later in the script, such as inside an `IF` condition or `WHILE` loop.

```
var inc = new GlideRecord('incident');
var qc1 = inc.addQuery('priority','1');
qc1.addOrCondition('priority','2');
var qc2 = inc.addQuery('impact','2');
qc2.addOrCondition('impact','3');
inc.query();
while(inc.next()) {
  // processing for the incident goes here
}
```

Reference a Glide list from a business rule

A field defined as a glide list is an array of values stored in a single field.

Here are some examples of how to process a glide_list field when writing business rules. Generally a glide_list field contains a list of reference values to other tables.

Examples

For example, the **Watch list** field within tasks is a glide_list containing references to user records.

The code below shows how to reference the field.

```
// list will contain a series of reference (sys_id) values
 separated by a comma
// array will be a javascript array of reference values
var list = current.watch_list.toString();
var array = list.split(",");
for (var i=0; i < array.length; i++) {
   gs.print("Reference value is: " + array[i]);
}
```

Output:

```
*** Script: Reference value is: 62826bf03710200044e0bfc8bcbe5df1
*** Script: Reference value is: c2826bf03710200044e0bfc8bcbe5d45
*** Script: Reference value is: 5f74e421c0a8010e01ec0d74a7ee2cc6
*** Script: Reference value is: 06826bf03710200044e0bfc8bcbe5d57
```

You can also get the display values associated with the reference values by using the *getDisplayValue()* method as shown below.

```
// list will contain a series of display values separated by a
 comma
// array will be a javascript array of display values
var list = current.watch_list.getDisplayValue();
var array = list.split(",");
for (var i=0; i < array.length; i++) {
   gs.print("Display value is: " + array[i]);
}
```

Output:

```
*** Script: Display value is: Abel Tuter
*** Script: Display value is:  Ashley Leonesio
*** Script: Display value is:  Charles Beckley
*** Script: Display value is:  Cherie Fuhri
```

Use indexOf("searchString") to find a string in a Glide list

Use *indexOf*("*searchString*") to return the location of the string passed into the method if the glide list field, such as a Watch list, has at least one value in it.

If the field is empty, it returns `undefined`. To avoid returning an undefined value, do any of the following:

- Force the field to a string, such as: *watch_list.toString().indexOf*("*searchString*")
- Check for an empty Glide list field with a condition before using *indexOf()*, such as: if (*watch_list.nil()* || *watch_list.indexOf*("*searchString*") == -1)

Lock user accounts

You can lock user accounts if the user is not active.

The following business rule script locks user accounts if the user is not active in the LDAP directory or the user does not have self-service, itil, or admin access to the instance.

```
// Lock accounts if bcNetIDStatus != active in LDAP and user
 does not
// have self-service, itil or admin role
var rls = current.accumulated_roles.toString();
if(current.u_bcnetidstatus == 'active' && (rls.indexOf(',itil,')
 > 0 ||
  rls.indexOf(',admin,') > 0 ||
  rls.indexOf(',ess,') > 0 )) {
  current.locked_out = false; }
else {
  current.locked_out = true; }

var now_GR = new GlideRecord("sys_user");
now_GR.query();
while(now_GR.next()) {
  now_GR.update();
  gs.info("updating " + gr.getDisplayValue());
}
```

Default before-query business rule

You can use a query business rule that executes before a database query is made.

Use this query business rule to prevent users from accessing certain records. Consider the following example from a default business rule that limits access to incident records.

- Name: incident query
- Table: Incident
- When: before, query
- Script:

```
if(!gs.hasRole("itil") && gs.isInteractive()) {
  var u = gs.getUserID();
  var qc =
 current.addQuery("caller_id",u).addOrCondition("opened_by",u).a
ddOrCondition("watch_list","CONTAINS",u);
  gs.print("query restricted to user: " + u); }
```

This example prevents users from accessing incident records unless they have the itil role, or are listed in the **Caller** or **Opened by** field. So, for example, when self-service users open a list of incidents, they can only see the incidents they submitted.

Note:
You can also use access controls to restrict the records that users can see.

Script includes

Script includes are used to store JavaScript that runs on the server.

Create script includes to store JavaScript functions and classes for use by server scripts. Each script include defines either an object class or a function.

Consider using script includes instead of global business rules because script includes are only loaded on request. See Privacy settings on Glide AJAX enabled script includes and Discovery script includes for more information.

For additional examples of scripts, see Useful scripts.

Script include form

Script includes have a name, description, and, script. They also specify whether they are active or not, and whether they can be called from a client script. View existing or create a new script include using the Script Include form.

To access script includes, navigate to **All** > **System Definitions** > **Script Includes**.

Script include form

Field	Description
Name	The name of the script include. If you are defining a class, this must match the name of the class, prototype, and type. If you are using a classless (on-demand) script include, the name must match the function name.
API Name	The internal name of the Script Include. Used to call the Script Include from out-of-scope applications.
Glide AJAX enabled	The script include is available to client scripts, list/report filters, reference qualifiers, or if specified as part of the URL. Glide AJAX enabled script includes

Script include form (continued)

Field	Description
(or Client callable)	are invoked from `GlideAjax` and require that users satisfy an ACL associated with the script include. When selected, the **Access Controls** Related Link is available. See Privacy settings on Glide AJAX enabled script includes for more information.
Mobile callable	The script include is available to client scripts called from mobile devices.
Sandbox enabled	The script include is available to scripts invoked from the script sandbox, such as a query condition. **Important:** Script includes should only be made available to the script sandbox if necessary. For more information about the sandbox, see Configuring Script sandbox property.
Application	The application where this script include resides.
Accessible from	Sets which applications can access this script include: **All application scopes** Can be accessed from any application scope. **This application scope only** Can be accessed only from the current application scope.
Active	Enables the script include when selected. Deselect the active field to disable the script include.
Description	Provides descriptive content regarding the script include.
Script	Defines the server side script to run when called from other scripts. The script must define a single JavaScript class or a global function. The class or function name must match the **Name** field.
Package	The package that contains this script include.
Created by	The user who created this script include.
Updated by	The user who most recently updated this script include.
Protection policy	Sets the level of protection for the script include: **None** Allows anyone to read and edit this downloaded or installed script include. **Read-only** Allows anyone to read values from this downloaded or installed script include. No one can change script values on the instance on which they download or install the script include. **Protected**

Script include form (continued)

Field	Description
	Provides intellectual property protection for application developers. Customers who download the script include cannot see the contents of the script field. The script is encrypted in memory to prevent unauthorized users from seeing it in plain text.
Related lists on the form view:	
Versions	Shows all versions of the script include. Use this list to compare versions or to revert to a previous version. See Versions.
Access Controls	Becomes available when the **Glide AJAX enabled** is selected and is hidden from standard script includes. Use to protect a script include against unauthorized use when public access is not granted.

Use script includes

Script includes are found under System Definition or System UI. You can call existing script includes from a script or create a new script include.

To create an entirely new script include, you can follow the format of any of the existing script includes. In this example, the name of your script include is `NewInclude` and there is a single function called `myFunction`. It is important that the name of the script include match the name of the class, prototype, and type. When you create a new script include and give it a name, the system provides a code snippet with the class and prototype properly set up.

```
var NewInclude =Class.create();

NewInclude.prototype={
  initialize :function(){},

  myFunction :function(){<Put function code here>},

  type :'NewInclude'};
```

You could then use the `myFunction` line like this:

```
var foo =new NewInclude();
foo.myFunction();
```

Glide AJAX enabled script includes

Glide AJAX enabled Script Includes make the script include available to client scripts, list/report filters, reference qualifiers, or if specified as part of the URL.

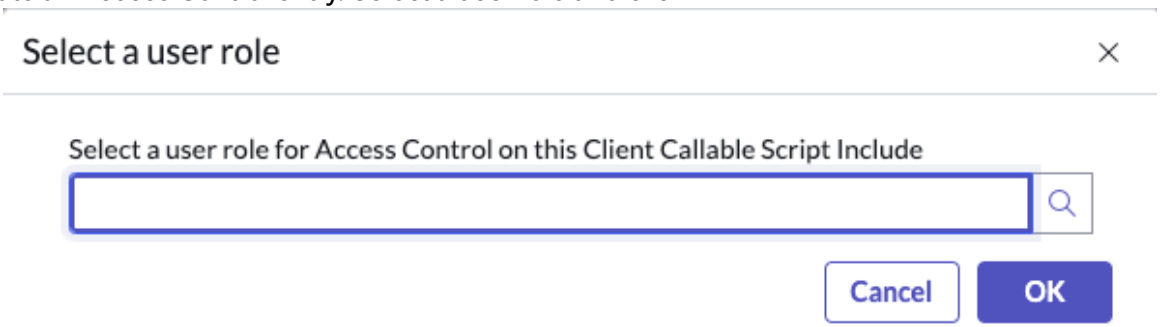
Before you begin

Role required: admin

Procedure

1. Navigate to **System Definition** > **Script Includes**.
2. Select **New** or select an existing script include for viewing or editing.
   See Use script includes for additional information on writing script includes.
3. Complete the form and select the **Glide AJAX enabled** option.

A role selector pops up to select a user role and automatically create an Access Control entry. Select a user role and click



OK.

Note:
To disable the role selector window, set the `glide.script.ccsi.enable_acl_create_ux` to **false**.

A script include record with a role-based Access Control is created. The Access Control Related Link becomes available with the selection of the **Glide AJAX enabled** check box.

Privacy settings on Glide AJAX enabled script includes

Privacy settings for Glide AJAX enabled script includes determine who can access a Glide AJAX enabled script include.

Private privacy-setting

The private privacy-setting means that guests who access public pages cannot access the Glide AJAX enabled script-include. A private script cannot be executed by a non-logged-in user.

Public privacy-setting

A public privacy-setting means that the client script can be executed by non-logged-in users that create an appropriate HTTP request. This can create a security problem if the client script provides confidential information.

The following script includes remain public by default because Make UI pages public or private need to access them:

- GlideSystemAjax
- SysMessageAjax
- KnowledgeMessagingAjax
- KnowledgeAjax
- PasswordResetAjax

Set privacy on all Glide AJAX enabled script includes

Change the privacy setting on all Glide AJAX enabled script includes.

To provide further control over all Glide AJAX enabled script includes, administrators can add the `glide.script.ccsi.ispublic` property. This property changes the visibility of Glide AJAX enabled script includes by making them all public or private. Configure the property as follows:

Configure property

Title	Property
Name	glide.script.ccsi.ispublic
Type	true|false
Value	false

Note:
To learn more about this property, see Require authentication by default for client-callable script includes [Updated in Security Center 1.3] in Instance Security Hardening Settings.

Change privacy on a single Glide AJAX enabled script include

Change the privacy setting for a single Glide AJAX enabled script include by adding the `isPublic()` function.

The `isPublic()` setting takes precedence over the `glide.script.ccsi.ispublic` property. For example, if the property is set to **false**, making all Glide AJAX enabled script-includes private, and a script sets `isPublic()` to **true**, the script is public.

To change the privacy for a single Glide AJAX enabled script include, add the following method to the script include:

```
isPublic:function(){return[true/false];},
```

Make the NewInclude client script private.

```
var NewInclude =Class.create();

NewInclude.prototype={
   initialize:function(){},

   myFunction:function(){//Put function code here},
   isPublic:function(){return false;},

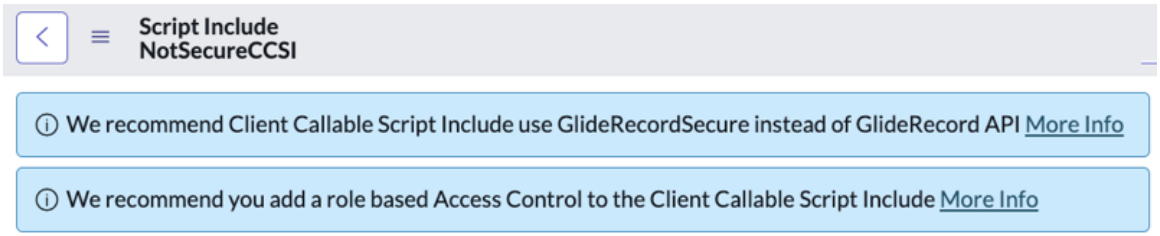
   type:'NewInclude'};
```

Security on Glide AJAX enabled script includes

Protect your Glide AJAX enabled script includes against unauthorized use. For all records which are created a customer application, recommendations display that may help reduce security risk.

When creating a Glide AJAX enabled script include, the system displays the following security recommendations if they have not yet been configured:

- Add or define an Access Control, unless the script include has public access.
- Use `GlideRecordSecure` instead of `GlideRecord` API for better security, if the script queries the database.



Note:
To disable the security recommendation messages, set the property `glide.script.ccsi.customer_scoped.security_msgs_enabled` to **false** in the sys_properties table. The default value is set to **true**.

See Instance Security Hardening Settings for additional information on security compliance.

Discovery script includes

Discovery script includes define JavaScript classes that you can use to accomplish Discovery tasks.

Note:
Users with discovery_admin role can write script includes. Follow best practices for server-side and client-side scripting to prevent security issues. See knowledge article KB0550828 for more information.

Using GlideRecordUtil to Work with GlideRecords

`GlideRecordUtil` is a utility class that provides methods that are useful for working with GlideRecords during Discovery. Refer to GlideRecordUtil for descriptions of available methods.

Getting a GlideRecord Instance

To get a `GlideRecord` instance for a given configuration item, and of the correct class and table, use the `getCIGR(sys_id)` method. For example, the following code gets the GlideRecord of a CI with the sys_id of 2dfd7c8437201000deeabfc8bcbe5d56:

```
var now_GR = new
 GlideRecordUtil().getCIGR("2dfd7c8437201000deeabfc8bcbe5d56");
```

To retrieve any hierarchical table without knowing its class type, use the `getGR(base_table, sys_id)` method. For instance, to get a GlideRecord for a computer class CI, you might have to distinguish whether it is a computer class, Windows server, or Linux server class. Using this method guarantees a GlideRecord with the correct class. Different classes have different attributes. In this use case, a Windows server has attributes different from a Linux server. The following example shows how to get a GlideRecord in the correct class with its attributes.

```
var now_GR = new
 GlideRecordUtil().getGR( "cmdb_ci_computer", "2dfd7c8437201000deeabfc8b
cbe5d56");
```

Getting All the Fields In a GlideRecord

The `getFields(now_GR)` method returns a JavaScript object, such as a hashmap, of all the fields or attributes that exist in a given GlideRecord.

```
var now_GR = new
 GlideRecordUtil().getGR("cmdb_ci_computer", "2dfd7c8437201000deeabfc8bc
be5d56");
var fields = new GlideRecordUtil().getFields(now_GR);
gs.log(fields.join(" ")); // List all the fields that are in a computer CI
```

Populating GlideRecord Object Fields

The *populateFromGR(hashmap, gr, ignore)* method enables you to take a GlideRecord object and populate its fields and values into a JavaScript object. The third argument (*ignore*) is an optional JavaScript object that enables you to exclude certain fields. For example, you may not care about *sys_created_by* or *sys_updated_by* fields in a GlideRecord.

```
var objectToPopulate = { };
var now_GR = new
 GlideRecordUtil().getGR("cmdb_ci_computer", "2dfd7c8437201000deeabfc8bc
be5d56");
var ignore = {"sys_created_on": true, "sys_updated_by": true};
new GlideRecordUtil().populateFromGR(objectToPopulate, now_GR,
 ignore);
// Now the objectToPopulate contains field/value pairs from the computer GlideRecord
```

The *mergeToGR(hashmap, gr, ignore)* method enables you to populate a GlideRecord with a field/value-paired object. The ignore argument stops specified fields from being updated. The following code example updates a computer record's *name* and *os* fields, but does not update the *sys_created_by* field:

```
var now_GR = new
 GlideRecordUtil().getGR("cmdb_ci_computer", "2dfd7c8437201000deeabfc8bc
be5d56");
var obj = {"name": "xyz", "os": "windows 2000", "sys_created_by", "aleck.lin"};
var ignore = {"sys_created_by": true};
new GlideRecordUtil().mergeToGR(obj, gr, ignore);
gr.update();
```

Getting Table Hierarchies

The *getTables(table)* method returns a list of table hierarchies, as shown in the following example:

```
var tables = new GlideRecordUtil().getTables("cmdb_ci_linux_server");
gs.log(tables.join(","));
// The result would be "cmdb_ci, cmdb_ci_computer, cmdb_ci_server, cmdb_ci_linux_server".
```

Using DiscoveryException and AutomationException

When writing Discovery sensors and sensor-related scripts, you may want to use DiscoveryException or AutomationException to indicate that an exception has come from Discovery.

The *DiscoveryException* script include extends *AutomationException*, which extends the *GenericException* class. The following example uses *DiscoveryException* to throw an exception:

```
function foo() {
   if(//condition matches) throw new DiscoveryException("The message", "The cause"); }
```

The first argument takes the message of the exception and the second argument (optional) takes the cause of the exception. You may also want to catch the exception and log it as shown in the example below:

```
try {
  foo();
}
catch(e) {
   if(e instanceof DiscoveryException)
     gs.log("A DiscoveryException occurred. It is " + e. getMessage() + "
caused by " + e.getCause()); }
```

The above example also applies for *AutomationException*. *DiscoveryException* is typically used to provide exception processing specifically for Discovery, while *AutomationException* is used for exception processing that applies to both Orchestration and Discovery.

Processors

Processors provide a customizable URL endpoint that can execute arbitrary server-side JavaScript code and produce output such as TEXT or JSON. Creating custom processors is deprecated.

Note:
This feature is deprecated. While legacy, existing custom processors continue to be supported, creating new custom processors has been deprecated. Instead, use the Scripted REST APIs.

Warning:
When creating a processor, ensure that you use parameter names that are specific to your processor. For example, if your processor exports a list of legal records, and a necessary parameter is the recipient's email address, don't use “email” as the parameter name. Create a more processor specific parameter name, such as legal_export_recipient_email. Failure to do so, and using instance parameter names, such as id, table, sys_id, service, catalog_id, or view (and others), can cause unexpected results.

When to create processors

Do not create custom processors. This feature is deprecated. Please use the REST APIs instead of creating custom processors. The remaining information is left for existing processors only.

Processor form

Field	Description
Name	Unique name of the processor.
Type	Programming language of the processor script. Options include: • java: do not select this option • script
Application	Application containing this record.
Active	Flag to enable or disable the record.

Field	Description
CSRF protect	Option to protect the processor from running unless the instance uses a CSRF token.
Description	Description of the processor's function or purpose.
Parameters	List of available input parameters. Specify parameter values in the URL as *<parameter name>=<parameter value>*. **Note:** Parameter names must be processor-specific. Do not choose common parameter names that another processor might use. If you use a common parameter name, such as `id`, `sys_id` or `table` in a processor, it can break other functionality, since the processor wins when that parameter exists in a URL. For example, a processor with an `id` parameter, regardless of the Path value in the same record, breaks the Service Portal, which depends on that parameter for page identification.
Path	URI path used to call this processor. Call a processor from the URL as: `https://<instance name>.service-now.com/<Path>.do`
Script	Immediately Invoked Function Expression to run when the system calls this processor. The function automatically provides input parameters for the following API objects. • g_request • g_response • g_processor
Protection policy	Policy to use to protect this record's script. Options include: • None • Read-only • Protected

Processor API components

Processors have access to dedicated API classes, objects, and methods.

Processor API components

Class, object, or method	Description
`g_response`	An object of type HttpServletResponse. See GlideServletResponse.
`setContentType('text/html;charset=UTF-8')`	A GlideServletResponse method to set the content type of the response being sent to the client.
`g_request`	An object of type HttpServletRequest. See HttpServletRequest.
`getParameter()`	A glide method to get the value of a URL parameter.
`canRead()`	A GlideRecord method to determine if the user can read data from a table. See GlideRecord.
`g_processor`	A simplified servlet for processors. See GlideScriptedProcessor.
`writeOutput()`	A GlideScriptedProcessor method to display information on the client.
`g_target`	An object containing the target table name of a processor URL. For example, a processor containing the URI `incident.do` applies to the Incident table.

Secure and protect a processor

You can protect your processor against unauthorized use by using role restrictions, and protect it by requiring a CSRF token.

About this task

Note:
This feature is deprecated. While legacy, existing custom processors continue to be supported, creating new custom processors has been deprecated. Instead, use the Scripted REST APIs.

You can re-use a table's user role restrictions to protect it from access by your processor. This protection method assumes the processor will access table data.

Procedure

1. Create or select a user role that has access to the table the processor script calls.
2. Navigate to **System Definition** > **Processors**.
3. In **Script**, add the following code block.

```
var now_GR = new GlideRecord('your_table_name');
// canRead() compares the table's ACL to the user making this
 request, and returns true if the logged-in user has read
 access to this table
if(gr.canRead())
{
  // Perform table query here
  g_processor.writeOutput('Success!');
} else {
```

```
  g_processor.writeOutput('You do not have permission to read
 table your_table_name');
}
```

4. Update the code block to use other access restrictions as needed.

   Available access functions include:

   - `canCreate()`
   - `canRead()`
   - `canWrite()`
   - `canDelete()`

5. Click **Update**.

Protect a processor with a CSRF token

You can protect a processor by requiring a CSRF token.

About this task

Script type processors can require a CSRF token check before the processor runs.

Procedure

1. Navigate to **All** > **System Definition** > **Processors**.
2. Open a processor record.
3. Select the **CSRF protect** option.
4. Click **Update**.

Create a simple processor

Create a simple processor to execute a script from a URL query. This feature is deprecated.

Before you begin

You must have your own demonstration instance.

Role required: admin

About this task

Note:
This feature is deprecated. While legacy, existing custom processors continue to be supported, creating new custom processors has been deprecated. Instead, use the Scripted REST APIs.

Procedure

1. Navigate to **All** > **System Definition** > **Processors**.
2. Select **New**.
3. Enter the following information.

4. Select **Submit**.

5. Enter a URL query to the instance with the following format: `https://instance.service-now.com/processor_name.do?parameter=value`
   For example: `https://<instancename>.service-now.com/Hello.do?name=world`.

Create a multi-table processor

Create a multi-table processor that reports the number of rows in any table on your instance. This feature is deprecated.

Before you begin
Role required: admin

About this task

Note:
This feature is deprecated. While legacy, existing custom processors continue to be supported, creating new custom processors has been deprecated. Instead, use the Scripted REST APIs

The multi-table processor protects itself from performance and security violations by confirming that the user is authorized to read the table. It does not report on certain tables that are too large to query safely.

Procedure

1. Navigate to **All** > **System Definition** > **Processors**.
   The list of processors appears.
2. Select**New**.
3. Enter the following information.

Name	TableSize
Type	Choose **Javascript**
Description	Return number of records in a table
Parameters	**SIZE**
Path	<leave empty>

Script:

```
g_response.setContentType('text/html;charset=UTF-8');
if(g_target === 'sys_email' || g_target === 'sys_log' )
{
  g_processor.writeOutput(g_target + ' table is too large to
 quickly count');
  } else {
    var count = new GlideAggregate(g_target);
    if( count.canRead() ) {
      count.addAggregate('COUNT');
      count.query();
      var records = 0;
      if (count.next()) {
        records = count.getAggregate('COUNT');
       }
```

```
      g_processor.writeOutput('table ' + g_target + ' has ' +
 records + ' records');
     } else {
      g_processor.writeOutput('You do not have access to table
 ' + g_target);
  }
}
```

4. Select **Save**.
5. Test the new processor by entering the following URLs:
   `https://<instancename>.service-now.com/incident.do?SIZE` and
   `https://<instancename>.service-now.com/sys_user.do?SIZE`
   Your instance reports the number of records in the table. For example, `table incident has 82 records`.

Create a custom processor

Create a custom processor to execute a script from a URL query. This feature is deprecated.

Before you begin

Role required: admin

About this task

Note:
This feature is deprecated. While legacy, existing custom processors continue to be supported, creating new custom processors has been deprecated. Instead, use the Scripted REST APIs.

When complete, you can do the following tasks:

- Create a new processor
- Run a script from a URL query

The following example steps assume you have your own demonstration instance.

Procedure

1. Navigate to **All** > **System Definition** > **Processors**.
2. Select **New**.
3. In the **Name** field, enter `Hello`.
4. In the **Type** field, select *script*.
5. In the **Path** field, enter `Hello`.
6. In the **Script** field, enter the following code.

```
var name = g_request.getParameter("name");
g_processor.writeOutput("text/plain", "Hello " + name);
```

7. Select **Submit**.
8. Log out of the instance and open a new browser window.
9. Enter a URL query to the instance with the following format: `https://instance.service-now.com/processor_name.do?parameter=value`.

For example: `https://<instance name>.service-now.com/Hello.do?name=world`.

10. When prompted, enter the credentials for a valid user.

Scripts - Background module

Administrators can use the Scripts - Background module to run arbitrary JavaScript code from the server.

The Scripts - Background module consists of the following components.

- Text box to enter JavaScript.
- Selector to specify the application scope.
- **Run script** button.
- List of available scopes.
- **Record for rollback?** check box. Selected by default. Creates a rollback context for the script execution. After the script is run, click the **Script execution and recovery available here** link to go to the **Script Execution History** form where you can rollback the script.
- **Execute in sandbox?** check box. Allows script to run with sandbox like restrictions. If checked, data cannot be inserted, updated, or deleted.
- **Execute as scriptlet?** check box. Allows the script to execute as a scriplet, which gives the script access to the global scope and any server-side functionality or objects. If the check box is not selected, the script executes in global scope, but does not have access to any server-side functionality or objects.
- **Cancel after 4 hours** check box. Selected by default. Cancels the script execution if it continues running after four hours.

When a script is run, the instance displays results, information, and error messages at the top of the screen.

Important:
Running free-form JavaScript can cause system disruption or data loss. Do not run free-form scripts from a production instance.

To stop a transaction, see View and kill active transaction.

For examples of scripts you could run, see Useful scripts.

Installation settings

Installation settings are global business rules with calculated names. Installation settings are calculated just before a record is displayed and facilitate dynamic determination of access and roles. Installation Settings permit the programmatic determination of a setting.

Installation settings controlling access to fields and records are:

- CanRead()
- CanWrite()
- CanCreate()
- CanDelete()

Functions can return true if access is permitted, false if not. No return value uses the permission calculated using roles. The function has access to the current record through the variable current code.

The name of the function checking the permission on a record is formed by prefixing the setting name with the record name:

```
record_nameCanRead()
```

Similarly, the permission on a field in a record is formed by prefixing the function name with the record name, underscore, and field name:

```
record_name_field_nameCanRead()
```

Naming examples:

```
function incidentCanWrite() {} //  can user write to this
 record?
 function incident_numberCanWrite() {}  // can user write to the
 number field?
```

This sample business rule restricts the writing of the name field in the sys_dictionary file when the entry exists:

```
  // the element name cannot be written unless this is a new
 record (not yet in database)
  function sys_dictionary_nameCanWrite() {
    if (current.isNewRecord())
      return;

    return false;
  }
```

Using DurationCalculator to calculate a due date

Using the DurationCalculator script include, you can calculate a due date, using either a simple duration or a relative duration base on schedules.

The following script demonstrates how to use the global API DurationCalculator to calculate a due date. The first part of the script illustrates how to set a start datetime using the setStartDateTime() method and then use the calcDuration() method to determine a due date that is "x" amount of continuous time (seconds) from the specified start datetime. The second half of the script illustrates how to use *`DurationCalculator`* to calculate a due date based on a schedule. Schedules enable you to apply a "filter" on future time, such as only including the days in a work week within the calculation. For example, if you apply a schedule "weekdays" (which only includes Monday through Friday) to your duration calculation, and the start datetime is Friday at 5:00 pm, when you add a duration of two days, your due date would be Tuesday at 5:00 pm. If you did not use a schedule, your due date would be Sunday at 5:00 pm. For additional information on schedules, see Creating and using schedules.

This script can be cut and pasted into the Scripts Background page and run as is. It can also serve as an example for authoring business rules, UI actions, or used any other place that server-side script can be authored.

```
/**
 * Demonstrate the use of DurationCalculator to compute a due
 date.
 *
 * You must have a start date and a duration. Then you can
 compute a
 * due date using the constraints of a schedule.
 */

gs.include('DurationCalculator');
executeSample();
```

```
/**
 * Function to house the sample script.
 */
function executeSample(){

    // First we need a DurationCalculator object.
    var dc = new DurationCalculator();

    // --------------- No schedule examples -----------------

    // Simple computation of a due date without using a
schedule. Seconds
    // are added to the start date continuously to get to a due
date.
    var gdt = new GlideDateTime("2012-05-01 00:00:00");
    dc.setStartDateTime(gdt);
    if(!dc.calcDuration(2*24*3600)){ // 2 days
      gs.log("*** Error calculating duration");
      return;
    }
    gs.log("calcDuration no schedule: " +
dc.getEndDateTime()); // "2012-05-03 00:00:00" two days later

    // Start in the middle of the night (2:00 am) and compute a
due date 1 hour in the future
    // Without a schedule this yields 3:00 am.
    var gdt = new GlideDateTime("2012-05-03 02:00:00");
    dc.setStartDateTime(gdt);
    if(!dc.calcDuration(3600)){
      gs.log("*** Error calculating duration");
      return;
     }
    gs.log("Middle of night + 1 hour (no schedule): "+
dc.getEndDateTime()); // No scheduled start date, just add 1
hour

    // -------------- Add a schedule to the date calculator
---------------------
    addSchedule(dc);

    // Start in the middle of the night and compute a due date 1
hour in the future.
    // Since we start at 2:00 am the computation adds the 1 hour
from the start
    // of the day, 8:00am to get to 9:00am
    var gdt = new GlideDateTime("2012-05-03 02:00:00");
    dc.setStartDateTime(gdt);
    if(!dc.calcDuration(3600)){
      gs.log("*** Error calculating duration");
      return;
    }
    gs.log("Middle of night + 1 hour (with 8-5 schedule): " +
dc.getEndDateTime()); // 9:00 am
```

```
    // Start in the afternoon and add hours beyond quiting time.
 Our schedule says the work day
    // ends at 5:00pm, if the duration extends beyond that, we
 roll over to the next work day.
    // In this example we are adding 4 hours to 3:00pm which
 gives us 10:00 am the next day.
    var gdt = new GlideDateTime("2012-05-03 15:00:00");
    dc.setStartDateTime(gdt);

    if(!dc.calcDuration(4*3600)){
      gs.log("*** Error calculating duration");
      return;}
    gs.log("Afternoon + 4 hour (with 8-5 schedule): " +
 dc.getEndDateTime()); // 10:00 am.

    // This is a demo of adding 2 hours repeatedly and examine
 the result. This
    // is a good way to visualize the result of a due date
 calculation.
    var gdt = new GlideDateTime("2012-05-03 15:00:00");
    dc.setStartDateTime(gdt);
    for(var i=2; i<24; i+=1){
      if(!dc.calcDuration(i*3600)){
        gs.log("*** Error calculating duration");
        return;
      }
      gs.log("add "+ i +" hours gives due date: " +
 dc.getEndDateTime());
    }

    // Setting the timezone causes the schedule to be
 interpreted in the specified timezone.
    // Run the same code as above with different timezone. Note
 that the 8 to 5 workday is
    // offset by the two hours as specified in our timezone.
    dc.setTimeZone("GMT-2");
    var gdt = new GlideDateTime("2012-05-03 15:00:00");
    dc.setStartDateTime(gdt);
    for(var i=2; i<24; i+=1){
      if(!dc.calcDuration(i*3600)){
        gs.log("*** Error calculating duration");
        return;
      }
        gs.log("add "+ i +" hours gives due date (GMT-2): " +
 dc.getEndDateTime());
    }
}

/**
 * Add a specific schedule to the DurationCalculator object.
 *
 * @param durationCalculator An instance of DurationCalculator
 */
function addSchedule(durationCalculator){
    // Load the "8-5 weekdays excluding holidays" schedule into
 our duration calculator.
    var scheduleName = "8-5 weekdays excluding holidays";
```

```
    var grSched = new GlideRecord('cmn_schedule');
    grSched.addQuery('name', scheduleName);
    grSched.query();
    if(!grSched.next()){
      gs.log('*** Could not find schedule "'+ scheduleName
 +'"');
      return;
    }

 durationCalculator.setSchedule(grSched.getUniqueValue(),"GMT");
}
```

Using DurationCalculator to compute a simple duration

A simple duration is the number of seconds between two date times.

If no schedule is used then this is a simple time date subtraction. If a schedule is used, then the schedule is consulted to remove non-work hours from the computation. Suppose schedule "8-5 weekdays excluding holidays" is used. In this case, the number of work hours from noon Monday to noon Tuesday is nine hours. To compute a simple duration, initialize the global API *`DurationCalculator`* and call the calcScheduleDuration() method.

This script demonstrates how to use *`DurationCalculator`* to compute a simple duration.

```
/**
 * Sample script demonstrating use of DurationCalculator to
 compute simple durations
 *
 */

gs.include('DurationCalculator');
executeSample();

/**
 * Function to house the sample script.
 */
function executeSample(){

    // First we need a DurationCalculator object.
    var dc = new DurationCalculator();

    // Compute a simple duration without any schedule. The
 arguments
    // can also be of type GlideDateTime, such as fields from a
 GlideRecord.
    var dur = dc.calcScheduleDuration("2012-05-01",
 "2012-05-02");
    gs.log("calcScheduleDuration no schedule: " + dur); // 86400
 seconds (24 hours)

    // The above sample is useful in limited cases. We almost
 always want to
    // use some schedule in a duration computation, let's load a
 schedule.
    addSchedule(dc);

    // Compute a duration using the schedule. The schedule
```

```
    // specifies a nine hour work day. The output of this is
 32400 seconds, or
    // a nine hour span.
    dur = dc.calcScheduleDuration("2012-05-23
 12:00:00","2012-05-24 12:00:00");
    gs.log("calcScheduleDuration with schedule: " + dur); //
 32400 seconds (9 hours)

    // Compute a duration that spans a weekend and holiday. Even
 though this
    // spans three days, it only spans 9 work hours based on the
 schedule.
    dur = dc.calcScheduleDuration("2012-05-25 12:00:00",
 "2012-05-29 12:00:00");
    gs.log("calcScheduleDuration with schedule spaning holiday:
 " + dur); // 32400 seconds (9 hours)

    // Use the current date time in a calculation. The output of
 this is
    // dependent on when you run it.
    var now = new Date();
    dur = dc.calcScheduleDuration("2012-05-15", new
 GlideDateTime());
    gs.log("calcScheduleDuration with schedule to now: " +
 dur); // Different on every run.
}

/**
 * Add a specific schedule to the DurationCalculator object.
 *
 * @param durationCalculator An instance of DurationCalculator
 */
function addSchedule(durationCalculator){
    // Load the "8-5 weekdays excluding holidays" schedule into
 our duration calculator.
    var scheduleName = "8-5 weekdays excluding holidays";
    var grSched = new GlideRecord('cmn_schedule');
    grSched.addQuery('name', scheduleName);
    grSched.query();
    if(!grSched.next()){
        gs.log('*** Could not find schedule "'+ scheduleName
 +'"');
        return;
    }
    durationCalculator.setSchedule(grSched.getUniqueValue());
}
```

Using relative duration

Relative duration is very similar to simple duration except a piece of script is used to determine what parts of a day to remove from the difference calculation.

This script is stored in table cmn_relative_duration and can be examined by navigating to **System Scheduler** > **Schedules** > **Relative Durations**. There are some example relative duration scripts in the out-of-the-box instance.

A relative duration sys_id is passed to the method *`calcRelativeDuration()`* of the global API DurationCalculator class after initialization. When this method is called,

the DurationCalculator object is passed to the relative duration script (stored in table cmn_relative_duration) as the variable *calculator*. So, the relative duration script you write and store in cmn_relative_duration has access to the executing DurationCalculator through the variable *calculator*.

The following script demonstrates how to use *DurationCalculator* to calculate a relative duration.

```
/**
 * Sample use of relative duration calculation.
 *
 */

gs.include('DurationCalculator');
executeSample();

/**
 * Function to house the sample script.
 */
function executeSample(){

    // First we need a DurationCalculator object. We will also
 use
    // the out-of-box relative duration "2 bus days by 4pm"
    var dc = new DurationCalculator();
    var relDur = "3bf802c20a0a0b52008e2859cd8abcf2"; // 2 bus
 days by 4pm if before 10am
    addSchedule(dc);

    // Since our start date is before 10:00am our result is two
 days from// now at 4:00pm.
    var gdt = new GlideDateTime("2012-05-01 09:00:00");
    dc.setStartDateTime(gdt);
    if(!dc.calcRelativeDuration(relDur)){
      gs.log("*** calcRelativeDuration failed");
      return;
    }
    gs.log("Two days later 4:00pm: "+ dc.getEndDateTime());

    // Since our start date is after 10:00am our result is three
 days from
    // now at 4:00pm.
    var gdt = new GlideDateTime("2012-05-01 11:00:00");
    dc.setStartDateTime(gdt);
    if(!dc.calcRelativeDuration(relDur)){
      gs.log("*** calcRelativeDuration failed");
      return;
    }
    gs.log("Three days later 4:00pm: "+ dc.getEndDateTime());}

/**
 * Add a specific schedule to the DurationCalculator object.
 *
 * @param durationCalculator An instance of DurationCalculator
 */
function addSchedule(durationCalculator){
```

```
    // Load the "8-5 weekdays excluding holidays" schedule into
 our duration calculator.
    var scheduleName ="8-5 weekdays excluding holidays";
    var grSched =new GlideRecord('cmn_schedule');
    grSched.addQuery('name', scheduleName);
    grSched.query();
    if(!grSched.next()){
      gs.log('*** Could not find schedule "'+ scheduleName
 +'"');
      return;}

 durationCalculator.setSchedule(grSched.getUniqueValue(),"GMT"
);}
```

Querying tables in script

Using methods in the GlideRecord API, you can return all records from a table, return records from a table that satisfy specific conditions, or return records that include a string from a single table or from multiple tables in a text index group.

Query tables using the GlideRecord API. For API reference, see GlideRecord - Scoped.

Return all records from a table

To query a table, first create a GlideRecord object. To create a GlideRecord, create the following in script:

```
var target = new GlideRecord('incident');
```

Creating a GlideRecord creates a `target` variable which is a GlideRecord object for the incident table.

To process all records from the incident table, add the following script:

```
target.query(); // Issue the query to the database to get all
 records
while (target.next()) {
  // add code here to process the incident record
}
```

This script issues the *`query()`* to the database. Each call to *`next()`* would load the next record for processing.

Return records from a table that satisfy query conditions

Most of the time, you want to retrieve a specific record or a specific set of records, and you have some criteria (query conditions) that define the records you want to obtain. For example, say that you want to obtain all the incident records that have a priority value of 1. Here is the code that would accomplish that.

```
var target = new GlideRecord('incident');
target.addQuery('priority',1);
target.query(); // Issue the query to the database to get
 relevant records
while (target.next()) {
  // add code here to process the incident record
}
```

Notice that the example script includes `target.addQuery('priority', 1);`. This line indicates that you only want the records where the *priority* field is equal to 1. In general, most queries that you want to perform are equality queries; queries where you want to find records with a field equal to a value. For this reason, you do not need to provide an equality operator. However, lets say you wanted to find all incidents where the *priority* field is greater than 1. In this case, you would provide the operator that you want to apply to the query.

```
var target = new GlideRecord('incident') ;
target.addQuery('priority','>',1);
target.query(); // Issue the query to the database to get
 relevant records
while (target.next()) {
  // add code here to process the incident record
}
```

Return records from a table that include a string

Use the `'123TEXTQUERY321'` reserved name to search for string matches in all fields on a table. For example, this script returns records from the Incident table with field values that include the 'email' string.

```
var now_GR = new GlideRecord('incident');
gr.addQuery('123TEXTQUERY321', 'email');
gr.query();
```

`'123TEXTQUERY321'` is a reserved option for the *name* parameter in the `addQuery()` method. You can use this option in an encoded query string. For example, instead of `gr.addQuery('123TEXTQUERY321', 'email');`, you can use `gr.addEncodedQuery('123TEXTQUERY321=email')`.

String search is case-insensitive. The system returns the same results whether you search for `email`, `Email`, or `EMAIL`.

Note:
Before you can query using a string search, you must configure text indexing (and optionally search attributes) for the table you want to search. For more information, see Configure a single table for indexing and searching.

Return records from multiple tables in a text index group that include a string

Use the `'123TEXTINDEXGROUP321'` reserved name to search for a string in a table from a text index group. This option returns results with relevancy scores computed using the text index group's settings.

Note:
You can only query one table in the text index group at a time. Use this option when you want to issue multiple single-table queries and merge their results, ordering them by relevancy score. The advantage of this option is that search result relevancy scores for the individual table queries are normalized consistently for all tables in the text index group.

For example, this script returns records from the Knowledge table that include the keyword 'email', with relevancy scores computed for the 'portal' index group.

```
var now_GR = new GlideRecord('kb_knowledge');
gr.addQuery('123TEXTQUERY321', 'email');
gr.addQuery('123TEXTINDEXGROUP321', 'portal');
gr.query();
```

You can create a similar query for each additional table in the 'portal' index group that you want to search, and then merge the individual queries' results, displaying the results with the highest relevancy scores first. Because all of these search queries use the same text index group search settings, the relevancy scores for their results are all normalized consistently. If you searched the same set of tables without using the `gr.addQuery('123TEXTINDEXGROUP321', 'portal')` method, the individual queries' relevancy scores would be normalized differently and would not be a useful basis for sorting the merged result set.

`'123TEXTINDEXGROUP321'` is a reserved option for the *name* parameter in the `addQuery()` method. You can use this option in an encoded query string. For example, instead of `gr.addQuery('123TEXTINDEXGROUP321', 'portal');`, you can use `gr.addEncodedQuery('123TEXTINDEXGROUP321=portal')`.

Multi-table string search is case-insensitive. The system returns the same results whether you search for `email`, `Email`, or `EMAIL`.

Note:
Before you can query tables in an index group, you must configure text indexing and search attributes for those tables and include them in the index group. For more information, see Configure multiple tables for indexing and searching. All tables in the index group must use the V4 indexing format.

Available JavaScript operators

Describes the operators that can be used within an *addQuery()* request.

Available JavaScript Operators

Field	Definition	addQuery
=	Field must be equal to value supplied.	addQuery('priority', '=', 1);
>	Field must be greater than value supplied.	addQuery('priority', '>', 1);
<	Field must be less than value supplied.	addQuery('priority', '<', 3);
>=	Field must be equal or greater than value supplied.	addQuery('priority', '>=', 1);
<=	Field must be equal or less than value supplied.	addQuery('priority', '<=', 3);
!=	Field must not equal the value supplied.	addQuery('priority', '!=', 1);
STARTSWITH	Field must start with the value supplied. The example shown on the right returns all records where the *short_description* field starts with the text Error.	addQuery('short_description', 'STARTSWITH', 'Error');
CONTAINS	Field must contain the value supplied somewhere in the text. The example shown on the right returns all records where the *short_description* field contains the text Error anywhere in the field. **Note:** The LIKE operation is not supported. Administrators must use CONTAINS in the query.	addQuery('short_description', 'CONTAINS', 'Error');

Available JavaScript Operators (continued)

Field	Definition	addQuery
IN	Takes a map of values that allows commas, and gathers a collection of records that meet some other requirement. Behaves as `Select * from <table> where short_description IN ('Error', 'Success', 'Failure')`, which is identical to `Select * from <table> where short_description='Error'`. For example, to query all variable values that belong to a specific Activity, use the *IN* clause, and store their sys_ids in a map, or comma-separated list. Then query the variable value table and supply this list of sys_ids.	addQuery('short_description', 'IN', 'Error,Success,Failure');
ENDSWITH	Field must terminate with the value supplied. The example shown on the right returns all records where the *short_description* field ends with text Error.	addQuery('short_description', 'ENDSWITH', 'Error');
DOES NOT CONTAIN	Selects records that do NOT match the pattern in the field. This operator does not retrieve empty fields. For empty values, use the operators "is empty" or "is not empty."The example shown on the right returns all records where the *short_description* field does not have the word "Error."	addQuery('short_description', 'DOES NOT CONTAIN', 'Error');
NOT IN	Takes a map of values that allows commas, and gathers a collection of records that meet some other requirement. Behaves as: `Select * from <table> where short_description NOT IN ('Error')`.	addQuery('short_description', 'NOT IN', 'Error,Success,Failure');
INSTANCEOF	Special operator that retrieves only records of a specified "class" for extended tables. The code example on the right, shows how to retrieve all configuration items that are classified as computers.	addQuery('sys_class_name', 'INSTANCEOF', 'cmdb_ci_computer');

For additional information on the operators that are available for filters and queries, see Operators available for filters and queries.

There are also some special methods that you can use to search for data that is NULL or NOT NULL. To search for all incidents where the *short_description* field has not been supplied (is null), use the following query:

```
var target = new GlideRecord('incident');
target.addNullQuery('short_description');
target.query(); // Issue the query to the database to get all
 records
while (target.next()) {
  // add code here to process the incident record
}
```

To find all incidents in which a *short_description* has been supplied, use the following query:

```
var target = new GlideRecord('incident');
target.addNotNullQuery('short_description');
target.query(); // Issue the query to the database to get all
 records
while (target.next()) {
  // add code here to process the incident record
}
```

For more information on the *GlideRecord* API and its available methods, see GlideRecord.

GlideRecord query examples

These examples demonstrate how to perform various *GlideRecord* queries.

query

```
var rec = new GlideRecord('incident');
rec.query();
while(rec.next()) {
  gs.print(rec.number + ' exists'); }
```

update

```
var rec = new GlideRecord('incident');
rec.addQuery('active',true);
rec.query();
while(rec.next()) {
  rec.active = false;
  gs.print('Active incident ' + rec.number = ' closed');
  rec.update(); }
```

insert

```
var rec = new GlideRecord('incident');
rec.initialize();
rec.short_description = 'Network problem';
rec.caller_id.setDisplayValue('Joe Employee');
rec.insert();
```

delete

```
var rec = new GlideRecord('incident');
rec.addQuery('active',false);
rec.query();
while(rec.next()) {
  gs.print('Inactive incident ' + rec.number + ' deleted');
  rec.deleteRecord(); }
```

Querying Service Catalog Tables

You cannot directly query the variables of the Service Catalog Request Item table [sc_req_item]. Instead, query the Variable Ownership table, [sc_item_option_mtom], by adding two queries, one for the variable name and another for the value. The query returns the many-to-many relationship, which you can dot-walk to the requested item. The following example finds the

request items that have the variable *item_name* with a value of *item_value* and displays the request item numbers:

```
var now_GR = new GlideRecord('sc_item_option_mtom');
gr.addQuery('sc_item_option.item_option_new.name','item_name');
gr.addQuery('sc_item_option.value','item_value');
gr.query();

while(gr.next()) {
  gs.addInfoMessage(gr.request_item.number); }
```

For additional information see GlideRecord.

Running order guides automatically

Service catalog order guides allow customers to make a single service catalog request that can generate several ordered items. Administrators can configure order guides to run automatically, from a workflow or a script to generate a set of ordered items without manually submitting a service catalog request. Administrators can also review and reprocess the order guide failures.

As a use case, an onboarding workflow for a new employee can run an order guide to automatically order items for that employee.

Note:
You can only save catalog items, not the order guide (that is, initial landing page options).

Running order guides from scripts

Running order guides with a server-side script is more complex than using workflows, but it allows more flexibility and can be used in non-workflow situations.

For example, you can use order guide scripts with UI actions or server-side business rules.

Note:
When order guides run automatically, order guide UI policies are not enforced. Also, options in the Choose Options screen cannot be selected, so make sure that order guide rules define sensible defaults for these options to avoid processing failures.

Use the *SNC.ScriptableOrderGuide* Java class to run order guides with a script.

Use the *SNC.ScriptableOrderGuide(String orderGuideId)* constructor to create a new ScriptableOrderGuide object.

Method summary

Method	Return Value	Description
process(String json)	boolean	Runs the order guide using the JSON encoded string parameter as the input for the order guide. Returns *true* or *false* depending on whether processing was successful or not. **Note:** Both *opened_by* and *requested_for* parameters must be passed to the order guide, and both must have valid user record sys_id values.

Method	Return Value	Description
		If processing is successful and a request is created by the order guide, you can retrieve the request GlideRecord using *getRequest()*. If the processing fails, you can retrieve the failure GlideRecord using *getFailure()*, then submit the script for reprocessing using reprocess.
reprocess(GlideRecord failure)	boolean	Runs the order guide again using the JSON encoded string parameter stored in the failure GlideRecord.
getMessage()	String	Retrieves the message populated after processing or reprocessing.
getRequest()	GlideRecord	Retrieves the request GlideRecord.
getFailure()	GlideRecord	Retrieves the failure GlideRecord from the Scriptable Order Guide Failures [sc_script_order_guide_failure] table.

Script example

This script processes an order guide called *IT Onboarding SOG*.

```
// Creating the object to later be JSON encoded
var json =
 {"opened_by":"62826bf03710200044e0bfc8bcbe5df1","requested_for"
:"06826bf03710200044e0bfc8bcbe5d8a","department":"221f3db5c61122
84009f4becd3039cc9"};

var now_GR = new GlideRecord("sc_cat_item_guide");
if (gr.get("name","IT Onboarding SOG")) {
  var sog = new SNC.ScriptableOrderGuide(gr.getValue("sys_id"));
  var result = sog.process(new JSON().encode(json));
  if(!result)
    gs.log("Processing the scriptable order guide failed with
 message: " + sog.getMessage());
  else {
    var request = sog.getRequest();
    gs.log("Request created - " + request.sys_id); } }
```

Running order guides from workflows

Running an order guide from a workflow is suitable if you include order guides as part of a broader workflow-based process.

For example, an activity within an onboarding workflow for a new employee can automatically run an order guide to order items for that employee.

Note:
When order guides run automatically, order guide UI policies are not enforced. Also, options in the Choose Options screen cannot be selected, so make sure that order guide rules define sensible defaults for these options to avoid processing failures.

To run order guides from a workflow, use the **Scriptable Order Guide** workflow activity.

Running order guides from workflows

Field	Description
Order Guide	The name of the order guide that this activity processes. For example, **Example Employee Onboarding IT**.
Script	A script passing information to the order guide. This information is sent as a JSON encoded string parameter assigned to the *answer* variable. The script must meet these requirements: • The names of the variables in the script must match the names used within the order guide. For example, if the order guide uses a *department* variable in a rule condition, the script must also pass a *department* parameter. • Both *opened_by* and *requested_for* parameters must be passed to the order guide, and both must have valid user record sys_id values.

Results

- **Success**: the activity successfully processed the order guide. This does not mean a request was created. If a request was created, the request sys_id is added to the workflow scratchpad under the *sc_request* variable.
- **Failure**: while processing the order guide a failure occurred, creating a failure record. If the processing fails, you can view and edit the failure record.

Workflow example

The **Example Employee Onboarding IT Workflow** workflow uses this example to generate IT catalog items for a new employee as part of an onboarding process.

The activity uses this script to:

1. Take a JSON string generated previously from the HR change record.
2. Append the mandatory *opened_by* and *requested_for* parameters to that string.
3. Submit the new string for processing by the order guide.

```
var parameters  = new JSON().decode(current.payload);

// Need to amend the json object to include additional values.
parameters.opened_by = current.opened_by + "";
parameters.requested_for = current.opened_for + "";

answer = new JSON().encode(parameters);
```

View order guide failures

Order guide processing can fail, for example if the order guide being run does not exist. When a failure occurs during the order guide processing, the **Scriptable Order Guide Failures** submodule allows you to review and reprocess the failures. A record is created for each failure and once you fix the errors that caused the initial failure, you can reprocess the failed order guides.

About this task

If a failure occurs, a failure record is created in the Scriptable Order Guide Failures [sc_script_order_guide_failure] table.

To view details of a failure, navigate to **Service Catalog** > **Catalog Administration** > **Scriptable Order Guide Failures**, then open a failure record.

Reprocessing failures: If you have fixed the error that caused the initial failure, you can reprocess failed order guides.

Procedure

1. Navigate to **Service Catalog** > **Catalog Administration** > **Scriptable Order Guide Failures**.
2. Open the failure record.
3. Click the **Reprocess** related link.

To reprocess one or more failures:

a. Navigate to **Service Catalog** > **Catalog Administration** > **Scriptable Order Guide Failures**.
b. Select the check box beside one or more records to reprocess.
c. Select **Reprocess** from the **Actions** choice list.

Scriptable assignment of execution plans

Each catalog item has an associated execution plan, used whenever an item of that type is ordered; if no plan is specified, the default plan is used. This default is effective for most organizations, but your execution plan may need to vary based on additional criteria.

For example, in the base system service catalog, a request for a new PC always uses the PC Delivery Plan. However, this plan may need to vary for unusual circumstances - such as when a requester is working from home, at a remote location.

To provide this flexibility, you can use a script to override the default execution plan on a specific catalog item.

Limitations during script execution

Execution plan scripts have limitations that need to be considered during their implementation.

While the execution plan script runs:

- You cannot interact with any catalog tasks as catalog tasks are only created after the execution plan is selected.
- Some fields such as **total delivery time** and **due date** are not yet calculated, although the request itself is available within the script via `current.request()`.
- Approvals have not yet been generated.

Writing the scripts

Follow these guidelines when writing execution plan scripts.

Execution plan scripts can access the same global variables and other functions as in any other server side execution plan.

- `current` is the currently-requested catalog item, `sc_req_item`.
- `current.delivery_plan()` is the assigned execution plan for this catalog item.

The evaluated value from the script is used as the `sys_id` of the execution plan.

Simple example:

```
current.delivery_plan.setDisplayValue('PC Delivery Plan')
```

If an invalid value is returned, such as undefined or not found, then the existing assigned value is used.

More complex example:

```
getexecutionplan();
function getexecutionplan() {
var location =
 current.request.requested_for.location.getDisplayValue();
// if we're in Atlanta
if (location == 'Atlanta') {
   // use the remote pc delivery plan instead of the normal one
   var remote_plan = new
 GlideRecord('sc_cat_item_delivery_plan');
   remote_plan.addQuery('name', 'Remote PC Delivery Plan');
   remote_plan.query();
   remote_plan.next();
   current.delivery_plan = remote_plan.sys_id;
   return remote_plan_sys_id;
   }
   return current_delivery_plan;
}
```

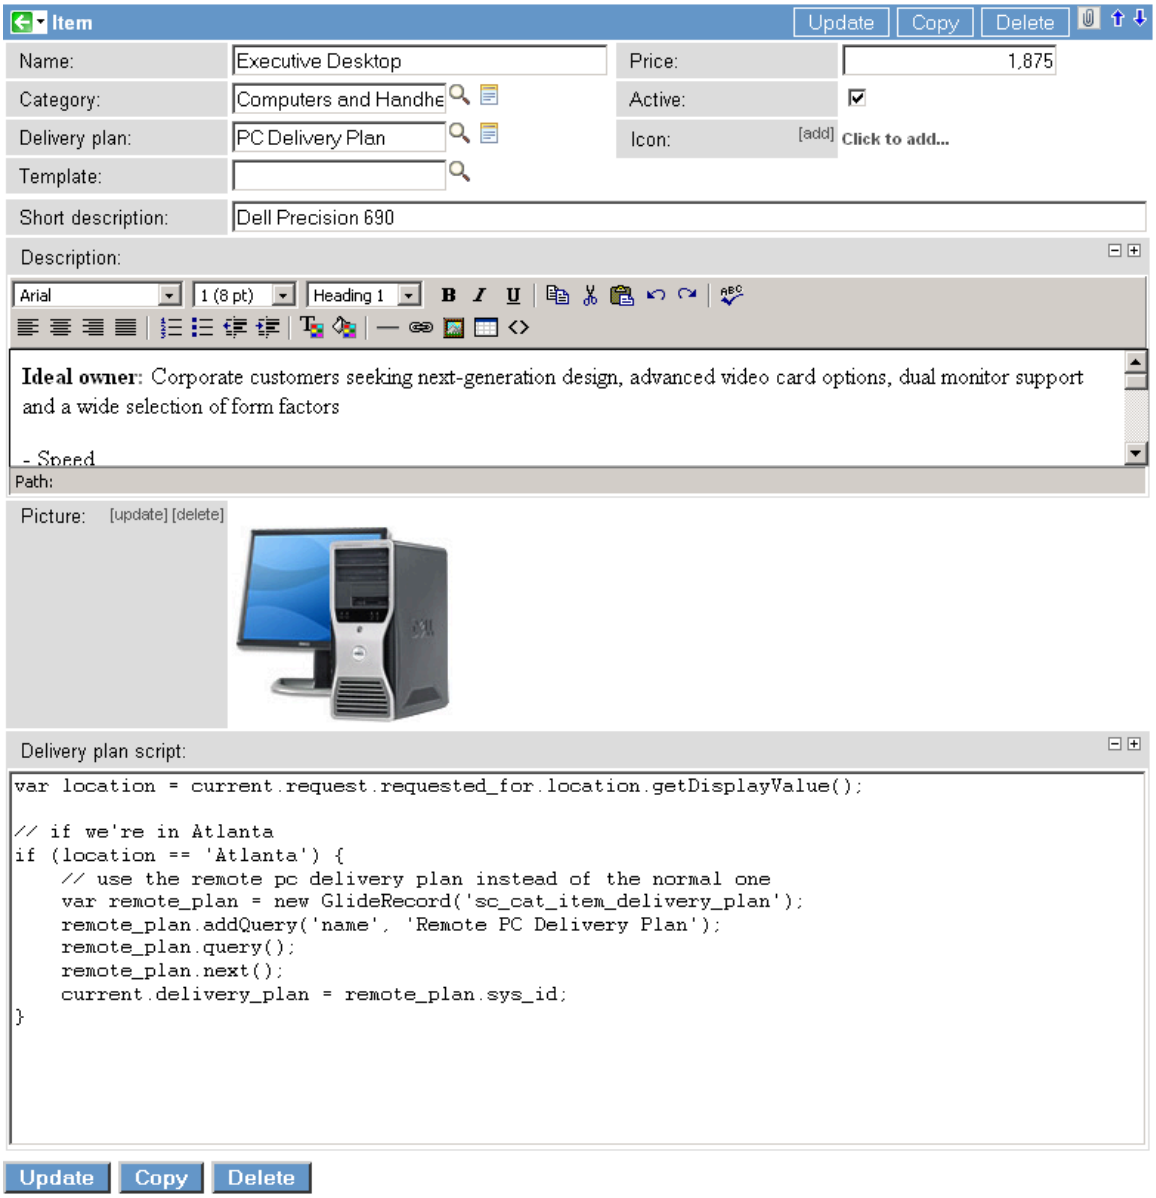
In this example, any time a request is for a user in Atlanta, ServiceNow uses the Remote PC Delivery Plan. Otherwise, the execution plan is not overridden and ServiceNow uses the catalog item's normal execution plan, the PC Delivery Plan.

Add a script to a catalog item

You can add a script to a catalog item so that the script runs each time a user requests that item.

Procedure

1. Navigate to **All** > **Service Catalog** > **Maintain Items**.
2. Select the relevant catalog item to which you wish to add the script.
3. Configure the catalog item form to add the execution plan script field, often named **Delivery Plan Script**.
4. Fill in the script details.



5. Update the item form with your changes.

Result

The script runs each time that item is requested, selecting the execution plan to run with that item.

Use a script to approve an execution plan

You can use an approval rule script to approve an execution plan.

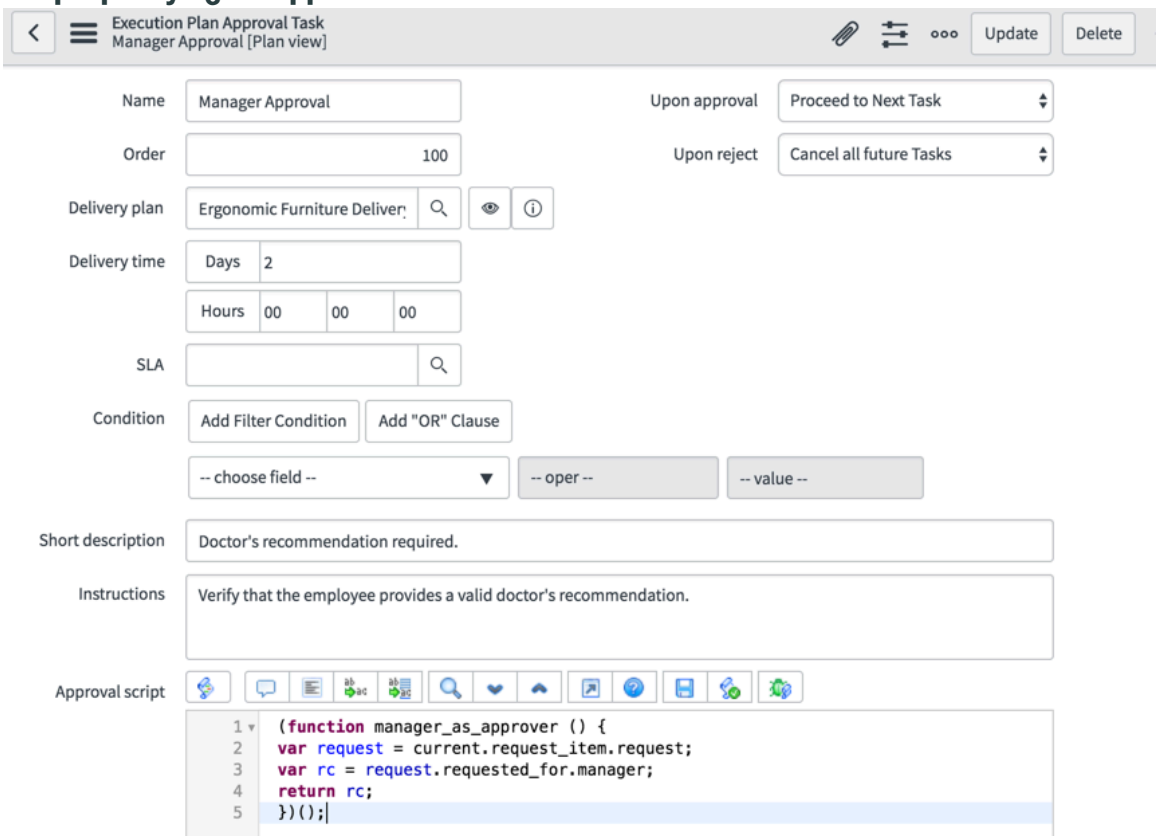
Procedure

1. Retrieve an approval execution plan task.
2. View the **Approval Script** field.
3. Fill in an approval script using the same syntax and rules you would use on an approval rule.

Example:

For example, in the script below, the requester's manager is the approver.

Script specifying the approver



Using regular expressions in server-side scripts

JavaScript regular expressions automatically use an enhanced regex engine, which provides improved performance and supports all behaviors of standard regular expressions as defined by Mozilla JavaScript. The enhanced regex engine supports using Java syntax in regular expressions.

The *SNC.Regex* API is not available for scoped applications. For scoped applications, remove the *SNC.Regex* API and use standard JavaScript regular expressions.

For more information on JavaScript regular expressions, see the Mozilla JavaScript documentation on regular expressions and RegExp.

Using Java syntax in JavaScript regular expressions

The enhanced regex engine includes an additional flag to allow Java syntax to be used in JavaScript regular expressions.

Regular expressions with the additional flag work in all places that expect a regular expression, such as `String.prototype.split` and `String.prototype.replace`. To use Java syntax in a regular expression, use the Java inline flag j, for example `/(?ims)ex(am)ple/j`

Extended regular expression flags

Flag	Description
j	Defines a regular expression that executes using the Java regular expression engine. It can be used to access Java-only features of regular expressions (such as look behind, negative look behind) or to use Java regular expressions without translating them into JavaScript regular expressions. For example: `var regex = /ex(am)ple/j;`

Convert SNC Regex expressions to enhanced regex expressions

When you upgrade to Eureka Patch 5 or later releases, you should convert scripts that use the *SNC.Regex* API to use regular JavaScript expressions.

Procedure

1. From the original expression, such as: `SNC.Regex("/expr/is");`, create a new regular expression object using the pattern with the slashes stripped.

   Example

   ```
   new RegExp('expr');
   ```

2. Move the *SNC.Regex* flags to the start of the expression using Java's inline flag special construct.

   Example

   ```
   new RegExp('(?is)expr');
   ```

3. Add the *j* flag to the `RegExp` to tell the engine to treat the expression as a Java expression.

   Note:
   If you know that the script being converted does not use Java syntax, it is not necessary to use the *j* flag.

   Example

   ```
   new RegExp('(?is)expr', 'j');
   ```

4. Add the *g* flag to handle multiple matches or a global replace.

   Example

   ```
   new RegExp('(?is)expr', 'jg');
   ```

Example:

Using SNC.Regex:

```
var r = new SNC.Regex('/world/');
var str = 'helloworld';
var replaced = r.replaceAll(str, 'there');
// replaced == 'hellothere'
```

Using a JavaScript regular expression:

```
var r = new RegExp('world', 'jg');
var str = 'helloworld';
var replaced = str.replace(r, 'there');
// replaced == 'hellothere'
```

Scriptable service catalog variables

You can use scripting to reference any request item variable from a table in scoped and non-scoped environment.

An example of a variable reference follows.

```
current.variables.<variable_name>
```

Where current refers to the current record, and *<variable_name>* is the name of your variable.

Note:
In order to reference a variable from JavaScript, it must have a name.

When a variable is part of a variable set, you can reference it as current.variables.<variable_name> or current.variables.<variable_set_name>.<variable_name>.

Variable set is also a first-class citizen in Service Catalog. Like variables, a variable set has read, write, and create roles. If roles are provided for a variable set, the roles are applicable for the variables within the set. Roles of an individual variable are overridden by the roles of the variable set.

Print a variable

```
var original = current.variables.original_number;
gs.print(original);
```

Set a variable

```
current.variables.name = "Auto-Generated:" +
 current.variables.asset_tag;
```

Create an inventory item with fields set from variables

```
doCreation();

function doCreation ( ) {
var create = current.variables.create_item;
if (create == 'true') { // we want to create an asset
  var computer = new GlideRecord('cmdb_ci_computer');
  computer.initialize();
  computer.asset_tag = current.variables.asset_tag;
  computer.serial_number = current.variables.serial_number;
  computer.name = current.variables.name;
  computer.manufacturer = current.variables.company;
  computer.insert(); } }
```

Get GlideElementVariable of variables and variable sets associated with a GlideRecord

```
now_GR.variables
```

Get the name value pair of variables associated with a GlideRecord

```
now_GR.variables.getVariableValue();
```

Get a list of GlideElementVariable for variables within a task record

```
now_GR.variables.getElements();
```

Get a list of GlideElementVariable for variables (including multi-row variable set) within a task record

```
now_GR.variables.getElements(true);
```

Note:
The `getElements()` method returns all the variables present on the given task record except for the formatter variables like label, break, container end, container split, and so on.

APIs for GlideElementVariable

- `now_GR.variables.<var_name>.isMultiRow()`: Get whether the GlideElementVariable is a multi-row variable set or a variable.
- `now_GR.variables.<var_name>.getQuestion()`: Get the Question object for a variable. Applicable only for a variable (`isMultiRow()` is false) and not for a multi-row variable set.
- `now_GR.variables.<var_name>.getLabel()`: Get the label of the GlideElementVariable. For a variable, the label of the variable is returned. For multi-row variable set, the title of the variable set is returned.
- `now_GR.variables.<var_name>.canRead()`: Get whether the user can view a variable or multi-row variable set.
- `now_GR.variables.<var_name>.canWrite()`: Get whether the user can edit a variable or multi-row variable set.
- `now_GR.variables.<var_name>.getDecryptedValue()`: Get the decrypted value for a masked variable. Applicable only for a masked variable.
- `now_GR.variables.<var_name>.getRows()`: Get the list of row objects for a multi-row variable set. Applicable only for a multi-row variable set (`isMultiRow()` is true).
- `now_GR.variables.<var_name>.getRowCount()`: Get the number of rows for multi-row variable set. Applicable only for a multi-row variable set (`isMultiRow()` is true).

Example to access variables of GlideRecord for the Task table

```
var now_GR = new GlideRecord('sc_req_item');
if (now_GR.get('635a1f538732030Oe0ef0cf888cb0b73')) {
    var variables = now_GR.variables.getElements();
    for (var i=0;i<variables.length;i++) {
        var question = variables[i].getQuestion();
        gs.log(question.getLabel() + ":" + question.getValue())
    }
}
```

Example to access a multi-row variable set of GlideRecord for the Task table

```
var now_GR = new GlideRecord('sc_req_item');
now_GR.get('02c38dcd87013300e0ef0cf888cb0bb2');

var vars = now_GR.variables.getElements(true);

for (var i=0; i<vars.length; i++) {
    var now_V = vars[i];
    if (now_V.isMultiRow()) {
        var rows = now_V.getRows();
        for (var j=0; j<now_V.getRowCount(); j++) {
            var row = rows[j];
            var cells = row.getCells();
            for (var k=0; k<cells.length; k++) {
                var cell = cells[k];
```

```
                gs.info(cell.getLabel() + ":" +
 cell.getCellDisplayValue())
            }
        }
    }
}
```

Multi-row variable set

Multi-row variable set

Operation	Usage
Table operations	
Return JSON array value as String	`now_GR.variables.table_var`
Set value of a multi-row variable set	`now_GR.variables.table_var = <val>` **Note:** An array of ordered (key, value) pairs is also applicable as input.
Get value of column, var1, of a multi-row variable set	`now_GR.variables.table_var.var1`
Set value of a variable set, var1	`now_GR.variables.table_var.var1 = <val>` **Note:** An array of ordered (key, value) pairs is also applicable as input.
Row operations	
Get the current row count	`now_GR.variables.table_var.getRowCount()`
Returns the row specified by the variable "i" - getRow(<int> i)	`var row = now_GR.variables.table_var.getRow(<int> i);`
Get the cell value for a question column mapped to <var_name>	`row.<var_name>`
Set the cell value for a question column mapped to <var_name>	`row.setCellValue('<var_name>', value)`
Set the cell value for a question column mapped to <var_name>	`row.<var_name> = value`

Multi-row variable set (continued)

Operation	Usage
Add an empty row at the end of the table and return a scriptable object	`var row = now_GR.variables.table_var.addRow()`
Delete a row	`row.deleteRow()`

Notes and limitations

- //Single column of table_Var
- now_GR.variables.table_var.var1
- now_GR.variables.table_var.var1 = <val>

1. You can only set a variable in a before business rule. Variables set in an after rule are not written to the database.
2. There is nothing in place to prevent namespace collision with variables. Creating two variables named computer_speed would result in only one of them showing up; the second one would overwrite the first one.
3. Date/time variables use the same time zone formatting and storage rules as all other dates in the system. They are stored internally in GMT, but translated into the user's local time zone and format for display.

Setting a GlideRecord variable to 'NULL'

GlideRecord variables (including current) are initially null in the database. Setting these back to an empty string, a space, or the JavaScript null value will not result in a return to this initial state.

Note:
This functionality requires a knowledge of JavaScript.

To set it back to the initial state, simply set the value to 'NULL'. Note that the *update()* function does not run on the current object but rather on the record. The object displays the initial value until it is called again from the record.

Note:
Functionality described here requires the **Admin** role.

Example 1

```
var grIncident = new GlideRecord('incident');
grIncident.addNotNullQuery("assigned_to");
grIncident.query();
if (grIncident.next()) {
  gs.log(“The incident record that is going to be updated is “ +
 grIncident.number);
  gs.log("Previous Value of 'Assigned To' field: " +
 grIncident.assigned_to);
  grIncident.assigned_to = "NULL";
  grIncident.update();
```

```
  gs.log("Current Value of 'Assigned To' field: " +
 grIncident.assigned_to);
}
```

Example 2 (Business Rule)

```
current.u_affected_value = 'NULL';
current.update();
```

Schedule Pages

A schedule page is a record that contains a collection of scripts that allow for custom generation of a calendar or timeline display.

Creation of timeline schedule pages requires understanding of the page/event flow and the ability to write client and server side JavaScript.

Schedule pages form

To access schedule pages, navigate to **System Scheduler** > **Schedules** > **Schedule Pages**.

The form provides the following fields, depending upon the *View Type* selected:

Schedule pages form

Field	Field Type	Description
Name	String	General name that is used to identity the current schedule page.
Schedule type	String	The schedule type is a string that is used to uniquely identity the schedule page via the "sy URI parameter. For example, a schedule page could be accessed as follows: `/show_schedule_page.do?sysparm_type=gantt_chart&sysparm_timeline_task_id=d530bf907f0` Alternatively, the schedule page can also be accessed by setting the "*sysparm_page_* of the unique 32 character hexadecimal system identifier of the schedule page.
View Type	Choice	Each view type displays different field combinations. There are two options available: • Calendars • Timelines
Description	String	General description that provides additional information about the current schedule page.
Init funciton name	String	**Note:** This functionality is only used by *Calendar* type schedule pages. The init function name specifies the name of the JavaScript function to call inside the *Clie* type schedule pages.
HTML	String	**Note:** This functionality is only used by *Calendar* type schedule pages. The HTML field is a scriptable section that is parsed by Jelly and injected into the display p calendar. It can be used to pass in variables from the server and define extra fields are nec

Schedule pages form (continued)

Field	Field Type	Description
Client script	String	The client script is a scriptable section that allows for configuring options of the schedule different depending on the schedule page view type and is discussed below.
Server AJAX processor	String	**Note:** This functionality is only used by *Calendar* type schedule pages. The Server AJAX processor is specific to calendar type schedule pages that is used to retu and spans to be displayed.

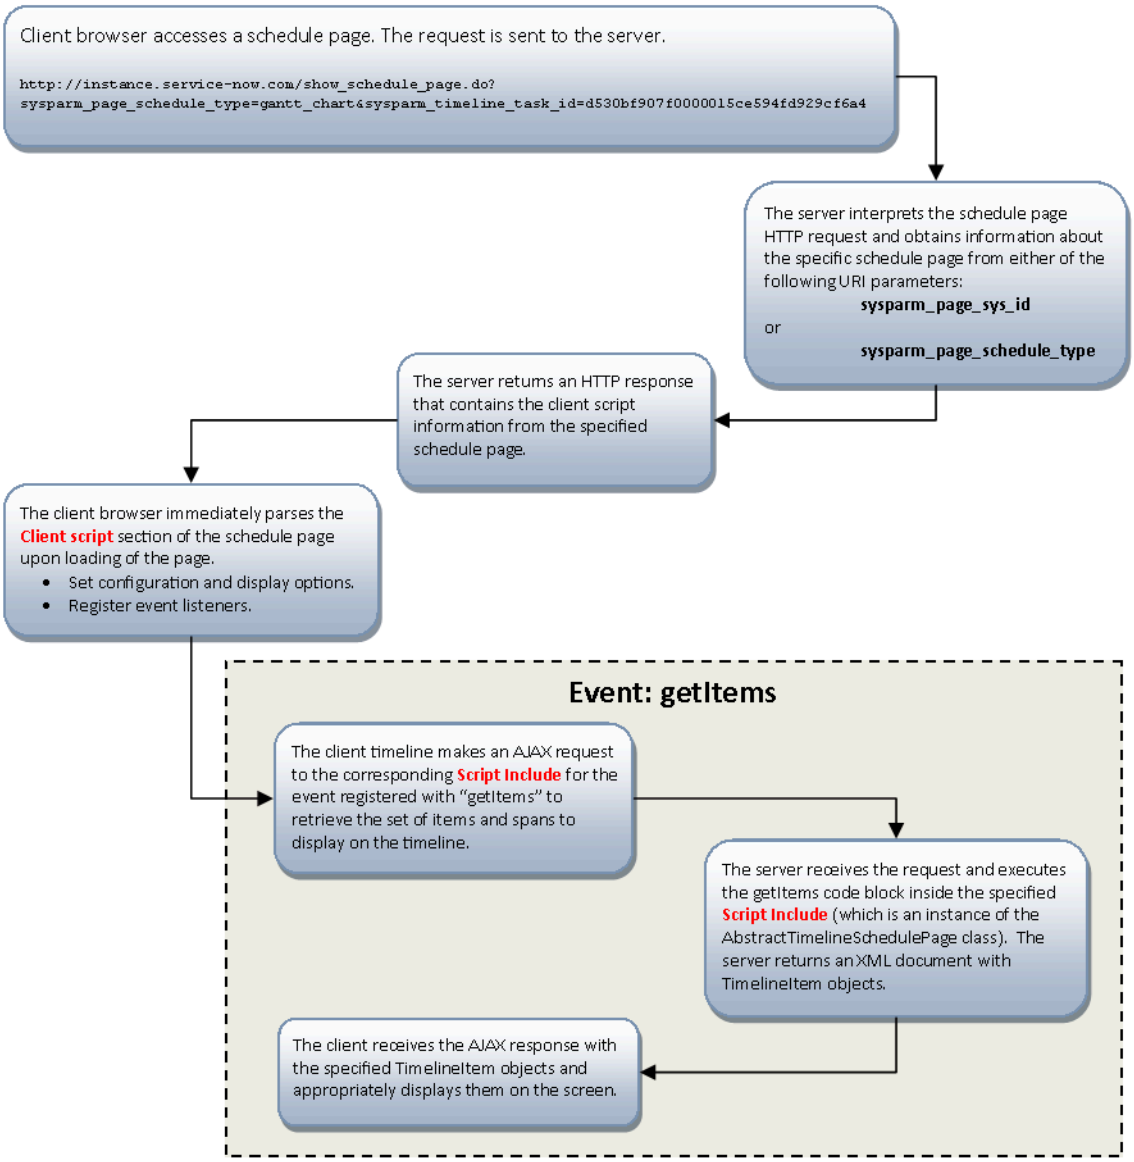
Timeline schedule pages

A Timeline Schedule Page is a specific record that contains configuration information for displaying time based points and spans in a "timeline" like fashion.

The timeline schedule page references a script include that extends from AbstractTimelineSchedulePage to perform dynamic modification to the timeline based on different events and conditions. Both the schedule page and the script include for timeline generation allow for extreme customization and their corresponding application programming interface (API) is documented below.

The following diagram shows the series of events that occur when a timeline schedule page is accessed. Once the timeline has been loaded, all subsequent events, such as events resulting from timeline interaction (e.g. moving a timeline span), follow the same logic flow shown in the gray event box.

Timeline Flow



Applications that use schedule pages to generate time lines

- Project Management
- Maintenance Schedules
- Group On-Call Rotation
- Field Service Management

Timeline schedule page example

The following example demonstrates how to create a timeline schedule page with corresponding script include utilizing a majority of the API described above.

For this example we are going to create an Incident Summary Timeline for a project support manager to visualize all of the new incidents. All new incidents should be displayed as single points where the priority of the incident is distinguished by a different point icon. Additionally, all closed incidents should be displayed on the timeline in a separate group that shows the duration of the incident before it was closed. Since the Project Manager wants to be able to easily close

new items that are resolved without using any form lists, we will handle the vertical move event allowing the new incidents to be dragged into the closed incident group or items within.

Schedule Page

Create a new schedule page with the following properties:

- **Name**: Hardware Incidents
- **Schedule type**: incident_timeline
- **View Type**: Timeline
- **Client Script**:

```
// Set our page configuration
glideTimeline.setReadOnly(false);
glideTimeline.showLeftPane(true);
glideTimeline.showLeftPaneAsTree(true);
glideTimeline.showTimelineText(true);
glideTimeline.showDependencyLines(false);
glideTimeline.groupByParent(true);
glideTimeline.setDefaultPointIconClass('milestone');

// We will define what items to display and provide a custom
 event handler for moving new items to the closed state
glideTimeline.registerEvent('getItems',
 'IncidentTimelineScriptInclude');
glideTimeline.registerEvent('elementMoveY',
 'IncidentTimelineScriptInclude');
```

Script Include

Now that the schedule page has been created we need to generate a matching script include for the events that were registered. Create a new script include with the following properties:

- **Name**: IncidentTimelineScriptInclude
- **Active**: Checked
- **Glide AJAX enabled**: Checked
- **Script**:

```
// Class Imports

var IncidentTimelineScriptInclude = Class.create();
IncidentTimelineScriptInclude.prototype =
 Object.extendsObject(AbstractTimelineSchedulePage, {

  ////////////////////// //
 GET_ITEMS ////////////////////////////////////
  getItems:function() {
    // Specify the page title
    this.setPageTitle('My Custom Incident Summary Timeline');

    var groupNew = new GlideTimelineItem('new');
    groupNew.setLeftLabelText('New Incidents');
    groupNew.setImage('../images/icons/all.gifx');
    groupNew.setTextBold(true);
```

```
   this.add(groupNew);

   var groupClosed = new GlideTimelineItem('closed');
   groupClosed.setLeftLabelText('Closed Incidents');
   groupClosed.setImage('../images/icons/all.gifx');
   groupClosed.setTextBold(true);
   groupClosed.setIsDroppable(true);

   // This allows us to drag an open incident onto the closed
group row.
   this.add(groupClosed);

   // Get all the incidents and let's add only the new/closed
ones appropriately
   var now_GR = new GlideRecord('incident');
   gr.query();
   while(gr.next()) {
      // Only loop through new/closed incidents
      if(gr.incident_state != '1' && gr.incident_state != '7')
continue;

      // Ok, we have a new/closed incident. Create the item and
the span first.
      var item = new GlideTimelineItem(gr.getTableName(),
gr.sys_id);
      var span = item.createTimelineSpan(gr.getTableName(),
gr.sys_id);

      // Specific properties for a new incident
      if(gr.incident_state == '1') { // New
        item.setParent(groupNew.getSysId());
        item.setImage('../images/icons/open.gifx');

span.setTimeSpan(gr.getElement('opened_at').getGlideObject().ge
tNumericValue(),

gr.getElement('opened_at').getGlideObject().getNumericValue());

        // We will show different colors based upon the
priorities only for new incidents
        switch(gr.getElement('priority').toString()) {
          case '1': span.setPointIconClass('red_circle');
break;
          case '2': span.setPointIconClass('red_square');
break;
          case '3': span.setPointIconClass('blue_circle');
break;
          case '4': span.setPointIconClass('blue_square');
break;
          case '5': span.setPointIconClass('sepia_circle');
break;
          default: // Otherwise, the default point icon class
will be used (Milestone)
         }
        }
       // Specific properties for a closed incident
       else if(gr.incident_state == '7') {
```

```
          item.setParent(groupClosed.getSysId());
          item.setImage('../images/icons/closed.gifx');

 span.setTimeSpan(gr.getElement('opened_at').getGlideObject().ge
tNumericValue(),

 gr.getElement('closed_at').getGlideObject().getNumericValue()
); }

        // Common item properties
        item.setLeftLabelText(gr.short_description);

        // Common span properties
        span.setSpanText(gr.short_description);
        span.setTooltip('<strong>' +
 GlideStringUtil.escapeHTML(gr.short_description) +
 '</strong><br>' + gr.number);
        span.setAllowXMove(false);
        span.setAllowYMove(gr.canWrite() ? true:false);
        span.setAllowYMovePredecessor(false);
        span.setAllowXDragLeft(false);
        span.setAllowXDragRight(false);

        // Now we add the actual item
        this.add(item);
        } } ,

   ////////////////////////// //
 ELEMENT_MOVE_Y //
////////////////////////////////////////////////////////////

   /**
   * This is one of the AbstractTimelineSchedulePage event
 handler methods that corresponds to a vertical
   * move. The arguments for this function are defined in the
 API section of the event handler methods.
   */
  elementMoveY: function(spanId, itemId, newItemId) {

    // Get information about the current incident
    var now_GR = new GlideRecord('incident');
    gr.addQuery('sys_id', spanId);
    gr.query();
    if(!gr.next())
      return this.setStatusError('Error', 'Unable to lookup the
 current incident.');

    // Only allow the new incidents to have their state
 adjusted.
    if(gr.incident_state != '1')
      return this.setStatusError('Error','Only new incidents can
 have their state adjusted.');

    // Get information about the dropped GlideTimelineItem. If
 it was dropped in an item on the "New Incidents"
```

```
   // group let's do nothing. If it was dropped in the "Closed
Incidents" then let's adjust the state automatically.
   var grDropped = new GlideRecord('incident');
   grDropped.addQuery('sys_id', newItemId );
   grDropped.query();
   if(!grDropped.next() || grDropped.incident_state == '7') {
      // This means the dropped item was either the 'Closed
Incidents' group (which has no record or sys_id) or an
      // existing incident that is closed. The 'New Incidents'
also has no sys_id; however, the default behavior for
      // items without a sysId is to be non-droppable. This is
why we explicitly denoted the 'Closed Incidents' to
      // be marked as "droppable".

      // Return a dialog prompt
      this.setStatusPrompt('Confirm', 'Are you sure you want to
close: ' +
            '<div style="margin:10px 0 10px
14px;padding:4px;background-color:#EBEBEB;"><strong>' +
             GlideStringUtil.escapeHTML(gr.short_description)
+
             '</strong><br/><div class="font_smaller">' +
now_GR. number + '</div></div>',
             'this._elementMoveYHandler_DoClose', // This
function is for when the OK button is clicked.
             'this._elementMoveYHandler_DoNothing', // This
function is for when the Cancel button is clicked.
             'this._elementMoveYHandler_DoNothing'); // This
function is for when the Close button is clicked.
      } } ,

 _elementMoveYHandler_DoClose: function(spanId, itemId,
newItemId) {
   // Notice that this function takes the same function
arguments as the original function for which it
   // is a custom event handler for.

   // Update the database record from 'New' to 'Closed'.
   var now_GR = new GlideRecord('incident');
   gr.addQuery('sys_id', spanId);
   gr.query();
   gr.next();
   gr.setValue('incident_state', '7');
   gr.update();

   // This will re-render the timeline showing the updated item
in the closed group.
   this.setDoReRenderTimeline(true);

   // Let's show a success message
   this.setStatusSuccess('Success', '<strong>' +
gr.short_description + '</strong> was successfully
closed.'); } ,

 // Since the user clicked cancel or close we simply do
nothing.
```

```
 _elementMoveYHandler_DoNothing: function(spanId, itemId,
newItemId) { }

});
```

Screenshots / Results

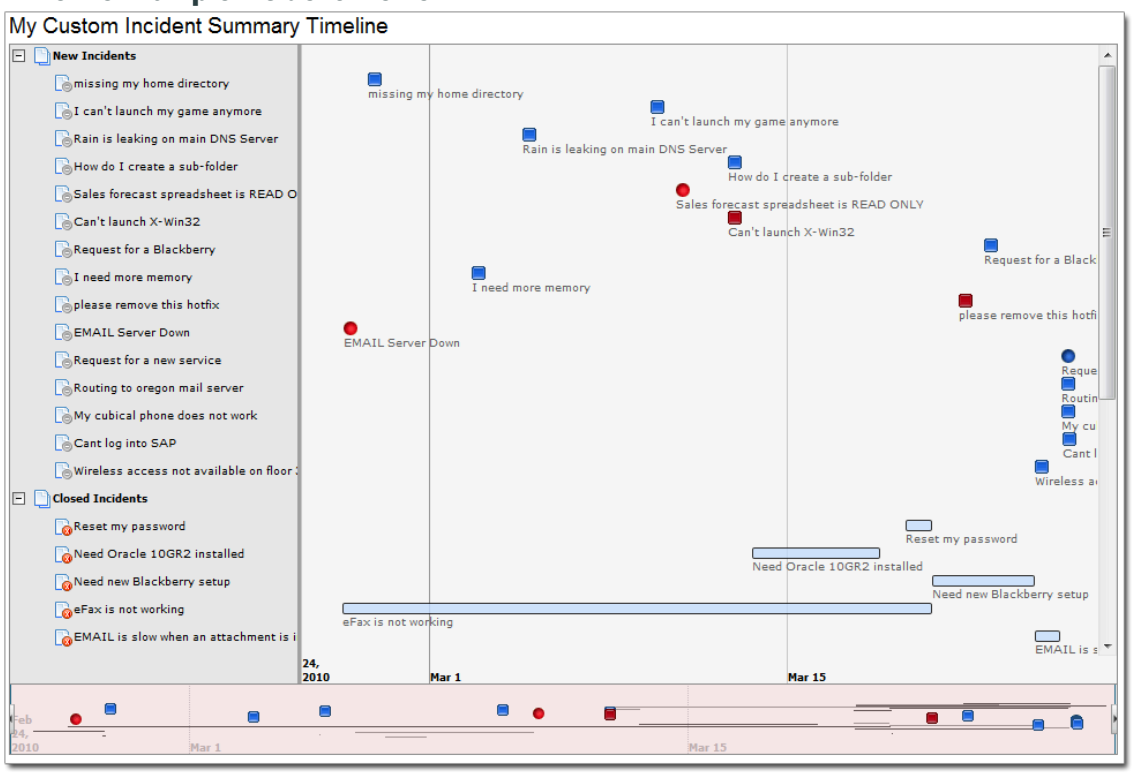
1. Navigate to:

   ```
   http://[YOURINSTANCE]:8080/show_schedule_page.do?
   sysparm_page_schedule_type=incident_timeline
   ```

   Notice the bold text is the value of the schedule page **Schedule type** field.

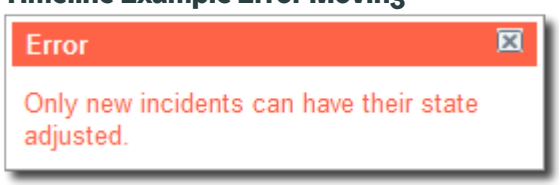
2. The page displays a timeline as specified by the schedule page and script include created. A link to this page can be created and placed as a module or UI action as necessary.

Timeline Example Incident Preview



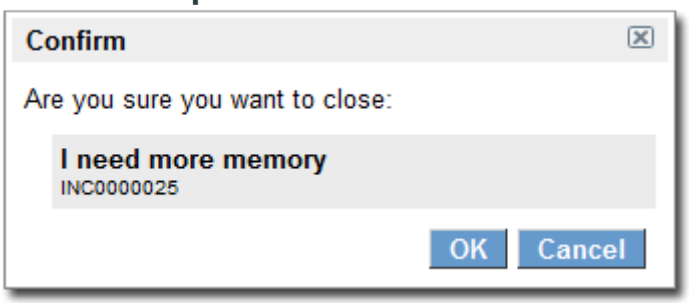
3. Attempting to move a closed incident anywhere displays the expected error message.

Timeline Example Error Moving



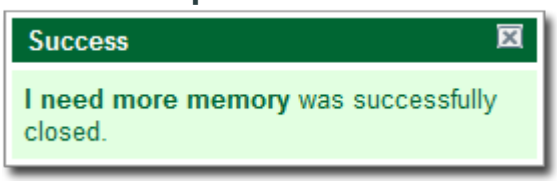
4. Moving the incident: *I need more memory* displays the following confirmation box.

Timeline Example Confirm Close



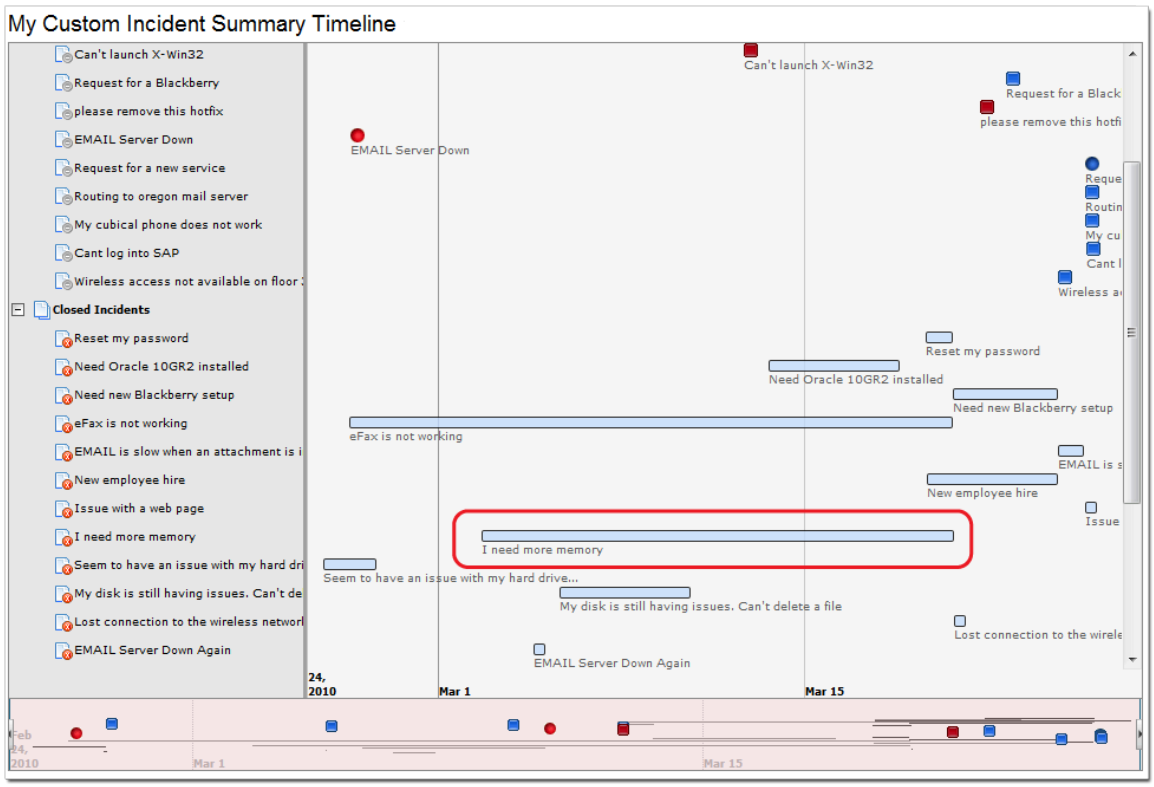
5. Clicking the **Cancel** button closes the overlay. Clicking the **OK** button actually updates the incident_state of the record and then displays the following success box.

Timeline Example Close Success



6. After clicking **OK**, it is clear the incident is now listed in the **Closed Incidents** group.

Timeline Example Incident Updated



XMLDocument script object

A JavaScript object wrapper for parsing and extracting XML data from an XML document (String).

Use this Javascript class to instantiate an object from an XML string, usually a return value from a Web Service invocation, or the XML payload of ECC Queue. Using the XMLDocument object in a Javascript business rule lets you query values from the XML elements and attributes directly.

Constructor

The constructor of a script object creates a new instance of the object to be used.

```
var xmlString = "<test>" +
                "  <one>" +
                "    <two att=\"xxx\">abcd1234</two>" +
                "    <three boo=\"yah\"
 att=\"yyy\">1234abcd</three>" +
                "    <two>another</two>" +
                "  </one>" +
                "  <number>1234</number>" +
                "</test>";

var xmldoc = new XMLDocument(xmlString);
```

To perform XML parsing of an XML string that is name space qualified, specify "true" for the second argument for the XMLDocument constructor. The following is an example of parsing and XML string that contains name space qualification of its elements.

```
var xmlString = "<bk:book xmlns:bk='urn:loc.gov:books'
 xmlns:isbn='urn:ISBN:0-395-36341-6'>" +
                  "<bk:title>Cheaper by the Dozen</bk:title>" +
                  "<isbn:number>1568491379</isbn:number>" +
                "</bk:book>";

var xmldoc = new XMLDocument(xmlString, true); // XML document
 is name space aware
```

Locating nodes and elements

Now that we have the XMLDocument object, we can call the following APIs to locate nodes and elements of the XML document, as well as extract text from it directly. The query syntax for locating nodes and attributes is based on XPath.

Note:
XML parsing with this object is not namespace aware, this means that if you are locating a node name with namespace in it eg. "<names:myelement> ...", the XPath search string would be "//myelement"

The following are examples of locating a node by its XPath and getting the text value out of the resulting node.

```
var str = xmldoc.getNodeText("//two"); // returns the first
 occurrence of the node
// str == "abcd1234"

str = xmldoc.getNodeText("//three");
// str == "1234abcd"

str = xmldoc.getNodeText("/test/one/*");
// str == "abcd1234"

str = xmldoc.getNodeInt("//number");
// str == 1234
```

The following examples locates the node by XPath and uses the API on node and element to get attributes and value.

```
var node = xmldoc.getNode("/test/one/two");
// node.getNodeName() == "two"
// node.getNodeType() == "1" // 1 == ELEMENT_NODE
// node.getLastChild().getNodeType() == "3" // 3 == TEXT_NODE
// node.getLastChild().getNodeValue() == "abcd1234"
```

Or you can use the following convenience functions to get the node name and type

```
str = xmldoc.getNodeName("//three");
// str == "three"

str = xmldoc.getNodeType("//three");
// str == "1"
```

You can also get a list of nodes that you can iterate or access directly by position

```
var nodelist = xmldoc.getNodes("//one/*"); // two, three, and
 two
// nodelist.getLength() == "3"
// nodelist.item(0).getNodeName() == "two"
// nodelist.item(1).getNodeName() == "three"
```

The following is an example of parsing an XML string that is qualifed with name spaces.

```
var xmlString = "<bk:book xmlns:bk='urn:loc.gov:books'
 xmlns:isbn='urn:ISBN:0-395-36341-6'>" +
                 "<bk:title>Cheaper by the Dozen</bk:title>" +
                 "<isbn:number>1568491379</isbn:number>" +
               "</bk:book>";

var xmldoc = new XMLDocument(xmlString, true);
var str = xmldoc.getNodeText("//bk:title"); // returns the first
 occurence of the node
gs.log(str);

str = xmldoc.getNodeText("/bk:book/*");
gs.log(str);

str = xmldoc.getNodeInt("//isbn:number");
gs.log(str);
```

Getting attribute values

An attribute is just an extension of a node and so it has all the same APIs.

The following example shows how to query for a node to get its attribute by position

```
node = xmldoc.getNode("//two");
// node.getAttributes().item(0).getNodeValue() == "xxx"

str = xmldoc.getAttribute("//two", "att");
// str == "xxx"
```

XPath also has a query syntax for locating the attribute node directly, for example

```
str = xmldoc.getNodeText("//*[@att=\"yyy\"]");
// str == "1234abcd"

str = xmldoc.getNode("//@boo").getNodeValue();
```

```
// str == "yah"
```

Creating new elements

An XML element can be created at any level of the XML document once it has been created. Use the *setCurrent* function to position where the new element will be created as a child element, and use the *createElement* function to create the element.

```
var xmlString = "<test>" +
                "  <one>" +
                "    <two att=\"xxx\">abcd1234</two>" +
                "    <three boo=\"yah\"
 att=\"yyy\">1234abcd</three>" +
                "    <two>another</two>" +
                "  </one>" +
                "  <number>1234</number>" +
                "</test>";

var xmldoc = new XMLDocument(xmlString);
xmldoc.createElement("new", "test"); // creates the new element
 at the document element level if setCurrent is never called
xmldoc.createElement("new2"); // calling without a value will
 create a new element by itself

var el = xmldoc.createElement("new3");
xmldoc.setCurrent(el); // this is now the parent of any new
 elements created subsequently using createElement()
xmldoc.createElement("newChild", "test");
```

The resulting XML document looks like this

```
<test>
  <one>
    <two att="xxx">abcd1234</two>
    <three boo="yah" att="yyy">1234abcd</three>
    <two>another</two>
  </one>
  <number>1234</number>
  <new>test<new>
  <new2/>
  <new3>
      <newChild>test</newChild>
  </new3>
</test>
```

XMLHelper

The XML helper script include makes it easy to parse XML in scripts.

Use the following methods to export XML to JSON, or JSON to XML.

- The `toObject()` method returns the XML elements as JSON properties. This method works properly whether the supplied parameter is an XML document or an XML string. This method has an optional parameter of the XML input for conversion as an alternative to specifying the XML input in the constructor.
- The `toXMLDoc()` method returns JSON provided as XML elements.

Note:
You must escape ampersand characters (&amp) in your XML or the conversion silently fails.

Example

The following example shows how to convert an XML document into JSON and uses a recursive function to output each member. The recursive function helps indicate how the XML document structure is rendered as JSON.

```
var xmlString = "<company>" + "<employee>" + "<id>10</id>"
 + "<firstname>Tom</firstname>" + "<lastname>Cruise</lastname>"
 + "<test>test1</test>"
 + "<test>test3</test>" + "</employee>" + "<employee>" +
 "<id>20</id>" + "<firstname>Paul</firstname>"
 + "<lastname>Enderson</lastname>" + "<test>test6</test>" +
 "<test>test5</test>" + "</employee>" + "<employee>"
 + "<id>30</id>" + "<firstname>Paul</firstname>" +
 "<lastname>Bush</lastname>" + "<test>test2</test>"
 + "<test>test4</test>" + "</employee>" + "</company>";
var helper = new XMLHelper(xmlString);
var obj = helper.toObject();
logObj(obj, "*");

function logObj(obj, sep) {
  for (x in obj) {
    if (typeof obj[x] != "function") {
      gs.log(sep + x + ":: " + obj[x]);
    }
    logObj(obj[x], sep + "*");
  }
}
```

Output:

```
*** Script: *employee:: [object Object],[object Object],[object
 Object]
*** Script: **2:: [object Object]
*** Script: ***id:: 30
*** Script: ***test:: test2,test4
*** Script: ****0:: test2
*** Script: ****1:: test4
*** Script: ***firstname:: Paul
*** Script: ***lastname:: Bush
*** Script: **0:: [object Object]
*** Script: ***id:: 10
*** Script: ***test:: test1,test3
*** Script: ****0:: test1
*** Script: ****1:: test3
*** Script: ***firstname:: Tom
*** Script: ***lastname:: Cruise
*** Script: **1:: [object Object]
*** Script: ***id:: 20
*** Script: ***test:: test6,test5
*** Script: ****0:: test6
*** Script: ****1:: test5
*** Script: ***firstname:: Paul
*** Script: ***lastname:: Enderson
```

JavaScript engine on the platform

The JavaScript engine that evaluates server-side scripts supports the ECMAScript 2021 (ES12) standard.

No plugins or properties are required to install the new JavaScript engine.

The benefits of the new engine are:

- Modern library code and scripting features, such as optional chaining, destructuring, const and let declarations, and arrow functions
- Follows standard ECMAScript 2021 behavior

What to know

The JavaScript engine provides an improved environment for developing scripts.

- Beginning with the Xanadu release, when you create new scripts, ECMAScript 2021 (ES12) mode is turned on by default regardless of the JavaScript mode configured for the application.
- Beginning with the Tokyo release, new and existing scoped applications can run in ECMAScript 2021 (ES12) mode.
- Compatibility mode supports the legacy modifications to the legacy JavaScript engine.
- Legacy code continues to work.

You configure the mode that the JavaScript engine uses in the design and runtime settings for applications. Available modes are ECMAScript 2021 (ES12), ES5 Standards, and Compatibility.

Related topics

Update a custom application record

JavaScript modes

JavaScript mode is a design and runtime setting for custom applications and scripts. To support existing server-side scripts and new scripts developed to the ECMAScript 2021 standard, the JavaScript engine has three modes: ECMAScript 2021 (ES12), ES5 Standards, and Compatibility.

The JavaScript mode controls which JavaScript features you have access to in an application or script. The default mode for new scoped applications is ECMAScript 2021 (ES12) and for new global applications, it's ES5 Standards. You can also turn on ECMAScript 2021 (ES12) mode for individual scripts in applications that use ES5 Standards or Compatibility mode.

For more information about features supported by the ECMAScript 2021 (ES12) and ES5 Standards modes, see JavaScript engine feature support.

ECMAScript 2021 (ES12) mode

ECMAScript 2021 (ES12) mode is the default mode when you create new scoped applications. When you create new scripts, ECMAScript 2021 (ES12) mode is turned on by default regardless of the JavaScript mode configured for the application. This mode doesn't preserve the legacy behaviors in the pre-Tokyo JavaScript engine or work with global scripts.

ECMAScript 2021 (ES12) mode supports a subset of ECMAScript 2021 (ES12) and ECMAScript 2022 (ES13) syntax and features, including the following features:

- Default function parameters
- Rest parameters
- For-of loops

- Template literals
- Destructuring
  - Declarations
  - Assignment
  - Parameters
- Const declaration
- Let declaration
- Arrow functions
- Class declarations
- Map set
- Optional chaining operator `(?.)`

To learn about specific ECMAScript 2021 (ES12) features, see the Let's Learn ECMAScript 2021 videos on the ServiceNow Dev Program YouTube channel.

ES5 Standards mode

ES5 Standards mode is the default mode for global applications and is an option for scoped applications. This mode doesn't preserve the legacy behaviors in the pre-Helsinki JavaScript engine.

ES5 standards mode supports ECMAScript5 syntax and features, including the following features:

- The "use strict" declaration
- Control over extensibility of objects
- Get and set properties on objects (accessors)
- Control over writability, configurability, and enumerability of object properties
- New Array and Date methods
- Native JSON support
- Support for modern third-party libraries such as lodash.js and moment.js

Compatibility mode

Compatibility mode is used for all scripts developed prior to the addition of ES5 Standards mode. Compatibility mode has some differences from the previous JavaScript engine.

JSON support changes:

- `JSON.stringify()` and `JSON.parse()` are implemented using the ES5 Native JSON object.
- The new `JSON().encode()` and new `JSON().decode()` are still supported, but should only be used when the legacy behavior is required.

The use of third-party JavaScript libraries isn't supported in Compatibility mode.

Considerations for switching JavaScript modes

Switching the JavaScript mode for an application or script might change the behavior of existing scripts. Review some examples of behavior changes before switching JavaScript modes or to troubleshoot any issues that you experience after switching.

For more information about each JavaScript mode, see JavaScript modes and JavaScript engine feature support.

This table highlights how JavaScript behavior has evolved from the lenient and error-prone pre-ES5 environment, to the stricter and more predictable ES5, and lastly the more feature-rich environment of ES12 (ECMAScript 2021).

Behavioral differences in JavaScript modes

Feature	Compatibility Mode	ES5 Standards Mode	ECMAScript 2021 (ES12)
Arguments object	The `arguments` object exists, but there's no `strict mode`, so modifications reflect on `arguments`. Prints: `*** Script: [object Arguments]` `*** Script: [object Arguments]` `*** Script: [object Arguments]` `*** Script: 123`	In strict mode, the arguments object doesn't reflect parameter modifications and throws an error. Prints: `sn_es5: 123` `sn_es5: undefined` `sn_es5: [object Arguments]` `sn_es5: 123`	The same as ES5.
Boolean overrides	Primitive Booleans (`true`, `false`) can be overridden, causing unexpected behavior.	Primitive Booleans are more protected, though still can be overridden when assigned to variables.	The same as ES5, but strict mode helps prevent some assignments. The conditional expression should be written in this form: `(cond_expr instanceof Boolean ? cond_expr.valueOf() : cond_expr).`
Exception for syntax errors	Syntax errors throw exceptions at runtime. Error handling is inconsistent. Example: `Javascript compiler`	More consistent syntax error handling, especially in strict mode. Example: `Evaluator: com.glide.scr`	The same as ES5, but with more robust handling and clearer error messages in updated engines. Example:

Behavioral differences in JavaScript modes (continued)

Feature	Compatibility Mode	ES5 Standards Mode	ECMAScript 2021 (ES12)
	`exception: unterminated string literal (null.null.script; line 1) in: var b = '`	`ipt.RhinoEcmaError: unterminated string literal script : Line(1) column(9) ==> 1: var b = '`	`SyntaxError: Unterminated string constant at line 1 ==> 1: var b = '`
Increment and decrement	Allowed on variables but could behave unexpectedly with complex expressions. Prints: `*** Script: c: 1 *** Script: gr.related_incidents: 1 *** Script: 2 *** Script: 3`	Improved clarity, but still allowed on variables (`var`, `let`, `const`). Prints: `sn_es5: c: 0 sn_es5: gr.related_incidents: 1 sn_es5: 1 sn_es5: 2`	The same as ES5, with stricter rules in some contexts (for example, `const`).
Line continuations	Allowed with a backslash (\) but discouraged due to readability issues. In this example, all three functions are called. `var expr = doFoo(); // do foo doBar(); // do bar finish(); // all done eval(expr);`	Same as Compatibility mode; no change in handling line continuations. In the previous example, ES5 only calls the first function and treats everything after the first comment including the newline as comment until the expression end.	The same as ES5, but template literals provide a more readable alternative.
Missing semicolons	Automatic semicolon insertion (ASI) often led to unexpected behavior.	Throws a syntax error when a semicolon is missing.	The same as ES5. Updated practices encourage explicit semicolons.
Non-existent functions	Calling a non-existent function throws a `ReferenceError`.	Throws a `TypeError` if a non-function is called.	Throws an EcmaError when a non-existent function is called

Behavioral differences in JavaScript modes (continued)

Feature	Compatibility Mode	ES5 Standards Mode	ECMAScript 2021 (ES12)
			or a property is referenced.
Non-existent properties	Accessing a non-existent property returns `undefined`; no error thrown.	Same as pre-ES5.	The same as Compatibility mode and ES5 Standards mode.
Numeric literals	Basic decimal and hexadecimal literals.	Introduced stricter parsing rules and better handling of numeric literals.	Added binary (`0b`), octal (`0o`), and BigInt literals (`123n`).
Reserved keyword as property	Using reserved keywords isn't possible.	Reserved keywords can be used as property names without error, for example, `obj.for`. Prints the object when returned.	The same as ES5.
Treat let and yield as keywords	`let` and `yield` aren't keywords and can be used as identifiers only.	`let` is introduced as a keyword. `yield` is reserved in strict mode.	Both are keywords. Using them as identifiers throws syntax errors.

Set the JavaScript mode for an application

Configure which ECMAScript features can be used in an application by selecting the JavaScript mode.

Before you begin

Role required: delegated developer role granting full access or admin

About this task

The JavaScript mode is a design and runtime setting for custom applications and scripts. To support existing server-side scripts and new scripts developed to the ECMAScript 2021 standard, the JavaScript engine has three modes: ECMAScript 2021 (ES12), ES5 Standards, and Compatibility. For more information about each mode, see JavaScript modes.

For applications that use ES5 Standards or Compatibility mode, you can also turn on ECMAScript 2021 (ES12) for individual scripts in the application. For more information, see Turn on ECMAScript 2021 (ES12) mode for a script.

Note:
Switching the JavaScript mode to ECMAScript 2021 (ES12) for an existing application might change the behavior of its scripts. For more information, see Considerations for switching JavaScript modes.

Procedure

1. In the application navigator, enter `sys_app.list`.
2. Select an application.
3. In the **JavaScript Mode** field, select the mode to use.

- ECMAScript 2021 (ES12): Supports a subset of ECMAScript 2021 (ES12) and ECMAScript 2022 (ES13) syntax and features.
- ES5 Standards Mode: Supports ECMAScript5 syntax and features.
- Compatibility Mode: Used for all scripts developed prior to the addition of ES5 Standards mode.

4. Select **Update**.

Turn on ECMAScript 2021 (ES12) mode for a script

Use the latest JavaScript features supported with ECMAScript 2021 (ES12) mode in server-side scripts in applications that use ES5 Standards mode or Compatibility mode.

Before you begin

Role required: delegated developer role or admin

About this task

Turning on ECMAScript 2021 (ES12) mode for individual scripts is an option for scripts in global or scoped applications configured to use ES5 Standards mode or Compatibility mode. All scripts in applications with the JavaScript mode set to ECMAScript 2021 (ES12) use ECMAScript 2021 (ES12). Switching the JavaScript mode to ECMAScript 2021 (ES12) for an existing script might change the behavior of the script. For more information, see Considerations for switching JavaScript modes.

Note:
Global applications can use ECMAScript 2021 (ES12) mode for individual scripts but not across the application.

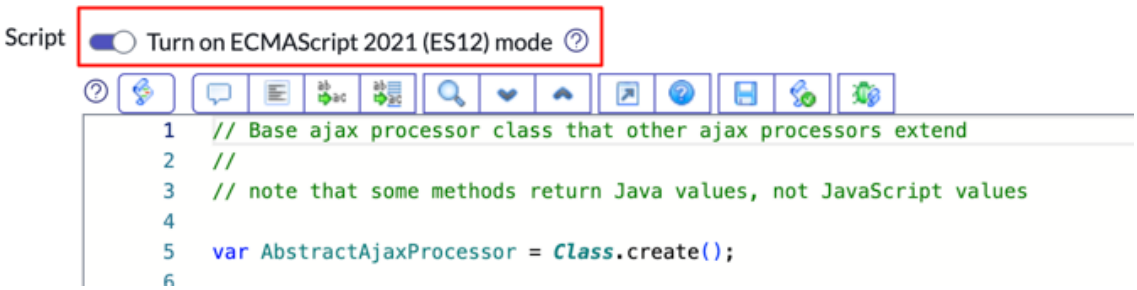
Procedure

1. Navigate to a form with a script field.

   Example
   For example, to open a script include form, navigate to **All** > **System Definition** > **Script Includes** or enter `sys_script_include.list` in the navigation filter.

2. Select an existing script or **New**.
3. Select **Turn on ECMAScript 2021 (ES12) mode**.

   Example



Note:
This option is read only for scripts in applications with the JavaScript mode set to ECMAScript 2021 (ES12), which automatically use ECMAScript 2021 (ES12).

4. Select **Submit** or **Update** to save your changes.

JavaScript engine feature support

Compare ECMAScript features between the ECMAScript 2021 (ES12) and ES5 Standards JavaScript modes in Xanadu. Both modes support a subset of ECMAScript features.

For more information about these features, see the ECMAScript language specifications (ECMA-262) on the Ecma International website.

Support definitions

Supported

The feature has been tested and validated.

Not Supported

The feature has not been validated in the current release.

Disallowed

The feature does not align with the ServiceNow AI Platform programming model or poses a security or performance risk. Disallowed features result in an error.

ECMAScript 2022 (ES13) features

Important:
Prior to deploying code to production, you should test scripts using supported ECMAScript 2022 (ES13) features thoroughly due to the newly added and partial support of features across this ECMAScript version.

Instance class fields

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
public instance class fields	Supported	Not Supported
private instance class fields basic support	Not Supported	Not Supported
private instance class fields initializers	Not Supported	Not Supported
optional private instance class fields access	Not Supported	Not Supported
optional deep private instance class fields access	Not Supported	Not Supported
computed instance class fields	Supported	Not Supported

Static class fields

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
public static class fields	Supported	Not Supported
static class fields use [[Define]]	Supported	Not Supported

Static class fields (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
private static class fields	Supported	Not Supported
computed static class fields	Supported	Not Supported

Private class methods

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
private instance methods	Not Supported	Not Supported
private static methods	Supported	Not Supported
private accessor properties	Not Supported	Not Supported
private static accessor properties	Supported	Not Supported

.at() method on the built-in indexables

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Array.prototype.at()	Not Supported	Not Supported
String.prototype.at()	Supported	Not Supported
%TypedArray%.prototype.at()	Disallowed	Disallowed

Object.hasOwn

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Basic functionality	Supported	Not Supported
ToObject called before ToPropertyKey	Supported	Not Supported

Error.cause property

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Error has cause	Supported	Not Supported
Error.prototype lacks cause	Supported	Not Supported
EvalError has cause	Supported	Not Supported
EvalError.prototype lacks cause	Supported	Not Supported
RangeError has cause	Supported	Not Supported
RangeError.prototype lacks cause	Supported	Not Supported
ReferenceError has cause	Supported	Not Supported
ReferenceError.prototype lacks cause	Supported	Not Supported
SyntaxError has cause	Supported	Not Supported
SyntaxError.prototype lacks cause	Supported	Not Supported
TypeError has cause	Supported	Not Supported

Error.cause property (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
TypeError.prototype lacks cause	Supported	Not Supported
URIError has cause	Supported	Not Supported
URIError.prototype lacks cause	Supported	Not Supported
AggregateError has cause	Supported	Not Supported
AggregateError.prototype lacks cause	Supported	Not Supported

RegExp Match Indices (`hasIndices` / `d` flag)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
constructor supports it	Not Supported	Not Supported
shows up in flags	Not Supported	Not Supported

Ergonomic brand checks for private fields

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Ergonomic brand checks for private fields	Not Supported	Not Supported

Class static initialization blocks

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Class static initialization blocks	Supported	Not Supported

ECMAScript 2021 (ES12) features

Promise.any

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
fulfillment	Disallowed	Disallowed
AggregateError	Disallowed	Disallowed

WeakReferences

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
WeakRef minimal support	Disallowed	Disallowed
FinalizationRegistry minimal support	Disallowed	Disallowed

Logical assignment

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
||= basic support	Supported	Not Supported

Logical assignment (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
||= short-circuiting behavior	Supported	Not Supported
||= setter not unnecessarily invoked	Supported	Not Supported
&&= basic support	Supported	Not Supported
&&= short-circuiting behavior	Supported	Not Supported
&&= setter not unnecessarily invoked	Supported	Not Supported
??= basic support	Supported	Not Supported
??= short-circuiting behavior	Supported	Not Supported
??= setter not unnecessarily invoked	Supported	Not Supported

Numeric separators

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
numeric separators	Supported	Not Supported

String.prototype.replaceAll

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
String.prototype.replaceAll	Supported	Supported

ECMAScript 2020 (ES11) features

String.prototype.matchAll

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Supported	Not Supported
throws on non-global regex	Supported	Not Supported

BigInt

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Not Supported	Not Supported
constructor	Not Supported	Not Supported
BigInt.asUintN	Not Supported	Not Supported
BigInt.asIntN	Not Supported	Not Supported
BigInt64Array	Not Supported	Not Supported
BigUint64Array	Not Supported	Not Supported
DataView.prototype.getBigInt64	Not Supported	Not Supported
DataView.prototype.getBigUint64	Not Supported	Not Supported

globalThis

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
"globalThis" global property is global object	Disallowed	Disallowed
"globalThis" global property has correct property descriptor	Disallowed	Disallowed

Optional chaining operator (?.)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
optional property access	Supported	Not Supported
optional bracket access	Supported	Not Supported
optional method call	Supported	Not Supported
optional function call	Supported	Not Supported
spread parameters after optional chaining	Supported	Not Supported

Promise.allSettled

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Promise.allSettled	Disallowed	Disallowed

Nullish coalescing operator (??)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
nullish coalescing operator (??)	Supported	Not Supported

ECMAScript 2019 (ES10) features

Symbol.prototype.description

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic	Supported	Not Supported
empty description	Supported	Not Supported
undefined description	Supported	Not Supported

String trimming

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
String.prototype.trimLeft	Supported	Supported
String.prototype.trimRight	Supported	Supported
String.prototype.trimStart	Supported	Not Supported
String.prototype.trimEnd	Supported	Not Supported

Array.prototype.{flat, flatMap}

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Array.prototype.flat	Supported	Not Supported
Array.prototype.flatMap	Supported	Not Supported
flat and flatMap in Array.prototype[@@unscopables]	Supported	Not Supported

Object.fromEntries

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Object.fromEntries	Supported	Not Supported

Optional catch binding

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic	Disallowed	Disallowed
await	Disallowed	Disallowed
yield	Disallowed	Disallowed

Function.prototype.toString revision

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
functions created with the Function constructor	Disallowed	Disallowed
arrows	Disallowed	Disallowed
[native code]	Disallowed	Disallowed
class expression with implicit constructor	Disallowed	Disallowed
class expression with explicit constructor	Disallowed	Disallowed
unicode escape sequences in identifiers	Disallowed	Disallowed
methods and computed property names	Disallowed	Disallowed

JSON superset

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Line separator can appear in string literals	Disallowed	Disallowed
Paragraph separator can appear in string literals	Disallowed	Disallowed

Well-formed JSON.stringify

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Well-formed JSON.stringify	Disallowed	Disallowed

ECMAScript 2018 (ES9) features

Object rest/spread properties

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
object rest properties	Supported	Not Supported
object spread properties	Supported	Not Supported

Promise.prototype.finally

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic support	Disallowed	Disallowed
don't change resolution value	Disallowed	Disallowed
change rejection value	Disallowed	Disallowed

Asynchronous iterators

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
async generators	Disallowed	Disallowed
for-await-of loops	Disallowed	Disallowed

s (dotAll) flag for regular expressions

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
s (dotAll) flag for regular expressions	Supported	Not Supported

RegExp named capture groups

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
RegExp named capture groups	Supported	Not Supported

RegExp Lookbehind Assertions

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
RegExp Lookbehind Assertions	Not Supported	Not Supported

RegExp Unicode Property Escapes

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
RegExp Unicode Property Escapes	Not Supported	Not Supported

Template literal revision

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
template literal revision	Disallowed	Disallowed

ECMAScript 2017 (ES8) features

Object static methods

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Object.values	Supported	Not Supported
Object.entries	Supported	Not Supported
Object.getOwnPropertyDescriptors	Supported	Not Supported
Object.getOwnPropertyDescriptors doesn't provide undefined descriptors	Not Supported	Not Supported

String padding

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
String.prototype.padStart	Supported	Not Supported
String.prototype.padEnd	Supported	Not Supported

Trailing commas in function syntax

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
in parameter lists	Supported	Not Supported
in argument lists	Supported	Not Supported

Async functions

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
return	Disallowed	Disallowed
throw	Disallowed	Disallowed
no line break between async and function	Disallowed	Disallowed
no "prototype" property	Disallowed	Disallowed

Async functions (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
await	Disallowed	Disallowed
await, rejection	Disallowed	Disallowed
must await a value	Disallowed	Disallowed
can await non-Promise values	Disallowed	Disallowed
cannot await in parameters	Disallowed	Disallowed
async methods, object literals	Disallowed	Disallowed
async methods, classes	Disallowed	Disallowed
async arrow functions in methods, classes	Disallowed	Disallowed
async arrow functions	Disallowed	Disallowed
correct prototype chain	Disallowed	Disallowed
async function prototype, Symbol.toStringTag	Disallowed	Disallowed
async function constructor	Disallowed	Disallowed

Shared memory and atomics

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
SharedArrayBuffer	Disallowed	Disallowed
SharedArrayBuffer[Symbol.species]	Disallowed	Disallowed
SharedArrayBuffer.prototype.byteLength	Disallowed	Disallowed
SharedArrayBuffer.prototype.slice	Disallowed	Disallowed
SharedArrayBuffer.prototype[Symbol.toStringTag]	Disallowed	Disallowed
Atomics.add	Disallowed	Disallowed
Atomics.and	Disallowed	Disallowed
Atomics.compareExchange	Disallowed	Disallowed
Atomics.exchange	Disallowed	Disallowed
Atomics.wait	Disallowed	Disallowed
Atomics.wake	Disallowed	Disallowed
Atomics.isLockFree	Disallowed	Disallowed
Atomics.load	Disallowed	Disallowed
Atomics.or	Disallowed	Disallowed
Atomics.store	Disallowed	Disallowed
Atomics.sub	Disallowed	Disallowed
Atomics.xor	Disallowed	Disallowed

Object.prototype getter/setter methods

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
__defineGetter__	Disallowed	Disallowed
__defineGetter__, symbols	Disallowed	Disallowed
__defineGetter__, ToObject(this)	Disallowed	Disallowed
__defineSetter__	Disallowed	Disallowed
__defineSetter__, symbols	Disallowed	Disallowed
__defineSetter__, ToObject(this)	Disallowed	Disallowed
__lookupGetter__	Disallowed	Disallowed
__lookupGetter__, prototype chain	Disallowed	Disallowed
__lookupGetter__, symbols	Disallowed	Disallowed
__lookupGetter__, ToObject(this)	Disallowed	Disallowed
__lookupGetter__, data properties can shadow accessors	Disallowed	Disallowed
__lookupSetter__	Disallowed	Disallowed
__lookupSetter__, prototype chain	Disallowed	Disallowed
__lookupSetter__, symbols	Disallowed	Disallowed
__lookupSetter__, ToObject(this)	Disallowed	Disallowed
__lookupSetter__, data properties can shadow accessors	Disallowed	Disallowed

Proxy internal calls, getter/setter methods

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
__defineGetter__	Disallowed	Disallowed
__defineSetter__	Disallowed	Disallowed
__lookupGetter__	Disallowed	Disallowed
__lookupSetter__	Disallowed	Disallowed

ECMAScript 2016 (ES7) features

Exponentiation (**) operator

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic support	Supported	Not Supported
assignment	Supported	Not Supported
early syntax error for unary negation without parentheses	Disallowed	Disallowed

Array.prototype.includes

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Array.prototype.includes	Supported	Not Supported
Array.prototype.includes is generic	Not Supported	Not Supported
%TypedArray%.prototype.includes	Disallowed	Disallowed

ECMAScript 2015 (ES6) features

Proper tail calls (tail call optimization)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
direct recursion	Disallowed	Disallowed
mutual recursion	Disallowed	Disallowed

Default function parameters

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Supported	Not Supported
explicit undefined defers to the default	Supported	Not Supported
defaults can refer to previous parameters	Supported	Not Supported
arguments object interaction	Supported	Not Supported
temporal dead zone	Disallowed	Disallowed
separate scope	Supported	Not Supported
new Function() support	Disallowed	Disallowed

Rest parameters

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Supported	Not Supported
function 'length' property	Supported	Not Supported
arguments object interaction	Not Supported	Not Supported
can't be used in setters	Disallowed	Disallowed
new Function() support	Disallowed	Disallowed

Spread syntax for iterable objects

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
with arrays, in function calls	Supported	Not Supported
with arrays, in array literals	Supported	Not Supported
with sparse arrays, in function calls	Supported	Not Supported

Spread syntax for iterable objects (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
with sparse arrays, in array literals	Supported	Not Supported
with strings, in function calls	Supported	Not Supported
with strings, in array literals	Supported	Not Supported
with astral plane strings, in function calls	Supported	Not Supported
with astral plane strings, in array literals	Supported	Not Supported
with generator instances, in calls	Disallowed	Disallowed
with generator instances, in arrays	Disallowed	Disallowed
with generic iterables, in calls	Supported	Not Supported
with generic iterables, in arrays	Supported	Not Supported
with instances of iterables, in calls	Supported	Not Supported
with instances of iterables, in arrays	Supported	Not Supported
spreading non-iterables is a runtime error	Supported	Not Supported

Object literal extensions

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
computed properties	Supported	Not Supported
shorthand properties	Supported	Not Supported
shorthand methods	Supported	Not Supported
string-keyed shorthand methods	Supported	Not Supported
computed shorthand methods	Supported	Not Supported
computed accessors	Supported	Not Supported

For-of loops

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
with arrays	Supported	Not Supported
with sparse arrays	Supported	Not Supported
with strings	Supported	Not Supported
with astral plane strings	Supported	Not Supported
with generator instances	Disallowed	Disallowed
with generic iterables	Supported	Not Supported
with instances of generic iterables	Supported	Not Supported
iterator closing, break	Supported	Not Supported
iterator closing, throw	Supported	Not Supported

Octal and binary literals

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
octal literals	Supported	Not Supported
binary literals	Supported	Not Supported
octal supported by Number()	Not Supported	Not Supported
binary supported by Number()	Not Supported	Not Supported

Template literals

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Supported	Not Supported
toString conversion	Supported	Not Supported
tagged template literals	Supported	Not Supported
passed array is frozen	Supported	Not Supported
line break normalization	Disallowed	Disallowed
TemplateStrings call site caching	Supported	Not Supported
TemplateStrings permanent caching	Supported	Not Supported

RegExp "y" and "u" flags

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
"y" flag	Supported	Not Supported
"y" flag, lastIndex	Supported	Not Supported
"u" flag	Not Supported	Not Supported
"u" flag, non-BMP Unicode characters	Not Supported	Not Supported
"u" flag, Unicode code point escapes	Not Supported	Not Supported
"u" flag, case folding	Not Supported	Not Supported

Destructuring, declarations

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
with arrays	Supported	Not Supported
with sparse arrays	Supported	Not Supported
with strings	Supported	Not Supported
with astral plane strings	Supported	Not Supported
with generator instances	Disallowed	Disallowed
with generic iterables	Supported	Not Supported
with instances of generic iterables	Supported	Not Supported
iterator closing	Supported	Not Supported

Destructuring, declarations (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
trailing commas in iterable patterns	Supported	Not Supported
with objects	Supported	Not Supported
object destructuring with primitives	Supported	Not Supported
trailing commas in object patterns	Supported	Not Supported
throws on null and undefined	Supported	Not Supported
computed properties	Supported	Not Supported
multiples in a single var statement	Supported	Not Supported
nested	Supported	Not Supported
in for-in loop heads	Supported	Not Supported
in for-of loop heads	Supported	Not Supported
in catch heads	Supported	Not Supported
rest	Supported	Not Supported
defaults	Supported	Not Supported
defaults, let temporal dead zone	Disallowed	Disallowed

Destructuring, assignment

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
with arrays	Supported	Not Supported
with sparse arrays	Supported	Not Supported
with strings	Supported	Not Supported
with astral plane strings	Supported	Not Supported
with generator instances	Disallowed	Disallowed
with generic iterables	Supported	Not Supported
with instances of generic iterables	Supported	Not Supported
iterator closing	Supported	Not Supported
iterable destructuring expression	Supported	Not Supported
chained iterable destructuring	Supported	Not Supported
trailing commas in iterable patterns	Supported	Not Supported
with objects	Supported	Not Supported
object destructuring with primitives	Supported	Not Supported
trailing commas in object patterns	Supported	Not Supported
object destructuring expression	Supported	Not Supported

Destructuring, assignment (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
parenthesized left-hand-side is a syntax error	Disallowed	Disallowed
chained object destructuring	Supported	Not Supported
throws on null and undefined	Supported	Not Supported
computed properties	Supported	Not Supported
nested	Supported	Not Supported
rest	Supported	Not Supported
nested rest	Supported	Not Supported
empty patterns	Supported	Not Supported
defaults	Supported	Not Supported

Destructuring, parameters

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
with arrays	Supported	Not Supported
with sparse arrays	Supported	Not Supported
with strings	Supported	Not Supported
with astral plane strings	Supported	Not Supported
with generator instances	Disallowed	Disallowed
with generic iterables	Supported	Not Supported
with instances of generic iterables	Supported	Not Supported
iterator closing	Supported	Not Supported
trailing commas in iterable patterns	Supported	Not Supported
with objects	Supported	Not Supported
object destructuring with primitives	Supported	Not Supported
trailing commas in object patterns	Supported	Not Supported
throws on null and undefined	Supported	Not Supported
computed properties	Supported	Not Supported
nested	Supported	Not Supported
'arguments' interaction	Supported	Not Supported
new Function() support	Disallowed	Disallowed
in parameters, function 'length' property	Supported	Not Supported
rest	Supported	Not Supported
empty patterns	Supported	Not Supported

Destructuring, parameters (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
defaults	Supported	Not Supported
defaults, separate scope	Supported	Not Supported
defaults, new Function() support	Disallowed	Disallowed
aliased defaults, arrow function	Supported	Not Supported
shorthand defaults, arrow function	Supported	Not Supported
duplicate identifier	Disallowed	Disallowed

Unicode code point escapes

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
in strings	Supported	Not Supported
in identifiers	Not Supported	Not Supported
in property key definitions	Not Supported	Not Supported
in property key accesses	Not Supported	Not Supported

New.target

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
in constructors	Not Supported	Not Supported
assignment is an early error	Disallowed	Disallowed

Const

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic support	Supported	Supported
is block-scoped	Supported	Not Supported
scope shadow resolution	Supported	Not Supported
cannot be in statements	Disallowed	Disallowed
redefining a const is an error	Disallowed	Disallowed
for loop statement scope	Supported	Not Supported
for-in loop iteration scope	Supported	Not Supported
for-of loop iteration scope	Supported	Not Supported
temporal dead zone	Not Supported	Not Supported
basic support (strict mode)	Supported	Supported
is block-scoped (strict mode)	Supported	Not Supported
scope shadow resolution (strict mode)	Supported	Not Supported
cannot be in statements (strict mode)	Disallowed	Disallowed

Const (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
redefining a const (strict mode)	Disallowed	Disallowed
for loop statement scope (strict mode)	Supported	Not Supported
for-in loop iteration scope (strict mode)	Supported	Not Supported
for-of loop iteration scope (strict mode)	Supported	Not Supported
temporal dead zone (strict mode)	Not Supported	Not Supported

Let

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic support	Supported	Not Supported
is block-scoped	Supported	Not Supported
scope shadow resolution	Supported	Not Supported
cannot be in statements	Disallowed	Disallowed
for loop statement scope	Supported	Not Supported
temporal dead zone	Not Supported	Not Supported
for/for-in loop iteration scope	Supported	Not Supported
for-in loop binding shadowing parameter	Disallowed	Disallowed
basic support (strict mode)	Supported	Not Supported
is block-scoped (strict mode)	Supported	Not Supported
scope shadow resolution (strict mode)	Supported	Not Supported
cannot be in statements (strict mode)	Disallowed	Disallowed
for loop statement scope (strict mode)	Supported	Not Supported
temporal dead zone (strict mode)	Not Supported	Not Supported
for/for-in loop iteration scope (strict mode)	Supported	Not Supported
for-in loop binding shadowing parameter (strict mode)	Disallowed	Disallowed

Block-level function declaration

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
block-level function declaration	Supported	Not Supported

Arrow functions

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
0 parameters	Supported	Not Supported

Arrow functions (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
1 parameter, no brackets	Supported	Not Supported
multiple parameters	Supported	Not Supported
lexical "this" binding	Supported	Not Supported
"this" unchanged by call or apply	Supported	Not Supported
can't be bound, can be curried	Supported	Not Supported
lexical "arguments" binding	Supported	Not Supported
no line break between parameters and `=>`	Disallowed	Disallowed
correct precedence	Disallowed	Disallowed
no "prototype" property	Not Supported	Not Supported
lexical "super" binding in constructors	Supported	Not Supported
lexical "super" binding in methods	Supported	Not Supported
lexical "new.target" binding	Not Supported	Not Supported

Class

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
class statement	Supported	Not Supported
is block-scoped	Supported	Not Supported
class expression	Supported	Not Supported
anonymous class	Supported	Not Supported
constructor	Supported	Not Supported
prototype methods	Supported	Not Supported
string-keyed methods	Supported	Not Supported
computed prototype methods	Supported	Not Supported
optional semicolons	Supported	Not Supported
static methods	Supported	Not Supported
computed static methods	Supported	Not Supported
accessor properties	Supported	Not Supported
computed accessor properties	Supported	Not Supported
static accessor properties	Supported	Not Supported
computed static accessor properties	Supported	Not Supported
class name is lexically scoped	Supported	Not Supported
computed names, temporal dead zone	Not Supported	Not Supported
methods aren't enumerable	Supported	Not Supported
implicit strict mode	Not Supported	Not Supported

Class (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
constructor requires new	Supported	Not Supported
extends	Supported	Not Supported
extends expressions	Supported	Not Supported
extends null	Supported	Not Supported
new.target	Supported	Not Supported

Super

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
statement in constructors	Supported	Not Supported
expression in constructors	Supported	Not Supported
in methods, property access	Supported	Not Supported
in methods, method calls	Supported	Not Supported
method calls use correct "this" binding	Supported	Not Supported
constructor calls use correct "new.target" binding	Supported	Not Supported
is statically bound	Supported	Not Supported
super() invokes the correct constructor	Supported	Not Supported

Generators

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Disallowed	Disallowed
generator function expressions	Disallowed	Disallowed
correct "this" binding	Disallowed	Disallowed
can't use "this" with new	Disallowed	Disallowed
sending	Disallowed	Disallowed
%GeneratorPrototype%	Disallowed	Disallowed
%GeneratorPrototype% prototype chain	Disallowed	Disallowed
%GeneratorPrototype%.constructor	Disallowed	Disallowed
%GeneratorPrototype%.throw	Disallowed	Disallowed
%GeneratorPrototype%.return	Disallowed	Disallowed
yield operator precedence	Disallowed	Disallowed
yield *, arrays	Disallowed	Disallowed
yield *, sparse arrays	Disallowed	Disallowed

Generators (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
yield *, strings	Disallowed	Disallowed
yield *, astral plane strings	Disallowed	Disallowed
yield *, generator instances	Disallowed	Disallowed
yield *, generic iterables	Disallowed	Disallowed
yield *, instances of iterables	Disallowed	Disallowed
yield * on non-iterables is a runtime error	Disallowed	Disallowed
yield *, iterator closing	Disallowed	Disallowed
yield *, iterator closing via throw()	Disallowed	Disallowed
shorthand generator methods	Disallowed	Disallowed
string-keyed shorthand generator methods	Disallowed	Disallowed
computed shorthand generators	Disallowed	Disallowed
shorthand generator methods, classes	Disallowed	Disallowed
computed shorthand generators, classes	Disallowed	Disallowed
shorthand generators can't be constructors	Disallowed	Disallowed

Typed arrays

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Int8Array	Disallowed	Disallowed
Uint8Array	Disallowed	Disallowed
Uint8ClampedArray	Disallowed	Disallowed
Int16Array	Disallowed	Disallowed
Uint16Array	Disallowed	Disallowed
Int32Array	Disallowed	Disallowed
Uint32Array	Disallowed	Disallowed
Float32Array	Disallowed	Disallowed
Float64Array	Disallowed	Disallowed
DataView (Int8)	Disallowed	Disallowed
DataView (Uint8)	Disallowed	Disallowed
DataView (Int16)	Disallowed	Disallowed
DataView (Uint16)	Disallowed	Disallowed
DataView (Int32)	Disallowed	Disallowed
DataView (Uint32)	Disallowed	Disallowed
DataView (Float32)	Disallowed	Disallowed
DataView (Float64)	Disallowed	Disallowed

Typed arrays (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
ArrayBuffer[Symbol.species]	Disallowed	Disallowed
constructors require new	Disallowed	Disallowed
constructors accept generic iterables	Disallowed	Disallowed
correct prototype chains	Disallowed	Disallowed
%TypedArray%.from	Disallowed	Disallowed
%TypedArray%.of	Disallowed	Disallowed
%TypedArray%.prototype.subarray	Disallowed	Disallowed
%TypedArray%.prototype.join	Disallowed	Disallowed
%TypedArray%.prototype.indexOf	Disallowed	Disallowed
%TypedArray%.prototype.lastIndexOf	Disallowed	Disallowed
%TypedArray%.prototype.slice	Disallowed	Disallowed
%TypedArray%.prototype.every	Disallowed	Disallowed
%TypedArray%.prototype.filter	Disallowed	Disallowed
%TypedArray%.prototype.forEach	Disallowed	Disallowed
%TypedArray%.prototype.map	Disallowed	Disallowed
%TypedArray%.prototype.reduce	Disallowed	Disallowed
%TypedArray%.prototype.reduceRight	Disallowed	Disallowed
%TypedArray%.prototype.reverse	Disallowed	Disallowed
%TypedArray%.prototype.some	Disallowed	Disallowed
%TypedArray%.prototype.sort	Disallowed	Disallowed
%TypedArray%.prototype.copyWithin	Disallowed	Disallowed
%TypedArray%.prototype.find	Disallowed	Disallowed
%TypedArray%.prototype.findIndex	Disallowed	Disallowed
%TypedArray%.prototype.fill	Disallowed	Disallowed
%TypedArray%.prototype.keys	Disallowed	Disallowed
%TypedArray%.prototype.values	Disallowed	Disallowed
%TypedArray%.prototype.entries	Disallowed	Disallowed
%TypedArray%.prototype[Symbol.iterator]	Disallowed	Disallowed
%TypedArray%[Symbol.species]	Disallowed	Disallowed

Map

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Supported	Not Supported
constructor arguments	Supported	Not Supported

Map (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
constructor requires new	Supported	Not Supported
constructor accepts null	Supported	Not Supported
constructor invokes set	Supported	Not Supported
iterator closing	Supported	Not Supported
Map.prototype.set returns this	Supported	Not Supported
-0 key converts to +0	Supported	Not Supported
Map.prototype.size	Supported	Not Supported
Map.prototype.delete	Supported	Not Supported
Map.prototype.clear	Supported	Not Supported
Map.prototype.forEach	Supported	Not Supported
Map.prototype.keys	Supported	Not Supported
Map.prototype.values	Supported	Not Supported
Map.prototype.entries	Supported	Not Supported
Map.prototype[Symbol.iterator]	Supported	Not Supported
Map.prototype isn't an instance	Supported	Not Supported
Map iterator prototype chain	Supported	Not Supported
Map[Symbol.species]	Supported	Not Supported

Set

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Supported	Not Supported
constructor arguments	Supported	Not Supported
constructor requires new	Supported	Not Supported
constructor accepts null	Supported	Not Supported
constructor invokes add	Supported	Not Supported
iterator closing	Supported	Not Supported
Set.prototype.add returns this	Supported	Not Supported
-0 key converts to +0	Supported	Not Supported
Set.prototype.size	Supported	Not Supported
Set.prototype.delete	Supported	Not Supported
Set.prototype.clear	Supported	Not Supported
Set.prototype.forEach	Supported	Not Supported
Set.prototype.keys	Supported	Not Supported
Set.prototype.values	Supported	Not Supported

Set (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Set.prototype.entries	Supported	Not Supported
Set.prototype[Symbol.iterator]	Supported	Not Supported
Set.prototype isn't an instance	Supported	Not Supported
Set iterator prototype chain	Supported	Not Supported
Set[Symbol.species]	Supported	Not Supported

WeakMap

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Disallowed	Disallowed
constructor arguments	Disallowed	Disallowed
constructor requires new	Disallowed	Disallowed
constructor accepts null	Disallowed	Disallowed
constructor invokes set	Disallowed	Disallowed
frozen objects as keys	Disallowed	Disallowed
iterator closing	Disallowed	Disallowed
WeakMap.prototype.set returns this	Disallowed	Disallowed
WeakMap.prototype.delete	Disallowed	Disallowed
no WeakMap.prototype.clear method	Disallowed	Disallowed
.has, .get and .delete methods accept primitives	Disallowed	Disallowed
WeakMap.prototype isn't an instance	Disallowed	Disallowed

WeakSet

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Disallowed	Disallowed
constructor arguments	Disallowed	Disallowed
constructor requires new	Disallowed	Disallowed
constructor accepts null	Disallowed	Disallowed
constructor invokes add	Disallowed	Disallowed
iterator closing	Disallowed	Disallowed
WeakSet.prototype.add returns this	Disallowed	Disallowed
WeakSet.prototype.delete	Disallowed	Disallowed
no WeakSet.prototype.clear method	Disallowed	Disallowed

WeakSet (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
.has and .delete methods accept primitives	Disallowed	Disallowed
WeakSet.prototype isn't an instance	Disallowed	Disallowed

Proxy

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
constructor requires new	Disallowed	Disallowed
no "prototype" property	Disallowed	Disallowed
"get" handler	Disallowed	Disallowed
"get" handler, instances of proxies	Disallowed	Disallowed
"get" handler invariants	Disallowed	Disallowed
"set" handler	Disallowed	Disallowed
"set" handler, instances of proxies	Disallowed	Disallowed
"set" handler invariants	Disallowed	Disallowed
"has" handler	Disallowed	Disallowed
"has" handler, instances of proxies	Disallowed	Disallowed
"has" handler invariants	Disallowed	Disallowed
"deleteProperty" handler	Disallowed	Disallowed
"deleteProperty" handler invariant	Disallowed	Disallowed
"getOwnPropertyDescriptor" handler	Disallowed	Disallowed
"getOwnPropertyDescriptor" handler invariants	Disallowed	Disallowed
"defineProperty" handler	Disallowed	Disallowed
"defineProperty" handler invariants	Disallowed	Disallowed
"getPrototypeOf" handler	Disallowed	Disallowed
"getPrototypeOf" handler invariant	Disallowed	Disallowed
"setPrototypeOf" handler	Disallowed	Disallowed
"setPrototypeOf" handler invariant	Disallowed	Disallowed
"isExtensible" handler	Disallowed	Disallowed
"isExtensible" handler invariant	Disallowed	Disallowed
"preventExtensions" handler	Disallowed	Disallowed
"preventExtensions" handler invariant	Disallowed	Disallowed
"ownKeys" handler	Disallowed	Disallowed
"ownKeys" handler invariant	Disallowed	Disallowed

Proxy (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
"apply" handler	Disallowed	Disallowed
"apply" handler invariant	Disallowed	Disallowed
"construct" handler	Disallowed	Disallowed
"construct" handler invariants	Disallowed	Disallowed
Proxy.revocable	Disallowed	Disallowed
Array.isArray support	Disallowed	Disallowed
JSON.stringify support	Disallowed	Disallowed

Reflect

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Reflect.get	Disallowed	Disallowed
Reflect.set	Disallowed	Disallowed
Reflect.has	Disallowed	Disallowed
Reflect.deleteProperty	Disallowed	Disallowed
Reflect.getOwnPropertyDescriptor	Disallowed	Disallowed
Reflect.defineProperty	Disallowed	Disallowed
Reflect.getPrototypeOf	Disallowed	Disallowed
Reflect.setPrototypeOf	Disallowed	Disallowed
Reflect.isExtensible	Disallowed	Disallowed
Reflect.preventExtensions	Disallowed	Disallowed
Reflect.ownKeys, string keys	Disallowed	Disallowed
Reflect.ownKeys, symbol keys	Disallowed	Disallowed
Reflect.apply	Disallowed	Disallowed
Reflect.construct	Disallowed	Disallowed
Reflect.construct sets new.target meta-property	Disallowed	Disallowed
Reflect.construct creates instances from third argument	Disallowed	Disallowed
Reflect.construct, Array subclassing	Disallowed	Disallowed
Reflect.construct, RegExp subclassing	Disallowed	Disallowed
Reflect.construct, Function subclassing	Disallowed	Disallowed
Reflect.construct, Promise subclassing	Disallowed	Disallowed

Promise

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Disallowed	Disallowed
constructor requires new	Disallowed	Disallowed
Promise.prototype isn't an instance	Disallowed	Disallowed
Promise.all	Disallowed	Disallowed
Promise.all, generic iterables	Disallowed	Disallowed
Promise.race	Disallowed	Disallowed
Promise.race, generic iterables	Disallowed	Disallowed
Promise[Symbol.species]	Disallowed	Disallowed

Symbol

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Supported	Not Supported
typeof support	Supported	Not Supported
symbol keys are hidden to pre-ES6 code	Supported	Not Supported
Object.defineProperty support	Supported	Not Supported
symbols inherit from Symbol.prototype	Supported	Not Supported
cannot coerce to string or number	Not Supported	Not Supported
can convert with String()	Not Supported	Not Supported
new Symbol() throws	Supported	Not Supported
Object(symbol)	Not Supported	Not Supported
JSON.stringify ignores symbol primitives	Supported	Not Supported
JSON.stringify ignores symbol objects	Not Supported	Not Supported
global symbol registry	Supported	Not Supported

Well-known symbols

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Symbol.hasInstance	Disallowed	Disallowed
Symbol.isConcatSpreadable	Disallowed	Disallowed
Symbol.iterator, existence	Disallowed	Disallowed
Symbol.iterator, arguments object	Disallowed	Disallowed
Symbol.species, existence	Disallowed	Disallowed
Symbol.species, Array.prototype.concat	Disallowed	Disallowed
Symbol.species, Array.prototype.filter	Disallowed	Disallowed

Well-known symbols (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Symbol.species, Array.prototype.map	Disallowed	Disallowed
Symbol.species, Array.prototype.slice	Disallowed	Disallowed
Symbol.species, Array.prototype.splice	Disallowed	Disallowed
Symbol.species, RegExp.prototype[Symbol.split]	Disallowed	Disallowed
Symbol.species, Promise.prototype.then	Disallowed	Disallowed
Symbol.replace	Disallowed	Disallowed
Symbol.search	Disallowed	Disallowed
Symbol.split	Disallowed	Disallowed
Symbol.match	Disallowed	Disallowed
Symbol.match, RegExp constructor	Disallowed	Disallowed
Symbol.match, String.prototype.startsWith	Disallowed	Disallowed
Symbol.match, String.prototype.endsWith	Disallowed	Disallowed
Symbol.match, String.prototype.includes	Disallowed	Disallowed
Symbol.toPrimitive	Disallowed	Disallowed
Symbol.toStringTag	Disallowed	Disallowed
Symbol.toStringTag affects existing built-ins	Disallowed	Disallowed
Symbol.toStringTag, new built-ins	Disallowed	Disallowed
Symbol.toStringTag, misc. built-ins	Disallowed	Disallowed
Symbol.unscopables	Disallowed	Disallowed

Object static methods

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Object.assign	Supported	Not Supported
Object.is	Supported	Not Supported
Object.getOwnPropertySymbols	Supported	Not Supported
Object.setPrototypeOf	Not Supported	Not Supported

Function "name" property

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
function statements	Supported	Supported
function expressions	Supported	Supported
new Function	Not Supported	Not Supported

Function "name" property (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
bound functions	Not Supported	Not Supported
variables (function)	Supported	Not Supported
object methods (function)	Supported	Not Supported
accessor properties	Not Supported	Not Supported
shorthand methods	Supported	Not Supported
shorthand methods (no lexical binding)	Supported	Not Supported
symbol-keyed methods	Not Supported	Not Supported
class statements	Supported	Not Supported
class expressions	Supported	Not Supported
variables (class)	Supported	Not Supported
object methods (class)	Not Supported	Not Supported
class prototype methods	Supported	Not Supported
class static methods	Supported	Not Supported
isn't writable, is configurable	Not Supported	Not Supported

String static methods

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
String.raw	Supported	Not Supported
String.fromCodePoint	Supported	Not Supported

String.prototype methods

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
String.prototype.codePointAt	Supported	Supported
String.prototype.normalize	Supported	Supported
String.prototype.repeat	Supported	Supported
String.prototype.startsWith	Supported	Supported
String.prototype.startsWith throws on RegExp	Not Supported	Not Supported
String.prototype.endsWith	Supported	Supported
String.prototype.endsWith throws on RegExp	Not Supported	Not Supported
String.prototype.includes	Supported	Supported
String.prototype[Symbol.iterator]	Supported	Not Supported
String iterator prototype chain	Supported	Not Supported

RegExp.prototype properties

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
RegExp.prototype.flags	Supported	Not Supported
RegExp.prototype[Symbol.match]	Not Supported	Not Supported
RegExp.prototype[Symbol.replace]	Supported	Not Supported
RegExp.prototype[Symbol.split]	Supported	Not Supported
RegExp.prototype[Symbol.search]	Not Supported	Not Supported
RegExp[Symbol.species]	Supported	Not Supported

Array static methods

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Array.from, array-like objects	Supported	Not Supported
Array.from, generator instances	Disallowed	Disallowed
Array.from, generic iterables	Supported	Not Supported
Array.from, instances of generic iterables	Supported	Not Supported
Array.from map function, array-like objects	Supported	Not Supported
Array.from map function, generator instances	Disallowed	Disallowed
Array.from map function, generic iterables	Supported	Not Supported
Array.from map function, instances of iterables	Supported	Not Supported
Array.from, iterator closing	Supported	Not Supported
Array.of	Supported	Not Supported
Array[Symbol.species]	Supported	Not Supported

Array.prototype methods

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Array.prototype.copyWithin	Supported	Not Supported
Array.prototype.find	Supported	Not Supported
Array.prototype.findIndex	Supported	Not Supported
Array.prototype.fill	Supported	Not Supported
Array.prototype.keys	Supported	Not Supported
Array.prototype.values	Supported	Not Supported
Array.prototype.entries	Supported	Not Supported
Array.prototype[Symbol.iterator]	Supported	Not Supported
Array iterator prototype chain	Supported	Not Supported

Array.prototype methods (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Array.prototype[Symbol.unscopables]	Supported	Not Supported

Number properties

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Number.isFinite	Supported	Not Supported
Number.isInteger	Supported	Not Supported
Number.isSafeInteger	Supported	Not Supported
Number.isNaN	Supported	Not Supported
Number.parseFloat	Disallowed	Disallowed
Number.parseInt	Disallowed	Disallowed
Number.EPSILON	Supported	Not Supported
Number.MIN_SAFE_INTEGER	Supported	Not Supported
Number.MAX_SAFE_INTEGER	Supported	Not Supported

Math methods

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Math.clz32	Supported	Not Supported
Math.imul	Supported	Not Supported
Math.sign	Supported	Not Supported
Math.log10	Supported	Not Supported
Math.log2	Supported	Not Supported
Math.log1p	Supported	Not Supported
Math.expm1	Supported	Not Supported
Math.cosh	Supported	Not Supported
Math.sinh	Supported	Not Supported
Math.tanh	Supported	Not Supported
Math.acosh	Supported	Not Supported
Math.asinh	Supported	Not Supported
Math.atanh	Supported	Not Supported
Math.trunc	Supported	Not Supported
Math.fround	Supported	Not Supported
Math.cbrt	Supported	Not Supported
Math.hypot	Supported	Not Supported

Date.prototype[Symbol.toPrimitive]

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Date.prototype[Symbol.toPrimitive]	Supported	Not Supported

Array is subclassable

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
length property (accessing)	Disallowed	Disallowed
length property (setting)	Disallowed	Disallowed
correct prototype chain	Disallowed	Disallowed
Array.isArray support	Disallowed	Disallowed
Array.prototype.concat	Disallowed	Disallowed
Array.prototype.filter	Disallowed	Disallowed
Array.prototype.map	Disallowed	Disallowed
Array.prototype.slice	Disallowed	Disallowed
Array.prototype.splice	Disallowed	Disallowed
Array.from	Disallowed	Disallowed
Array.of	Disallowed	Disallowed

RegExp is subclassable

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Disallowed	Disallowed
correct prototype chain	Disallowed	Disallowed
RegExp.prototype.exec	Disallowed	Disallowed
RegExp.prototype.test	Disallowed	Disallowed

Function is subclassable

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
can be called	Disallowed	Disallowed
correct prototype chain	Disallowed	Disallowed
can be used with "new"	Disallowed	Disallowed
Function.prototype.call	Disallowed	Disallowed
Function.prototype.apply	Disallowed	Disallowed
Function.prototype.bind	Disallowed	Disallowed

Promise is subclassable

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functionality	Disallowed	Disallowed
correct prototype chain	Disallowed	Disallowed
Promise.all	Disallowed	Disallowed
Promise.race	Disallowed	Disallowed

Miscellaneous subclassables

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Boolean is subclassable	Disallowed	Disallowed
Number is subclassable	Disallowed	Disallowed
String is subclassable	Disallowed	Disallowed
Error is subclassable	Disallowed	Disallowed
Map is subclassable	Disallowed	Disallowed
Set is subclassable	Disallowed	Disallowed

Prototype of bound functions

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
basic functions	Disallowed	Disallowed
generator functions	Disallowed	Disallowed
arrow functions	Disallowed	Disallowed
classes	Disallowed	Disallowed
subclasses	Disallowed	Disallowed

Proxy, internal 'get' calls

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
ToPrimitive	Disallowed	Disallowed
CreateListFromArrayLike	Disallowed	Disallowed
instanceof operator	Supported	Disallowed
HasBinding	Disallowed	Disallowed
CreateDynamicFunction	Disallowed	Disallowed
ClassDefinitionEvaluation	Disallowed	Disallowed
IteratorComplete, IteratorValue	Disallowed	Disallowed
ToPropertyDescriptor	Disallowed	Disallowed
Object.assign	Disallowed	Disallowed
Object.defineProperties	Disallowed	Disallowed

Proxy, internal 'get' calls (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Function.prototype.bind	Disallowed	Disallowed
Error.prototype.toString	Disallowed	Disallowed
String.raw	Disallowed	Disallowed
RegExp constructor	Disallowed	Disallowed
RegExp.prototype.flags	Disallowed	Disallowed
RegExp.prototype.test	Disallowed	Disallowed
RegExp.prototype.toString	Disallowed	Disallowed
RegExp.prototype[Symbol.match]	Disallowed	Disallowed
RegExp.prototype[Symbol.replace]	Disallowed	Disallowed
RegExp.prototype[Symbol.search]	Disallowed	Disallowed
RegExp.prototype[Symbol.split]	Disallowed	Disallowed
Array.from	Disallowed	Disallowed
Array.prototype.concat	Disallowed	Disallowed
Array.prototype iteration methods	Disallowed	Disallowed
Array.prototype.pop	Disallowed	Disallowed
Array.prototype.reverse	Disallowed	Disallowed
Array.prototype.shift	Disallowed	Disallowed
Array.prototype.splice	Disallowed	Disallowed
Array.prototype.toString	Disallowed	Disallowed
JSON.stringify	Disallowed	Disallowed
Promise resolve functions	Disallowed	Disallowed
String.prototype.match	Disallowed	Disallowed
String.prototype.replace	Disallowed	Disallowed
String.prototype.search	Disallowed	Disallowed
String.prototype.split	Disallowed	Disallowed
Date.prototype.toJSON	Disallowed	Disallowed

Proxy, internal 'set' calls

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Object.assign	Disallowed	Disallowed
Array.from	Disallowed	Disallowed
Array.of	Disallowed	Disallowed
Array.prototype.copyWithin	Disallowed	Disallowed
Array.prototype.fill	Disallowed	Disallowed

Proxy, internal 'set' calls (continued)

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Array.prototype.pop	Disallowed	Disallowed
Array.prototype.push	Disallowed	Disallowed
Array.prototype.reverse	Disallowed	Disallowed
Array.prototype.shift	Disallowed	Disallowed
Array.prototype.splice	Disallowed	Disallowed
Array.prototype.unshift	Disallowed	Disallowed

Proxy, internal 'defineProperty' calls

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
[[Set]]	Disallowed	Disallowed
SetIntegrityLevel	Disallowed	Disallowed

Proxy, internal 'deleteProperty' calls

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Array.prototype.copyWithin	Disallowed	Disallowed
Array.prototype.pop	Disallowed	Disallowed
Array.prototype.reverse	Disallowed	Disallowed
Array.prototype.shift	Disallowed	Disallowed
Array.prototype.splice	Disallowed	Disallowed
Array.prototype.unshift	Disallowed	Disallowed

Proxy, internal 'getOwnPropertyDescriptor' calls

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
[[Set]]	Disallowed	Disallowed
Object.assign	Disallowed	Disallowed
Object.prototype.hasOwnProperty	Disallowed	Disallowed
Function.prototype.bind	Disallowed	Disallowed

Proxy, internal 'ownKeys' calls

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
SetIntegrityLevel	Disallowed	Disallowed
TestIntegrityLevel	Disallowed	Disallowed
SerializeJSONObject	Disallowed	Disallowed

Object static methods accept primitives

Feature	ECMAScript 2021 (ES12) mode	ES5 Standards mode
Object.getPrototypeOf	Disallowed	Disallowed
Object.getOwnPropertyDescriptor	Disallowed	Disallowed
Object.getOwnPropertyNames	Disallowed	Disallowed
Object.seal	Disallowed	Disallowed
Object.freeze	Disallowed	Disallowed
Object.preventExtensions	Disallowed	Disallowed
Object.isSealed	Disallowed	Disallowed
Object.isFrozen	Disallowed	Disallowed

JavaScript API Context-sensitive help

The syntax editor can display context-sensitive API information.

JavaScript API Context-sensitive help includes the ability to:

- List script elements that are valid at the cursor's location. The system displays suggestions in a pop-up window.
- Add a selected script element at the cursor's location. If the cursor is within or adjacent to a partial entry, the system completes the entry with the selected script element.
- View API documentation for a selected suggestion.
- View the expected parameters and format of the current script element.

If the cursor is adjacent to a text string, the system searches for script elements that start with this text string. For example, while the cursor is within or adjacent to the string `GlideR`, the system displays script elements such as:

- *`GlideRecord`*
- *`GlideRecordSecure`*

Context-sensitive suggestions are based on script type. For example, when working on a business rule, only suggestions from the server API and for objects such as *`current`* and *`previous`* display. When working on a client script, the system only displays suggestions from the client API.

Client-side scripting

Run JavaScript on the client (web browser) when client-based events occur, such as when a form loads, after form submission, or when a field changes value.

The client-side Glide API provides classes and methods that you can use in client scripts.

Before you begin

Understand the limitations of your scripting environment. For example, client scripts run on forms in the Service Portal or Mobile environments can only include certain APIs. For more information, see Mobile client GlideForm (g form) scripting and migration.

Client-side scripting design and processing

Well-designed client scripts can reduce the amount of time it takes users to complete a form.

Proper client-side processing depends on the form loading first. Making record updates prior to form load can produce unexpected results that bypass client-side processing.

If you create client scripts to control field values on a form, you must use another method to control these field values in a list. You can:

- Disable list editing for the table.
- Create appropriate business rules or access controls for list editing.
- Create data policies.
- Create a separate onCellEdit client script.

Restrict list editing

If you create UI policies or client scripts for fields on a form, you must use another method to ensure that data in those fields is similarly controlled in a list.

With the exception of onCellEdit client scripts, UI policies and client scripts apply to forms only. Use the following methods to restrict list editing when using client scripts:

- Disable list editing for the table.
- Create appropriate business rules or access controls for list editing.
- Create data policies.
- Create a separate onCellEdit client script.

Minimize server lookups

Use client data as much as possible to eliminate the need for time-consuming server lookups.

Client scripting uses either data available on the client or data retrieved from the server. The top ways to get information from the server are g_scratchpad and asynchronous GlideAjax lookup.

The primary difference between these methods is that g_scratchpad is sent once when a form is loaded (information is pushed from the server to the client), whereas GlideAjax is dynamically triggered when the client requests information from the server.

Note:
GlideRecord and g_form.getReference() are also available for retrieving server information. However, these methods are no longer recommended due to their performance impact. Both methods retrieve all fields in the requested GlideRecord when most cases only require one field.

Example: Retrieve server data using g_scratchpad

The g_scratchpad object passes information from the server to the client, such as when the client requires information not available on the form.

For example, if you have a client script that needs to access the field u_retrieve, and the field is not on the form, the data is not available to the client script. A typical solution to this situation is to place the field on the form and then always hide it with a client script or UI policy. While this solution may be faster to configure, it is slower to execute.

If you know what information the client needs from the server before the form is loaded, a display business rule can create g_scratchpad properties to hold this information. Theg_scratchpad is sent to the client when the form is requested, making it available to all client-side scripting methods. This is a very efficient means of sending information from the server to the client. However, you can only load data this way when the form is loaded. The business rule cannot be triggered dynamically. In those cases, use an asynchronous GlideAjax call.

For example, assume you open an incident and need to pass this information to the client:

- The value of the system property css.base.color
- Whether or not the current record has attachments
- The name of the caller's manager

A display business rule sends this information to the client using the following script:

```
g_scratchpad.css = gs.getProperty('css.base.color');
g_scratchpad.hasAttachments = current.hasAttachments();
g_scratchpad.managerName =
 current.caller_id.manager.getDisplayValue();
```

To access scratchpad data using a client script:

```
// Check if the form has attachments
if (g_scratchpad.hasAttachments)
    // do something interesting here
else
    alert('You need to attach a form signed by ' +
 g_scratchpad.managerName);
```

Example: Retrieve server data using asynchronous GlideAjax

Asynchronous GlideAjax allows you to dynamically request information from the server.

This script compares the support group of the CI and the assignment group of the incident by name:

```
//Alert if the assignment groups name matches the support group
function onChange(control, oldValue, newValue, isLoading) {

    if (isLoading)
        return;

    var ga = new GlideAjax('ciCheck');

    ga.addParam('sysparm_name', 'getCiSupportGroup');
    ga.addParam('sysparm_ci', g_form.getValue('cmdb_ci'));
    ga.addParam('sysparm_ag',
 g_form.getValue('assignment_group'));
    ga.getXML(doAlert); // Always try to use asynchronous
 (getXML) calls rather than synchronous (getXMLWait)
}

// Callback function to process the response returned from the
 server
function doAlert(response) {

    var answer =
 response.responseXML.documentElement.getAttribute("answer");

    alert(answer);
}
```

This script relies on the accompanying script include:

```
var ciCheck = Class.create();

ciCheck.prototype = Object.extendsObject(AbstractAjaxProcessor,
 {

    getCiSupportGroup: function() {

        var retVal = ''; // Return value
        var ciID   = this.getParameter('sysparm_ci');
        var agID   = this.getParameter('sysparm_ag');
        var ciRec  = new GlideRecord('cmdb_ci');

        // If we can read the record, check if the sys_ids match
        if (ciRec.get(ciID)) {
```

```
            if (ciRec.getValue('support_group') == agID)
                retVal = 'CI support group and assignment group
 match';
            else
                retVal = 'CI support group and assignment group
 do not match';

            // Can't read the CI, then they don't match
        } else {
            retVal = 'CI support group and assignment group do
 not match';
        }

        return retVal;
    }

});
```

Use the setValue() displayValue parameter for reference fields

When using setValue() on a reference field, include the displayValue parameter to avoid additional server calls.

When using *setValue()* on a reference field, be sure to include the reference field display value as the 3rd parameter. If you set the value without the displayValue, the instance does a synchronous call to retrieve the display value for the record you specified. This extra round trip to the server can impact performance.

This example demonstrates the incorrect way to call setValue:

```
var id = '5137153cc611227c000bbd1bd8cd2005';

g_form.setValue('assigned_to', id); // Client needs to go back
 to the server to
                                    // fetch the name that goes
 with this ID
```

Instead, include the display value as an optional parameter in *setValue()*:

```
var id = '5137153cc611227c000bbd1bd8cd2005';
var name = 'Fred Luddy';

g_form.setValue('assigned_to', id, name); // No server call
 required
```

Use UI policy instead of a client script

When possible, consider using a UI policy instead of a client script.

UI policies provide these benefits over client scripts:

- UI policies have an **Order** field to allow full control over the order in which client-side operations take place.
- UI policies do not require scripting to make a field mandatory, read-only, or visible.

Note:
UI policies apply after client scripts.

Validating the input by using a client script

An excellent use for a client script is to validate the input from the user.

This validation improves the user experience because the user finds out if there are data issues before submitting the information.

An example of validation is to verify that the **Impact** field value is valid with the **Priority** field value. In this example, Low impact is not allowed with High priority.

```
if (g_form.getValue('impact') == '3' &&
 g_form.getValue('priority') == '1')
   g_form.showFieldMsg('impact', getMessage('Low impact now
 allowed with High priority'), 'error');
```

Set client script order

Control the order of execution for your client scripts using the Order field. To avoid having two or more client scripts run concurrently and then conflict, you can add an order for the scripts to run in.

Before you begin

Role required: admin

About this task

Adding an order to the client script creates a processing sequence, ordered from lowest to highest number. If two scripts conflict, the client script with the lower number executes first.

Procedure

1. Navigate to **All** > **System Definition** > **Client Script** and open an existing client script or click **New**.
2. Configuring the form layout to include the **Order** field.
3. Add a number to the order field based on what order you want it to run in relation to other client scripts.
   Choose a lower number for the script you want to execute first.

Avoid DOM manipulation

Avoid Document Object Model (DOM) manipulation if possible. It can cause a maintainability issue when browsers are updated.

Instead, use the GlideForm API or consider a different approach for the solution. In general, when using DOM manipulation methods, you have to reference an element in the DOM by ID or using a CSS selector. When referencing out-of-box DOM elements, there is a risk that the element ID or placement within the DOM could change, causing the code to stop working and/or generate errors. Use forethought, caution, and have a full understanding of the risk you are incurring. Review these objects and reduce the use of DOM manipulation methods as much as possible.

Avoid global client scripts

A global client script is any client script where the selected Table is Global. Global client scripts have no table restrictions, therefore they will load on every page in the system introducing browser load delay in the process.

There is no benefit to loading this kind of scripts on every page.

As an alternative, and for a more modular and scalable approach, consider moving client scripts to a base table (such as Task[task] or Configuration Item[cmdb_ci]) that can be derived for all the

child/extending tables. This eliminates the system loading the scripts on every form in the UI - such as home pages or Service Catalog where they are rarely (if ever) needed.

Enclose code in functions

Enclose the code in a client script inside a function.

Client scripts without a function cause issues with variable scope. When code is not enclosed in a function, variables and other objects are available and shared to all other client-side scripts. If you are using the same variable names, it is possible that they could collide. This can lead to unexpected consequences that are difficult to troubleshoot.

Consider this example:

```
var state = "6";

function onSubmit() {

   if(g_form.getValue('incident_state') == state) {
     alert("This incident is Resolved");
   }
}
```

Because the *state* variable is not enclosed in a function, all client-side scripts, have access to it. Other scripts may also use the common variable name *state*. The duplicate names can conflict and lead to unexpected results. These issues are difficult to isolate and resolve. To avoid this issue, ensure that all code is wrapped in a function:

```
function onSubmit() {

   var state = "6";

   if(g_form.getValue('incident_state') == state) {
     alert("This incident is Resolved");
   }
}
```

This solution is much safer because the scope of the variable *state* is limited to the onSubmit() function. Therefore, the *state* variable does not conflict with *state* variables in other client-side scripts.

Run only necessary scripts

To avoid running time-consuming scripts unnecessarily, make sure that client scripts perform only necessary tasks.

The following examples demonstrate improvements to the initial code sample. Each example demonstrates a particular enhancement to the script to improve performance and avoid unnecessary calls.

Remember that client scripts have no **Condition** field. This means that onLoad() and onChange() scripts run in their entirety every time the appropriate form is loaded. This example is an inefficient onChange() client script set to run when the **Configuration item** field changes.

```
//Set Assignment Group to CI's support group if assignment group
 is empty
function onChange(control, oldValue, newValue, isLoading) {

    var ciSupportGroup =
 g_form.getReference('cmdb_ci').support_group;
```

```
    if (ciSupportGroup != '' &&
 g_form.getValue('assignment_group) != '')
        g_form.setValue('assignment_group',
 ciRec.support_group.sys_id);
}
```

This example improves upon the first by replacing the getReference() or GlideRecord lookup with an asynchronous GlideAjax call.

```
//Set Assignment Group to support group if assignment group is
 empty
function onChange(control, oldValue, newValue, isLoading) {

    var ga = new GlideAjax('ciCheck');

    ga.addParam('sysparm_name', 'getSupportGroup');
    ga.addParam('sysparm_ci', g_form.getValue('cmdb_ci'));
    ga.getXML(setAssignmentGroup);
}

function setAssignmentGroup(response) {

    var answer =
 response.responseXML.documentElement.getAttribute("answer");

    g_form.setValue('assignment_group', answer);
}
```

The *isLoading* flag is the simplest way to prevent unnecessary code from taking up browser time in onChange scripts. The *isLoading* flag should be used at the beginning of any script that is not required to run when the form is loading. There is no need to run this script on a form load because the logic would have already run when the field was last changed. Adding the *isLoading* check to the script prevents it from doing a cmdb_ci lookup on every form load.

The *isTemplate* flag indicates that a template is loading.

```
//Set Assignment Group to CI's support group if assignment group
 is empty
function onChange(control, oldValue, newValue, isLoading,
 isTemplate) {

    if (isLoading)
        return;

    var ga = new GlideAjax('ciCheck');

    ga.addParam('sysparm_name', 'getSupportGroup');
    ga.addParam('sysparm_ci', g_form.getValue('cmdb_ci'));
    ga.getXML(setAssignmentGroup);
}

function setAssignmentGroup(response) {

    var answer =
 response.responseXML.documentElement.getAttribute("answer");

    g_form.setValue('assignment_group', answer);
```

```
}
```

If the onChange script should run during loading, use the following convention:

```
function onChange(control, oldValue, newValue, isLoading,
 isTemplate) {

    if (isLoading) {}; // run during loading

    // rest of script here

}
```

The newValue check tells this script to continue only if there is a valid value in the relevant field. This prevents the script from running when the field value is removed or blanked out. This also ensures that there will always be a valid value available when the rest of the script runs.

```
//Set Assignment Group to CI's support group if assignment group
 is empty
function onChange(control, oldValue, newValue, isLoading,
 isTemplate) {

    if (isLoading)
        return;

    if (newValue) {
        var ga = new GlideAjax('ciCheck');

        ga.addParam('sysparm_name', 'getSupportGroup');
        ga.addParam('sysparm_ci', g_form.getValue('cmdb_ci'));
        ga.getXML(setAssignmentGroup);
    }
}

function setAssignmentGroup(response) {

   var answer =
 response.responseXML.documentElement.getAttribute("answer");

   g_form.setValue('assignment_group', answer);
}
```

To have the script react to a value that changes after the form loads, use the newValue != oldValue check.

Note:
This example does not catch users changing a value and then changing it back to its original value.

```
//Set Assignment Group to CI's support group if assignment group
 is empty
function onChange(control, oldValue, newValue, isLoading,
 isTemplate) {

    if (isLoading)
        return;

    if (newValue) {
```

```
        if (newValue != oldValue) {
            var ga = new GlideAjax('ciCheck');

            ga.addParam('sysparm_name', 'getSupportGroup');
            ga.addParam('sysparm_ci',
 g_form.getValue('cmdb_ci'));
            ga.getXML(setAssignmentGroup);
        }
    }
}

function setAssignmentGroup(response) {

   var answer =
 response.responseXML.documentElement.getAttribute("answer");

   g_form.setValue('assignment_group', answer);
}
```

In this example, the GlideAjax call is buried one level deeper by rearranging the script to check as many things available to the client as possible before running the server calls. The script checks the assignment before executing the GlideAjax call. This prevents the server lookup when the **assignment_group** field is already set.

```
//Set Assignment Group to CI's support group if assignment group
 is empty
function onChange(control, oldValue, newValue, isLoading,
 isTemplate) {

    if (isLoading)
       return;

    if (newValue) {
        if (newValue != oldValue) {
            if (g_form.getValue('assignment_group') == '') {
                var ga = new GlideAjax('ciCheck');

                ga.addParam('sysparm_name', 'getSupportGroup');
                ga.addParam('sysparm_ci',
 g_form.getValue('cmdb_ci'));
                ga.getXML(setAssignmentGroup);
            }
        }
    }
}

function setAssignmentGroup(response) {

   var answer =
 response.responseXML.documentElement.getAttribute("answer");

   g_form.setValue('assignment_group', answer);
}
```

Client scripts

Client scripts allow the system to run JavaScript on the client (web browser) when client-based events occur, such as when a form loads, after form submission, or when a field changes value.

Introduction to client scripts, script types, APIs, and good practices

Use client scripts to configure forms, form fields, and field values while the user is using the form. Client scripts can:

- make fields hidden or visible
- make fields read only or writable
- make fields optional or mandatory based on the user's role
- set the value in one field based on the value in other fields
- modify the options in a choice list based on a user's role
- display messages based on a value in a field

Warning:

Client scripts are intended to optimize the user experience on a form. Client scripts are not meant to protect unwanted access to data.

To prevent unwanted access to data, ensure that sensitive fields are hidden or read-only through ACLs or data policies.

For more information, see Access Control List Rules or Data policy.

Where client scripts run

With the exception of `onCellEdit()` client scripts, client scripts only apply to forms and search pages. If you create a client script to control field values on a form, you must use one of these other methods to control field values when on a list.

- Create an access control to restrict who can edit field values.
- Create a business rule to validate content.
- Create a data policy to validate content.
- Create an `onCellEdit()` client script to validate content.
- Disable list editing for the table.

Note:
Client scripts are not supported on ServiceNow mobile applications.

Client script form

Field	Description
Name	Name of the client script.
Table	Table to which the client script applies.
UI Type	Target user interface to which the client script applies.
Type	`onLoad()` — runs when the system first renders the form and before users can enter data. Typically, `onLoad()` client scripts perform client-side-manipulation of the current form or set default record values.

Field	Description
	onSubmit() — runs when a form is submitted. Typically, *onSubmit()* scripts validate things on the form and ensure that the submission makes sense. An *onSubmit()* client script can cancel form submission by returning a value of false. *onChange()* — runs when a particular field value changes on the form. The *onChange()* client script must specify these parameters. • *control*: the DHTML widget whose value changed. **Note:** *control* is not accessible in mobile and service portal. • *oldValue*: the value the widget had when the record was loaded. **Note:** Old values aren't returned for the HTML field type. • *newValue*: the value the widget has after the change. • *isLoading*: identifies whether the change occurs as part of a form load. • *isTemplate*: identifies whether the change occurs as part of a template load. *onCellEdit()* — runs when the list editor changes a cell value. The *onCellEdit()* client script must specify these parameters. • *sysIDs*: an array of the sys_ids for all items being edited. • *table*: the table of the items being edited. • *oldValues*: the old values of the cells being edited. • *newValue*: the new value for the cells being edited. • *callback*: a callback that continues the execution of any other related cell edit scripts. If *true* is passed as a parameter, the other scripts are executed or the change is committed if there are no more scripts. If *false* is passed as a parameter, any further scripts are not executed and the change is not committed.
Field Name	Name of the field to which the script applies. Available only if the script responds to a field value change (onChange or onCellEdit script types).
Application	Application where this client script resides.
Active	Enables the client script when selected. Unselect this field to disable the client script.
Inherited	Indicates whether the client script applies to extended tables.
Global	If true, the client script runs on all views of the table.
View	Only visible when **Global** is unselected. Views on which the client script will run.
Description	Content describing the functionality and purpose of the client script.

Field	Description
Messages	Text string (one per line) available to the client script as localized messages using `getmessage('[message]')`. For additional information, see Translate a client script message.
Script	Contains the client script.
Isolate script	New client scripts are run in strict mode, with direct DOM access disabled. Access to jQuery, prototype, and the window object are also disabled. To disable this on a per-script basis, configure this form and select the **Isolate script** check box. To disable this feature for all new globally-scoped client-side scripts set the system property glide.script.block.client.globals to false.

UI scripts

UI scripts provide a way to package client-side JavaScript into a reusable form, similar to how script includes store server-side JavaScript. Administrators can create UI scripts and run them from client scripts and other client-side script objects and from HTML code.

UI scripts are not supported for mobile.

Global UI scripts

You can create a UI script and designate it as global, which makes the script available on any form in the system. You cannot create a global UI script in a scoped application.

You can mark a UI script as Global to make it available on any form in the system. For example, you can create a UI script that has a function `helloWorld()`, and has the **Global** field checked:

```
function helloWorld() {
  alert('Hi');
}
```

After you create this global UI script, you can call the `helloWorld()` function from any client script or UI policy you write.

Create a UI script

Create a UI script to define reusable client-side JavaScript code.

Procedure

To create UI scripts, navigate to **System UI** > **UI Scripts** and create or edit a record (see table for field descriptions).

UI scripts

Field	Description
Script Name	Name of the UI script. Ensure the name is unique on your system.
API Name	The API name of the UI script, including the scope and script name (for example, x_custom_app.HelloWorld).
Application	Application that contains the UI script.
Active	Indicator of whether the UI script is active. Only active UI scripts can run.

Field	Description
Global	Indicator of whether the script loads on every page in the system. **Note:** Use caution when creating global UI scripts because they can impact performance. You cannot create a global UI script in a scoped application.
Description	Summary of the purpose of the script.
Script	Client-side script to run when called from other scripts.

Run UI scripts

Follow these guidelines when running UI scripts.

Run a UI script from a form

To run a UI script on a form, Create a formatter and add it to a form. In the associated UI macro, include a `g:requires` tag and specify the *name=* parameter as the name of the UI script followed by the .jsdbx extension. Add the formatter on the form view.

This code ensures that the definitions and results of the UI script are immediately available in the browser.

```
<?xml version="1.0" encoding="utf-8" ?>
<j:jelly trim="false" xmlns:j="jelly:core" xmlns:g="glide"
 xmlns:j2="null" xmlns:g2="null">
    <g2:evaluate var="jvar_stamp">
        var now_GR = new GlideRecord('sys_ui_script');
        gr.orderByDesc('sys_updated_on');
        gr.query();
        gr.next();
        gr.getValue('sys_updated_on');
    </g2:evaluate>
    <g:requires name="<UI SCRIPT NAME>.jsdbx"
 params="cache=$[jvar_stamp]" />
</j:jelly>
```

Call a UI script in HTML

To run a UI script from HTML code, use the `<script>` tag and specify the `src=` argument as the API name of the UI script followed by the .jsdbx extension. For example, include the UI script named *CoolClock* with this code:

```
<script language="javascript" src="CoolClock.jsdbx" />
```

Call a UI script from client-side code

Access UI scripts from within client-side code using the *g_ui_scripts* global object. For more information, see GlideUIScripts - Client.

Note:
This class does not support UI scripts with the **Global** field set to true.

Catalog client scripts

Client-side scripts can add dynamic effects and validation to forms. Scripts can apply to service catalog items or variable sets, allowing administrators to use the same functionality that is available on other forms.

You can use client side scripts to:

- Get or set variable values.
- Hide or display variables.
- Make variables mandatory or not.
- Validate form submission.
- Add something to the cart.
- Order something immediately.

Catalog client script considerations

When you create catalog client scripts, be aware of the following considerations.

- Catalog client scripts run when a user orders an item from the service catalog. Catalog client scripts can also run when variables or variable sets for a catalog item are displayed when a user requests that item.
- For a variable to be accessible using a catalog client script, it must have a variable name. Variables without names do not appear in the list of available variables.
- When using standard client scripts on a Requested Item or Catalog Task form, make a note of fields with the same name as variables. If a table field and a variable of the same name are both present on a form, the table field is matched when it is accessed using a script. If this happens, specifically address the variable by naming it `variables.variable name`. For example: `g_form.setValue('variables.replacement', 'false');`
- If you are using record producers to pass variables from the service catalog to other types of records, these variables are made visible in those records with a variable editor, such as the Change Variable Editor UI formatter on Change request forms. You can manipulate these variables using standard client script methods, such as `setDisplay`, `setMandatory`,`setValue`, and `getValue`.
- Catalog client scripts can be used for catalog items included in a wizard.
- You can use the `g_form.refreshSlushbucket(fieldName)` API to update a list collector variable.

Catalog client script differences

Catalog client scripts are very similar to standard client scripts, with a few important differences.

- Instead of selecting a table such as Incident for the script, select a catalog item or variable set. As your system may have a large number of catalog items, you should select a catalog item or variable set using a reference field instead of the choice list that the standard Client Script form uses.
- When using an *onChange()* catalog client script, it is linked to a particular variable instead of a field. The system automatically populates the variable name selection list with any named variables from the catalog item or variable set selected.

Create a catalog client script

Follow this procedure to create a catalog client script.

Procedure

1. Navigate to **All** > **Service Catalog** > **Catalog Administration** > **Catalog Client Scripts**.
   A list of current custom catalog client scripts appears.
2. Click **New**.
3. Fill in the fields, as appropriate (see table).

Field	Description
Name	Enter a unique name for the catalog client script.
Applies to	Select the item type this client script applies to: ○ **A Catalog Item**: enables the Catalog item field. ○ **A Variable Set**: enables the Variable set field.
Active	Select the check box to enable the client script. Clear the check box to disable the script.
UI Type	Whether to apply this to desktop, mobile, or both.
Script	Enter the client script that should run on the service catalog item.
Type	Select when the script should run, such as **onLoad** or **onSubmit**.
Catalog item or Variable set	Select a catalog item or variable set from the list. The field name and options available depend on the selection in the **Applies to** field.
Applies on a Catalog Item view	Select the check box to apply the catalog client script to catalog items displayed within the order screen on the service catalog. Available in the requester view.
Applies on Requested Items	Select the check box to apply the catalog client script on a Requested Item form, after the item is requested. Available in the fulfiller view. See VEditor .
Applies on Catalog Tasks	Select the check box to apply the catalog client script when a Catalog Task form for the item is being displayed. Available in the fulfiller view. See VEditor .
Applies on the Target Record	Select the check box to support the catalog UI policy on a record created for task-extended tables via record producers. See Default variable editor .

4. Click **Submit**.

Catalog client script examples

Examples of client scripts to perform common actions.

Example: Get the value of a variable

Use the following syntax to obtain the value of a catalog variable. Note that the variable must have a name. Replace `variable_name` with the name of the variable.

```
g_form.getValue('variable_name');
```

Example: Restrict the number of characters a user can type in a variable

This is an example of a script that runs when the variable is displayed, rather than when the item is ordered.

```
function onLoad(){
  var sd = g_form.getControl('short_description');
  sd.maxLength=80;
}
```

Mobile client GlideForm (g form) scripting and migration

Client scripting for mobile is identical to scripting for the web, with some exceptions. All new scripts must conform to certain guidelines. The following items are affected on the mobile platform: client scripts, UI policies, navigator modules, and UI actions.

Client scripts

For new or existing scripts to be valid for mobile, they must conform to the following requirements:

- Use the new mobile methods in place of `g_form.getControl()`.
- Do not use deprecated methods.
- Do not reference unsupported browser objects.
- Do not make synchronous JavaScript, `GlideAjax`, and `GlideRecord` calls.
- Do not call methods that are not available for mobile.
- Enable scripts to run on the mobile UI.

Requirements	
Use the new mobile methods	Several new methods are available for modifying form fields instead of directly manipulating the HTML. These methods replace previous usages of `g_form.getControl()`, which is deprecated for the mobile platform. In your existing scripts, ensure that the new methods are used in place of methods that are not valid on the mobile platform. For information on these new methods, refer to Mobile GlideForm() API.
Do not use deprecated methods	The following methods have been deprecated for the mobile platform because direct access to HTML elements is not allowed: • `g_form.getControl()` • `g_form.getFormElement()` • `g_form.getElement()` To ensure that existing scripts are compatible, remove all calls to deprecated methods from your code. For new scripts, do not use deprecated methods if you want the script to be valid for mobile. For `g_form.getControl()`, some of the functionality previously included with this method has been extracted to individual methods. Instead of `g_form.getControl()`, use the new methods described on the developer site.

Requirements (continued)

Do not reference unsupported browser objects	The following browser objects are not supported in mobile scripts: • Window • jQuery or Prototype ($, $j, or $$) • Document Make sure that new scripts do not use these objects, and remove any usage of these objects from your existing scripts. Use *GlideForm (g_form)* instead, which provides methods such as *setLabel()*, *addDecoration()*, and *hasField()* for accomplishing the same tasks.
Do not make synchronous JavaScript calls	The mobile platform does not allow synchronous JavaScript calls. The *g_form.getReference()* method must now have the callback parameter defined. For example: `g_form.getReference(fieldName, callback)` Be sure that all *g_form.getReference()* calls include the callback parameter. For example, the following script does not include a callback and is incompatible with the mobile platform: `var userName = g_form.getReference('assigned_to').user_name; g_form.setValue('u_assigned_user_name', userName);` The following script has been updated to include the callback and is compatible with the mobile platform: `g_form.getReference('assigned_to', function(now_GR) { g_form.setValue('u_assigned_user_name', gr.user_name); });`
Do not make synchronous Ajax calls	The mobile platform does not allow synchronous *GlideAjax* calls. Any use of *getXMLWait()* in a *GlideAjax* call will not work on the mobile platform. Be sure that all *GlideAjax* calls are asynchronous. For more on synchronous versus asynchronous *GlideAjax* calls and *getXMLWait()*, see AJAX. For information on the available *GlideAjax* methods, refer to the GlideAjax API.
Do not make synchronous *GlideRecord* calls	The mobile platform does not allow synchronous GlideRecord calls. Make sure that any existing *GlideRecord* calls include a callback. For example, the following script does not include a callback and is incompatible with the mobile platform: `var now_GR = new GlideRecord('incident'); gr.addQuery('number', g_form.getValue('related_incident')); gr.query(); gr.next();`

Requirements (continued)

```
g_form.setValue('u_related_incident_description',
gr.short_description);
```

The following script has been updated to include the callback, and is compatible with the mobile platform:

```
var now_GR = new GlideRecord('incident');
gr.addQuery('number',
g_form.getValue('related_incident'));
gr.query(function(now_GR) {
    gr.next();

g_form.setValue('u_related_incident_description',
gr.short_description);
});
```

Do not use methods unavailable on the mobile platform	Due to the limitations and reduced functionality that is imposed by the mobile platform, the following methods are not deprecated but are not available on the mobile platform. If these run on the mobile platform, no action occurs: • `showRelatedList ()` • `hideRelatedList ()` • `showRelatedLists ()` • `hideRelatedLists()` • `flash()` • `getSections()` • `enableAttachments()` • `disableAttachments()` • `setReadonly()` (Note that `setReadOnly()` is available) • `getParameter()`
Enable scripts for mobile	Scripts must be enabled for the mobile platform.

Note:
Focusing an element on a mobile form is not supported.

UI policies

Use the **Run scripts in UI type** field to determine whether scripts run on the mobile platform, the desktop, or both. Update existing policies so that they apply to either the mobile platform or both. For new scripts, also ensure that the mobile option or both is selected.

Navigator modules

For existing code, modules must be transferred to either the sys_ui_application or sys_ui_module tables to be available on the mobile platform. When developing new code, be sure that all modules are created in the sys_ui_application or sys_ui_module tables.

UI actions

UI actions must be transferred to the sys_ui_ng_action table to appear on the mobile platform. UI action scripts that do not use deprecated methods do not require changes to the script itself. For new UI actions, be sure that they are created in the sys_ui_ng_action table.

AJAX

AJAX (asynchronous JavaScript and XML) is a group of interrelated, client-side development techniques used to create asynchronous Web applications.

AJAX enables web applications to send and retrieve information to and from a server in the background, without impacting the user experience with the displayed web page.

GlideAjax

The `GlideAjax` class allows the execution of server-side code from the client. `GlideAjax` calls pass parameters to the script includes, and, using naming conventions, allows the use of these parameters.

Note:
This functionality requires a knowledge of JavaScript.

Using `GlideAjax`:

- Initialize `GlideAjax` with the name of the script include that you want to use.
- When creating the script include, you must set the name field to be exactly the same as the class name.
- When creating the script include, you must select the **Client callable** check box.
- Specify the parameter `sysparm_name`. `GlideAjax` uses `sysparm_name` to find which function to use.
- Any extra parameters may be passed in, all of which must begin with `sysparm_`. Avoid using predefined parameter names:
  - `sysparm_name`
  - `sysparm_function`
  - `sysparm_value`
  - `sysparm_type`
- Code is then executed with the `getXML()` or `getXMLWait()` functions.

For additional information, refer to the GlideAjax API.

Examples of asynchronous GlideAjax

There are two parts to the asynchronous `GlideAjax` script: client-side and server-side code.

Hello World: Returning a value from the server

Example: Client side

This code runs on the client (the web browser). Create a client script as normal. This sends the parameters to server, which then does the processing. So that the client does not wait for the result, a callback function is used to return the result, passed to the `getXML()` function. (In this case it is called `HelloWorldParse`.)

The `getXMLWait()` function does not need a separate callback function, but this will block the client. If the client-server communication takes a long time (for example on slow networks), the

application will seem unresponsive and slow. An example of *getXMLWait()* is in the following section.

```
var ga = new GlideAjax('HelloWorld');
ga.addParam('sysparm_name', 'helloWorld');
ga.addParam('sysparm_user_name', "Bob");
ga.getXML(HelloWorldParse);

function HelloWorldParse(response) {
  var answer =
 response.responseXML.documentElement.getAttribute("answer");
  alert(answer); }
```

Example: Server side

The server-side code for the above function. Do not create a business rule, but instead navigate to **System Definition > Script Include** and create a new script. Paste in the code below.

Note:
You must set the name of the script include to `HelloWorld`.

- The *sys_script_include* code must extend the *AbstractAjaxProcessor* class and be Glide AJAX enabled.
- Function names starting with "_" are considered private and are not callable from the client.
- Avoid overriding methods of *AbstractAjaxProcessor*, including `initialize`. While it is possible to invoke methods of your superclass object which you have overridden, it is complicated and best avoided altogether.

```
var HelloWorld = Class.create();
HelloWorld.prototype =
 Object.extendsObject(AbstractAjaxProcessor, {
   helloWorld:function() { return "Hello " +
 this.getParameter('sysparm_user_name') + "!"; } ,
   _privateFunction: function() { // this function is not client
 callable
    }
 });
```

This results in an alert box that says 'Hello Bob!' when you visit the form.

Returning multiple values

Since the response is an XML document we are not limited to returning a single `answer` value. Here is a more complex example returning multiple XML nodes and attributes.

Example: AJAX processor script include

```
/*
 * MyFavoritesAjax script include Description - sample AJAX
 processor returning multiple value pairs
 */
var MyFavoritesAjax = Class.create();
MyFavoritesAjax.prototype =
 Object.extendsObject(AbstractAjaxProcessor, {

  /*
```

```
  * method available to client scripts call using:
  * var gajax = new GlideAjax("MyFavoritesAjax");
  * gajax.addParam("sysparm_name","getFavorites");
  */
 getFavorites: function() { // build new response xml element
 for result
        var result = this.newItem("result");
   result.setAttribute("message","returning all favorites");

   //add some favorite nodes with name and value attributes
        this._addFavorite("color","blue");
        this._addFavorite("beer","lager");
        this._addFavorite("pet","dog");
      },
  // all items are returned to the client through the inherited
 methods of AbstractAjaxProcessor
  _addFavorite: function(name, value) {
         var favs = this.newItem("favorite");
    favs.setAttribute("name",name);
    favs.setAttribute("value",value); },

 type:"MyFavoritesAjax"

 });
```

Example: Client script

```
// new GlideAjax object referencing name of AJAX script include
var ga = new GlideAjax("MyFavoritesAjax");
// add name parameter to define which function we want to call
// method name in script include will be getFavorites
ga.addParam("sysparm_name","getFavorites");

// submit request to server, call ajaxResponse function with
 server response

ga.getXML(ajaxResponse);

function ajaxResponse(serverResponse) {
  // get result element and attributes
  var result =
 serverResponse.responseXML.getElementsByTagName("result");
  var message = result[0].getAttribute("message");

  //check for message attribute and alert user
  if(message) alert(message);

  //build output to display on client for testing
  var output = "";

  // get favorite elements
  var favorites =
 serverResponse.responseXML.getElementsByTagName("favorite");
  for(var i = 0; i < favorites.length; i ++) {
    var name = favorites[i].getAttribute("name");
    var value = favorites[i].getAttribute("value");
    output += name + " = " + value + "\n "; }
```

```
  alert(output); }
```

Example: XML response

```
<xml sysparm_max= "15" sysparm_name="getFavorites"
 sysparm_processor="MyFavoritesAjax">
  <result message = "returning all favorites"></result>
  <favorite name = "color" value = "blue"></favorite>
  <favorite name = "beer" value = "lager"></favorite>
  <favorite name = "pet" value = "dog"></favorite>
</xml>
```

Examples of synchronous GlideAjax

Use synchronous when your script cannot continue without the *GlideAjax* response. This stops the session until the response is received.

If your use case demands that no further processing can occur until the *GlideAjax* response has been received, you can use *getXMLWait()*. However, because this will slow down your code and lock the user session until the response is received, it is generally recommended that you use *getXML()* with a callback function.

Note:
Do not use *AJAXEvaluateSynchronously*.

The *getXMLWait()* method is not available in scoped applications.

This code results in a client-side alert that displays `The Server Says Hello Bob!`.

The client code.

```
var ga = new GlideAjax('HelloWorld') ;
ga.addParam('sysparm_name','helloWorld');
ga.addParam('sysparm_user_name',"Bob");
ga.getXMLWait();
alert(ga.getAnswer());
```

The server-side script include code.

```
var HelloWorld = Class.create();
HelloWorld.prototype =
 Object.extendsObject(AbstractAjaxProcessor, {
helloWorld: function()
 { return "The Server Says Hello " +
 this.getParameter('sysparm_user_name') + "!"; } } );
```

AJAXClientHelper

Provides helper functions for Ajax clients to retrieve a value from an Ajax client.

Where to use

Use this script include wherever your need to retrieve a value from an Ajax client.

Method summary

Method summary	Description
`getDisplay()`	Gets the display value from the choice list.

Method detail

API method	Description	Input parameters	Output returns
`getDisplay()`	Gets the display value from the choice list.	none	The display value.

Example: Curl

```
// getDisplay
(function(table, sysId) {
    var ga = new GlideAjax('AjaxClientHelper');
    ga.addParam("sysparm_name", "getDisplay");
    ga.addParam('sysparm_table', 'incident');
    ga.addParam('sysparm_value',
 "0598b22b877313003c1c8467a7cb0b71");
    ga.getXMLWait();
    return ga.getAnswer();
}("incident", "0598b22b877313003c1c8467a7cb0b71")); // Returns
 'INC0010001'
```

Useful scripts

Server-side and client scripts that provide useful functionality not included in the core system.

Business rule use cases

Use cases for business rules include aborting a database action and restricting record access.

Abort a database action

You can use a before business rule script to cancel or abort the current database action using the `current.setAbortAction(true)` method.

If the before business rule is executed during an insert action, and a condition in the script calls `current.setAbortAction(true)`, the new record stored in `current` is not created in the database.

Restricting record access

You can use a query business rule that executes before the database query to prevent users from accessing certain records.

Warning:
The customization described here was developed for use in specific instances, and is not supported by Now Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

Consider the following example from a default business rule that limits access to incident records.

Default business rule limits access to incident records

Name	Table	When
incident query	Incident	before, query

Example: Restricting record access

In the following example, users are restricted from accessing incident records unless they have the itil role and are listed in the *Caller* or *Opened by* field. When self-service users open a list of incidents, they can only see the incidents they submitted.

```
if (!gs.hasRole("itil")&& gs.isInteractive()) {
  var u = gs.getUserID();
  var qc = current.addQuery("caller_id",
 u).addOrCondition("opened_by",
 u).addOrCondition("watch_list","CONTAINS", u);
  gs.print("query restricted to user: " + u);}
```

Note:
You can also use access controls to restrict the records that users can see. For information, see Access Control List Rules.

Schedule script for weekdays

Type: Business Rules/Client Scripts.

This script schedules the script for weekdays. Insert any script where it says "Your Script Here."

```
var go ='false';
var now =new Date();

// Correct time zone, which is by default GMT -7
now.setHours(now.getHours()+8);
var day = now.getDay();

// No go on Saturday or Sunday
if(day !=0&& day !=6){

// (your script here)

}
```

Set date field according to current date

This script sets a date field depending on the current day of the week. In this example, if the day is Monday through Wednesday, it sets the date to this coming Monday; otherwise it sets the date field to next Monday.

```
function setCabDate(){
var today = new Date();
var thisDay = today.getDay();

//returns 0 for Sunday, 1 for Monday, through 6 for Saturday.
var thisMon = new GlideDateTime();
thisMon.setDisplayValue(gs.beginningOfThisWeek());
var nextMon = thisMon.getNumericValue();
```

```
nextMon +=(1000*60*60*24*7);

if((thisDay <4)&&(thisDay >0))
  //if today is Mon thru Wed (thisDay = 1, 2, or 3), set cab to
 this coming Monday.

 current.u_req_cab_rev_date.setDateNumericValue(thisMon.getNumer
icValue());
else if((thisDay >=4)||(thisDay ==0))
  //if today is Thurs thru Sun (thisDay = 4, 5, 6, or 0), set
 cab to next Monday.
  current.u_req_cab_rev_date.setDateNumericValue(nextMon);
}
```

To validate the input of all date/time fields, you can use the following in a validation script (**System Definition** > **Validation Scripts**). Because the date/time format is hard coded in this script, it must match your instance's date/time format. If your instance's date/time format changes, you must update your validation script.

Set the validation script's type to *Date/Time*. Then, with this validation script, if a user enters an incorrect format in a date/time field, they receive an error message.

```
function validate(value){
// empty fields are still valid dates
if(!value)
    return true;

// We "should" have the global date format defined always
 defined. But there's always that edge case.
if(typeof g_user_date_time_format !=='undefined')
    return isDate(value, g_user_date_time_format);

// if we don't have that defined, we can always try guessing
return parseDate(value)!==null;}
```

For more information, see Validation script use case - Date and time.

Client-side script use cases

Use cases for client-side scripts include displaying field messages, changing form colors, adding fields, and creating UI routing actions.

Add a field to the service catalog checkout

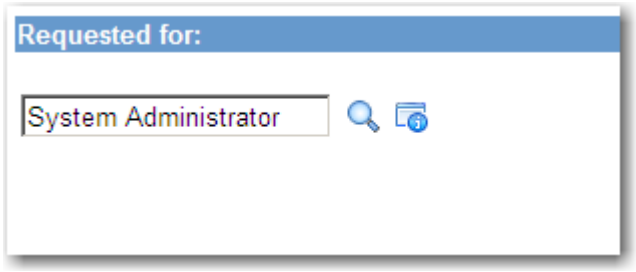
This is an example of adding a **Company** field to the checkout below the **Requested for** field using non-cart layout macros, that is, *glide.sc.use_cart_layouts* is `false`.

Before you begin

Role required: Admin

About this task

Requested for field



This field passes a provided value to the **Company** field of the Service Catalog Request.

This example makes the following assumptions:

- The instance using two-step checkout. If two-step checkout is not enabled, enable it before beginning. For more information, see Service Catalog checkout models.
- This example populates the **Company** field on the Service Catalog Request form. If the field does not appear on the form, configure the form before beginning. For instructions, see Personalize a form.

Procedure

1. Go to **System UI > UI Macros** and select **servicecatalog_cart_template**.
2. Find where there are hidden variables declared and add the following line:

```
<input type="HIDDEN" name="cart_id" id="cart_id"
 value="$[sc_cart.sys_id]" />
```

3. Find the following code, which generates the **Requested For** code:

```
<tr class="header">
<td width = "30%">
  ${gs.getMessage('Requested for')}:
  </td>
  <td width="70%">
    <label for="requestor_location">${gs.getMessage('Deliver
 to')}:</label>
  </td>
</tr>
<tr><td>$[SP]</td>
</tr>
  <tr><td valign="top">
    <j2:if test="$[jvar_can_delta_rf == false]">
      $[sc_cart.requested_for.getDisplayValue()]
    </j2:if>
    <j2:if test="$[jvar_can_delta_rf != false]">
      <g2:catalog_requested_for />
    </j2:if>
  </td>
  <td>
    <textarea id="requestor_location" style="width:100%"
 rows="4"
```

```
      name="requestor_location" wrap="soft"
 onChange="catDeliveryAddress('$[sc_cart.sys_id]',
 'requestor_location');">
      $[sc_cart.delivery_address]
    </textarea>
  </td>
</tr>
<tr>
  <td>$[SP]</td>
</tr>
```

4. Add the following code afterward:

```
<tr class="header">
  <td colspan="2">Company</td>
</tr>
<tr>
  <td>$[SP]</td>
</tr>
<tr>
  <td colspan="2">
    <g2:ui_reference name="core_company" table="core_company"
 onchange="setCartValue()"/>
  </td>
</tr>
<tr>
  <td>$[SP]</td>
</tr>
```

Note:
The `'ui_reference'` macro defines a reference field. There are several macros for different field types. You can see examples of these field types under **System UI -> UI Macros**. These macros start with `'ui_'`. For this example, the reference field created is named **core_company**. For more information, see UI macros.

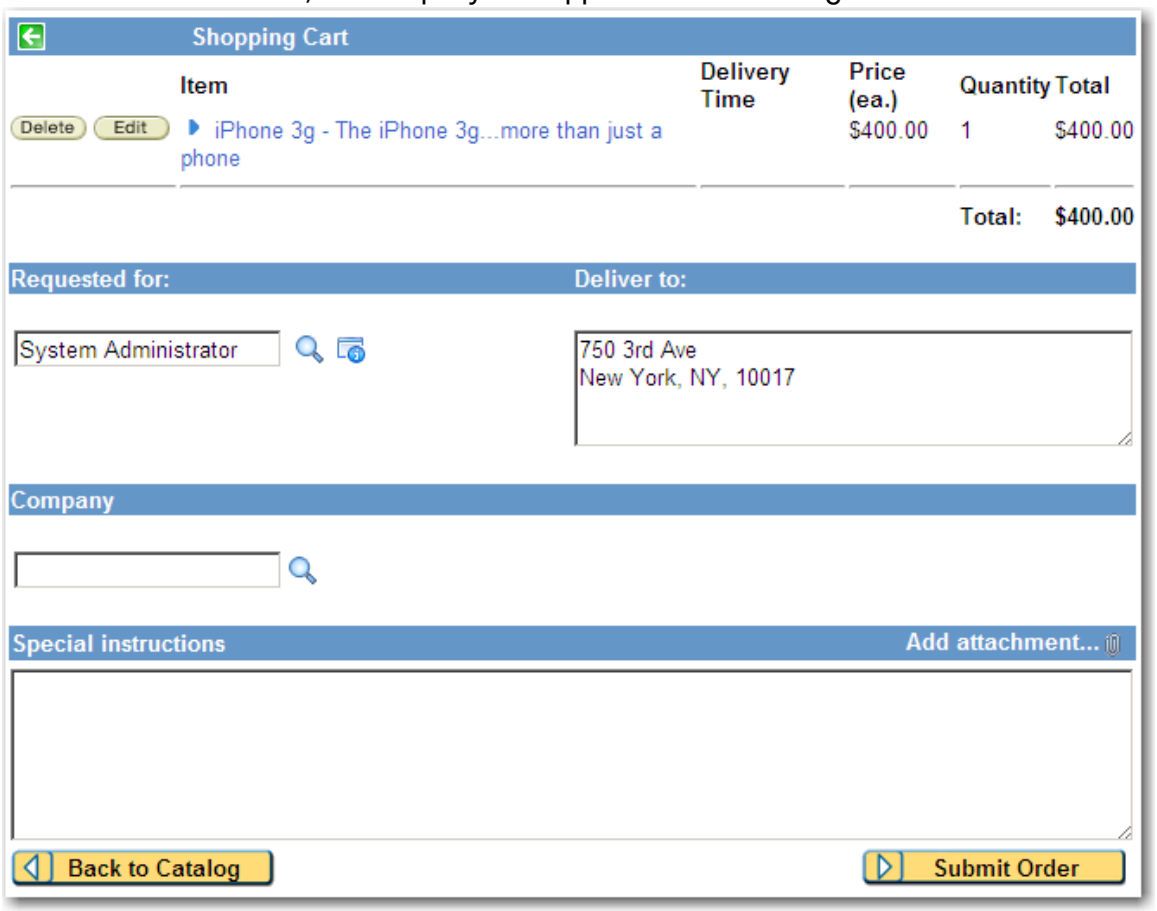
5. Now navigate to **System UI > UI Pages** and select the **servicecatalog_checkout_one** UI Page.
6. Add the followings script to the **Client script** field.

```
function setCartValue() {
  var newField = gel('core_company');
  var myCart = gel('cart_id');
  var cart_item = new GlideRecord('sc_cart_item');
  cart_item.addQuery('cart', myCart.value);
  cart_item.query();
  if(cart_item.next()) {
    cart_item.hints = "<hints><entry
 key='sysparm_processing_hint'
 value='setfield:request.company=" + newField.value +
 "'/></hints>";
    cart_item.update();
  }
}
```

For this example, the reference field was called **core_company**, and the field being populated on the request is **company**. If different fields are used:

- Find this line: `var company = gel('core_company');` and replace **core_company** with the name of the field in the checkout.
- In the line that starts with `'cart_item.hints'` replace `'request.company'` with the name of the field to be populated on the request ticket where `'request'` is the request being generated and `'company'` is the name of the field.

Result
When an item is ordered, the company field appears on the Catalog form:



Add autofill functionality

Add autofill functionality is also called incident template, auto assignments, quick calls, call script, or auto populate.

To auto-fill a **Short Description** field based on the **Subcategory** selected:

1. Create a lookup table.
2. Populate the key field, **Subcategory**.
3. Populate the auto-filled field, **Short Description**.

```
function onChange(control, oldValue, newValue, isLoading) {
  if (isLoading) { return; }
  var newrec = gel('sys_row');
  //Check if new record
  if (newrec.value == -1) {
    var lookup = new GlideRecord('u_short_desc_lookup');
    lookup.addQuery('u_subcategory',
 g_form.getValue('subcategory'));
```

```
    lookup.query();
    var temp; //temp var - reusable
    if (lookup.next()) {
      temp = lookup.u_short_description;
        if (null != temp) { //Set the form value from lookup if
 there is a lookup value
          g_form.setValue('short_description', temp); }
        else {
          g_form.setValue('short_description', "" ); } }
   else {
     //If a lookup record does not exist based on
 lookup.addQuery
     //Then set to UNDEFINED or NULL depending on type
      g_form.setValue('short_description', ""); } }
}
```

You can populate many fields or pull in call script questions into the **Comments** field so call center personnel gather good information to pass on to a technician.

Setting a field to password reset

Lookup table has a record with the following key and auto-fill settings:

- **Subcategory** = *Password*
- **Short Description** = *Password Reset*

Client script settings:

- **Type** = *onChange*
- **Table name** = *incident*
- **Field name** = *Subcategory*

When the user selects the subcategory of *Password* on the Incident form, a client script looks up the matching record and sets the short description equal to *Password Reset*.

Change form color on state change

Changes color of a form field of the form on state change. The script can easily be changed to adjust any property of any object on the page accessible via the HTML DOM.

> **Warning:**
> The customization described here was developed for use in specific instances, and is not supported by Now Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

Name: Change Form Color on State Change

Type: Client script

Description: Changes color of a form field of the form on state change. The script can easily be changed to adjust any property of any object on the page accessible via the HTML DOM.

Script:

```
function onChange(control, oldValue, newValue, isLoading) {
  var elementID = gel("incident.priority");
    switch(newValue) {
```

```
     case "1": elementID.style.backgroundColor = "red"; break;
     case "2": elementID.style.backgroundColor = "tomato";
break;
     case "3": elementID.style.backgroundColor = "orange";
break;
     case "4": elementID.style.backgroundColor = "yellow";
break;
     case "5": elementID.style.backgroundColor = "green";
break;
     default: elementID.style.backgroundColor = "white";
break; } }
```

Create a UI routing action

This solution enables you to create a record with the service desk without knowing whether it is an incident or request item; the service desk can then route the record to the appropriate table.

Before you begin

Role required: **Admin**

Procedure

1. Create a new table that extends the `task` table (for example, New Call).
2. Create a module to create a new New Call record.
3. Create any fields that you want on the New Call table.

   The only fields you need are those fields necessary to determine whether the new call should route to an Incident or a Request Item. Ensure that the form contains any fields that you want to pass to the Incident or Request Item. In this example, the following are created on the form:

   - **Requested for** (reference)
   - **Location** (reference)
   - **Call type** (choice with two values--Incident and Request)
   - **Request Item** (reference to the `sc_cat_item` Item table)
4. Add some UI policies to set a couple of fields to mandatory and hide the **Request item** field based on the **Call type** selection.
5. Remove unnecessary buttons and functionality from the form.
6. Create a new UI Action button.
   This button redirects the user to either an incident or a request. It also creates the incident record and copies values to the incident and the Request Item form.

```
var reqItem = current.u_item;
var requestedFor = current.u_requested_for;
var location = current.location;

if(current.u_incident_request == 'Incident'){
  //Create a new incident record and redirect to the new
 incident
  var rec = new GlideRecord('incident');
  rec.initialize();
  rec.caller_id = requestedFor;
  rec.location = location;
  rec.insert();
  action.setRedirectURL(rec);
```

```
}

if(current.u_incident_request == 'Request'){
  //Build the url and route the user to the request item
  var url = '';
  if(current.u_item.sys_class_name == 'sc_cat_item_guide'){
    url =
 'com.glideapp.servicecatalog_cat_item_guide_view.do?sysparm_in
itial=true&sysparm_guide=' +
      reqItem + '&sysparm_user=' + requestedFor +
 '&sysparm_location=' + location;
  }
  else{
    url =
 'com.glideapp.servicecatalog_cat_item_view.do?sysparm_id=' +
 reqItem + '&sysparm_user=' +
      requestedFor + '&sysparm_location=' + location;
  }
  action.setRedirectURL(url);
}
```

7. The **Route** button in the preceding example passes the **Requested for** and **Location** values in the URL to the Request Item form.
   Ensure that you have variables called *requested_for* and *location* on your item, record producer, or order guide that map these values using the following client script. There is a limit as to how much information you can pass, as the URL has a restricted length. Avoid sending information from long text fields using this method.

```
function onLoad() {
  var url = document.location.toString();
  var userKey = 'sysparm_user=';
  var locKey = 'sysparm_location=';
  var userPosition = url.indexOf(userKey);
  var locPosition = url.indexOf(locKey)
  if (userPosition != -1) {
    var user = url.substr(userPosition+userKey.length, 32);
    g_form.setValue('requested_for', user);
  }
  if (locPosition != -1) {
    var loc = url.substr(locPosition+locKey.length, 32);
    g_form.setValue('location', loc);
  }
}
```

Display field messages

Rather than use JavaScript *alert()*, for a cleaner look, you can display an error on the form itself. The methods *showFieldMsg()* and *hideFieldMsg()* can be used to display a message just below the field itself.

showFieldMsg and *hideFieldMsg* are methods that can be used with the *g_form* object.

These methods are used to change the form view of records (Incident, Problem, and Change forms). These methods may also be available in other client scripts, but must be tested to determine whether they work as expected.

When a field message is displayed on a form on load, the form scrolls to ensure that the field message is visible. Ensuring that users do not miss a field message because it was off the screen.

The global property *glide.ui.scroll_to_message_field* controls automatic message scrolling when the form field is offscreen (scrolls the form to the control or field).

Method Detail

Method Detail	Parameters	Example
showFieldMsg(input, message, type, [scrollform])	• input — name of the field or control • message — message you would like to appear • type — 'info', 'error', or 'warning'; defaults to info if not supplied • scroll form — (optional) Set *scrollForm* to false to prevent scrolling to the field message offscreen	Error Message `g_form.showFieldMsg('impact','Low impact not allowed with High priority','error');`  Informational Message `g_form.showFieldMsg('impact', 'Low impact response time can be one week','info');` `//or this defaults to info type` `//` `g_form.showFieldMsg('impact', 'Low impact response time can be one week');` hideFieldMsg(input)	• input — name of the field or control • clearAll — (optional) boolean parameter indicating whether to clear all messages. If true, all messages for the field are cleared. If false or empty, only the first message is removed	Removing a Message `//this will clear the first message printed to the field` `g_form.hideFieldMsg('impact');`

Legacy support

The *showErrorBox()* and *hideErrorBox()* methods are not recommended.

Using client and server code in a UI action

You can use a script to validate input upon a UI Action click on the client side before updating the record on the server side. The user will not have to click the button twice to validate the required fields and update the record.

The script calls the client function for client-side validation, and the UI action completes the task if it passes. The `code that runs without onclick` statement ensures that the server-side function does not run until the client function is no longer running. If successful, the server-side function runs and updates the record.

```
// Client-side onclick function
function resolveIncident() {
  // Set the 'Incident state' and 'State' values to 'Resolved',
 and display mandatory fields
  g_form.setValue('incident_state', 6);
  g_form.setValue('state', 6);
  g_form.setValue('resolved_by', g_user.userID);

  // Call the UI action and skip the 'onclick' function
  gsftSubmit(null, g_form.getFormElement(),
 'resolve_incident'); //MUST call the 'Action name' set in this
 UI Action
}

// Code that runs without 'onclick'
// Ensure call to server-side function with no browser errors
if (typeof window == 'undefined')
  serverResolve();

// Server-side function
function serverResolve() {
  current.incident_state = IncidentState.RESOLVED;
  current.state = IncidentState.RESOLVED;
  current.resolved_by = gs.getUserID();
  current.update();
}
```

gsftSubmit(String control, Object form, String action_name)

Submits a form as if the user had clicked a UI Action after checking for required fields and executing *`onSubmit()`* client scripts. Enables calling client-side code and server-side code and in a single UI action.

Parameters

Name	Type	Description
control	String	Name of a form button on which you want to simulate a user click. Use `null` otherwise.
form	Object	Optional. The form element that contains the submitted input. You can retrieve this value by calling the *`g_form.getFormElement()`* method.
action_name	String	Action name. This value is provided in the record listed in the UI Actions [sys_ui_action] table.

Parameters (continued)

Name	Type	Description
		For example, `'resolve_incident'` is the action name of the **Resolve** button in the Incident [incident] table.

Field script use cases

Common use cases for field customization scripts.

> **Warning:**
> The customization described here was developed for use in specific instances, and is not supported by Now Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

For more information, see Server API reference.

Automatically populate a field

The following example shows how to use a client script to auto-fill a **Short Description** based on the selected **Subcategory**.

In this case, if the table has a record with **Subcategory** = Password and **Short Description** = Password Reset. When the user selects the **Subcategory** of **Password** on the Incident form, a client script looks up the matching record and sets **Short Description** equal to Password Reset.

Client script settings:

- *Type* = onChange
- *Table name* = incident
- *Field name* = Subcategory

```
function onChange(control, oldValue, newValue, isLoading){
    if(isLoading){return;}
    var newrec = gel('sys_row');
    //Check if new record
    if (newrec.value == -1) {
        var lookup = new GlideRecord('u_short_desc_lookup');
        lookup.addQuery('u_subcategory',
 g_form.getValue('subcategory'));
        lookup.query();
        var temp; //temp var - reusable
        if(lookup.next()){
            temp = lookup.u_short_description;
```

```
            if(null != temp) {
                //Set the form value from lookup if there is a
 lookup value
                g_form.setValue('short_description', temp);
            } else {
                g_form.setValue('short_description',"");
                }
         } else {
             //If a lookup record does not exist based on
 lookup.addQuery
             //Then set to UNDEFINED or NULL depending on type
             g_form.setValue('short_description',"");
             }
    }
}
```

Disable HTML tags in descriptions

This code disables HTML tags in **Description** and **Short Description** fields by substituting the tags with non-executing versions.

```
doit();

function doit(){
 var desc = current.description.toString();
 var shdesc = current.short_description.toString();
 if(desc.indexOf('script>')>-1|| shdesc.indexOf('script>')>-1){
   desc = desc.replace(/<script>/g,"(script)");
   current.description =
 desc.replace(/<\/script>/g,"(\/script)");
   shdesc = shdesc.replace(/<script>/g,"(script)");
   current.short_description =
 shdesc.replace(/<\/script>/g,"(\/script)");}
}
```

Eliminate leading and trailing spaces in fields

This example of the script trims trailing and leading spaces in the *FirstName* and *LastName* fields of the sys_user.

```
doit();

function doit(){
  var now_GR =new GlideRecord('sys_user');
  gr.query();
  while(gr.next()){
    if((gr.first_name.toString().length!=
 gr.first_name.toString().trim().length)||(gr.last_name.toString
().length!= gr.last_name.toString().trim().length)){
     gr.first_name= gr.first_name.toString().trim();
     gr.last_name= gr.last_name.toString().trim();
     gr.autoSysFields(false);
     gr.update();}}
}
```

Make a field label flash

The following client script example is for the number field on incident. The label flashes for two seconds.

```
g_form.flash("incident.number","#FFFACD",0);
```

The arguments for the flash method are as follows:

- *tablename.fieldname*
- RGB color or acceptable CSS color like "blue" or "tomato"
- Integer that determines how long the label flashes:
  - 2 for a 1-second flash
  - 0 for a 2-second flash
  - -2 for a 3-second flash
  - -4 for a 4-second flash

Note:
Do not specify this argument if you want the field label colored the specified color.

Make a field label bold

This client script makes the label of a particular field bold. In this case, the field is the **Short Description** on the **Incident Table**.

```
function onLoad(){
  var l = g_form.getLabel('incident.short_description');
  l.style.fontWeight = 'bold';}
```

Make fields read-only

This onLoad client script makes the following fields on the Incident [incident] table read-only:

- **Incident state**
- **Impact**
- **Urgency**
- **Priority**
- **Configuration item**
- **Assigned to**

The script also removes the magnifying glass for the read-only Reference Fields (**Configuration item** and **Assigned to**).

```
function onLoad(){
var incidentState = g_form.getValue('incident_state');
if( incidentState == '6'|| incidentState == '7'){
   g_form.setReadonly('incident_state',true);
   g_form.setReadonly('impact',true);
   g_form.setReadonly('urgency',true);
   g_form.setReadonly('priority',true);
   g_form.setReadonly('cmdb_ci',true);
   g_form.setReadonly('assigned_to',true);}}
```

Set current date/time in field

You can set date and time values in client scripts and script includes.

Client script

You can use the following two lines to set the current date and time in a date/time field. This approach bypasses the problem of getting the value into the proper format and proper time zone.

```
var ajax = new GlideAjax('MyDateTimeAjax');
  ajax.addParam('sysparm_name','nowDateTime');
  ajax.getXML(function(){
    g_form.setValue('put your field name here',
 ajax.getAnswer());});
```

For more information on running server-side scripts with the client, refer to GlideAjax.

System script include

```
// Be sure the Glide AJAX enabled option is checked

var MyDateTimeAjax = Class.create();
MyDateTimeAjax.prototype =
 Object.extendsObject(AbstractAjaxProcessor,{
  nowDateTime:function(){
    return gs.nowDateTime();}});
```

Toggle the timer field by field name

The following client script toggles the timer field based on a particular field name.

```
function toggleTimerByFieldName(fieldName){
 //Step 1: Find the timer object
 //timeObjectName: the timer objects name as it would normally
 be referenced
 //timeObjectHidden: the hidden input node in the field td
 //timeObjectParent: the parent td node containing the field and
 it's constituent nodes
 //timeObjectFields: anchor tag with onclick to stop timer

 var timeObjectName = fieldName;
 var timeObjectHidden = gel(timeObjectName);

 //Step 2: simulate click stop button
 var timeObjectParent;
 var timeObjectFields;

 //verify that we got the correct object
 if(timeObjectHidden.type=="hidden"){

    //Get Parent td node
    timeObjectParent = timeObjectHidden.parentNode;

    //Get input fields
    timeObjectFields =
 timeObjectParent.getElementsByTagName("input");
```

```
    //simulate click of stop button
    var timerTestString ="paused";
    var timerImg;

    //loop through input objects looking for the pause timer
 object
    for(var elIt=0; elIt < timeObjectFields.length; elIt++){
      if(timeObjectFields[elIt].id.match(timerTestString)){
        if(timeObjectFields[elIt].value=="false"){
          timeObjectFields[elIt].value="true";
          timerImg =
 timeObjectParent.getElementsByTagName("img")[0];
          timerImg.src="images/timer_start.gifx";}
      elseif(timeObjectFields[elIt].value=="true"){
          timeObjectFields[elIt].value="false";
          timerImg =
 timeObjectParent.getElementsByTagName("img")[0];
          timerImg.src="images/timer_stop.gifx";}}}}}
```

Modify GlideDateTime field value

The following example uses a server-side script to access a *GlideDateTime* field.

The following server-side script example shows how to modify values using the *GlideDateTime* API. The same concept also applies to the *GlideDate* object.

```
//You first need a GlideDateTime object
//this can be from instantiating a new object "var gdt = new
 GlideDateTime()"
//or getting the object from a GlideDateTime field
//getting the field value (for example: var gdt =
 current.start_date)
//only returns the string value, not the object
//to get the object use var gdt =
 current.start_date.getGlideObject();
//now gdt is a GlideDateTime object
var gdt = current.start_date.getGlideObject();

//All methods can use negative values to subtract intervals

//add 1 hour (60 mins * 60 secs)
gdt.addSecondsLocalTime(3600);

//add 1 day
gdt.addDaysLocalTime(1);

//subtract 1 day
gdt.addDaysLocalTime(-1);

//add 3 weeks
gdt.addWeeksLocalTime(3);

//subtract 6 months.
gdt.addMonthsLocalTime(-6);
```

```
//add 1 year, representing the date and time using the UTC
 timezone instead of the local user's timezone.
gdt.addYearsUTC(1);
```

Approval assignment scripts

This is a searchable version of the useful approval and assignment scripts.

Warning:
The customization described here was developed for use in specific instances, and is not supported by Now Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

For see Viewing my approvals.

Assign a group for ESS requests

The following Assignment Rulescript automatically assigns a group for all ESS Requests.

```
if(current.opened_by.roles==""){

 current.assignment_group.setDisplayValue('Network');
    current.update();}
```

Assign catalog item to group based on delivery plan task

This assignment rule assigns a service catalog item to the database group if it uses a delivery plan that has a catalog task assigned to the desktop group.

```
//Return catalog items that have no group but do have a
 delivery plan assigned
var ri =new GlideRecord("sc_cat_item");
ri.addQuery("group","=",null);
ri.addQuery("delivery_plan","!=",null);
ri.query();
while(ri.next()){
    gs.log("Found an item");
    //Return tasks that point to the same delivery plan
 as the above item
    var dptask =new
 GlideRecord("sc_cat_item_delivery_task");

 dptask.addQuery("delivery_plan","=",ri.delivery_plan);
    dptask.query();while(dptask.next()){
        gs.log("Found a task");var gp =
 dptask.group.getDisplayValue();
        gs.log(gp);//If the task is assigned to
 desktop, assign the item's group to desktop
        if(dptask.group.getDisplayValue()=="Desktop"){
            ri.group.setDisplayValue("Desktop");
            gs.log("updating "+ ri.getDisplayValue());
            ri.update();break;}}}
```

Assign items with one task

This assignment rule automatically assigns any catalog items with only one task associated to a particular group.

```
//Get the catalog item for the current requested item
var scCatItem =new GlideRecord("sc_cat_item");
if(scCatItem.get('sys_id', current.cat_item)){
// If the catalog item already has an assignment
 group or if using workflow we don't need to make an
 assignment
  if(!scCatItem.delivery_plan.nil()&&
 scCatItem.group.nil()){
        var dpTask =new
 GlideRecord("sc_cat_item_delivery_task");

 dpTask.addQuery("delivery_plan","=",scCatItem.delivery
_plan);
        dpTask.query();
        if(dpTask.getRowCount()==1&& dpTask.next()){
        // Check that there is only 1 record in the
 GlideRecord
            dpTask.group;}}}
```

Assignment based on workload

Type: Business Rule.

Description: Populate the assigned to based on the assignment group member who has the least amount of active incidents.

Parameters:

- order: >1000 if you want to execute after assignment rules
- condition: current.assigned_to == '' && current.assignment_group != ''
- when: before, insert/update

```
var assignTo = getLowestUser();
gs.addInfoMessage("assigning to is "+ assignTo);
current.assigned_to= assignTo;

function getLowestUser(){
  var userList =new Array();
  var cg =new GlideRecord('sys_user_grmember');
  cg.addQuery('group', current.assignment_group);
  cg.query();
  while(cg.next()){
    var tech = cg.user.toString();
    var cnt = countTickets(tech);
    gs.addInfoMessage("Tech counts "+ cg.user.name+' '+
 cnt +" "+ tech);
    userList.push({ sys_id: tech,name: cg.user.name,
 count: cnt });}

  for(var i=0; i < userList.length; i++){
    gs.addInfoMessage(userList[i].sys_id+" "+
 userList[i].name+" "+ userList[i].count);}
  userList.sort(function(a, b){
    gs.addInfoMessage("Sorting: "+ a.sys_id+"("+
 a.count+");
    "+ b.sys_id+"("+ b.count+")");
    return a.count- b.count;});
```

```
  if(userList.length<=0)return"";
  return userList[0].sys_id;}

function countTickets(tech){
  var ct =new GlideRecord('incident');
  ct.addQuery('assigned_to',tech);
  ct.addQuery('active',true);
  ct.query();
  return ct.getRowCount();}
```

Run assignment rules when category is changed

Type: Client script.

Table: Incident.

Description: This example is an onChange client script on the category field within Incident. Note: this script used to use synchronous AJAX (asynchronous behavior is specified by the third parameter of the ajaxRequest call). The implementation below uses asynchronous AJAX. The drawback of using the synchronous version is that a network response problem could cause the browser to hang.

```
// Make an AJAX request to the server to get who this
 incident would be
// assigned to given the current values in the record.
 This runs the assignment
// rules thathave been defined in System Policy and
 returns the assigned_to and
// the assignment_group

function onChange(control, oldValue, newValue,
 isLoading){
  if(isLoading){return;
  // No change, do not do anything
  }

   // Construct the URL to ask the server for the
 assignment
  var url
 ="xmlhttp.do?sysparm_processor=AJAXAssignment&sys_targ
et=incident";
  var uv = gel('sys_uniqueValue');
  if(uv){
        url +="&sys_uniqueValue="+ uv.value;}
  // Make the AJAX request to the server and get the
 response
  var serial = g_form.serialize();
  // get all values currently assigned to the incident
  var response = ajaxRequest(url, serial,true,
 responseFunc);}

// This callback function handles the AJAX response.
function responseFunc(response){
  varitem=
 response.responseXML.getElementsByTagName("item")[0];
  // Process the item returned by the server
  if(item){
```

```
 // Get the assigned_to ID and its display value and
put them on the form
   varname=item.getAttribute("name");
   var name_label =item.getAttribute("name_label");
   if(name_label &&name){
     g_form.setValue('assigned_to',name, name_label);}
   else{
     g_form.setValue('assigned_to','','');}
   // Get the assignment_group ID and its display
value and put then on the form
   var group =item.getAttribute("group");
   var group_label =item.getAttribute("group_label");
   if(group_label && group){
     g_form.setValue('assignment_group', group,
group_label);}
   else{
     g_form.setValue('assignment_group','','');}}}
```

Custom approval UI macro

For information on creating a custom approval UI macro, see UI macros.

Scheduling script use cases

A business rule script specifies the actions that the business rule takes. Scripts commonly include predefined global variables to reference items in your system, such as the current record. Global variables are available to all business rules.

Warning:
The customization described here was developed for use in specific instances, and is not supported by Now Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

Calculate duration given a schedule

Type: Before update/insert business rule.

Description: A business duration calculates the open to close duration on an incident based on the particular Creating and using schedules. If there is no schedule specified, the script will simply use the first schedule returned by the query.

Script example:

The example below sets the resolved duration when the incident state moves to resolved.

```
var gr_rec = new GlideRecord('incident');
gr_rec.get('ed92e8d173d023002728660c4cf6a7bc');
if (gr_rec.incident_state == 6) {
var dur = calcDurationSchedule(gr_rec.opened_at,
 gr_rec.sys_updated_on);
}

function calcDurationSchedule(start, end){
  // Get the user
  var usr = new GlideRecord('sys_user');
  usr.get(gs.getUserID());
  // Create schedule - pass in the sys_id of your standard work
 day schedule and pass in the users timezone
```

```
  var sched = new
 GlideSchedule('08fcd0830a0a0b2600079f56b1adb9ae',usr.time_zon
e);
  // Get duration based on schedule/timezone
  return(sched.duration(start.getGlideObject(),
 end.getGlideObject()));
}
```

Check upcoming termination dates

Type: Scheduled script.

Description: This script checks nightly for termination dates on contracts coming up in 90, 50, or 10 days (depending on the contract duration field).

Script example:

```
function contractNoticeDue(){
  var now_GR = new GlideRecord("contract");
  now_GR.addQuery("u_contract_status","Active");
  now_GR.query();
  while(now_GR.next()){
    if((now_GR.u_termination_date<=
 gs.daysAgo(-90))&&(now_GR.u_contract_duration=="Long")){
      now_GR.u_contract_status="In review";}
    elseif((now_GR.u_termination_date<=
 gs.daysAgo(-50))&&(now_GR.u_contract_duration=="Medium")){
      now_GR.u_contract_status="In review";}
    elseif((now_GR.u_termination_date <=
 gs.daysAgo(-10))&&(now_GR.u_contract_duration=="Short")){
      now_GR.u_contract_status="In review";}
    now_GR.update();
  }
}
```

Use scripts in business rules to accomplish common tasks such as:

- Comparing two date fields.
- Parsing XML payloads.
- Aborting a database action in a business rule.

With scripts, you can also:

- Specify the operation that triggers the business rule.
- Use the scratchpad with display business rules to change form values just before a user loads the form.
- Use the OR condition like you would in a condition builder.

You can also utilize the system's scripting functionality available for server-side scripts.

You can use options on the Business Rules form to build conditions, set field values, and display alert messages without needing to write a script.

Server-side script use cases

Use cases for server-side scripts include logging output, getting user objects, and modifying date/time values.

Accessing the workflow scratchpad from business rules

A catalog item has been requested, and the attached workflow contains a run script activity that populates a value in the scratchpad. From a business rule running on the requested item, you want to retrieve or set scratchpad values.

Prerequisites

Role required: admin.

Name: Access Workflow Scratchpad from Business Rules.

Type: Business Rule.

Table: sc_req_item (Requested Item).

Description: A catalog item has been requested, the attached workflow contains a run script activity that populates a value in the scratchpad. From a business rule running on the requested item, you want to retrieve or set scratchpad values.

Parameters: n/a.

Script:

```
//the run script activity sets a value in the scratchpad
workflow.scratchpad.important_msg = "scratch me";

//get the workflow script include helper
var workflow = new Workflow();

//get the requested items workflow context
//this will get all contexts so you will need to get the proper
 one if you have multiple workflows for a record
var context = workflow.getContexts(current);
//make sure we have a valid context
if (context.next()) {
  //get a value from the scratchpad
  var msg = context.scratchpad.important_msg;
  //msg now equals "scratch me", that was set in the run script
 activity

  //add or modify a scratchpad value
  context.scratchpad.status = "completed";
  //we need to save the context record to save the scratchpad
  context.update();
}
```

Assign a catalog item to a group based on a delivery plan task

Assign a service catalog item to the database group if it uses a delivery plan that has a catalog task that is assigned to the desktop group.

Prerequisites

Role required: admin

Warning:
The customization described here was developed for use in specific instances, and is not supported by Now Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

Name: Assign Catalog Item to Group Based on Delivery Plan Task.

Type: Assignment Rule.

Description: This assignment rule assigns a service catalog item to the database group if it uses a delivery plan that has a catalog task assigned to the desktop group.

Script:

```
//Return catalog items that have no group but do have a delivery
 plan assigned var ri  = new GlideRecord ( "sc_cat_item" ) ;
ri.addQuery("group", "=", null);
ri.addQuery("delivery_plan", "!=", null);
ri.query();
while(ri.next()) {
    gs.log("Found an item");
    //Return tasks that point to the same delivery plan as the
 above item
    var dptask = new GlideRecord("sc_cat_item_delivery_task");
    dptask.addQuery("delivery_plan", "=", ri. delivery_plan);
    dptask.query();
    while(dptask.next()) {
        gs.log("Found a task");
        var gp = dptask.group.getDisplayValue();
        gs.log(gp);
        //If the task is assigned to desktop, assign the item's
 group to desktop
        if (dptask.group.getDisplayValue() == "Desktop") {
            ri.group.setDisplayValue("Desktop");
            gs.log("updating " + ri.getDisplayValue());
            ri.update();
            break; } } }
```

Calculating durations

Often you may need to provide users with a way to specify when a task or process is due. Using the DurationCalculator script include, you can calculate the due date using either a simple duration or relative duration.

Typically, setting a due date requires that you calculate work time rather than the total time. Only the part of the day when work is performed is considered when determining the due date. For example, a task is due in 10 hours, but is restricted to a business day schedule. If the work starts at 10am on Monday, it is due on Tuesday at 12pm as calculated below.

```
10am-5pm on Monday (6 hours) + 8am-12pm on Tuesday (4 hours)
```

For information on schedules, which you can use as inputs to DurationCalculator methods, see Creating and using schedules.

This script demonstrates how to use DurationCalculator to compute a due date.

```
/**
* Demonstrate the use of DurationCalculator to compute a due date.
```

```
*
* You must have a start date and a duration. Then you can compute a
* due date using the constraints of a schedule.
*/

gs.include('DurationCalculator');
executeSample();

/**
* Function to house the sample script.
*/function executeSample(){

	// First we need a DurationCalculator object.var dc =new DurationCalculator();

	// ---------- No schedule examples ----------

	// Simple computation of a due date without using a schedule. Seconds// are added to the start date continuously to get to a due date.
	dc.setStartDateTime("5/1/2012");if(!dc.calcDuration(2*24*3600)){// 2 days
	 gs.log("*** Error calculating duration");return;}
	gs.log("calcDuration no schedule: "+ dc.getEndDateTime());// "2012-05-03 00:00:00" two days later

	// Start in the middle of the night (2:00 am) and compute a due date 1 hour in the future// Without a schedule this yields 3:00 am.
	dc.setStartDateTime("5/3/2012 02:00:00");if(!dc.calcDuration(3600)){
		gs.log("*** Error calculating duration");return;}
	gs.log("Middle of night + 1 hour (no schedule): "+ dc.getEndDateTime());// No scheduled start date, just add 1 hour

	// ---------- Add a schedule to the date calculator ----------
	addSchedule(dc);

	// Start in the middle of the night and compute a due date 1 hour in the future.// Since we start at 2:00 am the computation adds the 1 hour from the start// of the day, 8:00am to get to 9:00am
	dc.setStartDateTime("5/3/2012 02:00:00");if(!dc.calcDuration(3600)){//
		gs.log("*** Error calculating duration");return;}
	gs.log("Middle of night + 1 hour (with 8-5 schedule): "+
 dc.getEndDateTime());// 9:00 am

	// Start in the afternoon and add hours beyond quiting time. Our schedule says the work day// ends at 5:00pm, if the duration extends beyond that, we roll over to the next work day.// In this example we are adding 4 hours to 3:00pm which gives us 10:00 am the next day.
	dc.setStartDateTime("5/3/2012 15:00:00");if(!dc.calcDuration(4*3600)){//
		gs.log("*** Error calculating duration");return;}
	gs.log("Afternoon + 4 hour (with 8-5 schedule): "+ dc.getEndDateTime());// 10:00 am.

	// This is a demo of adding 2 hours repeatedly and examine the result. This// is a good way to visualize the result of a due date calculation.
```

```
    dc.setStartDateTime("5/3/2012 15:00:00"); // for(var i=2; i<24;
i+=1){if(!dc.calcDuration(i*3600)){//
            gs.log("*** Error calculating duration");return;}
        gs.log("add "+ i +" hours gives due date: "+
 dc.getEndDateTime());}

    // Setting the timezone causes the schedule to be interpreted in the specified
timezone.// Run the same code as above with different timezone. Note that the 8 to 5 workday
is// offset by the two hours as specified in our timezone.
    dc.setTimeZone("GMT-2");
    dc.setStartDateTime("5/3/2012 15:00:00");for(var i=2; i<24;
 i+=1){if(!dc.calcDuration(i*3600)){//
            gs.log("*** Error calculating duration");return;}
        gs.log("add "+ i +" hours gives due date (GMT-2): "+
 dc.getEndDateTime());}}

/**
* Add a specific schedule to the DurationCalculator object.
*
* @param durationCalculator An instance of DurationCalculator
*/function addSchedule(durationCalculator){// Load the "8-5 weekdays
excluding holidays" schedule into our duration calculator.var scheduleName ="8-5 weekdays
excluding holidays";var grSched =new GlideRecord('cmn_schedule');
    grSched.addQuery('name', scheduleName);
    grSched.query();if(!grSched.next()){
        gs.log('*** Could not find schedule "'+ scheduleName +'"');return;}

 durationCalculator.setSchedule(grSched.getUniqueValue(),"GMT");}
```

Simple duration vs relative duration

How much work is required to complete a task can be expressed as a "relative duration".

Relative duration determines the expected due date and time relative to the starting time. Examples of relative durations include "Next business day by 4pm", or "2 business days by 10:30am".

To calculate a relative duration, the calendar and time zone must be considered to determine what "next business day" means since it is the calendar that defines which days are valid work days and the time zone will affect the result as well. As an example, consider "Next business day by 4pm":

- If it is Monday at 12pm: Next business day by 4pm => Tuesday at 4pm
- If it is Friday at 2pm: Next business day by 4pm => the following Monday at 4pm

Note:
Next business day is often defined by a starting day and time. For example, "next business day at 4pm if before 2pm" indicates that if the current time is after 2pm on a business day, then "Next business day" really means 2 business days since today does not count.

For more information on relative durations, see Define a relative duration.

Calculating a simple duration

This business rule and script example demonstrate how to calculate a simple duration.

```
var dur =new DurationCalculator();
dur.setSchedule(current.schedule);
```

```
dur.setStartDateTime("");

if(current.duration_type==""){

 dur.calcDuration(current.duration.getGlideObject().getNumericVa
lue()/1000);}else{
         dur.calcRelativeDuration(current.duration_type);}

    current.end_date_time= dur.getEndDateTime();
    current.work_seconds= dur.getSeconds();
```

This script demonstrates how to use DurationCalculator to calculate a simple duration.

```
/**
 * Sample script demonstrating use of DurationCalculator to
 compute simple durations
 *
 */

gs.include('DurationCalculator');
executeSample();

/**
 * Function to house the sample script.
 */
function executeSample(){

    // First we need a DurationCalculator object.
    var dc =new DurationCalculator();

    // Compute a simple duration without any schedule. The
 arguments
    // can also be of type GlideDateTime, such as fields from a
 GlideRecord.
    var dur = dc.calcScheduleDuration("5/1/2012","5/2/2012");
    gs.log("calcScheduleDuration no schedule: "+ dur);
    // 86400 seconds (24 hours)

    // The above sample is useful in limited cases. We almost
 always want to
    // use some schedule in a duration computation, let's load a
 schedule.
    addSchedule(dc);

    // Compute a duration using the schedule. The schedule
    // specifies a nine hour work day. The output of this is
 32400 seconds, or
    // a nine hour span.
    dur = dc.calcScheduleDuration("5/23/2012 12:00","5/24/2012
 12:00");
    gs.log("calcScheduleDuration with schedule: "+ dur);
    // 32400 seconds (9 hours)

    // Compute a duration that spans a weekend and holiday. Even
 though this
    // spans three days, it only spans 9 work hours based on the
 schedule.
```

```
    dur = dc.calcScheduleDuration("5/25/2012 12:00","5/29/2012
 12:00");
    gs.log("calcScheduleDuration with schedule spaning holiday:
 "+ dur);
    // 32400 seconds (9 hours)

    // Use the current date time in a calculation. The output of
 this is
    // dependent on when you run it.
    var now =new Date();
    dur = dc.calcScheduleDuration("5/15/2012",new
 GlideDateTime());
    gs.log("calcScheduleDuration with schedule to now: "+ dur);
    // Different on every run.}

/**
 * Add a specific schedule to the DurationCalculator object.
 *
 * @param durationCalculator An instance of DurationCalculator
 */
function addSchedule(durationCalculator){
   //  Load the "8-5 weekdays excluding holidays" schedule into
 our duration calculator.
   var scheduleName ="8-5 weekdays excluding holidays";
   var grSched =new GlideRecord('cmn_schedule');
   grSched.addQuery('name', scheduleName);
   grSched.query();if(!grSched.next()){
        gs.log('*** Could not find schedule "'+ scheduleName
 +'"');
        return;}
    durationCalculator.setSchedule(grSched.getUniqueValue());}
```

Calculating a relative duration

An example of a relative duration calculation script.

This script calculates the relative duration for "Next day at 4pm if after 10am":

```
// Next day at 4pm if before 10am
var days =1;
if(calculator.isAfter(calculator.startDateTime,"10:00:00"))
      days++;

calculator.calcRelativeDueDate(calculator.startDateTime,
 days,"16:00:00");
```

This script demonstrates how to use DurationCalculator to calculate a relative duration.

```
/**
 * Sample use of relative duration calculation.
 *
 */

gs.include('DurationCalculator');
executeSample();

/**
 * Function to house the sample script.
```

```
 */
function executeSample(){

    // First we need a DurationCalculator object. We will also
 use
    // the out-of-box relative duration "2 bus days by 4pm"
    var dc =new DurationCalculator();
    var relDur ="3bf802c20a0a0b52008e2859cd8abcf2";
    // 2 bus days by 4pm if before 10am
    addSchedule(dc);

    // Since our start date is before 10:00am our result is two
 days from
    // now at 4:00pm.
    dc.setStartDateTime("5/1/2012 09:00:00");
    if(!dc.calcRelativeDuration(relDur)){
        gs.log("*** calcRelativeDuration failed");
        return;}
    gs.log("Two days later 4:00pm: "+ dc.getEndDateTime());

    // Since our start date is after 10:00am our result is three
 days from
    // now at 4:00pm.
    dc.setStartDateTime("5/1/2012 11:00:00");
    if(!dc.calcRelativeDuration(relDur)){
        gs.log("*** calcRelativeDuration failed");
        return;}
    gs.log("Three days later 4:00pm: "+ dc.getEndDateTime());}

/**
 * Add a specific schedule to the DurationCalculator object.
 *
 * @param durationCalculator An instance of DurationCalculator
 */
function addSchedule(durationCalculator){
  //  Load the "8-5 weekdays excluding holidays" schedule into
 our duration calculator.
  var scheduleName ="8-5 weekdays excluding holidays";
  var grSched =new GlideRecord('cmn_schedule');
  grSched.addQuery('name', scheduleName);
  grSched.query();
  if(!grSched.next()){
        gs.log('*** Could not find schedule "'+ scheduleName
 +'"');
        return;}

 durationCalculator.setSchedule(grSched.getUniqueValue(),"GMT"
);}
```

How to implement a relative duration

You can implement a relative duration by creating the cmn_relative_duration table and the *DurationCalculator* script include.

Before you begin

Role required: admin

Procedure

1. Create the cmn_relative_duration table.
2. Create the DurationCalculator script include.
3. Create a sample relative duration entry (for example, "Next business day by 4pm").
4. Add the needed fields to SLA tables to support relative durations.
5. Modify duration calculation for SLAs.
6. Modify SLA Percentage timer calculation for SLAs (this must use work_seconds).
7. Add schedule fields to the Workflow: Schedule and Timezone (selected based on the field from workflow table).
8. Add duration support fields to the Workflow Task activity.
9. Implement duration calculation script for the task activity.

The relative duration table and the DurationCalculator methods

The cmn_relative_duration table supports the definition of a due date as either a duration of time or a relative duration.

This table consists of two fields: "name" and "script." The "script" field contains the relative duration calculation script. This script includes the "calculator" variable, which is used to calculate the due date.

The DurationCalculator script include can be used to perform the duration calculations. The following are methods that are available in this script include.

DurationCalculator script include table

Method	Description
setSchedule(String schedID, [String timezone])	Sets the schedule and time zone to be used for calculating the due date.
setStartDateTime(GlideDateTime start)	Sets the start time for the duration calculations. If 'start' is blank, uses current date/time.
calcDuration(int seconds)	Calculates the end date and time. Upon completion the this.endDateTime and this.seconds properties will be set to indicate the results of the calculation.
calcRelativeDuration(String relativeDurationID)	Calculates the duration using the specified relative duration script. Upon completion the this.endDateTime and this.seconds properties will be set to indicate the results of the calculation.
getEndDateTime()	Gets the this.endDateTime property that was set by calcDuration/calcRelativeDuration indicating the end date and time for the duration.
getSeconds()	Gets the this.seconds property that was set by calcDuration/calcRelativeDuration indicating the total number of seconds of work to be performed for the duration.

DurationCalculator script include table (continued)

Method	Description
	Note: This is the total work time, not the total time between start and end times and may be used to determine percentages of the work time
getTotalSeconds()	Gets the this.totalSeconds property that was set by calcDuration/calcRelativeDuration indicating the total number of seconds between the start and end times of the duration.

The following functions are used in relative duration scripts:

Relative duration script functions

Function	Description
boolean isAfter(GlideDateTime dt, String time)	Is 'time' of day after the time of day specified by 'dt'? dt, if blank, uses current date/time. time is in "hh:mm:ss" in 24-hour format.
calcRelativeDueDate(GlideDateTime start, int days, String endTime)	Calculates the due date starting at 'start' and adding 'days' using the schedule and time zone. When we find the day that the work is due on, set the time to 'endTime' of that day. Upon completion, this.endDateTime and this.seconds properties will be set to indicate the results of the calculation. If endTime is blank, use end of the ending work day.

Get a user object

In a business rule or other server script, the `gs.getUser()` method returns a user object. The user object is an internal representation of the currently logged in user and provides information about the user and various utility functions.

About this task

For a list and description of the available scoped methods for the user object, see GlideUser.

Procedure

1. Retrieve the current user.

```
var myUserObject = gs.getUser()
```

2. Use the `getUserByID` method to fetch a different user using the `user_name` field or `sys_id` on the target record.
   For example:

```
var ourUser = gs.getUser();
gs.print(ourUser.getFirstName()); //print the first name of the
 user you are currently logged in as
newUser = ourUser.getUserByID(<user_sys_id>); //fetch a
 different user, using the sys_id of the target user record.
```

```
gs.print(newUser.getFirstName()); //first name of the user you
 fetched above
gs.print(newUser.isMemberOf('Capacity Mgmt'));
```

Log output

GSLog is a script include that simplifies script logging and debugging by implementing levels of log output, selectable by per-caller identified sys_properties values.

Log level

Logs can be at the level of debug, info, notice, warning, err, or crit (after BSD syslog.h and followers). The default logging level is notice, so levels should be chosen accordingly.

Where to use

Use for any server-side script where you want to implement event logging.

For the API reference, see GSLog() .

For more information, see Debugging scripts

Modify a GlideDateTime field value

This example demonstrates how to modify a *GlideDateTime* field value using a server-side script.

Given a *GlideDateTime* field or script object, show a variety of ways to easily modify value. The same concept also applies to the *GlideDate* object.

Note:
The following script is only intended for global applications.

```
//You first need a GlideDateTime object
//this can be from instantiating a new object "var gdt = new
 GlideDateTime()"
//or getting the object from a GlideDateTime field
//getting the field value (for example: var gdt =
 current.start_date) only returns the string value, not the
 object
//to get the object use var gdt =
 current.start_date.getGlideObject();
//now gdt is a GlideDateTime object
var gdt = current.start_date.getGlideObject();

//All methods can use negative values to subtract intervals

//add 1 hour (60 mins * 60 secs)
gdt.addSeconds(3600);

//add 1 day
gdt.addDaysLocalTime(1);

//subtract 1 day
gdt.addDaysLocalTime(-1);

//add 3 weeks
gdt.addWeeksLocalTime(3);
```

```
//subtract 6 months
gdt.addMonthsLocalTime(-6);

//add 1 year, representing the date and time using the UTC
 timezone instead of the local user's timezone.
gdt.addYearsUTC(1);

//set the value of the GlideDateTime object to the current
 session timezone/format
GlideSession.get().setTimeZoneName('US/Eastern');
gdt.setDisplayValue('2018-2-28 00:00:00');
gs.info('In ' + GlideSession.get().getTimeZoneName() + ": " +
 gdt.getDisplayValue());
```

Using custom queues to process events

You can use custom queues for applications that create a large volume of events or events that take a long time to process. This task shows how to create a custom queue, its monitoring process, and use a script to send events to the queue.

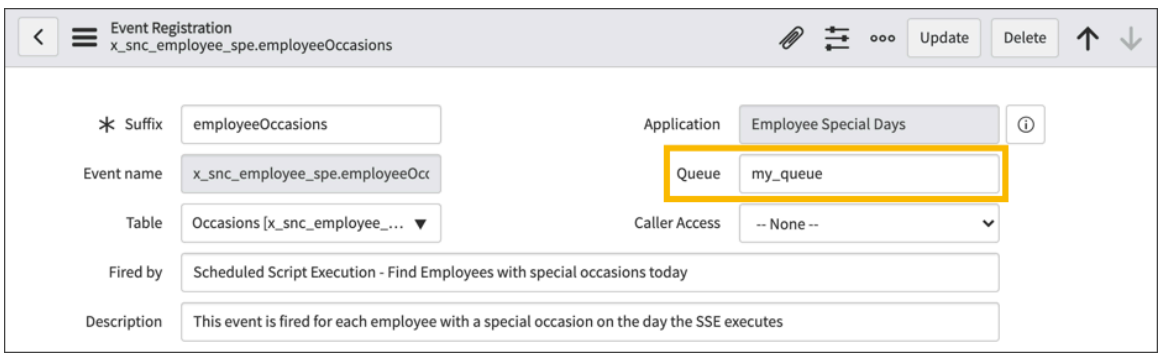
Before you begin

Role required: admin

Note:
This information is for advanced users who understand event processing.

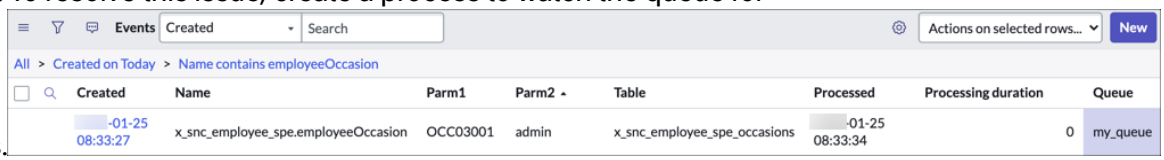
Procedure

1. Navigate to **System Policy** > **Events** > **Registry**.
2. Select the event for which you want to create a custom queue.
   The **Event Registration** form displays.
3. Populate the **Queue** field for the event in the Event Registry.
   Use only lowercase letters, no spaces, and no special characters except underscore (_).

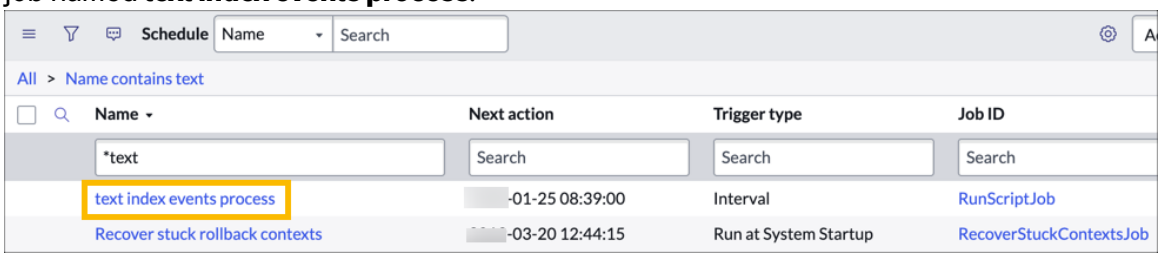


4. Click **Submit**.
   A new event is listed in the Events [sysevent] table.

   In the following example, when the employeeOccasion event is generated, the event is added to my_queue. The events are stuck in the queue. To resolve this issue, create a process to watch the queue for events.



5. Navigate to **System Scheduler** > **Scheduled Jobs** > **Scheduled Jobs** and open the scheduled job named **text index events process**.



6. Click the additional actions menu icon)--> and select **Insert and Stay** to create a copy of **text index events process**.

> **Important:**
> Be sure to copy the job and not overwrite the **text index events process** Scheduled Job.

7. In the copied schedule item, change the value in the **Name** field.
8. In the **Job context** field, replace the value for the `GlideEventManager()` parameter with the name of the new queue.

   The queue monitoring process looks for and processes events in the example **my_queue** event queue.

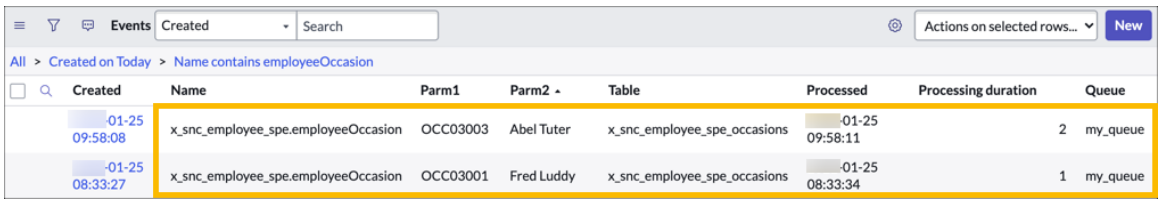
9. Use the `gs.eventQueue()` method's fifth parameter to send events to the custom queue.

   The following code shows how to send an event to the my_queue custom queue.

```
gs.eventQueue('x_60157_employee_spe.employeeOccasion',
 todaysOccasions, todaysOccasions.number,
 todaysOccasions.u_employee.name, 'my_queue');
```

Note:
If an event is in the **Event Registry** and no queue name is provided to `gs.eventQueue`, the queue from the **Event Registry** is still assigned to the event. For example, `gs.eventQueue('x_60157_employee_spe.employeeOccasion')` still associates the event with `my_queue`. If the queue name is provided in the `gs.eventQueue()` call, the queue takes priority.

You can verify that the event called was processed by checking the **Events** [sysevent] table.



Validation script use case - Date and time

To validate the input of all date/time fields, you can use the following in a validation script (**System Definition** > **Validation Scripts**).

Because the date/time format is hard-coded in this script, it must match your instance's date/time format. If your instance's date/time format changes, you must update your validation script.

Set the validation script's type to "`glide_date_time`". Then, with this validation script, if a user enters an incorrect format in a date/time field, they will receive an error message.

```
function validate (value){
 if (!value) {
    return true;
 }

 return (getDateFromFormat(value, 'yyyy-MM-dd HH:mm:ss') != 0);
}
```

For a comprehensive use case, see Restricting record access.

Creating custom UI Pages and UI macros

Use UI pages to create custom pages for an application and UI macros for custom controls or interfaces.

Every UI Page is a Jelly template. Jelly turns XML into executable code. A UI Page works similar to how an index.html file is used in an AngularJS application. Jelly tags in the HTML field of the UI Page form contain AngularJS logic.

Creating UI macros requires knowledge of Jelly script. Review the existing UI macros for examples and suggested approaches. Those who want to build custom interfaces with JavaScript technologies should consider Service Portal as an alternative.

UI pages

UI pages can be used to create and display forms, dialogs, lists, and other UI components.

Use UI pages as widgets on dashboards. To find the UI pages, navigate to **System UI** > **UI Pages**.

This functionality requires a knowledge of HTML or Jelly. You can also create simple AngularJS applications using UI pages.

The UI page form contains the following fields:

UI page

Field	Description
Name	Name used to invoke the page via a URL (must not contain spaces).
Application	Displays the current application scope.
Description	The description of the UI page and what it's used for.
Direct	Select this check box for a direct UI page [sys_ui_page]. A direct UI page doesn't include the common HTML, CSS, and scripts. This setting requires adding custom CSS and JavaScript to use in the page.
HTML	Main component of the page where you define what is rendered when the page is shown. It can contain either static XHTML, dynamically generated content defined as Jelly, or call script includes and UI Macros. **Note:** If `GlideRecord/GlideDBQuery` is used instead of `GlideRecordSecure`, a security recommendation message displays.
Client Script	Include client-side JavaScript that runs in the browser, such as functions called by buttons. It's intended to handle any client-side processing needed, like setting focus to a field or other interactive DHTML features after a page is loaded. Client scripts for the UI page are deployed to the browser within a `<script/>` tag, so the content can similarly be defined within the HTML field. The Client Script field can be used instead to define these scripts concisely to maintain the Jelly and HTML manageability.
Processing Script	Script that runs on the server when the page is submitted. This is useful if your page has a form defined with the `<g:ui_form/>` or `<g:form/>` tags. **Note:** If `GlideRecord/GlideDBQuery` is used instead of `GlideRecordSecure`, a security recommendation message displays.
obsolete-custom-processors	**Note:** This feature is deprecated. While legacy, existing custom processors continue to be supported, creating new custom processors has been deprecated. Instead, use the Scripted REST APIs.
Related lists on the form view:	
Access Controls	View and configure access controls for the UI page. See Use access controls on UI pages for more information.
Versions	Shows all versions of the UI page. Use this list to compare versions or to revert to a previous version.

Access control

A UI page can be secured by creating an ACL with the following parameters:

- **Type**: *ui_page*
- **Operation**: *read*
- **Name**: Name of the UI page to be protected
- **Role**: User role that is allowed to access the record

When saving a new UI page, you are prompted to assign a role for access control.

Note:
An entry with the same name as the UI page is created in the Access Control table.

For details on creating an ACL rule, see Create an ACL rule.

High risk UI pages

UI Pages are considered high risk with any of the following attributes:

- Uses *GlideRecord* or *GlideDBQuery* instead of *GlideRecordSecure*.

  Note:
  This is applicable for *HTML* and *Processing* script fields and not *Client* scripts.

- Does not have a corresponding ACL configured.
- Indicates to be a public UI Page and is entered in the *sys_public* record.
- Shows a message to indicate high risk UI page.
- For instances with *glide.installation.developer* is set to **true**.
- If resource is customized content for a customer instance.

UI page access

Each UI page has a URL computed from the application scope, page name, and the `.do` file extension.

For example, to display the page called glidewindow_example on the demo system, you would navigate to `https://<instance name>.service-now.com/glidewindow_example.do`. If the page was part of a custom application called example_app, you would instead navigate to `https://<instance name>.service-now.com/x_example_app_glidewindow_example.do`.

You can also add additional parameters to a URL that can be accessed within a page's HTML section as jelly variables. That is, appending arguments to the URL as follows: `/my_test_page.do?sysparm_verbose=true` creates jelly variables called *verbose* that can be accessed as follows:

```
<j2:if test="$[!empty(sysparm_verbose)]"> <span>show extra stuff
 </span> </j2:if >
```

A common practical example of this might be retrieving a database record for display. To build a list of a user's roles, pass in a parameter with the user's sys_id. Invoke the following UI page to display a list of roles for that user with Jelly code:

```
role_select.do?sysparm_user=5137153cc611227c000bbd1bd8cd2007
```

```
<j:set var = "jvar_user_id" value = "${sysparm_user}" />

 <g:evaluate> var userRoles = new
GlideRecord('sys_user_has_role');
   userRoles.addQuery('user','${jvar_user_id}');
   userRoles.query();
 </g:evaluate>

 <select id='select_role'>
     <j:while test = "${userRoles.next()}">
         <option value = "${userRoles.sys_id}">
${userRoles.role.name} </option>
     </j:while>
 </select>
```

An exception to be careful of, though, is the reserved variable name sys_id. This variable always contains the ID of the UI page itself, regardless of what is specified in the URL. A common substitute variable name is sysparm_id.

Do not use URL parameters to load client scripts in UI pages. The system no longer evaluates scripts that are passed by URL parameter. If your implementation depends on this behavior, you can add the system property [glide.security.disable_ui_pages_sysparm_client_script] and set it to **false** to temporarily allow the evaluation of URL parameters passing scripts in UI pages.

Use access controls on UI pages

See access controls directly from the UI Page form and add role-based access control when creating or editing a UI Page record.

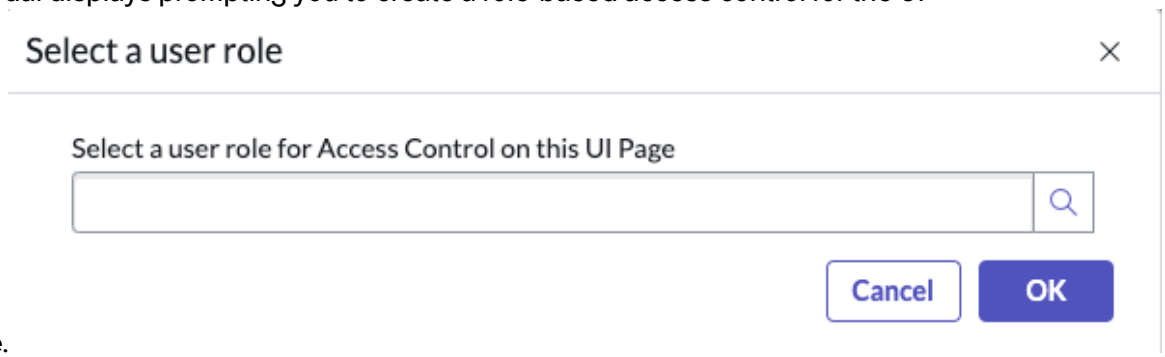
Before you begin

Access controls that have been added to an existing UI page can be accessed and edited by opening the UI page record under related links.

Role required: security_admin and admin

Procedure

1. Elevate to the **security_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **All** > **System UI** > **UI Pages**.
3. Select **New**.
4. Complete the form.
   See UI pages for additional information for UI field descriptions.
5. Select **Submit** or **Save**.
   A modal displays prompting you to create a role-based access control for the UI page.



6. Select a role.
7. Select **OK** to assign the role.
   You are returned to the UI pages list.

Add, edit, or view access controls for an existing UI page:

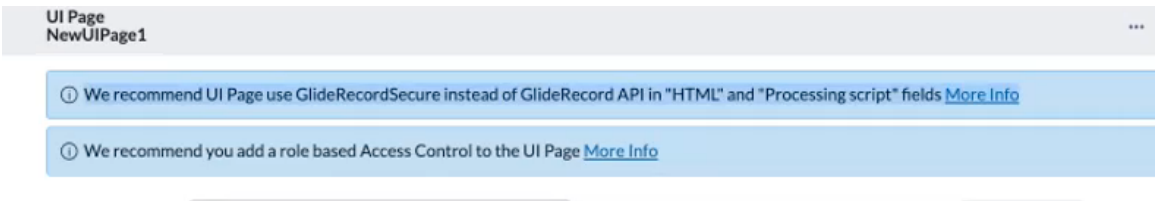
8. Open a UI page from the UI pages table.
9. View the **Access Controls** under the related lists.
10. Select **New** to create a new access control or select an existing entry for editing.
    The Access Control form loads. UI Page details are displayed.
11. Complete the form and assign a role to the UI page.
    For additional information on access control, see Create an ACL rule.
12. Select **Submit** for a new access control or **Update** for edits.

> **Note:**
> There can be multiple access controls per UI page.

Secure UI pages

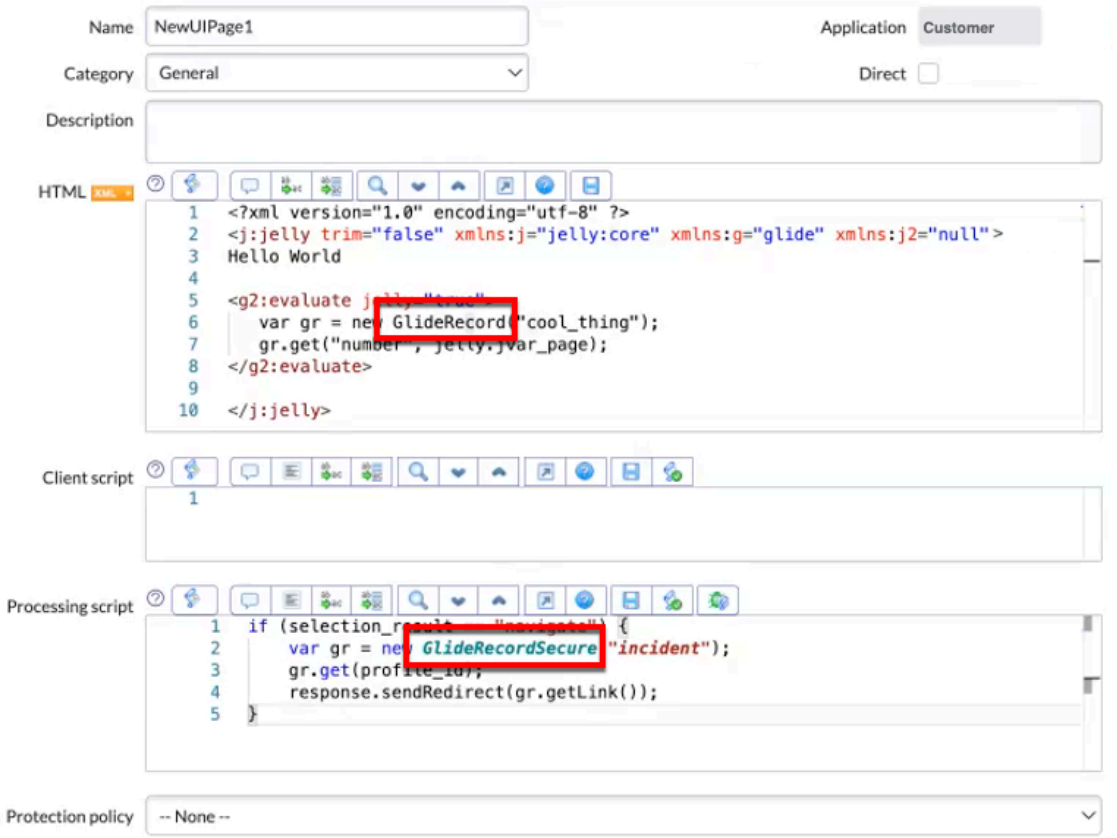
Access controls and related security messages are integrated on high risk UI Pages for increased security.

An informational message displays on high risk UI pages to inform the customer to add a role-based Access Control to the UI page.



The message displays under the following conditions:

- If an ACL (access control list) is missing
- If `GlideRecord/GlideDBQuery` is used instead of `GlideRecordSecure` in either the **HTML** or **Processing script**



sections

- If the UI page is configured as public in `sys_public`

> **Note:**
> Public UI Pages that are public or that use `GlideRecord` don't show a missing ACL warning.

See UI pages for details on high risk UI pages.

Conditions that display the security recommendations message

The message displays under the following conditions:

- All internal instances eclipse/IJ where `glide.installation.developer=true`.
- All customer scoped UI Page resources.
- Any customized UI Page when the `glide.script.ui_page.customer_scoped.security_msgs_enabled` property is set to `true`. (The default value is `true`).

Conditions that don't display the security recommendations message

The message won't display under the following conditions:

- UI Page is public.
- UI Page is in the **Global** scope.
- The *glide.script.ui_page.customer_scoped.security_msgs_enabled* is set to *false*.

Note:
To disable the role-based ACL creation prompt, set the *glide.ui_page.enable_acl_create_ux* property to **false**. The property is set to **true** by default.

UI page process scripts

If your UI page contains a form (uses the *<g:form>* tag), you can submit the form and have the process script run.

The processing script can naturally access fields on the form. For example, if your form contained the *application_sys_id* field:

```
<g:ui_form>
  <p>Click OK to run the processing script.</p>
  <g:dialog_buttons_ok_cancel ok="return true" />
  <input type="hidden" name="application_sys_id"
 value="499836460a0a0b1700003e7ad950b5da" />
</g:ui_form>
```

You can access the field using *application_sys_id*:

```
var application = new GlideRecord('hr_application');
 application.get(application_sys_id);
 application.status = "Rejected";
 application.update();
 var urlOnStack = GlideSession.get().getStack().bottom();
 response.sendRedirect(urlOnStack);
```

Important:
The preceding script is usable only with Global applications.

If you are using the UI page for a dialog, you can also reference the most recent URL on the stack using the code above and then send the response to that location. This is useful if you want to have the dialog's processing script update something and then redisplay the screen that brought up the dialog.

UI macros

UI macros are discrete scripted components administrators can add to the user interface.

UI macros are typically controls that provide inputs or information not provided by existing field types. By default, the system provides UI macros for a variety of user interface elements such as:

- All formatters
- The Service Catalog cart
- The action icons next to fields
- The action icons on forms and lists
- The widgets of a content management system
- The Orchestration activity designer

Administrators can create their own UI macros to provide custom controls or interfaces. Creating UI macros requires knowledge of Jelly script. Review the existing UI macros for examples and suggested approaches. Those who want to build custom interfaces with JavaScript technologies should consider Service Portal as an alternative.

Note:
To view available UI macros, navigate to **All** > **System UI** > **UI Macros**.

UI macro basics

UI macros can be used to build solutions that can't be built using the available catalog variable types.

Accessible UI macros

Several UI macros are available in the UI macros [ui_macros] table. These UI macros have names starting with `ui_` and emulate the behavior of a subset of standard form field types for use in UI pages. For example, the ui_date_time UI macro can act like a glide_date_time field in a UI page, providing a type-able input field with a date/time selector.

A UI macro can be included in a UI page with the <g:> Jelly tag. The following example includes the ui_date_time UI Macro, providing two optional attributes to the UI Macro:

```
<g:ui_date_time name="due_date" value="2023-11-24 08:30:00"
 onchange="checkDateValue()" />
```

The attribute values in the <g:> Jelly tag are provided to the UI macro as jvar-prefixed variables. The UI macro can use the jvar-prefixed variables in its XML.

Jelly tag attributes used as jvar-prefixed variables

Attributes	jvar-prefixed variables
name	jvar_name
value	jvar_value
onchange	jvar_onchange

Note:
These UI macros aren't intended to support all features of their corresponding form field type. In many cases, the macros are only intended for specific ServiceNow application use cases.

The `ui_`-prefixed UI macros include descriptions specifying supported attributes that can (or must) be provided in the UI page's <g:> Jelly tag. To view available UI macros, navigate to **All** > **System UI** > **UI macros**.

/

Custom UI macros

The ui_example UI macro uses three jvar-prefixed variables: jvar_name, jvar_test_attribute and jvar_laptop_type. These variables can be provided to the UI macro as name, test_attribute and laptop_type attributes in a <g:> Jelly tag in a UI page.

Creating the ui_example UI macro

Navigate to **All** > **System UI** > **UI Macros** and select **New**.

Name the macro `ui_example` and add the following script to the **XML** field:

```
<?xml version="1.0" encoding="utf-8" ?>
<j:jelly trim="true" xmlns:j="jelly:core"
 xmlns:g="glide">
    <div>name jvar: ${jvar_name}</div>
    <div>test_attribute jvar:
 ${jvar_test_attribute}</div>
    <div>laptop_type jvar: ${jvar_laptop_type}</div>
</j:jelly>
```

Using the macro in a UI page

Navigate to **All** > **System UI** > **UI Pages** and select **New**. You will be asked to select an administrator role.

Name the UI page and add the following script to the **HTML** field:

```
<?xml version="1.0" encoding="utf-8" ?>
<j:jelly trim="false" xmlns:j="jelly:core"
 xmlns:g="glide" xmlns:j2="null" xmlns:g2="null">
    <div style="text-decoration:underline">Template
 include one:</div>
    <g:ui_example name="Fred Luddy" test_attribute="I
 am an attribute" laptop_type="ThinkPad" />
    <hr/>
    <div style="text-decoration:underline">Template
 include two:</div>
    <g:ui_example name="Pat Casey" test_attribute="I am
 a different attribute" laptop_type="Macbook Pro" />
</j:jelly>
```

Checking output

In the UI page, you can click **Try It** to view the results.

Note:
If you create a macro and it doesn't display as expected in the UI page, clearing the cache might help. To clear the cache of your instance, in your browser, enter `<server_url>/cache.do`.

Calling UI macros

Administrators can call UI macros from certain record types associated with the user interface.

Calling UI macros by record type

Record type	Example
Dictionary attribute	Display an icon for a reference field:

Calling UI macros by record type (continued)

Record type	Example
	`ref_contributions=ui_macro_name`
UI page	Display something on a UI page: `<g:macro_invoke macro="ui_macro_name" />`
UI macro	Call a UI macro from another UI macro: `<?xml version= "1.0" encoding="utf-8" ?>` `<j:jelly trim= "false" xmlns:j="jelly:core"` `xmlns:g="glide" xmlns:j2="null" xmlns:g2="null">` `<g:ui_macro_name />` `<g:ui_macro_name_2 />` `</j:jelly>`

UI macro form

Each UI macro record consists of a name and an XML document written in Jelly code.

UI macro fields

Field	Description
Name	A unique and descriptive name for this macro.
Active	Select the check box to render the element as defined. Clear the check box to disable the element without deleting the code. For example, the **email_reply** macro is inactive by default.
Description	Describe the purpose of the macro and parameters passed to it.
XML	Jelly script that defines the macro.

Custom approval UI macro

This section describes how to create a custom approval UI macro.

Warning:
The customization described here was developed for use in specific instances, and is not supported by Now Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

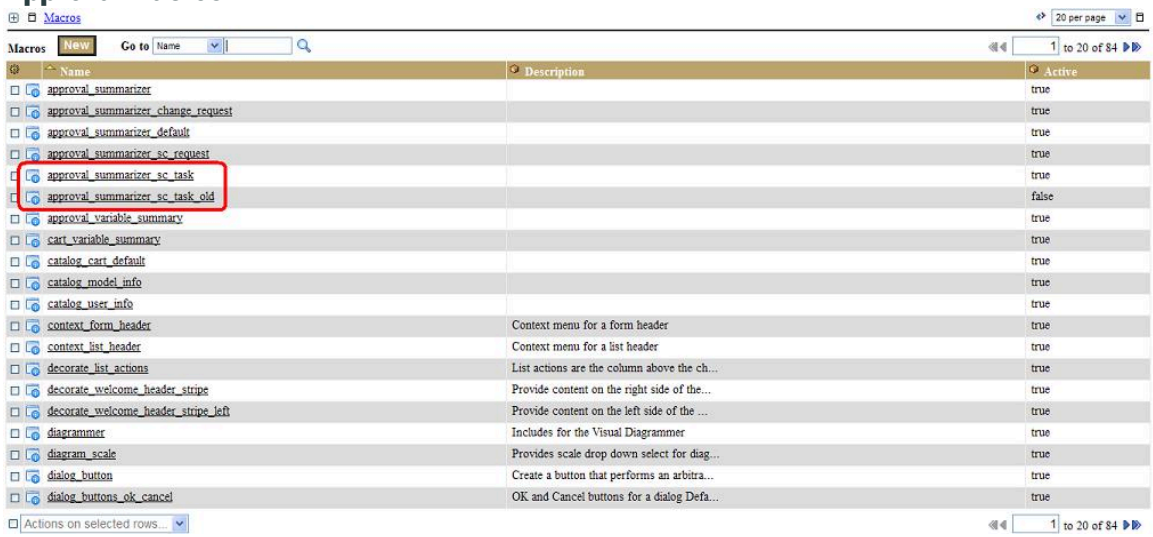
Script Name: Custom Approval UI Macro

Type: UI Macro

Description: Here is an option to get more detail out of the My Approvals view of an Execution Plan. This can be done by creating a new UI macro. Navigate to **System UI** and click **UI Macros**. First, you will need to rename the existing `approval_summarizer_sc_task` to something like `approval_summarizer_sc_task_old` and deactivate it. Then you will need to create a new one using the same name (`approval_summarizer_sc_task`). The name should

basically tell you what the macro does and what it applies to. In this case, we're replacing an existing one so we decided to re-use the existing name.

Approval macros



Then you should copy the xml script at the bottom of this article into the xml code window in the new UI macro. This is great way to give some detail to an approver when you are doing line item approvals via approval tasks within the Service Catalog Execution Plans.

The old way

This is the view you see in My Approvals when using an approval task via the old method.

My Approvals (old way)

Notice there is not much detail telling the approver what they are actually approving. You can see the short description of the task but not much around what the item is.

The new way

This is the view you will see if you use the xml script below in place of the OOB (out-of-box) UI macro.

Using this method you can see details much like the request approval. You have a link into the item ordered, a short description (which contains the ability to expand the variables from the item), price, quantity and the total price. This helps the approver in that it shows more detail. They can now see what they are actually approving.

Script:

```
<?xml version="1.0" encoding="utf-8" ?>
    <j:jelly trim="true" xmlns:j="jelly:core" xmlns:g="glide"
 xmlns:j2="null" xmlns:g2="null">
    <tr>
        <td class="label_left" width="100%">
            <label style="margin-left: 10px">
                ${gs.getMessage('Summary of Item being
 approved')}:
                <input style="visibility: hidden"
 NAME="make_spacing_ok"></input>
            </label>
        </td>
    </tr>
    <g:evaluate var="jvar_ni" expression="
        var sc_task = ${ref}.sysapproval;
        var sc_req_labels = new GlideRecord('sc_req_item');
        sc_req_labels.initialize();
        var sc_req_item = new GlideRecord('sc_req_item');
        sc_req_item.addQuery('request_item',
 sc_task.request_item.sys_id);
        sc_req_item.query();
    " />
    <tr>
        <td width="100%">
            <table width="100%">
                <tr>
                    <td class="label_left" width="150px">
                        <label style="margin-left: 10px">

 ${sc_task.request_item.request.opened_by.sys_meta.label}:
                        </label>
                    </td>
                    <td>

 ${sc_task.request_item.request.opened_by.getDisplayValue()}
                    </td>
                </tr>
                <tr>
```

```
                    <td class="label_left" width="150px">
                        <label style="margin-left: 10px">

${sc_task.request_item.request.requested_for.sys_meta.label}:
                        </label>
                    </td>
                    <td>

${sc_task.request_item.request.requested_for.getDisplayValue()}
                    </td>
                </tr>
                <tr>
                    <td class="label_left" width="150px">
                        <label style="margin-left:
10px">${gs.getMessage('Total')}:</label>
                    </td>
                    <td>
                        <g:currency_format
value="${sc_task.request_item.request.price}" />
                    </td>
                </tr>
            </table>
        </td>
    </tr>
    <j:set var="jvar_line_num" value="0" />
    <tr>
        <td width="100%">
            <table width="100%">
                <tr class="header">
                    <td colspan="2">
                        ${sc_req_labels.number.sys_meta.label}
                    </td>
                    <td>

${sc_req_labels.description.sys_meta.label}
                    </td>
                    <td>
                        ${sc_req_labels.price.sys_meta.label}
                    </td>
                    <td>
                        ${sc_req_labels.quantity.sys_meta.label}
                    </td>
                    <td>
                        ${gs.getMessage('Total')}
                    </td>
                </tr>
                <j:set var="jvar_item_price"
value="${sc_task.request_item.price *
sc_task.request_item.quantity}"/>
                <j:set var="jvar_overall_total"
value="${jvar_overall_total + jvar_item_price}"/>
                <j:set var="jvar_line_color" value="odd"/>
                <j:set var="jvar_line_num"
value="${jvar_line_num + 1}"/>
                <j:if test="${jvar_line_num % 2 == 0}">
                    <j:set var="jvar_line_color" value="even"/>
                </j:if>
```

```
                <g:evaluate var="ni" expression="
                    var smart_description =
sc_task.request_item.cat_item.short_description;
                    if (smart_description == null ||
smart_description == '' || smart_description == 'undefined')
                    smart_description =
sc_task.request_item.cat_item.name;
                "/>
                <tr class="${jvar_line_color}">
                    <td valign="top">
                        <g2:evaluate var="jvar_pop_target"
expression="$[ref].getRecordClassName()" />
                        <a class="linked" target="gsft_main"

href="sc_req_item.do?sys_id=${sc_task.request_item.sys_id}"
                            onmousemove="popListDiv(event,
'sc_req_item',
'${sc_task.request_item.sys_id}','${sysparm_view}')"
                            onmouseout="lockPopup(event)">
                            <img
src="images/icons/hover_icon.gifx" class="clsshort"/>

                    <td valign="top"> <g:currency_format
value="${jvar_item_price}"/></td>
                </tr>
            </table>
        </td>
    </tr>
</j:jelly>
```

Jelly tags

Use Jelly to turn XML into HTML.

Watch these introductory videos to learn about using Jelly in the ServiceNow AI Platform.

- Introducing Jelly Scripting - Part 1 (Video)
- Introducing Jelly Scripting - Part 2 (Video)
- Introducing Jelly Scripting - Part 3 (Video)

Jelly Tags

if

- Description: The `if` tag is just what it looks like, an `if` tag. This is like an `if` statement in any programming language, but keep in mind that there is no `elseif` tag and no `else` tag. If you want to create that kind of structure, try the `choose/when/otherwise` syntax.
- Parameters: `test` - The condition to evaluate in order to determine if the block will execute.
- Example:

```
<g:evaluate var="jvar_now_GR" object="true">
   var now_GR = new GlideRecord("incident");
   now_GR.addQuery("active", true);
   now_GR.query();
   now_GR;
</g:evaluate>

<j:if test="${!jvar_now_GR.hasNext()}">
   We did not find any active incidents.
</j:if>
<j:if test="${jvar_now_GR.next()}">
   We found ${jvar_now_GR.getRowCount()} active
 incidents.
</j:if>
```

while

- Description: The `while` tag does a while loop.
- Parameters: `test` - The condition to evaluate in order to determine if the statement will loop through. This should be an expression enclosed in `${}` or `$[]` that evaluates to true or false.
- Example:

```
<g:evaluate var="jvar_now_GR" object="true">
   var now_GR = new GlideRecord("incident");
   now_GR.addQuery("active", true);
   now_GR.query();
   now_GR;
</g:evaluate>

<j:while test="${jvar_now_GR.next()}">
  <a
 href="incident.do?sys_id=${jvar_now_GR.getValue('sys_
id')}">${jvar_now_GR.getValue('number')}</a>
</j:while>
```

set

- Description: The `set` tag sets a variable.
- Parameters:
  - `var` - The variable to set. Often the system prefixes these variables with `jvar_` for consistency.
  - `value` - The value to set `var` to. This is often an expression enclosed in `${}` or `$[]`.
  - `defaultValue` - If the value results to null or empty, this value is put into the `var`.
- Example:

```
<j:set var="jvar_incident_number"
 value="${jvar_now_GR.getValue('number')}"/>
```

set_if

- Description: The `set_if` tag sets a variable based on a test. This tag is similar to the `ternary` operator in other programming languages (`var = <test> ? <if_true> : <if_false>`).
- Parameters:
  - `var` - The variable to set. Often the system prefixes these variables with `jvar_` for consistency.
  - `test` - The condition to evaluate in order to determine if the statement will evaluate the true value or the false value. This should be an expression enclosed in `${}` or `$[]` that evaluates to true or false.
  - `true` - The value to set the variable to if `test` evaluates to `true`. This parameter is optional, so if the field is blank, and if test evaluates to true, the variable is left blank.
  - `false` - The value to set the variable to if `test` evaluates to false. This parameter is optional, so if the field is blank, and if test evaluates to false, the variable will be left blank.

choose

- Description: The `choose` tag starts a choose block of code. This is similar to the `if-elseif-else` kind of syntax in most programming languages. With a `choose` tag, you can use `when` and `otherwise` tags to specify other blocks of code.
- Parameters: None
- Example:

```
<j:choose>
   <j:when test="${jvar_now_GR.getRowCount() ${AMP}lt;
 1}">We found multiple records!</j:when>
   <j:when test="${jvar_now_GR.next()}">We found
 record ${jvar_now_GR.getValue('number')}</j:when>
   <j:otherwise>Sorry, we could not find the record
 you specified.</j:otherwise>
</j:choose>
```

when

- Description: The `when` tag is used within a choose block to indicate a condition. This tag is similar to an `if` or an `elseif` in that it specifies a condition, executes the inner content, and then implies a break at the end to leave the `if-elseif` construct.
- Parameters: `test` - The condition to evaluate in order to determine if the statement will loop through. This should be an expression enclosed in `${}` or `$[]` that evaluates to true or false.
- Example:

```
<j:choose>
   <j:when test="${jvar_now_GR.getRowCount() ${AMP}lt;
 1}">We found multiple records!</j:when>
   <j:when test="${jvar_now_GR.next()}">We found
 record ${jvar_now_GR.getValue('number')}</j:when>
   <j:otherwise>Sorry, we could not find the record
 you specified.</j:otherwise>
</j:choose>
```

otherwise

- Description: The `otherwise` tag is used within a `choose/when/otherwise` block, and is like the `else` or `default` case.
- Parameters: None
- Example:

```
<j:choose>
   <j:when test="${jvar_now_GR.getRowCount() ${AMP}lt;
 1}">We found multiple records!</j:when>
   <j:when test="${jvar_now_GR.next()}">We found
 record ${jvar_now_GR.getValue('number')}</j:when>
   <j:otherwise>Sorry, we could not find the record
 you specified.</j:otherwise>
</j:choose>
```

Glide Tags

evaluate

- Description: The `evaluate` tag evaluates JavaScript code (server side), and makes variables visible to future code. Unlike other tags, the `evaluate` tag evaluates the content that is inside the tag as server side JavaScript.

  The context is the same as that of script includes in the system. Other script includes, global business rules, *`GlideRecord`*, *`GlideSystem`*, and Jelly variables (prefixed with jelly. if the parameter `jelly="true"` is set) are available.

- Parameters:
  - `var` - The name of the variable that will be set to the result of the script.
  - `object` - If set to `true`, the result of the expression is treated as an object instead of a primitive variable (string or integer variable values).
  - `jelly` - If set to `true`, allows Jelly context variables to be referenced in the script.

- `expression` - This is an expression to be executed for the value to put in `var`. The expression can be either of two places. First, it can be an attribute on the `evaluate` tag itself. Otherwise, the content between the beginning tag and ending tag is the expression. The last line of the expression is the actual value passed into `var`.

- Example:

```
<g:evaluate var="jvar_now_GR" object="true">
  var now_GR = new GlideRecord("incident");
  now_GR.addQuery("active", "true");
  now_GR.query();
  now_GR; // this is the variable put into the
 variable jvar_now_GR
</g:evaluate>
```

```
<g:evaluate var="jvar_now_GR" object="true"
 expression="
  var now_GR = new GlideRecord('incident');
  now_GR.addQuery('active', 'true');
  now_GR.query();
  now_GR; // this is the variable put into the
 variable jvar_now_GR" />
```

messages

- Description: The `messages` tag helps with translation. When *`gs.getMessage()`* is called anywhere on a page, there are two possible places where the translation is found. First, the page checks a local cache of translations. Second, the page makes an AJAX call to the server to find the translation. What `g:messages` does is allow pages to cache certain messages.
- Parameters: None
- Example:

```
<g:messages>
  Yes
  No
  Cancel
</g:messages>
```

breakpoint

- Description: When the `breakpoint` tag is called, it prints a list of all the variables in Jelly at the current moment, with their respective values. If a variable is specified, it prints the requested variable and its value. The output is placed in the system log.
- Parameters: `var` - (Optional) The variable to log the value for. If `var` is not specified, then all variables are dumped into the log.
- Example:

```
<g:breakpoint />
```

```
<g:breakpoint var="sysparm_view"/>
```

no_escape

- Description: The system, by default, uses escaped output as a security measure. Output placed inside of `no_escape` tags is not escaped before output. Be careful when using these tags, because if user input is displayed here it can open a security vulnerability on the page.
- Parameters: None
- Example (phase 1) – Disables automatic output escaping of all contained ${} expressions:

```
<g:no_escape>
 ${jvar_raw_html_data}
</g:no_escape>
```

- Example (phase 2) – Use NOESC to disable escaping for the specified string. This implies the expression must evaluate to a string.

```
<g:no_escape>$[NOESC:jvar_expr]</g:no_escape>
```

For information on phase 1 and phase 2 evaluation, refer to the Jelly introduction videos listed at the beginning of this section.

macro_invoke

- Description: The `macro_invoke` tag calls a UI macro that you have specified in the database. You may also call a UI macro by specifying it in the tag name. For example, if you had a UI macro named my_macro, you could call that macro with the tag `<g:my_macro/>`. For information, see UI macros.
- Parameters:
  - `macro` - The name of the UI macro to execute. If your tag name is `g:macro_invoke`, then the macro attribute specifies the name of the macro. If the tag name includes the name of the macro, then there is no need to include a macro attribute.
  - Other attributes - For each attribute you specify, a variable with that name will be available in the context of the UI macro, prefixed with `jvar_`.
- Example:

```
<!-- Will invoke the contents of the UI macro
 named "sample_macro", which will have the variable
 jvar_message available within it-->
<g:macro_invoke macro="sample_macro" message="This is
 a sample macro variable." />
```

```
<!-- Will invoke the contents of the UI macro
 named "sample_macro", which will have the variable
 jvar_message available within it-->
<g:sample_macro message="This is a sample macro
 variable." />
```

if_polaris

- Description: The `if_polaris` tag checks if Next Experience is enabled for the current page. It must include at least one of the child tags `<g:then />` or `g:else />`.
- Parameters: None
- Example:

```
<g:if_polaris>
    <g:then><g:inline
 template="polaris_nav"/></g:then>
    <g:else><g:inline
 template="classic_nav"/></g:else>
</g:if_polaris>

<g:if_polaris>
    <g:then><a href="…">Click here to see what's
 new!</a></g:then>
</g:if_polaris>

<g:if_polaris>
    <g:else>Core UI only code here!</g:else>
</g:if_polaris>
```

then

- Description: The `then` tag is used within an `if_polaris` block to set the page content when Next Experience is enabled.
- Parameters: None
- Example:

```
<g:if_polaris>
    <g:then><g:inline
 template="polaris_nav"/></g:then>
    <g:else><g:inline
 template="classic_nav"/></g:else>
</g:if_polaris>

<g:if_polaris>
    <g:then><a href="…">Click here to see what's
 new!</a></g:then>
</g:if_polaris>

<g:if_polaris>
    <g:else>Core UI only code here!</g:else>
</g:if_polaris>
```

else

- Description: The `else` tag is used within an `if_polaris` block to set the page content when Next Experience isn't enabled.
- Parameters: None
- Example:

```
<g:if_polaris>
    <g:then><g:inline
 template="polaris_nav"/></g:then>
    <g:else><g:inline
 template="classic_nav"/></g:else>
</g:if_polaris>

<g:if_polaris>
```

```
    <g:then><a href="…">Click here to see what's
 new!</a></g:then>
</g:if_polaris>

<g:if_polaris>
    <g:else>Core UI only code here!</g:else>
</g:if_polaris>
```

Jelly escaping types

You use different methods when escaping characters in JavaScript and HTML. JavaScript uses the backslash character, and HTML uses the ampersand character.

Note:
This functionality requires a knowledge of JavaScript, HTML, and Apache Jelly (a Java and XML based scripting and processing engine for turning XML into executable code).

There are two different types of escaping that is required when generating output from Jelly:

- JavaScript
- HTML

The escaping for each of these consists of the following types.

Jelly escaping types

Type	From	To
JavaScript	' (single quote)	\'
	" (double quote)	\"
	CR (carriage return)	(blank)
	NL (newline)	\n ('\' followed by 'n')
HTML	& (ampersand)	&
	< (less than)	<
	> (greater than)	>

You can also escape HTML using the getHTMLValue() function which will enforce all line breaks and escape the characters mentioned above. It can be used as follows:

```
${test.getHTMLValue()}
```

Add escaping to a Jelly replacement

You can handle character escaping in Jelly files. XML escaping behavior can be modified only by users with the security_admin role.

About this task

Note:
This functionality requires a knowledge of JavaScript, HTML, and Apache Jelly (a Java and XML based scripting and processing engine for turning XML into executable code).

Procedure

Add a prefix to the `${expression}` or `$[expression]` indicating the escaping to be performed.

```
${JS:expression}
${HTML:expression}
```

The prefix tells the system to take the result of the expression and escape it before outputting. The escaping may be combined by specifying a comma-separated list of prefixes:

```
${JS,HTML:expression}
```

Extensions to Jelly syntax

Apache's Jelly syntax is used to render forms, lists, UI pages, and many other things rendered in ServiceNow.

With Jelly, logic can be embedded within static content and computed values may be inserted into the static content.

Important:
This functionality requires a knowledge of Apache Jelly (a Java and XML based scripting and processing engine for turning XML into executable code).

This page from Apache has a summary of the standard Jelly tags: http://commons.apache.org/jelly/tags.html

Namespaces

Jelly often includes multiple namespaces when invoking tags.

The "j" namespaces are standard Jelly whereas the "g" namespaces are unique to ServiceNow scripts. For example, the <g:evaluate> tag is supplied by ServiceNow to allow you to compute a value using JavaScript. The standard Jelly tag <j:test> is used to evaluate a condition.

Phases

Usually, there are two phases indicated by namespaces <j> versus <j2> and <g> versus <g2>.

The namespaces without the "2" happen in the first phase of processing and these are cached except when used in a UI page. Those with the "2" are never cached. Care must be taken when selecting whether to use phase 1 or phase 2 for efficiency and correct results.

In addition to the namespaces, the syntax used to insert values into static content differs depending on which phase is to supply the value. A dollar with braces surrounding a value inserts the value in phase 1. For example, `${jvar_ref}` inserts the value `jvar_ref` during phase 1 of the jelly process. A dollar with brackets surrounding a value inserts the value in phase 2. For example, `$[jvar_ref]` inserts the value `jvar_ref` during phase 2. A value surrounded by quotes is treated as a string. For example, `'[jvar_ref]'` inserts the value `jvar_ref` as a string during phase 2.

```
 <script>
if (confirm("$[gs.getMessage('home.delete.confirm') ]"))
```

```
   ...
</script>
```

```
<input type="hidden" id="${jvar_name}" name="${jvar_name}"
 value="${jvar_value}" class="${jvar_class}" />
```

If tests

You can use if statements in Jelly scripts.

Testing whether something is true or not can be done as follows:

```
<j:if test="${jvar_something}">...do something...</j:if>
<j:if test="${!jvar_something}">...do something...</j:if>
```

The reason this statement works, is that, in Jelly, a term like jvar_something is "truthful" in an if tag if:

1. it is Boolean and true
2. it is a String and = "true", "yes", "on", or "1"

Testing whether something exists can be done as follows:

```
<j:if test="${empty(jvar_something)}">...do something...</j:if>
```

The reason this statement works is that the JEXL empty function returns true if its argument is:

1. null
2. an empty string
3. a zero length collection
4. a map with no keys
5. an empty array

Note:
You cannot mix javascript and jvar variables in a JEXL expression. They must be broken into separate expressions.

Set_If

Sets a variable to one of two different values depending on whether a test is true or false.

```
<g2:set_if var="jvar_style"
 test="$[gs.getPreference('table.compact') != 'false']"
   true="margin-top:0px; margin-bottom:0px;"
   false="margin-top:2px; margin-bottom:2px;" />
```

<g:insert> versus <g:inline> versus <g:call>

This page provides a comparative explanation of three tags: <g:insert>, <g:inline>, and <g:call>.

<g:insert>

The <g:insert> tag inserts a Jelly file into your Jelly in a new context. This means you cannot access the variables previously established in your Jelly.

```
<g:insert template="get_target_form_function.xml" />
```

<g:inline>

The <g:inline> tag inserts a Jelly file into your Jelly in the same context. This means that the inserted Jelly can access the variables you previously established and it can change the values of those variables.

```
<g:inline template="element_default.xml" />
```

<g:call>

For better encapsulation, the <g:call> tag may be used. Your function will only have access to the values passed to it. The Jelly context will look the same after a call as before the call. This means you cannot set a global variable here and read it later. This also means you can't mistakenly set a global variable called "jvar_temp" and overwrite a variable that somebody else was relying on.

Passing values, if needed, is done explicitly by including the name of the parameter on the <g:call> line followed by the equal sign followed by the value in quotes:

```
<g:call function="collapsing_image.xml" id="${jvar_section_id}"
 image="$[jvar_cimg]"
   first_section_id="${jvar_first_section_id}"
 image_alt="${jvar_cimg_alt}"/>
```

If values are passed, and you want to have defaults or required parameters, your Jelly referenced in the function must then include a line to declare whether the parameters are required or have a default value:

```
<g:function id="REQUIRED" image="REQUIRED" image_prefix=""
 image_alt="REQUIRED"/>
```

The example above indicates that 3 of the parameter are required and one parameter is option with a blank default value. Note that if you are not passing values or if you do want to have default or required values, you do not need to include the <g:function> line at all. In general, however, you will want to include a <g:function> line.

The value can then be referenced in your template by prepending the "jvar_" prefix to the parameter's name:

```
<img id="img.${jvar_id}" src="images/${jvar_image}"
 alt="${jvar_image_alt}"
   onclick="toggleSectionDisplay('${jvar_id}',
 '${jvar_image_prefix}','${jvar_first_section_id}');"/>
```

For <g:call>, parameters may also be pass implicitly as a list of named variables in an "arguments" parameter:

```
 <g:call function="item_link_default.xml"
 arguments="sysparm_view,ref_parent,jvar_target_text"/>
```

As an alternative to passing variables into the function via separate tag arguments, it is possible to pass a list of variables in a single 'arguments' argument. All variables identified by name (comma separated) in the *`argument`* parameter are re-introduced within the function under the exact same name (e.g. inside the function template, we'd have variables sysparm_view, ref_parent, and jvar_target_text available to us).

The function template may return a value to the calling template using the `return=` attribute. Within the function the `jvar_answer` variable sets the return value.

```
<g:call function="item_body_cell_calc_style.xml"
 arguments="jvar_type" return="jvar_style"/>
```

<g:evaluate>

The <g:evaluate> tag is used to evaluate an expression written in Rhino JavaScript and sometimes to set a variable to the value of the expression.

The last statement in the expression is the value the variable will contain.

```
<g2:evaluate var="jvar_page" jelly="true">
     var page = "";
     var pageTitle = "";
     var pageGR = new GlideRecord("cmn_schedule_page");
     pageGR.addQuery("type", jelly.jvar_type");
     pageGR.query();
     if (pageGR.next()) {
        page = pageGR.getValue("sys_id");
        pageTitle = pageGR.getDisplayValue();
     }
     page;
</g2:evaluate>
```

```
<g2:evaluate var="not_important"
 expression="sc_req_item.popCurrent()"/>
```

object="true"

If you would like to have the evaluate return an object (for example an array), use the argument object="true".

```
<g2:evaluate object="true" var="jvar_items"
 expression="SncRelationships.getCMDBViews()" />
```

jelly="true"

If you would like to access Jelly variables inside an evaluate, include jelly="true" in the evaulate and add "jelly." before the Jelly variable's name. For example, to access the GlideJellyContext:

```
<g2:evaluate var="jvar_row_no" jelly="true">
   var gf = jelly.context.getGlideForm();
   var row = gf.getRowNumber();
   row;
</g2:evaluate>
```

Another example of accessing a jvar using the jelly="true" parameter. The value of `jvar_h` was set previously and we can access it inside the `evaluate`:

```
$[NLBR:jvar_h.getHTMLValue('newvalue')]
<g2:evaluate var="jvar_fix_escaping" jelly="true">
    var auditValue = jelly.jvar_h.getHTMLValue('newvalue');
    gs.log("************ " + auditValue);
</g2:evaluate>
```

copyToPhase2="true"

If you have a need to take the results of an evaluation that occurs in phase 1 and propagate it to phase 2, use copyToPhase2="true". There is some protection for escaping in this use. For example:

```
<g:evaluate var="jvar_has_special_inc" copyToPhase2="true">
   var specialInc = gs.tableExists("special_incident");
   specialInc;
</g:evaluate>
$[jvar_has_special_inc]
```

If you do not need to evaluate something, you can do this more directly. Beware of escaping issues here (double quotes in jvar_rows would cause a problem in the example):

```
<j2:set var="jvar_rows" value="${jvar_rows}"/>
```

<g:breakpoint/>

This tag can be used to display the current Jelly variables and their values in the log.

Be sure to remove this tag before going to production.

<g:ui_form/>

This tag defines a form on the UI page.

For example, if your form contained the `application_sys_id` field, the g:ui_form might benefit from a processing script.

```
<g:ui_form>
    <p>Click OK to run the processing script.</p>
    <g:dialog_buttons_ok_cancel ok="return true" />
    <input type="hidden" name="application_sys_id"
 value="499836460a0a0b1700003e7ad950b5da"/>
 </g:ui_form>
```

For more information, see UI macros.

<g:ui_input_field />

This tag adds a reference to a UI macro that creates an input field on a page that allows users to input information. The `ui_input_field` passes a label, name, value, and size into the UI macro.

Here is an example from a UI page:

```
<g:ui_input_field label="sys_id" name="sysid"
 value="9d385017c611228701d22104cc95c371" size="50"/>
```

For more information, see UI macros.

<g:ui_checkbox/>

This tag puts a user-editable check mark on a page. The name and value are passed into the UI macro.

Here is an example from a table on a UI page:

```
<table>
    <tr>
      <td nowrap="true">
          <label>Time Card Active:</label>
      </td>
      <td>
          <g:ui_checkbox name="timecard_active"
 value="${sysparm_timecard_active}"/>
      </td>
```

```
   </tr>
</table>
```

For more information, see UI macros.

<g:dialog_buttons_ok_cancel/>

This tag puts buttons on the UI page that run a specified processing script if the tag returns true.

If your UI page contains a form (uses the <g:form> tag), you can submit the form and have the Processing Script run. The Processing Script can naturally access fields on the form. For example, if your form contained the application_sys_id field:

```
<g:ui_form>
    <p>Click OK to run the processing script.</p>
    <g:dialog_buttons_ok_cancel ok="return true" />
    <input type="hidden" name="application_sys_id"
 value="499836460a0a0b1700003e7ad950b5da"/>
 </g:ui_form>
```

<g:ui_reference/>

This tag adds a reference to a page that can be referenced by a Processing Script.

The following example creates a reference defined by name, ID, and table parameters in the tag:

```
<g:ui_reference name="QUERY:active=true^roles=itil"
 id="assigned_to" table="sys_user" />
```

Then in the Processing Script, reference the name field like this:

```
newTask.assigned_to =
 request.getParameter("QUERY:active=true^roles=itil");
```

You can specify a reference qualifier, so that the "name" attribute can be unique. The following example creates a reference defined by name, ID, and table parameters in the tag.

Note:
The "columns" attribute only applies to the auto-completer.

```
<g:ui_reference name="parent_id" id="parent_id"
 table="pm_project" query="active=true"
 completer="AJAXTableCompleter"
columns="project_manager;short_description"/>
```

Ampersand

Ampersands in Jelly can cause you grief because Jelly is XML.

Use `${AMP}` to insert an ampersand in Jelly. If you are writing JavaScript that appears in the HTML part of say a UI page or UI macro that is actually going to run on the browser you are better off putting this code in the "client script" field and that way you can avoid escaping issues. However, if you really must put it in the "HTML" field, you will need to do something like this:

```
ta = ta[1].split('$[AMP]');
```

And

Use `${AND}` to insert a JavaScript and in Jelly.

For example:

```
if (d ${AND} e)
   var color = d.value;
```

Alternately, in a Jelly test you would use `&amp`. For example:

```
<j:if test="${jvar_form_name == 'sys_form_template'
 &amp;amp;amp; !RP.isDialog()}">
```

Less than

Similar to ampersands, less than ("<") signs can also cause problems due to Jelly being XML. This can be resolved by reversing your test such that it is not necessary or by using `${AMP}lt;` in place of the less than sign.

```
<g2:evaluate var="jvar_text">
     var days = "";
     var selectedDays = '$[${ref}]';
     for (var i = 1; i ${AMP}lt;= 7; i++) {
        if (selectedDays.indexOf(i.toString()) >= 0) {
           days += gs.getMessage("dow" + i);
           days += " ";
        }
     }
     days;
 </g2:evaluate>
```

Many times you can avoid the "less than" operator all together by just using "not equals" which doesn't have escaping issues. For example:

```
for (var i=0; i != ta.length; i++) {
}
```

Whitespace

Normally, white space is removed by Jelly. To keep it, you must specify that it not be trimmed.

For example, the following keeps the space after the colon.

```
<j2:whitespace trim="false">${gs.getMessage('Did you mean')}:
 </j2:whitespace>
```

Spaces

To encode a non-breaking space ( ), you can use `$[SP]`.

For example:

```
<span id="gsft_domain" style="display: inline">
    ${gs.getMessage('Domain')}:$[SP]
    <span id="domainDD" class="drop_down_element"
 style="text-decoration: none; color: white">
        ${gs.getMessage("Loading...")}
   </span>
</span>
```

Tracing Jelly

ServiceNow has a feature that allows the evaluation of Jelly to be traced.

The trace is sent to the log. This should only be turned on during debugging as this produces a lot of logging. To turn on the trace, set the property glide.ui.template.trace to true. For example, the following script can be executed to do this:

```
GlideProperties.set ( 'glide.ui.template.trace' , true ) ;
```

If you want to see your log entries on your web browser at the bottom of each page, navigate to **System Diagnostics** > **Debug Log**.

Debugging scripts

Debug scripts using session logs and ServiceNow AI Platform debugging tools such as a walk-through script debugger and error messages that display in the UI.

Debugging server-side scripts

Use the Script Debugger and session logs to debug server-side code. For more information, see Script Debugger and Session Log.

You can also use session debug to display error messages related to a server-side script that runs as a result of a client-side change. For more information, see Session debug.

GSLog is a script include that simplifies script logging and debugging by implementing levels of log output, selectable by per-caller identified sys_properties values. For more information, see GSLog API.

Debugging client-side scripts

Use session debug to display debugging messages in the user interface. For more information, see Session debug. Use the session log to view logging information for script includes and custom UIs, such as Agent Workspace.

You can also debug client-side scripts using browser-based developers tools.

Debugging applications and scopes

Use the application debugging options to understand how a script's application scope might affect your application, table, or record. You may need to update cross-scope privileges to troubleshoot scope access issues. See Debugging applications.

Script Debugger and Session Log

The Script Debugger enables users with the script_debugger role to debug server-side JavaScript. Users with the log_debugger role can use the Session Log to view and download required logs.

Users with the script_debugger role can perform these actions using Script Debugger:

- Have a dedicated debug transaction, which applies only to the current session.
- Set and remove breakpoints.
- Pause the current session at a breakpoint.
- Evaluate expressions during runtime.
- Step through code line-by-line.
- Step into and out of function and method calls.
- View the value of local and global variables.
- View the value of private variables from function closures.

- View the call stack.
- View the transaction that the system is processing.
- Turn off the script debugger to resume running paused scripts.

Use the Session Log tab to retrieve the session log for business rules, script includes, and a custom UI such as ServiceNow® Agent Workspace that has a GraphQL component. Users with the log_debugger role can:

- View session logs in a separate tab.
- Download a log.
- View logs for Agent Workspace.
- Specify debug options to view or download only the required logs.

By default, 100 transactions and 10,000 messages appear on the Session Log tab. If the transaction or message count exceeds the default value, the session log is cleared and the next transactions or messages appear. You can configure this transaction and message count using the *glide.debugger.log.transaction.count* and *glide.debugger.log_messages_limit* user preferences respectively. For more information about the *glide.debugger.log.transaction.count* and *glide.debugger.log_messages_limit* user preferences, see User preference settings.

Note:
Enable Session Log as a separate tab with Script Debugger using the *glide.debugger.log.ui* system property.

- The **Page** option displays logs under forms and lists and on the **Session Log** tab.
- The **Session** option displays logs only on the **Session Log** tab.

For more information about the *glide.debugger.log.ui* system property, see Available system properties.

When you execute a statement in the Console, the executed statement is stored in the browser cache. You can use the up arrow key to get the previous statement and down arrow key to get the next statement from the browser cache. The user preference setting, *glide.debugger.console.cached_stmt_limit*, defines the number of statements cached in a browser session. The default statement cache value is 20 and the maximum value is 100. You can configure the statement cache value from user preferences.

Note:
The cached statements are not available when the browser cache is cleared or when you log in from a different browser or a different computer.

The Script Debugger can pause any server-side script that runs in an interactive transaction such as business rules, script includes, script actions, or UI actions that require a response to proceed. If the GlideSystem method `isInteractive()` returns **True** when running the script in context, then the Script Debugger can pause it.

Note:
Some script objects, such as script includes, can be called from multiple contexts. For example:

- when a business rule runs a script include on a form submit that is an interactive transaction waiting on the form data to change before continuing.
- when a scheduled job runs the same script include that is a non-interactive background transaction that can also run other scripts simultaneously.

To debug client-side scripts, you can use browser-based developers tools.

A debugger transaction remains open as long as the user session is valid. If a user logs out or their session times out, the system closes the debugger transaction.

To view debug logs, see Display debugging logs.

Note:
When the Script Debugger is enabled, code is executed in interpreted mode. If parts of the script are set to run in strict mode, the debugger is not able to find the correct objects and the debugger fails. The Script Debugger must run on scripts outside of strict mode.

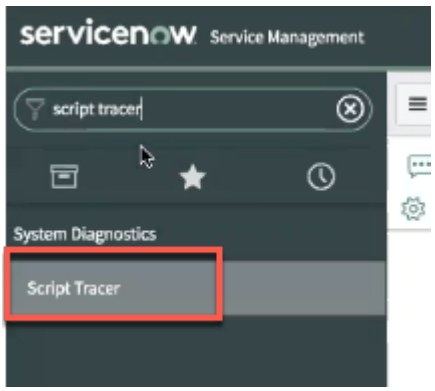
Script Tracer and debugging scripts

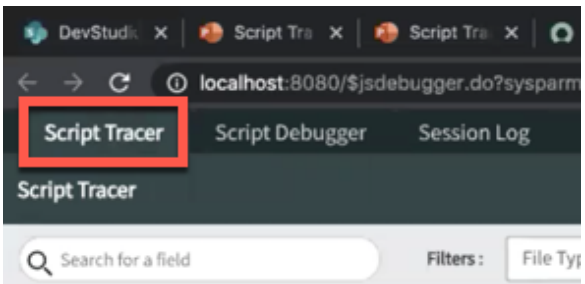
The Script Tracer can help you filter your debugging search to quickly narrow down script problems. You can identify lines of scripts in the Glide record that have undergone change during execution. Finding those specific lines of scripts rather than doing a wide search helps save time and improves productivity.

Overview

Use the Script Tracer to narrow your search so you can debug scripts and business rules more efficiently. You can find the Script Tracer by searching in the left navigation pane.

Note:
To use the Script Tracer, your role must be admin.

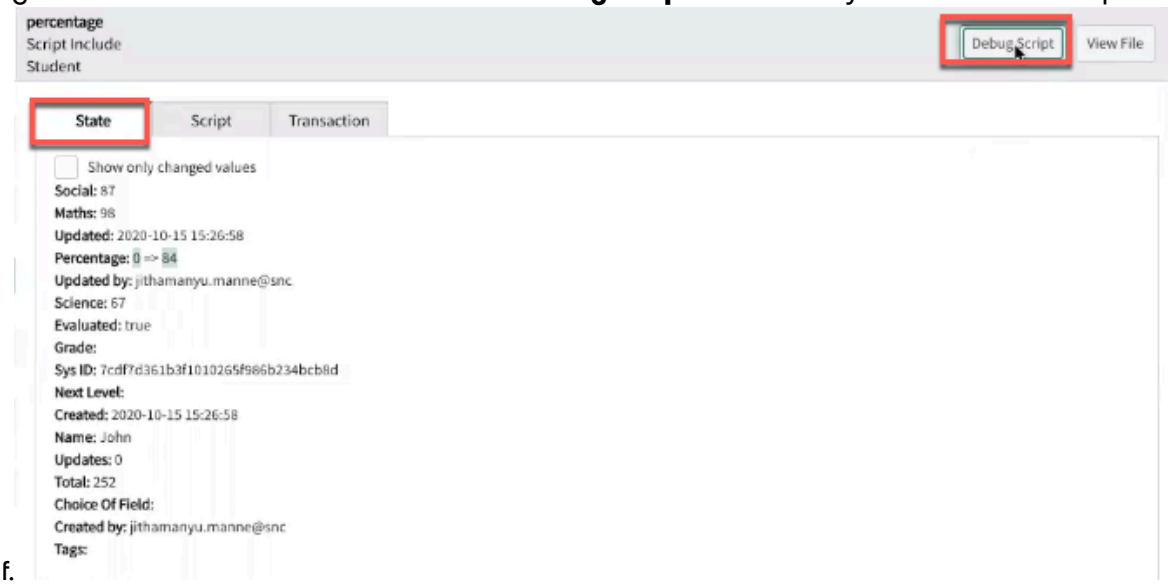




Once you enable Script Tracer and execute a UI transaction, the Tracer searches through all the scripts being executed. The following filters are available:

- **File type**: Search for a specific file type
- **Table**: Look in the specific table for the script being executed

The Script Tracer searches for changes in the script during execution and presents them in a list for you to examine. When you click **Start Tracer**, the Tracer begins searching for changes in the Glide record. You can click the **Debug Script** button at any time to see the script itself.



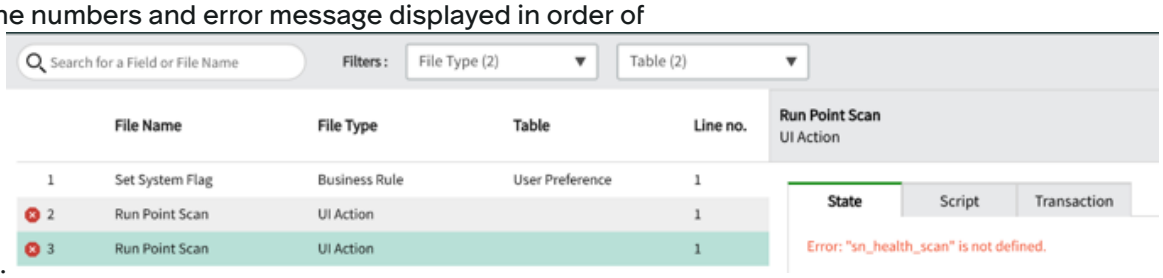
Use the tabs to see specific information from the Tracer.

The **State** tab displays the differences between the old and new scripts.

- By default, the **Show only changed values** check box is enabled, so you can avoid fields that have not changed.
- To view all the fields (changed or not), you can clear that check box.

Note:
If the file is not reflected in the trace statement, it means the changes in the Glide record is not recognized by the system.

If there are any errors, they display at the top of the State tab, with their line numbers and error message displayed in order of occurrence.



- **Script**: Displays the line of changed scripts that the Glide record has undergone during execution. You can view the entire line of script by clicking the **Show Script** button.
- **Transaction**: Shows all transaction records of the trace
- **Debug Script**: Opens the script in Debugger to debug the script
- **View File**: Opens the script in the ServiceNow platform for editing
- **Clear trace**: Clears the trace when you are finished.

Limiting the tracer

You may want to set a limit for your trace so that you don't generate too many returns. By default there will be up to 1,000 lines of script traced. Once this number is reached you must clear the

trace and start tracing again. If you want to change the maximum number of lines for tracing you can configure your limit using the property *glide.debug.trace.trace_line_limit*.

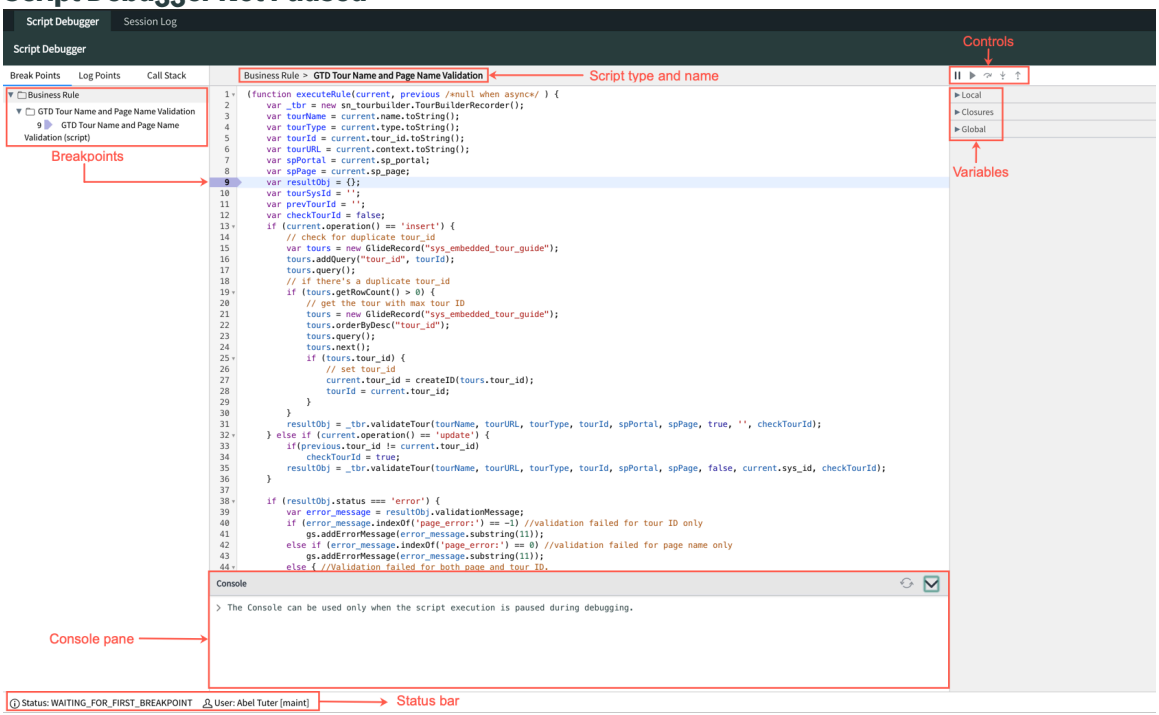
Since each trace you run is new, make sure you're finished reading the results of one trace before clearing it and beginning another one.

To learn more, see Debugging scripts.

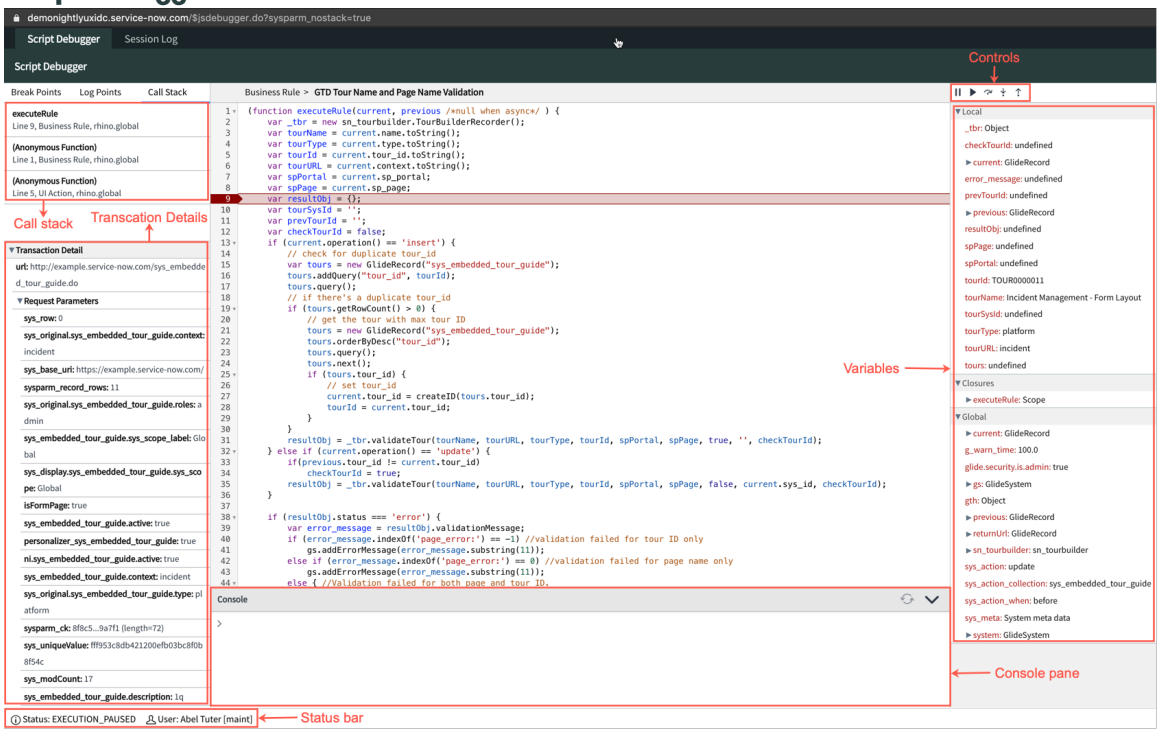
Parts of the user interface

The Script Debugger interface displays information about breakpoints set, the call stack and line number of the currently executing script line, details about variables and transactions, and status of console.

Script Debugger Not Paused



Script Debugger Paused



Parts of the Script Debugger

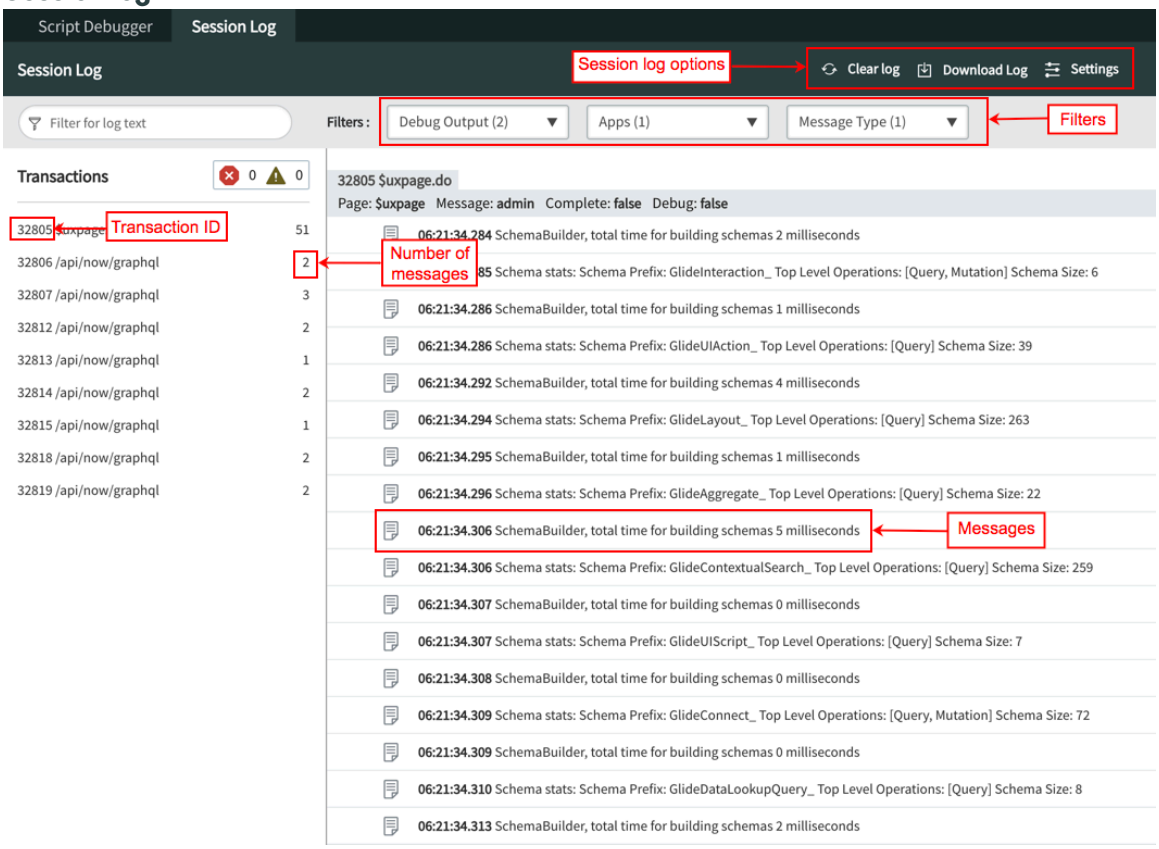
User interface element	Description
Breakpoints	Displays a list of the breakpoints set by script type, script name, and line number. The debugger updates this list as you add and remove breakpoints.
Call stack	Displays a list of script calls that preceded or invoked the current line number. This information is only visible when the debugger pauses on a breakpoint.
Transaction details	Displays information about the current transaction. This information is only visible when the debugger pauses on a breakpoint.
Status	Displays if the debugger is waiting for a breakpoint, paused on a breakpoint, or has encountered an exception.
User	Displays the name of the user who is running the current debugger session.
Coding pane header	Displays the script type and name of the script in the coding pane.
Breakpoint icon	Indicates the line number where the debugger pauses when evaluating the current script.
Pause debugging button	Stops any current debugging session, and disables the Script Debugger for the current user. The Script Debugger doesn't pause on breakpoints for the current user until it's restarted.

Parts of the Script Debugger (continued)

User interface element	Description
Console	Displays a command line interface used for evaluating expressions during runtime. The console is available only when the script execution is paused.
Resume script execution button	Advances from the current breakpoint to the next breakpoint. If there are no other breakpoints, the script runs to completion.
Step over next function call button	Advances past the method that's about to be called, executing the method as a single step.
Step into next function call	Advances to the first line of executed code within a method call. Stepping into a method updates the current position within the call stack. If the user doesn't have read access to the method call, then this control acts like step over instead.
Step out of current function	Exits from current method call and returns to the calling script from the call stack. If the user isn't within a method call, then this control acts like step over instead.
Local	Displays a list of local scope JavaScript variable names and their values. This information is only visible when the debugger pauses on a breakpoint.
Closures	Displays a list of global scope JavaScript variable names and their values set by function closure. This information is only visible when the debugger pauses on a breakpoint.
Global	Displays a list of global scope JavaScript variable names and their values. This information is only visible when the debugger pauses on a breakpoint.

Session Log

Session log



Session Log user interface elements

User interface element	Description
Transactions	Transaction ID. Displays information about the current transaction.
Filter for log text	Field to enter text to filter the logs that contain a specific text.
Debug Output	Option to filter logs based on the dynamically loaded debug output types. For example, **Security Rule**.
Apps	Option to filter logs based on the dynamically loaded apps. For example, **Service Management Integrations**.
Message Type	Option to filter logs based on the dynamically log levels. For example, **Info**.
Clear log	Clears all logs.
Download log	Download the logs in HTML file format.
Settings	Session debug options. For information about the debug options, see Session debug.

Script Debugger step-through and console controls

After the Script Debugger pauses a script, use the step-through controls to move between script lines and move between scripts in the call stack. Use the Console controls to expand console, collapse console, clear console, and rerun expressions.

Step-through controls

Control	Icon	Description
Stop debugging SHIFT+F2		Stops any current debugging session, and disables the Script Debugger for the current user. The Script Debugger does not pause on breakpoints for the current user until it is restarted.
Start debugger - F2		Enables the Script Debugger for the current user. The Script Debugger pauses on breakpoints.
Resume script execution - F9		Advances from the current breakpoint to the next breakpoint. If there are no other breakpoints, the script runs to completion.
Step over next function call - OPTION +F9		Advances to the next evaluated line of script based on current conditions. The Script Debugger skips any lines of code that do not need to run because their conditions are not met. For example, when the condition of an `if` statement is not true, the debugger skips the code block for the condition.
Step into next function call - OPTION +F10		When the Script Debugger pauses on a method call, this control allows the user to advance to the first line of executed code within the method call. Stepping into a method updates the current position within the call stack. If the user does not have read access to the method call, then this control acts like step over instead.
Step out of current function - OPTION +F11		When the Script Debugger pauses within a method call, this control allows the user to exit the current method call and return to the calling script from the call stack. If the user is not within a method call, then this control acts like step over instead.

Console controls

Control	Icon	Description
Open Console		Expands the Console.
Close Console		Collapses the Console.
Clear expressions		Clears all the expressions in the Console.
Re-execute expression		Re-executes the expression which is already executed.

Related topics

Set or remove breakpoints

Evaluate expressions in runtime using Console

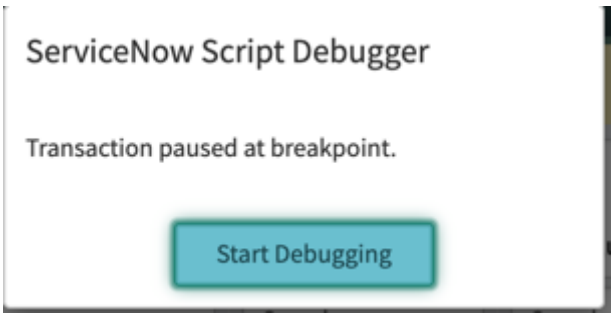
Define, declare, and verify new variables and functions while you debug a script in runtime using Console. The script execution must be paused to use Console.

Before you begin

- Review Limitations with using Console
- Role required: script_debugger, admin

Procedure

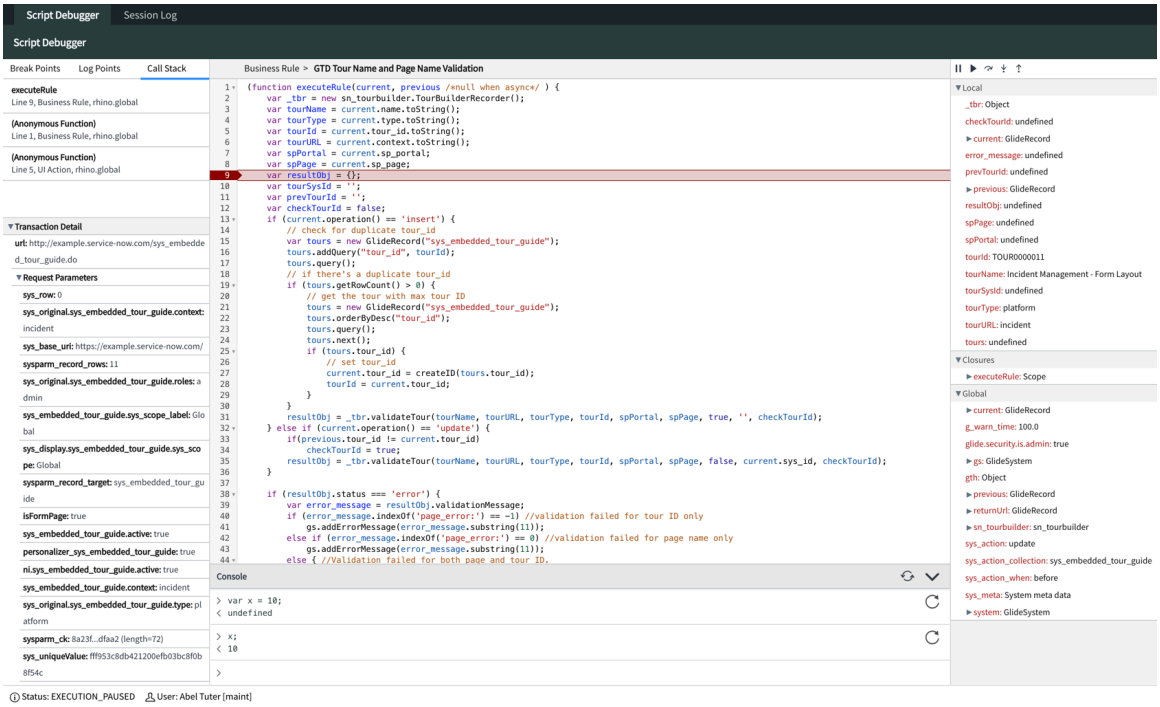
1. Launch the Script Debugger in one of the following ways.
   The Script Debugger modal is displayed.
2. Trigger the script.
   For example, create a record to trigger an insert business rule script. The Script Debugger pauses the script on the first line that contains a breakpoint, and then you see the ServiceNow Script Debugger confirmation window.



3. Click **Start Debugging**.
   The focus shifts to the Script Debugger window and you see the target script that paused at the first breakpoint.

   Note:
   Make sure that the status of Script Debugger is EXECUTION_PAUSED. You can use Console only when the script execution is paused during debugging.

4. Click the expand console (^) to expand the Console pane.
   To start evaluating expressions, enter one or more expressions in the Console and press Enter. For example, enter `var x = 10;` and press Enter. To enter multiple lines of expressions, press Shift + Enter after each line and press Enter after the last expression. To clear all the expressions in the Console, click the clear console icon (⟳). For more information on Console controls, see Script Debugger step-through and console controls.



After a statement is executed, it is stored in the browser cache. You can use the up arrow key to get the previous statement and the down arrow key to get the next statement from the browser cache. You can configure the number of cached statements for a session from user preferences. For more information about user preferences settings, see Script Debugger and Session Log.

Result

After a statement is executed, it is stored in the browser cache. You can use the up arrow key to get the previous statement and down arrow key to get the next statement from the browser cache. You can configure the number of cached statements for a session from user preferences. For more information about user preferences settings, see Script Debugger and Session Log.

Related topics

Limitations with using Console

Limitations with using Console

You need to be aware of a few limitations when you use Console to evaluate expressions while debugging a script in runtime.

- The properties and values of an object don't display in Console. When you try to display an object to Console, only the string value of the object appears.
- Console doesn't support GlideSystem printing methods, such as info() and print().
- You can't use the `this` keyword in Console.
- A script debugger timeout occurs when you evaluate expressions in Console.
- While executing long scripts, if you see the response `Awaiting response from server`, you can't resume debugging or stop debugging using the resume or stop controls.

Launch the Script Debugger

Developers can launch the Script Debugger from the application navigator, Studio, or from the syntax editor.

Before you begin
Role required:

- admin
- script_debugger

Procedure

Select a path based on your starting point.
The system opens the Script Debugger in a new window.

Set or remove breakpoints

Set breakpoints or conditional breakpoints to pause scripts at specific lines, and remove breakpoints when you are done debugging them.

Before you begin
Role required:

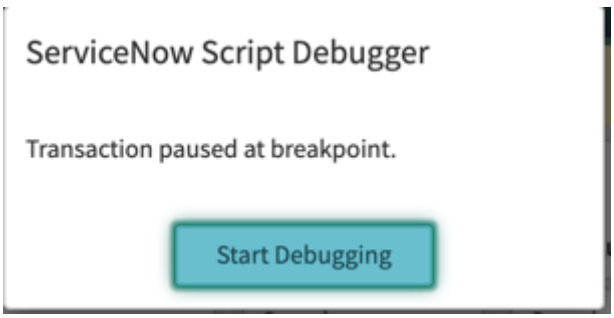
- admin
- script_debugger

About this task
Breakpoints belong to the developer who sets them. Developers must set and remove their own breakpoints.

Note:
At a specific line, you can set either a logpoint or breakpoint but not both.

Procedure

1. Navigate to the server script to debug.
   For example, navigate to **All** > **System Definition** > **Business Rules**.
2. From the Syntax Editor, click the gutter next to a script line.
3. From the Syntax Editor toolbar, click the **Open Script Debugger** icon.
   The system opens a Script Debugger window.
4. Trigger the script.
   For example, create a record to trigger an insert business rule script.
   The Script Debugger pauses the script on the first line containing a breakpoint, and the system displays a confirmation window.



5. Click **Start Debugging**.

The system switches focus to the Script Debugger window and displays the target script paused at the first breakpoint. Console pane is enabled.

6. When debugging is complete, remove breakpoints from the script.

Related topics

Script Debugger step-through and console controls

Set or remove logpoints

Set breakpoints or conditional logpoints to log messages to the console at specific lines, and remove logpoints when you are done debugging them.

Before you begin

- Set the *glide.debug.log_point* system property to `true`. See Available system properties for more information.
- Role required: admin or script_debugger

About this task

Logpoints belong to the developer who sets them. Developers must set and remove their own logpoints.

Note:
At a specific line, you can set either a logpoint or breakpoint but not both.

Procedure

1. Navigate to the server script to debug.
   For example, navigate to **All** > **System Definition** > **Business Rules**.
2. From the Syntax Editor, click the gutter next to a script line.

   Note:
   The script entered for the logpoint must have the same format as that of the script in GSLog and GSInfo script includes.

3. From the Syntax Editor toolbar, click the **Open Script Debugger** icon .
4. On the Script Debugger window, trigger the script.
   For example, create a record to trigger an insert business rule script.

   Note:
   You can also add logpoints in the Script Debugger window.

5. In the Script Debugger window, click **Session Log** to view the logpoints.
6. When debugging is complete, remove logpoints from the script.

Script Debugger status

The Script Debugger status determines what debugging actions are available and what information it can display.

The Script Debugger displays its status at the bottom left of the user interface.

Sample Script Debugger status

Possible Script Debugger status values

Status	Occurs when	Description	Actions available
WAITING_FOR_FIRST_BREAKPOINT	The user opens a Script Debugger window or tab.	The Script Debugger is ready to pause script and display debugging information.	Pause script at the first breakpoint in the call stack.
EXECUTION_PAUSED	• The Script Debugger pauses on a breakpoint. • The user steps over, steps into, or steps out to the next line of evaluated code.	The Script Debugger has paused on a line of code, and the user can debug the script. Console is enabled.	• Resume processing until the Script Debugger reaches the next breakpoint. • Step through a script. • Display the call stack. • Display transaction information. • Display variable values. • Evaluate expressions in Console during runtime.
WAITING_FOR_BREAKPOINT	• The user resumes processing until the Script Debugger reaches the next breakpoint. • The user steps through a script until the Script Debugger reaches the next line of code to evaluate or the transaction completes.	The Script Debugger is searching for the next line of code at which to pause. Users will typically never see this status because the Script Debugger changes status after it locates the next breakpoint or script line to evaluate.	• Pause script at the next breakpoint. • Pause script at the next script line requiring evaluation.
OFF	• The user pauses the Script Debugger. • The user closes the Script Debugger window or tab. • The user session ends for any reason. • The administrator resets all Script	The Script Debugger is inactive and does not pause scripts or display debugging information.	• Start the Script Debugger. • Open a Script Debugger window or tab.

Possible Script Debugger status values (continued)

Status	Occurs when	Description	Actions available
	Debugger instances by navigating to the `debugger_reset.do` page.		

Log entries

Every time a debug transaction finishes executing, the system creates a log entry for it with a DEBUGGED prefix. For example:

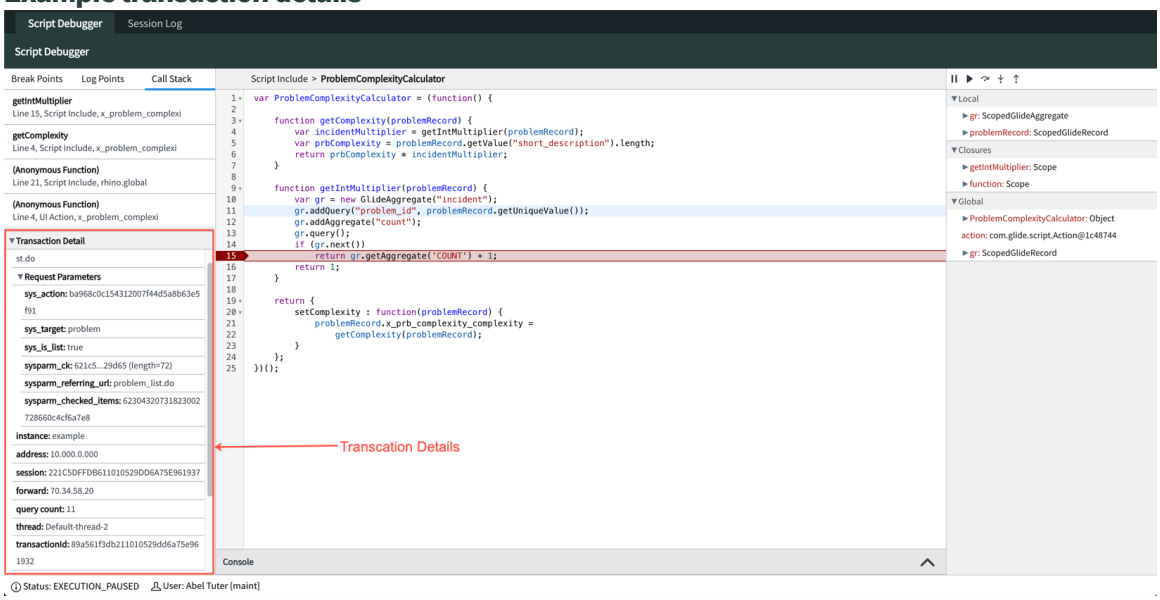
```
2016-08-15 15:57:32 (197) Default-thread-3
 900F5101671122O0C4098C7942415A75 *** End
#39, path: /my-app.do, user: admin, DEBUGGED total transaction
 time: 0:00:11.010,
transaction processing time: 0:00:11.010, network: 0:00:00.000,
 chars: 6,058, uncompressed
chars: 20,731, SQL time: 50 (count: 34), business rule: 0
 (count: 0), phase 1
form length 56,464, largest chunk written: 10,428, request parms
 size: 40, largest input read: 0
```

Transaction details

The Script Debugger displays transaction details for the current paused user session.

Transaction details are available in a dedicated resizeable section underneath the Call Stack on the bottom left of the Script Debugger.

Example transaction details



The Script Debugger only displays transaction details when it pauses on a script. Developers can use transaction details to:

- Inspect the URL of the currently paused transaction.
- Inspect the request parameters for the currently paused transaction.

- Inspect network information about the current transaction.
- Inspect the user and session ID that initiated the debug transaction.

Related topics

Available transaction details

Available transaction details

The Script Debugger provides a standard set of transaction details for developers to debug and troubleshoot scripts.

Available transaction details

Transaction element	Description
url	The URL of the currently paused transaction.
Request parameters	The list of request parameters for this transaction. Each transaction has its own list of request parameters, but record transactions typically include the field values used to insert, update, or delete a record.
instance	The instance name.
address	The IP address of the end-user client system.
session	The user session ID.
forward	The IP address of the load balancer.
query count	The number of database queries the Script Debugger has made.
thread	The name of the thread running the Script Debugger instance.
transactionid	The Sys ID of the current transaction.
token	The Script Debugger token of the currently paused transaction. The system uses this token to identify different Script Debugger instances.
name	The name of the currently paused transaction. You can use this name to identify transactions in the logs.
processor	The name of the processor processing the current transaction, if present.
method	The HTTP request method the currently paused transaction uses.
startTime	The date-time stamp when the Script Debugger instance started.
page	The current table or UI page associated with the transaction.
user	The user who triggered the debug transaction.
nodeid	The Sys ID of the node running the Script Debugger instance.

Related topics

Transaction details

Script Debugger multiple developer support

The Script Debugger allows multiple developers to debug their own transactions without affecting each other.

The Script Debugger only allows developers to see and interact with items related to their current debugging session such as:

- Breakpoints
- Call stack
- Console
- Transactions
- Status

The Script Debugger prevents one developer from seeing or modifying another debug session. Administrators, however, can impersonate another user, open the Script Debugger, and debug transactions generated by the impersonated user.

The Script Debugger displays the debug session user at the bottom left of the user interface.

Sample Script Debugger user

Concurrent Script Debugger usage

By default, the system supports debugging `[(The number of semaphores on the instance) / 4]` concurrent transactions. Administrators can specify the number of concurrent transactions the system can debug by setting the *`glide.debugger.config.max_node_concurrency`* system property. The system can debug up to `[(The number of semaphores on the instance) - 2]` concurrent transactions.

Administration of debugging sessions

Debugging sessions can remain actively debugging (in the EXECUTION_PAUSED or WAITING_FOR_BREAKPOINT statuses) until:

- The user pauses the Script Debugger.
- The user closes the Script Debugger.
- The user session ends.

Administrators can view the currently running debugger sessions by navigating to the page `xmlstats.do`.

Administrators can stop all currently running debugging sessions by navigating to the page `debugger_reset.do`. Only users with the admin role can access this page.

Related topics

Script Debugger impersonation support

Script Debugger impersonation support

You can use the Script Debugger while impersonating another user, but only if the impersonated user has the script_debugger role and has read access to the target script.

While impersonating another user, you can:

- See and change breakpoints that belong to the impersonated user.
- View and pause on scripts that the impersonated user has read access to.
- Evaluate expressions in Console on behalf of the impersonated user.

The Script Debugger step-through controls also use the read access of the impersonated user. For example, if the impersonated user does not have read access to a function in the call stack, any **Step into** action instead becomes a **Step over** action.

The impersonated debugging session lasts until:

- You stop impersonating the user.
- You log out or the user session ends.
- You pause the Script Debugger.
- You close the Script Debugger.

Related topics

Script Debugger multiple developer support

Script Debugger Scripts - Background support

The Scripts - Background module does not support setting breakpoints directly in the script field. You can however, set breakpoints in the script objects called or triggered by the Scripts - Background module.

While running arbitrary JavaScript code in the **Scripts - Background** module, the Script Debugger can only pause scripts when you:

- Call a script include containing breakpoints.
- Trigger a business rule containing breakpoints.
- Trigger a script action containing breakpoints.

Domain separation and Script Debugger

Domain separation is supported in Script Debugger. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Basic

- Business logic: Ensure that data goes into the proper domain for the application's service provider use cases.
- The application supports domain separation at run time. The domain separation includes separation from the user interface, cache keys, reporting, rollups, and aggregations.
- The owner of the instance must set up the application to function across multiple tenants.

Sample use case: When a service provider (SP) uses chat to respond to a tenant-customer's message, the customer must be able to see the SP's response.

For more information on support levels, see Application support for domain separation.

How domain separation works in Script Debugger

Script Debugger is not a full application but rather, a feature in the Platform suite, meaning it works alongside other features, including domain separation.

Related topics

Domain separation for service providers

Session debug

Enable session debugging to display debugging messages in the user interface.

Troubleshooting slow performance with the Session Debug feature.

You can enable all areas for abundant logging on the bottom of each page load, or you can enable each module one by one, for more specific information about what is happening during this session, and specifically, for the previous transaction. Select session debug options under **System Diagnostics** > **Session Debug**. When enabled, session debugging is active during the user session or until disabled. To view debug logs, see Display debugging logs.

The system provides the following session debugging options.

Session debug options

Debug option	Description
Enable All	Displays all available debugging messages.
Disable All	Stops displaying all debugging messages.
Debug Business Rule	Displays debugging messages for business rules. If there are business rules from multiple applications affecting a table or record, the system displays which application the business rule comes from.
Debug Upgrade	Displays detailed information logged for records processed during the last family-to-family or patch version upgrade session. See Debug Upgrade .
Debug Business Rule (Details)	Displays debugging messages for business rules and any changes made by business rules. If there are business rules from multiple applications affecting a table or record, the system displays which application the business rule comes from.
Debug Log	Displays all log entries.
Debug NLQ	Displays debugging messages for Natural Language Query (NLQ) queries.
Debug Date/Time	Displays Date/Time failures when inputs do not match required formats.
Debug SQL	Displays debugging messages for SQL queries.
Debug SQL (Detailed)	Displays debugging messages for SQL statements and any changes made by SQL statements.
Debug Security	Displays debugging messages for access controls. If there are access controls from multiple applications affecting a table or record, the system displays which application the access controls comes from.
Debug Escalations	Displays debugging messages for SLA and SLO escalations.
Debug AI Search	Displays debugging messages for AI Search.
Debug Metric Statistics	Displays an aggregate view of performance data (slow transactions, scripts, queries, events, and mutexes). These aggregate metrics are sorted by transaction, to help identify items that affect page performance.
Debug Text Search	Displays debugging messages for search result relevance and indexing.

Session debug options (continued)

Debug option	Description
Debug UI Policies	Displays debugging messages for UI policies.
Disable UI Policies Debug	Stops displaying debugging messages for UI policies.
Debug UI Macro	Displays the start and end of the UI Macro in the DOM as HTML comments. The comments consist of table name and UI macro name.
Disable Debug UI Macro	Stops displaying the start and end of the UI Macro in the DOM as HTML comments.
Debug Data Policies	Displays debugging messages for data policies.
Debug Quotas	Displays debugging messages for transaction quotas.
Debug Homepage Render	Displays debugging messages for homepages.
Debug Scopes	Displays debugging messages for entering or exiting application scopes when running script objects.

Display debugging logs

Display session debug logs to help diagnose script and application problems.

Before you begin

Role required: none

Procedure

1. Navigate to **All** > **Session Debug** and select **Enable All**.
2. Under **Session Debug**, select **Debug Log**.
   The Debug log displays.

Debugging applications

Application developers can display debug messages about configuration records to help them troubleshoot issues. The Debug Scopes module provides information about the system switching between custom applications to run server-side scripts.

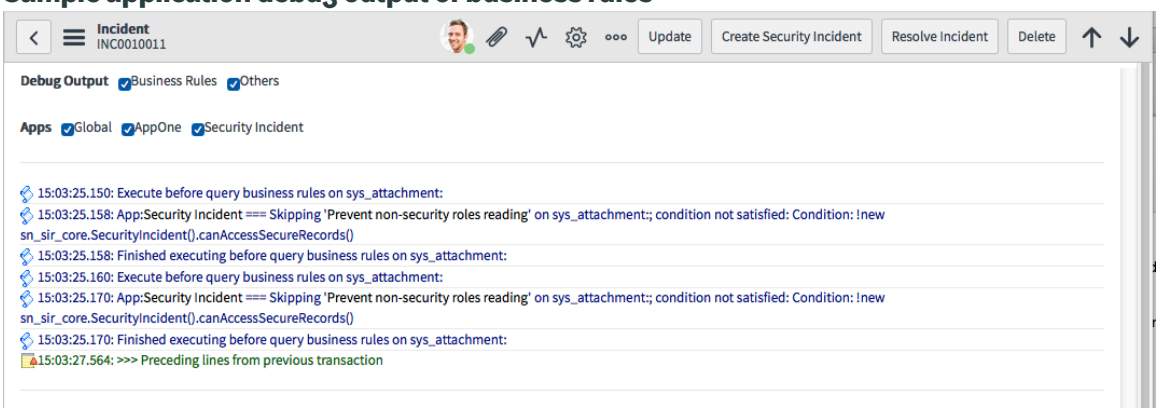
The system offers the following debugging options to help application developers determine how applications affect configuration records.

Application debug options

Debugging option	Description
Debug Business Rule	Use this module to determine which application's business rules are running against tables. The system only displays application information if business rules from different application scopes run on the same table.
Debug Business Rule (Details)	Use this module to determine the results of running business rules against tables. The system only displays application information if business rules from different application scopes run on the same table.
Debug Security	Use this module to determine which application's access controls apply to a given table or record.
Debug Scopes	Use this module to determine the application scope context in which a script runs. Since one script can call another script it is possible to have multiple application scope context changes while running a series of scripts.
Enable Session Debug	Use this related link to enable the generation of log messages for a particular application. Application scripts that use GlideSystem logging methods will generate output to the log at the indicated verbosity level.

When multiple applications contribute to the debug output, the system adds a new section called **Apps** to the display a list of the applications writing to the session log. Clicking on the check box next to the application name hides or displays the application's associated debug messages.

Sample application debug output of business rules

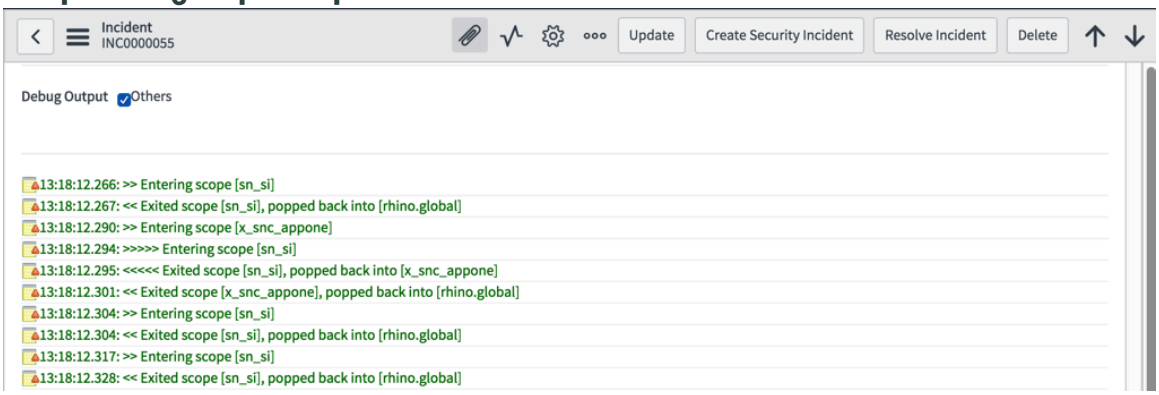


Debugging scopes

Application developers can use the **Debug Scopes** module to display information about when the system switches between custom applications to run server-side scripts.

When enabled, the system displays a message whenever the system switches to a custom application to run a server-side script.

Sample debug scopes output from the incident table



Every time the system runs a server-side script object it enters the script's scope context. When the script finishes running, the script exits the scope context. The debugging messages track changes to the script scope context.

The debugging message displays a greater than character > each time the system enters a script object's context, and displays a less than character < every time the system exits a script object's context. In cases where one script calls another the debugging message adds another greater than character to the path for each call. For example, if a business rule calls a script include, which in turn calls another script object there would three characters in the path such as:

```
> Entering scope [x_app_one]
>> Entering scope [x_app_two]
>>> Entering scope [x_app_three]
```

Note:
The system does not display entering or exiting messages for script objects in the global scope.

Application developers may want to enable other debugging options to in conjunction with this option to see information about the possible source of the server-side script such as Debug Business Rule.

Debugging business rules

Debugging business rules can be achieved with resources available in the ServiceNow product.

1. Tools

The first step in the process is to identify tools which will help you figure out what's wrong.

Debugging tools

Debugging tool	Description
System Dictionary	Navigate to **System Definition** > **Dictionary**. The dictionary provides a list of all tables within your instance and can be invaluable when trying to locate information.
System Log	Navigate to **System Logs** > **System Log**. You can place alert statements in your business rule which can write information to the log.
Debug Business	Navigate to **System Diagnostics** > **Session Debug** > **Debug Business Rule (Details)**. This debugging module displays the results business rules. Use this module to see if conditions are being met and values are being set as expected.

Debugging tools (continued)

Debugging tool	Description
Rule (Details)	
Alert Messages	There are several system functions that allow you to print messages to the page, the field or the log file. See Scripting alert, info, and error messages.
Business Rule Examples	Sometimes you can find what you're looking for in scripts others have written, including business rule error messages, or by building an OR query.
GlideRecord Information	This is the basic syntax used to query the database for information. See Querying tables in script. GlideRecord also includes aggregation support.

2. Variables

The next step is to gain some insight into the behavior of your business rule. For every action except an insert, you will more than likely use a query to get your record(s).

```
var rec = new GlideRecord('incident');
rec.addQuery('active',true);
rec.query();
while (rec.next()) {
 gs.print(rec.number + ' exists');
 }
```

To verify whether your query is actually returning records you can use *gs.addInfoMessage* to display information at the top of the screen.

```
var rec = new GlideRecord('incident');
rec.addQuery('active',true);
rec.query();
gs.addInfoMessage("This is rec.next: " + rec.next());
while (rec.next()) {
 gs.print(rec.number + ' exists');
 }
```

If your query returns no records you see the following:

```
This is rec.next: false
```

Use this technique to verify every variable within your business rule contains expected values.

Tip:
If necessary, break your script down into individual pieces and verify each piece works separate from the whole and then put them all back together one step at a time.

3. Locating information

The last step is to make sure you know where to find the information your rule is looking for.

In the ServiceNow application, one table can extend another table. This means when searching for information, you might need to query the parent table for the extended table's sys_id to find what you seek.

A good example is the sc_task table, which extends the task table. The script below queries the extended table (sc_task) for the current sys_id and then query the parent table (task) for records with the matching sys_id, and then prints out the work notes field.

```
var kids = new GlideRecord('sc_task');
kids.query();

gs.addInfoMessage("This is requested item number: " +
 current.number);
gs.print("This is the requested item number: " +
 current.number);

while (kids.next()) {
 var parents = new GlideRecord('task');
 parents.addQuery('sys_id', '=', kids.sys_id);
 parents.query();

 while(parents.next()) {
  gs.addInfoMessage("This is task number: " + parents.number);
  gs.print("This is task number: " + parents.number);
  gs.addInfoMessage("These are the work notes: " +
 parents.work_notes);
  gs.print("These are the work notes: " + parents.work_notes);
  }

 }
```

Debugging classifications

You must add a system property to enable classification debugging.

Debugging classifications

The resulting log entries list the name of each classifier that runs, along with all the names and values that are available to the criteria in the classifier. To log debugging information about classifications, add the following system property.

System Property	Description
glide.discovery.debug.ci_identification	Enables debugging information for process classification. • Type: true | false • Default Value: false • Location: Add to the System Properties [sys_properties] table

Field watcher

The field watcher tool tracks and displays all actions that the system performs on a selected form field.

Note:
Field watcher is not supported with Next Experience in Utah. For more information about supported features in Next Experience, see Considerations for activating Next Experience.

Administrators can use the field watcher to figure out what happens to the field and how the value of the field changes when an event such as the firing of a business rule or enforcement of a data policy, takes place. Administrators can also impersonate non-admin users to debug what happens when those users make changes on an instance. Only one field can be watched at a time. Non-admin users with the impersonator role have access to the field watcher feature.

How the field watcher works

The Field Watcher tool logs activity when any of the following events occur on a field:

- The default value is set on the field.
- User access rights for the field change due to an ACL or dictionary setting.
- A data policy prevents the value from being set.
- A reference qualifier query of the field value executes.
- A UI policy changes a field to or from read-only, visible, mandatory, or editable.
- A dependent value in another field restricts field choices.
- The value of the field is set or changed based on:
  - Assignment rules
  - Actions from an engine, such as the workflow engine
  - Business rules
  - User entries
  - Client scripts
  - UI actions

Note:
The field watcher works only on form fields. It cannot be used on list fields. Also, field watcher is not available on password-protected fields or encrypted fields. Field watcher is only available within the UI frame. The option to watch a field does not appear in the context menu if you open a record outside of the UI frame, for example, in a new tab.

Use field watcher

Access field-level debugging information using the field watcher.

Before you begin
Role required: none

Procedure

1. Navigate to the form for which you want to view field-level debugging information.
2. Activate field watcher by right-clicking any field label on a form and select **Watch - '<field name>'**.

   The debug icon ( ) appears next to the field label. From this point on, the field watcher records every action taken on the selected field. For example, if you are watching a *Priority* field, if the priority is changed from Moderate to Low and the record is updated, the field watcher will display information about that change.
3. View the field watcher log by clicking the debug icon.
   A new pane opens at the bottom of the screen, showing a field watcher tab. It may also show tabs for JavaScript Logging and JavaScript Debugger.
4. Click the **Field Watcher** tab, if needed.

5. Stop watching a field by right-clicking the field and selecting **Unwatch - <field name>**.
   To watch another field, right-click that field and select **Watch - <field name>**.
6. Clear the field watcher log by clicking the clear log button ().
7. Resize the field watcher pane by dragging the splitter bar up or down.
   Dragging the splitter bar to the bottom of the screen closes the field watcher pane. Reopen the pane by clicking the debug icon again.

Field watcher tab details

The field watcher displays field information and configuration options.

The left-side of the Field Watcher tab shows the following information for the watched field.

- **Table**: table to which the field belongs.
- **Element**: field label.
- **Type**: type of data stored in the field.
- **Dependent**: field on which the current field depends.
- **Reference**: table from which the field's value originates, if applicable.
- **Reference Qual**: reference qualifiers that may be restricting data on the field.
- **Attributes**: attributes on the field as specified in the dictionary entry for that field.

On the right-side of the Field Watcher tab, select the types of activity information you want to see for the selected field. Clear the check box for any type of information that is not needed.

Watching a hidden field

Administrators may need to watch a hidden field.

Procedure

1. Use the dictionary to determine the column name of the field.
2. Elevate privileges to the security_admin role.
3. Navigate to **System Definition** > **Scripts Background**.
4. In *Run script (JavaScript executed on server)*, enter the following command:

   ```
   gs.getSession ( ). setWatchField ( "hidden_field" ) ;
   ```

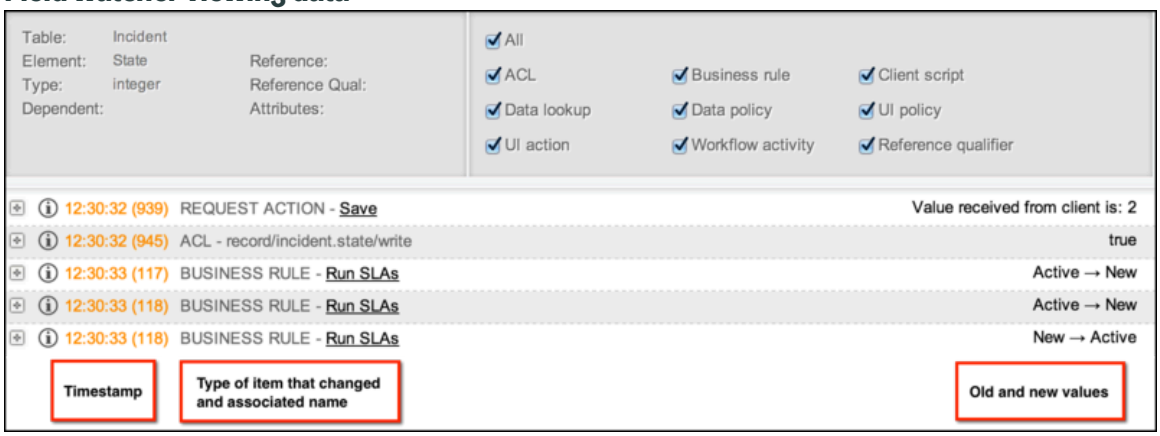
   Replace hidden_field with the column name of the hidden field.
5. Navigate to the form containing the missing field.

   The Field Watcher tab output contains information about the hidden field.

Viewing information for the watched field

When information for a watched field is changed and the record is updated, the field watcher tab displays relevant information at the bottom.

Field watcher viewing data



Field watcher information includes:

- **Timestamp**: time the field was changed using the HH:MM:SS (ms) format.
  - **Orange text**: server-side changes, such as ACLs.
  - **Blue text**: client-side changes, such as client scripts.
- **Type of object that changed the field and its associated name**: The type of item that changed on the field; for example, **CLIENT SCRIPT**, **BUSINESS RULE**, or **ACL**. In the case of scripts, business rules, or other configuration-type fields, field watcher displays the name of the script or business rule that changed the field, if any. Click the name to go directly to the record for that item.
- **Old and new values**: The old and new values for the field, if the value changed0. Field watcher does not record the value if it was inserted in the form by default at the time the record was created.
- **Additional information**: Call tracing information, such as the name of the script engine or workflow that changed the field. Click the plus icon to expand the selection.
  - **Orange text**: Indicates server-side activity.
  - **Blue text**: Indicates client-side activity.

Example: Watching the incident priority

The following example shows what happens to the **Priority** field on the incident form when both the **Impact** and **Urgency** fields change.

The Incident form has two client-side data lookups change the priority. Additionally, server-side ACLs and the data lookup engine fire when the record is saved. Finally, a client-side UI policy sets the **Priority** field back to read-only, which is the default setting.

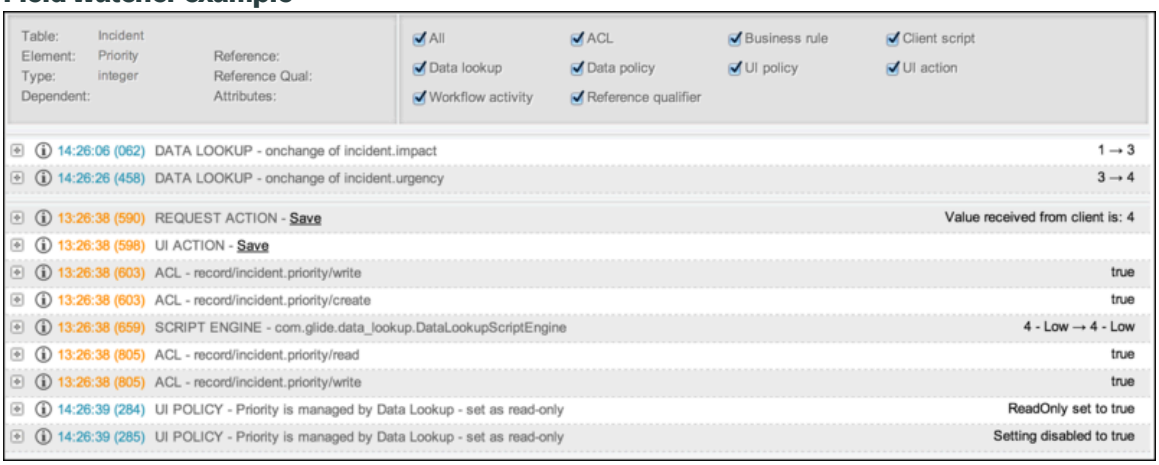
Watching the incident priority

Original values
• Priority:1 - Critical • Impact:1 - High • Urgency:1 - High
First Change

Watching the incident priority (continued)

Original values
1. The user changes the **Impact** value to **3 - Low**. **2.** The priority automatically changes to **3 - Moderate** based on the **Priority Lookup** data lookup definition used by default in ServiceNow incidents. **Note:** At this point, the record has not been saved.
Second Change
1. The user changes the **Urgency** value to **2 - Medium**. **2.** The priority automatically changes to **4 - Low** based on the same **Priority Lookup** data lookup definition. **3.** The user saves the record by right-clicking the form header and choosing **Save**.

Field watcher example



Note:
The values that change from 1 to 3, and then from 3 to 4, refer to the numerical values in the choice list.

Writing to the debug log

To write to the debug log in your client-side JavaScript, or UI policies, make a call to the global function `jslog()`.

An example of using `jslog()` in JavaScript:

```
function logData (r ) {
    lastLogDate  = r. responseXML. documentElement. getAttribute
 ( "last_log_entry" ) ; var items  = r. responseXML.
 getElementsByTagName ( "log" ) ;
    jslog ( "response=" + r. responseText ) ; }
```

Additionally, when client scripts run, the name of the client script and timing information is displayed. This can be useful in determining which scripts are running and whether they are impacting performance.

Debug UI policies

Enabling the *glide.ui.ui_policy_debug* property lets you monitor the processing of UI actions.

Here are some sample log events from an incident policy that sets fields to read-only if the incident_state is closed.

```
GlideFieldPolicy: Evaluating condition
GlideFieldPolicy:     incident_state (7) = 7 -> true
GlideFieldPolicy: --->>> TRUE
GlideFieldPolicy:    Setting opened_at disabled to true
GlideFieldPolicy:    Setting opened_by disabled to true
GlideFieldPolicy:    Setting closed_at disabled to true
GlideFieldPolicy:    Setting closed_by disabled to true
GlideFieldPolicy:    Setting company disabled to true
```

Access the JavaScript log

JavaScript that runs on the browser, such as client scripts, can include a call to jslog() to send information to the JavaScript Log. Users with the admin role can access this log.

Before you begin

Role required: admin

About this task

The steps to access the JavaScript debug window depend on which UI version you are using.

Note:
The JavaScript debug window is not supported with Next Experience in Utah. For more information about supported features in Next Experience, see Considerations for activating Next Experience.

Procedure

1. Open the JavaScript log by navigating to the appropriate location for your version of the UI.

Core UI	**a.** Click the gear icon in the banner frame. **b.** Click the **Developer** section. **c.** Toggle the **JavaScript Log and Field Watcher** switch.
UI15	**a.** Click the gear icon in the banner frame. **b.** Click **JavaScript Log and Field Watcher**.
UI11	Click the debug icon ( ) in the banner frame.

A new pane opens at the bottom of the screen. It shows the JavaScript Log tab and may also show the Field Watcher tab.

2. If needed, select the **JavaScript Log** tab.
3. Click the clear icon ( ) to clear the contents of the log, as needed.

JavaScript debug window

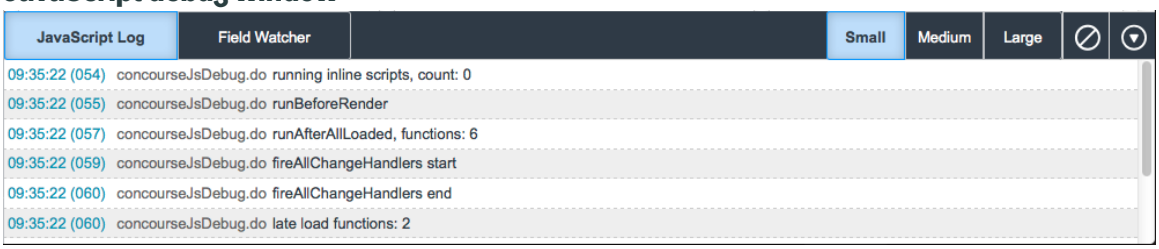
The JavaScript debug window appears in a bottom pane of the user interface when an administrator turns on debugging.

Note:
The JavaScript debug window is not supported with Next Experience in Utah. For more information about supported features in Next Experience, see Considerations for activating Next Experience.

Use the debug window to access these tools.

- JavaScript Log: JavaScript that runs on the browser, such as client scripts, can include a call to `jslog()` to send information to the JavaScript log.
- Field Watcher: a tool that tracks and displays all actions that the system performs on a selected form field.

JavaScript debug window



Using the JavaScript debug window

The JavaScript debug window enables access to the JavaScript Log and the Field Watcher tools.

Before you begin

Role required: admin

About this task

The steps to access the JavaScript debug window depend on which UI version you are using.

Note:
The JavaScript debug window is not supported with Next Experience in Utah. For more information about supported features in Next Experience, see Considerations for activating Next Experience.

Procedure

1. Open the JavaScript debug window by navigating to the appropriate location for your version of the UI.

Core UI	**a.** Click the gear icon in the banner frame. **b.** Click the **Developer** section. **c.** Toggle the **JavaScript Log and Field Watcher** switch.
UI15	**a.** Click the gear icon in the banner frame. **b.** Click **JavaScript Log and Field Watcher**.

UI11	Click the debug icon () in the banner frame.

The JavaScript debug window re-opens at the bottom of the screen. The tab that is currently active in the window is the last tab that was active when the window was closed.

2. Click a tab to use one of the debug window features.
   - JavaScript Log
   - Field Watcher

Writing to the debug log

Field watcher

JS Code Coverage Debug

The JS Code Coverage Debug application allows administrators and application developers to log the server-side scripts triggered during a user session and then review which lines of code the system ran.

Users with the js_coverage_debugger role can debug server-side scripts without having to set breakpoints or review onscreen debug messages. Instead, the system saves script usage data in the JavaScript Code Coverage [sys_js_code_coverage] table. Each JavaScript Code Coverage record contains:

- The user session that called the script.
- The script record the system called identified by table, sys_id, and script field.
- The script record the system called identified by type and name.
- The transaction that called the script.
- The start time of the transaction.
- The contents of the script field highlighted to indicate which lines the system ran.

Note:
The JS Code Coverage Debug application doesn't log information for client-side scripts.

Sample code coverage highlighting

Script

```
1  var build = gs.getProperty("glide.buildname");
2  if (GlideStringUtil.notNil(build))
3      build = build.substring(0,1).toLowerCase();
4
5  var collision = new GlideRecord("sys_embedded_help_content");
6  collision.addActiveQuery();
7  collision.addQuery("page", current.page);
8  collision.addQuery("modifier", current.modifier);
9  collision.addQuery("product", current.product);
10 if (current.isValidRecord() && GlideStringUtil.notNil(current.sys_id))
11     collision.addQuery("sys_id", "!=", current.sys_id);
12
13 if (GlideStringUtil.notNil(current.qualifier))
14     collision.addQuery("qualifier", current.qualifier);
15 else
16     collision.addNullQuery("qualifier");
17
18 if (current.version == "all" && GlideStringUtil.notNil(build))
19     collision.addQuery("version", build).addOrCondition("version", "all");
20 else
21     collision.addQuery("version", current.version);
22
23 collision.query();
24 if (collision.next()) {
25     if (collision.canWrite())
26         gs.addErrorMessage(gs.getMessage("Embedded Help Composite Key
Validation"));
```

JS Code Coverage highlighting

The JS Code Coverage application highlights script fields to indicate whether the system ran or skipped each line.

Sample code highlighting

Script

```
1  var build = gs.getProperty("glide.buildname");
2  if (GlideStringUtil.notNil(build))
3      build = build.substring(0,1).toLowerCase();
4
5  var collision = new GlideRecord("sys_embedded_help_content");
6  collision.addActiveQuery();
7  collision.addQuery("page", current.page);
8  collision.addQuery("modifier", current.modifier);
9  collision.addQuery("product", current.product);
10 if (current.isValidRecord() && GlideStringUtil.notNil(current.sys_id))
11     collision.addQuery("sys_id", "!=", current.sys_id);
12
13 if (GlideStringUtil.notNil(current.qualifier))
14     collision.addQuery("qualifier", current.qualifier);
15 else
16     collision.addNullQuery("qualifier");
17
18 if (current.version == "all" && GlideStringUtil.notNil(build))
19     collision.addQuery("version", build).addOrCondition("version", "all");
20 else
21     collision.addQuery("version", current.version);
22
23 collision.query();
24 if (collision.next()) {
25     if (collision.canWrite())
26         gs.addErrorMessage(gs.getMessage("Embedded Help Composite Key
Validation"));
```

The color of the highlight indicates how the system evaluated the code line.

Meaning of code highlighting

Highlight color	Meaning
Green	This is an executable line of code that the system ran during the session.
Red	This is an executable line of code that the system skipped for some reason. The system may have skipped an executable line of code because the necessary script conditions were not met or because the script function was never called. You may want to use the Script Debugger to determine why the system skipped the line of executable code.
Gray	This is a non-executable line of code such as white space, code comment, or a portion of an expression split across multiple lines that cannot run on its own.

Administrators and application developers can use this information to conduct more targeted debugging activities such as using the Script Debugger to determine why script conditions are not being met.

Activate JS Code Coverage Debug

You can activate the JS Code Coverage Debug plugin (com.glide.js.coverage) if you have the admin role.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

What to do next

To see the components the plugin installed, refresh the plugin form and select the **Plugin Files** related list.

Debug with JS Code Coverage Debug

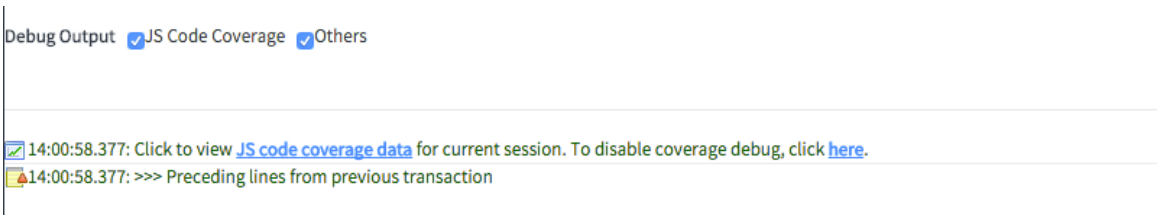
Use JS Code Coverage Debug to record a user session and then review which server-side scripts and lines of code the system ran.

Before you begin

Role required: js_coverage_debugger or admin

Procedure

1. Navigate to **All** > **JS Code Coverage Debug** > **Enable Coverage**.
   The system logs which server-side scripts and code lines the system runs as well as displays session debug messages in the JS Code Coverage namespace.



2. Navigate to the table or page whose logic you want to test.

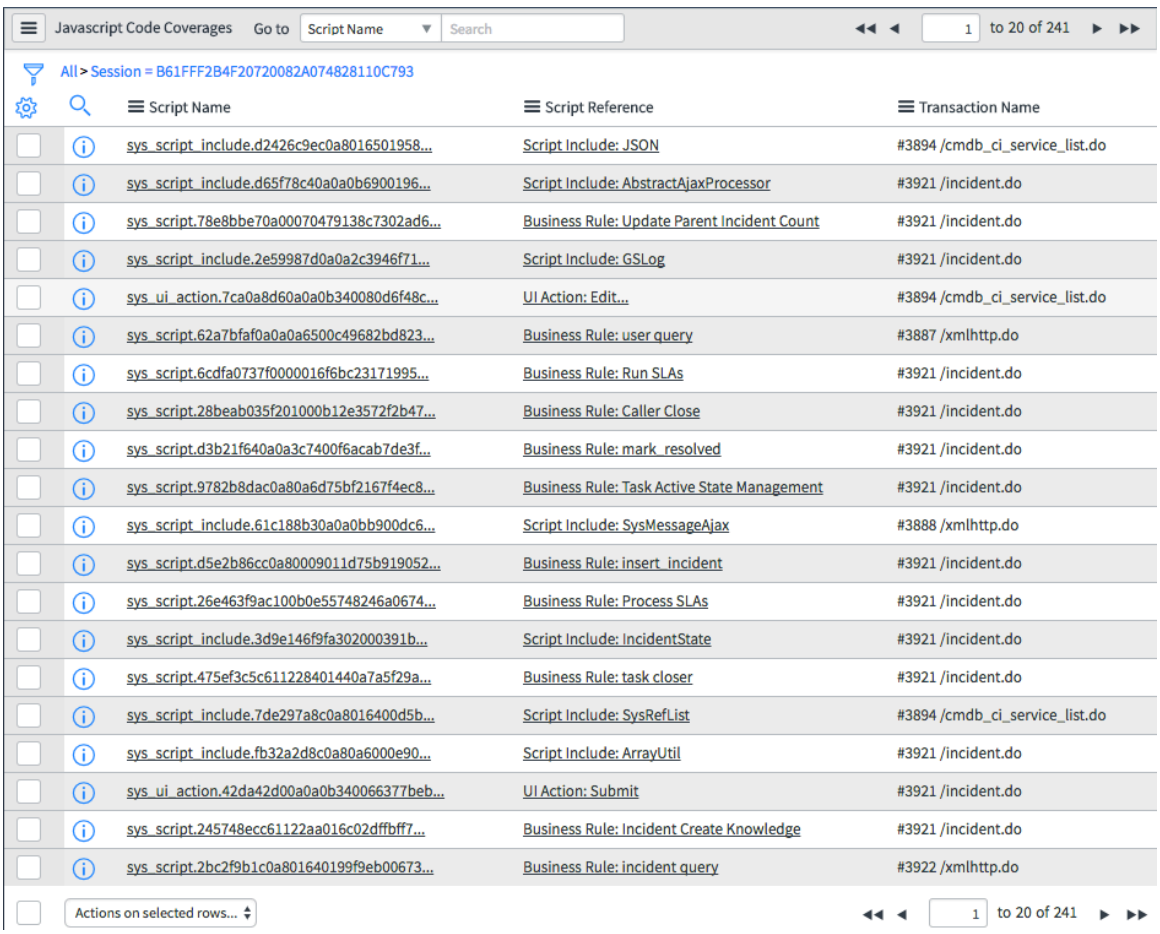
   Example
   For example, navigate to **Incident** > **Create New**.

3. Trigger the server-side script or scripts you want to test.

   Example
   For example, create an incident with an associate CI item to test several business rules.

4. When you have completed testing, navigate to **JS Code Coverage Debug** > **Disable Coverage**.
   The system stops logging script and code lines run.

5. Navigate to **JS Code Coverage Debug** > **Coverage Data**.
   The system displays the list of coverage data associated with the current user session.

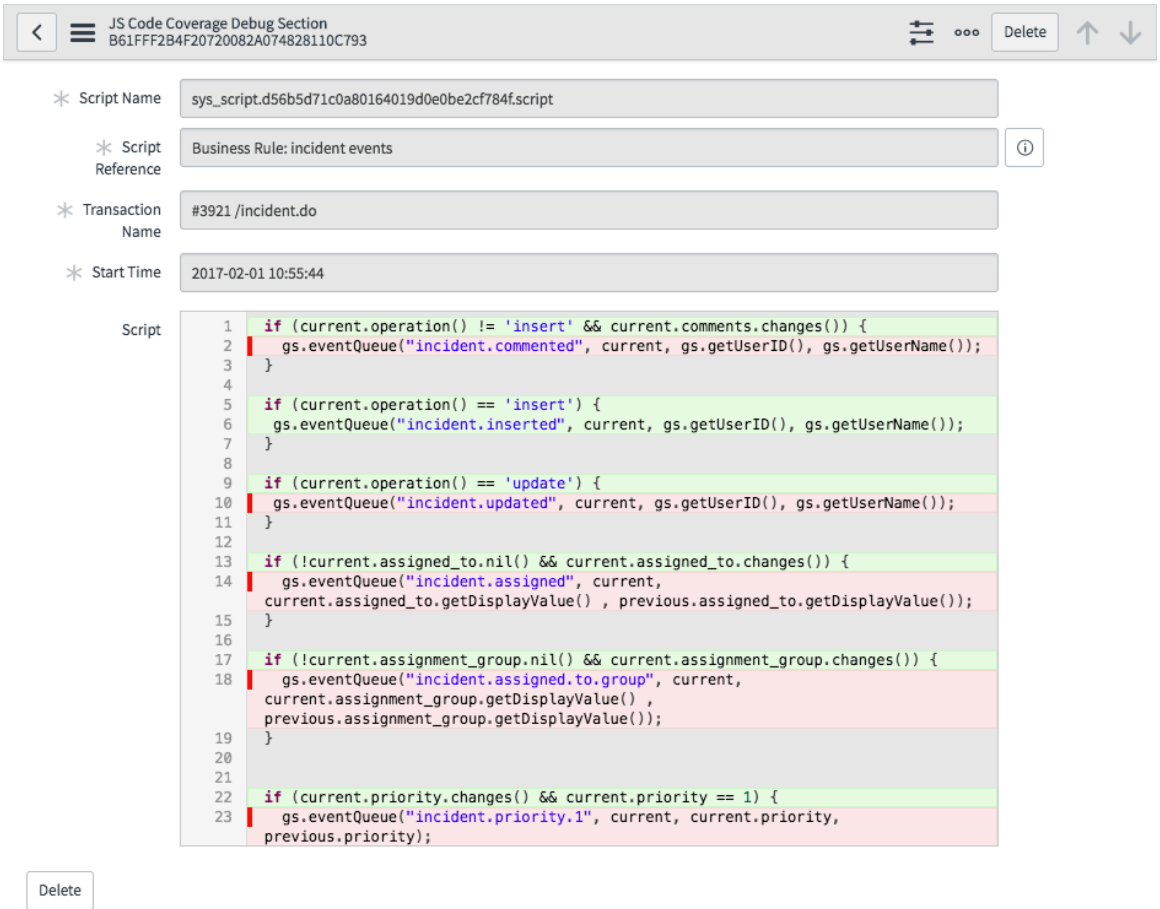


6. Select the script or transaction you want to review.

JavaScript Code Coverage fields

Field	Description
Script Name	Displays the script run by table name, sys_id value, and script field.
Script Reference	Displays the script run by script type and name.
Transaction Name	Displays the transaction that called the script by thread ID and URI.

Example
For example, select the **Script Reference** Business Rule: incident events.
The system displays the JS Code Coverage Debug record.



7. Review the **Script** field to determine which lines of code the system ran.

Example
For example, the business rule added the incident.inserted event to the event queue.

Result
You determine which lines of code the system ran.

What to do next
Use the code coverage information to do more targeted debugging activities such as set breakpoints and review variable values with the Script Debugger.

Packages Call Removal tool

The Packages Call Removal Tool provides modules to identify fields that might contain scripts, find scripts that contain Packages calls to ServiceNow Java classes, and to examine proposed script changes that eliminate those Packages calls.

Note:
This tool is not activated by default, and is only available to users with the admin role.

Packages calls to ServiceNow Java classes will be prevented in a future release. The Packages Call Removal tool helps prepare your instance to use the new API and includes the following scripts and pages:

- The Find Packages Fields script scans scripts for Packages calls to ServiceNow Java classes.
- The Find Packages Calls script proposes changes that remove Packages calls or replaces them with GlideScriptable names.
- The Packages Call Items page lists and enables you to work on proposed changes to scripts.

The tool might generate errors as it tries to generate preferred, scriptable alternatives for Packages calls to ServiceNow Java classes.

Note:
Create an update set before migrating the changes that result from running the Packages Call Removal Tool. For information, see Get started with update sets.

Activate the Packages Call Removal Tool

You must activate the Packages Call Removal Tool plugin to access the tool.

Before you begin

Role required: admin.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Packages Call Removal Tool plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

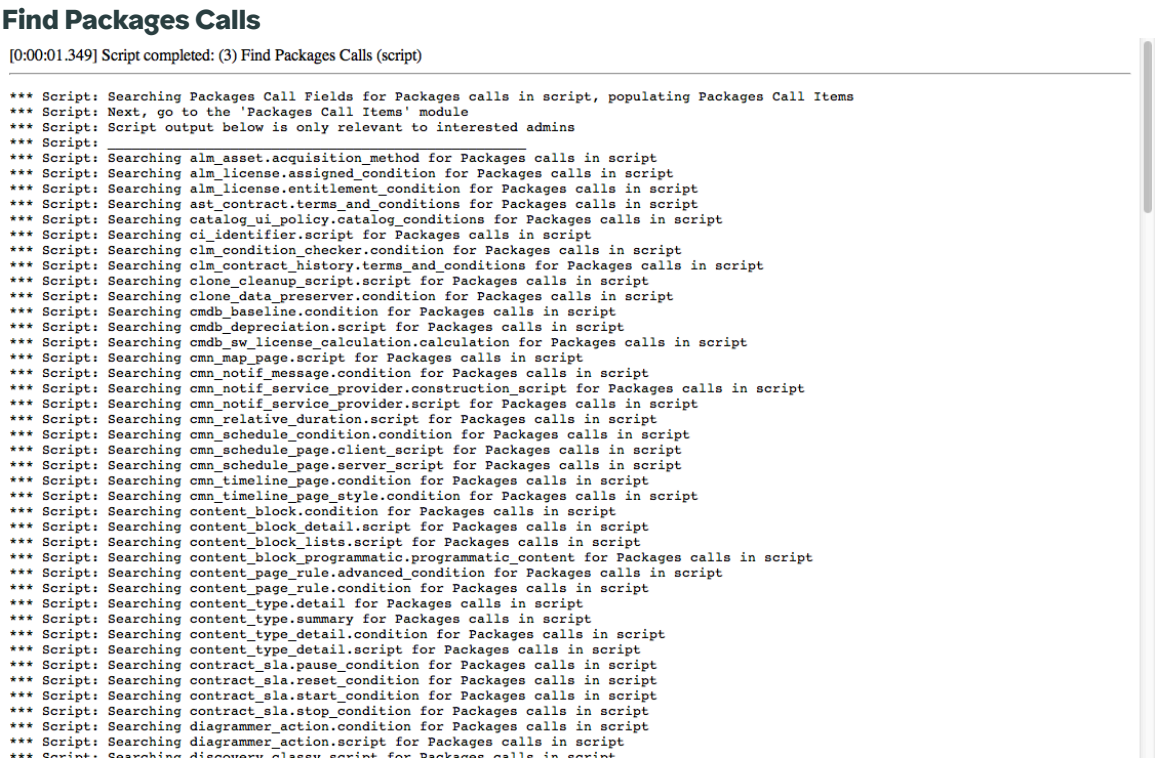
Find a Packages call

After you run the Find Packages Fields script to define the list of fields to search for Packages calls, run the Find Packages Calls script to generate the list of fields with Packages calls to ServiceNow Java classes. The script also proposes changes.

Procedure

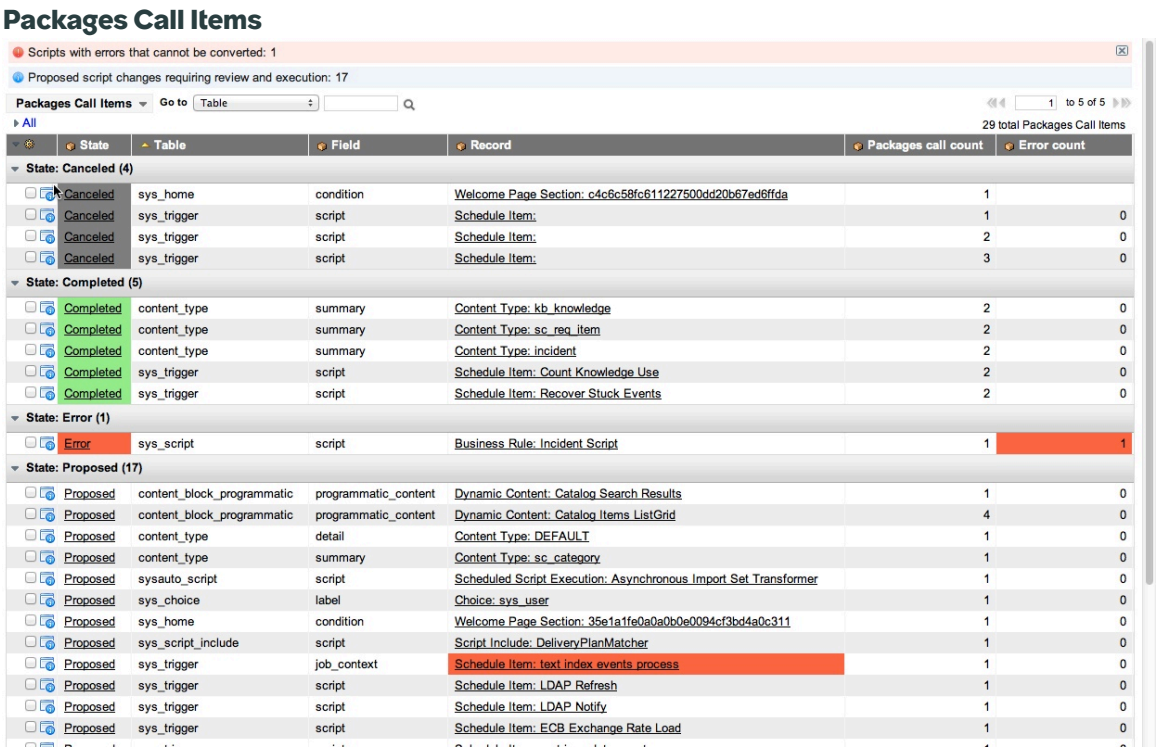
1. Click **(3) Find Packages Calls (script)** to execute a script that searches the fields for packages calls and populates the Packages Call Items list with proposed changes.

   Example

2. Click **(4) Packages Call Items** to display the list of affected fields on the Packages Call Items page.
   The Packages Call Items page lists the items with Packages calls, shows each item's current state, the table that contains the field, the affected record, the number of Packages calls contained in the field's script, and the number of errors that occurred when the proposed script was generated.

Example



3. On the Packages Call Items page, click a record for any of the listed items to open the form and revise as described in Replacing Packages Calls.

   As you work through the list, the **State** of the items are updated and the items are grouped by State:

   - **Proposed:** A proposed revision exists for the field.
   - **Error**(red): One or more errors occurred when the proposed script was generated.
   - **Rejected**(gray): A proposed change has been rejected.
   - **Completed**(green): The field has been successfully revised to remove Packages calls to ServiceNow Java classes.
   - **Canceled** (gray): Since the proposed change was generated, either the original script has been changed to no longer require modification, or the original record no longer exists.

Glide object name

The names of the new Glide objects that replace Packages calls are derived from the Java package name used in the Packages call.

About this task

Although the tool automatically substitutes the appropriate new scriptable name for each Packages call it encounters, in some circumstances it can be useful to know how to manually replace a Packages call with its new scriptable object equivalent. Use the steps below to determine the new script object name from the Packages call name. The replacement objects include the same methods and properties as the objects they replace.

To determine the new object name:

Procedure

1. Note the third term in the Java package name.
   This term is usually glide, but is sometimes snc or glideapp.
2. Drop all of the prefix terms, leaving only the last.
   For example, `Packages.com.glide.monitor.AbstractBucketCollector` becomes AbstractBucketCollector.
3. Capitalize the first letter of the term noted in the first step above and add it to the front of the term defined in step 2.
   For example, `Packages.com.glide.monitor.AbstractBucketCollector` becomes GlideAbstractBucketCollector and `Packages.com.snc.cmdb.BaselineCMDB` becomes SncBaselineCMDB.
4. Verify that the name is valid by executing a gs.print() command in Scripts Background, specifying only the name with no quotes.
   For example:

   ```
   gs.print( SncBaselineCMDB );
   ```

   *** Script: `[JavaClass com.snc.cmdb.BaselineCMDB]`

   Note that there are exceptions to this rule, such as "Glide", which replaces "Packages.com.glide.Glide", "TestExtension", which replaces "Packages.com.glide.junit.misc.TestExtension"; and "UINotification", which replaces "Packages.com.glide.ui.UINotification".

Glide object replacement list

This table lists the Glide classes and the Packages calls they replace.

Note:
The publication of this list does not imply that these scriptable objects are for use by customers, consultants, and partners. The use of the Glide prefix does not imply that these scriptable objects are in the same category as or have the same status as objects such as GlideRecord. Except where documentation is provided in the API Reference, these undocumented APIs are not intended for general use, and ServiceNow, Inc., does not make any commitment to document them, answer questions about them, or maintain them indefinitely in their current form. Over time, ServiceNow, Inc., intends to migrate a subset of the functionality represented by these objects into the documented API and remove the rest.

GlideScriptable object replacement list

GlideScriptable Class	Packages Call

Packages Call Removal Tool error types

Possible error types generated by the Packages Call Removal Tool.

Error types

Error message	Description	Solution
Class Name Could Not Be Parsed	A line of script has what appears to be a Packages call (for example, the line contains `Packages.com.glide`) but on examination there is insufficient text to parse out a class name that corresponds to a scriptable object name.	This error type generally does not pr nevertheless flagged as an error in c a valid class that the parser, for what parse.
Class Does Not Exist	A line of script has an identifiable Packages call to a Java class that does not exist. This may be because it was incorrectly typed, or because the Java class no longer exists.	This error type usually identifies a sc what its author intended, if it ever did should be revisited, and the invalid P

Error types (continued)

Error message	Description	Solution
	Either way, the line of script is currently not doing anything and is potentially generating errors whenever it is run.	
Class Is Not a Scriptable Class	A line of script has an identifiable Packages call to an existing ServiceNow Java class that is not currently marked as scriptable. The call cannot be replaced, because there is currently no corresponding scriptable name.	To convert this script, either rewrite t not use the Java class or wait until Se a scriptable name for the class.
Class Does Not Have a Scriptable Name	A line of script has an identifiable Packages call to an existing ServiceNow Java class that does not currently have a scriptable name.	This error is less likely to occur than a Scriptable Class error; however, as w this script, either rewrite the script so Java class or wait until ServiceNow, l name for the class.
Variable Name Being Assigned Conflicts With a Scriptable Name	A variable name has the same name as a scriptable name. For example, `var GlideSession = Packages.com.glide.sys.GlideSession.get();` would generate this error because the variable name `GlideSession` is the same as the scriptable name for the GlideSession Java class.	Before this script can be converted, t must be changed wherever it occurs example, the line could be changed t `Packages.com.glide.sys.Gl` to remove the conflict. Also, be sure t name elsewhere in the script wherev
Internal Error - Unable To Find String To Be Replaced	The tool is unable to find the script text it is currently evaluating for Packages call replacement.	This error type is very unlikely. If it do code and correct any errors. If the er open an incident with Technical Sup

Service Creator

Service creator enables a department to offer custom services through the service catalog, such as the HR department offering tuition reimbursement for further education.

Each published service has an associated record producer catalog item. Users designated as managers and editors create and design these catalog items. End users can request services by ordering the catalog item.

All services belong to a published service category, which has an associated application and modules. When a user orders the catalog item for a service, the ServiceNow system creates a new task record within the application for that service category. Users designated as service fulfillers for the department complete these tasks to fulfill the service request.

Service creator process

The service creator process involves requesting and publishing a service category, designating editors and service fulfillers, creating and publishing services, and submitting and fulfilling service requests.

Request and publish a service category

A user, typically the department manager, can request a service category for the department. This user provides high-level information regarding the service category, such as the name, the department, and the manager for the service category.

A catalog administrator can approve the request which publishes the service category, creates a ServiceNow application for managing service requests associated with the category, and creates system components for the application.

Designate editors and service fulfillers

After a service category is published, the associated manager designates editors and service fulfillers. Editors can create and modify services within that service category. Service fulfillers can complete tasks that are generated by service requests.

The manager, editors, and service fulfillers must be members of the department the service category belongs to.

Create and publish services

The manager and editors create services within a service category. The service design interface provides a work area for creating and modifying services.

When the service is complete, the manager publishes the service to the service catalog.

Submit and fulfill service requests

End users can request published services by submitting a service catalog request. This request creates a new task record within the service category application. Service fulfillers then complete the task to fulfill the service request.

Service Creator

Activate Service Creator

If the Service Creator plugin is not already activated, an administrator can activate it to access the application.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Installed with Service Creator

Several types of components are installed with Service Creator.

Demo data is available with Service Creator. The demo data provides the Departmental Services service catalog category.

Creating a new service category also creates components for that service category.

The following components are added with Service Creator:

Tables

Service Creator tables

Table	Description
Service Category [catalog_category_request]	Stores all service categories.
Service Category Request User [catalog_category_request_user]	Tracks fulfillers for a service category. Use these records to grant or remove roles as needed.
Service [sc_cat_item_producer_service]	Stores all services.
Service Category App Menu [service_category_app_menu]	Stores the application menus for each service category.
Service Category User Role [service_category_user_role]	Tracks users who have been granted a role due to being an editor of a service category.

UI actions

UI action	Description
Create Category and Table	Approves a requested service category and creates system components for that category.
Request Category Publication	Lets a service creator request their category be published.
Create New Service	Creates a new service within the service category.
View Table Definition	Opens the task table definition [sys_db_object] for a service category.
View Task List	Opens the list of tasks associated with the service category.

UI policies

UI policy	Description
Hide Due Date	Hides the Due date field on the Service Category form if State is Requested or Due date is empty.
Hide Category If Empty	Hides the Category field, if empty, on the Service Category form.
Show Published	Shows the Published check box on the Service Category form if State is Created but Unpublished or Ready for Publication.

UI policy	Description
Hide Table name	Shows Table and hides Table name on the Service Category form if Table has a value.
Hide Category Name	Hides Name on the Service Category form if State is Requested or Rejected.
Table name read only	Makes Department and Table name read only on the Service Category form if State is not Requested.
Hide Editors	Hides the Editors field on the Service Category form if State is Requested or Rejected.

Properties

Property	Description
glide.citizen_developer.category.auto_publish	Automatically adds new service categories to the service catalog as subcategories of the Departmental Services category. • Type: true|false • Default value: true • Location: System Properties [sys_properties] table
glide.citizen_developer.set_category_roles	Comma-separated list of roles that can set the category for a new service. • Type: String • Default value: admin, catalog_admin • Location: System Properties [sys_properties] table
glide.service_creator.auto_add_to_category	Automatically adds new services to the Departmental Services service catalog category, in addition to the department-specific category. • Type: true|false • Default value: true • Location: System Properties [sys_properties] table

Script includes

Script include	Description
serviceCategoryIsUnpublished	Global function that returns true if the service category is unpublished.

Script include	Description
getMyCatalogCategories	Global function that returns a list of categories for which the current user is the manager or an editor.

Client scripts

Client script	Description
Duplicate Category Name Check	Displays a warning on the Service Category Request form when the requested service category has the same name as an existing service category.
Fix Table Name	Ensures a valid table name on the Service Category Request form.
Hide Draft Services	Hides the Draft Services related list on the Service Category Request form when appropriate.
Propose Table Name	Proposes a valid table name on the Service Category Request form for new service category requests.
Category Published	Displays a help message when Published is selected on the Service Category Request form.
Hide Fulfillers	Hides the Fulfillers related list on the Service Category Request form when appropriate.
Editors Message	Displays a help message for the Editors field when appropriate.
Other Tables Message	Provides information about existing service category tables for the selected Department.
State Message	Displays a help message for the State field.

Business rules

Business rule	Description
Service Query	Restricts users without the catalog_admin role to viewing service records within service categories they are the manager or editor of.
New Service	Provides a message when a new sc_cat_item_producer_service record is created.
Table Name Required	Ensures a service category request has a valid table name before approval.
Remove Fulfiller Role	Removes relevant role from service fulfillers when they are removed from a category.
Category Request query	Restricts users without the catalog_admin role to viewing service category records they are a manager or editor of.
Editor Role	Adds and removes relevant roles from service category editors.
Delete User Role	Removes the relevant role from service category editors when appropriate.
Category Published	Sets State to Published to Catalog when the Published check box is selected on the Service Category Request form.

Business rule	Description
Populate Service Name if Empty	Populates a service name if none is provided.
Add Departmental Services Category	Adds a new service to the Departmental Services service catalog category.
Default Fulfillment User	Makes a category manager the assignee of service tasks if no assignee is specified.
Scratchpad Draft Services Count	Generates field help messages.
Catalog Category Request Approved	Creates components necessary to use of a new service category.
Manager Role	Grants relevant roles to category managers.
New Service Script	Populates the script of a new Service to set assignment group or user.
getDepartmentUsers	Returns the users of a department.
Draft Item Query	Restricts users without the catalog_admin role to viewing draft service records they are a manager or editor of.
Grant Fulfiller Role	Grants relevant role to service fulfillers.
Scratchpad Department Name	Generates field help messages.
Scratchpad	Generates field help messages.
Other Tables For Department	Generates field help messages.
Set Single Catalog from Single Category	Populates a default Catalog for a new service.

Email notifications

Service Creator email notifications

Name	Description
Service Category Published	Notifies the manager of a service category when the category request is approved.
Service Category Rejected	Notifies the manager of a service category when the category request is rejected.
Service Category Request Inserted	Notifies catalog administrators when a new category request is created.
Service Category Created	Notifies the manager of a service category when the category is created.
Service Category Publication Requested	Notifies catalog administrators when publication of a category has been requested.
Service Category Request Opened	Notifies the manager of a service category when a new category request is created on their behalf.

Components created with new service categories

When you publish a new service category using the Service Creator application, the ServiceNow system creates components for the services in that category.

These components are distinct from the components installed with the Service Creator application. The following components are added for each new service category:

Tables created with new service categories

Name	Description
<Department Name> Tasks [<service category table name>]	The table that stores request task records for the service category. This table extends the Task table. The name of this table is defined by the department the service category is associated with, and the **Table name** field on the service category record. A new application menu and modules are created to allow users to access records on this table. Records on this table are numbered using a new Numbers [sys_numbers] record.

User roles created with new service categories

Role	Description
<service category table name>_user	The user role required to access request records for a service category. The Table name for the service category determines the name of the role. Users designated as the manager, editors, or service fulfillers for a service category automatically receive this role. Only users with this role can be assigned task records for the service category. ACLs are created to allow users with this role to access the relevant service task table.

Email notifications created with new service categories

Name	Description
Task commented for group	Notifies the group a service task record is assigned to when a user adds a comment.
Task commented for assignee	Notifies the user a service task record is assigned to when a user adds a comment.
Task closed for group	Notifies the group a service task record is assigned to when the record is closed.
Task worknoted for assignee	Notifies the user a service task record is assigned to when a user adds a work note.
Task assigned to group	Notifies the group a service task record is assigned to when the record is assigned to that group.
Task assigned to assignee	Notifies the user a service task record is assigned to when the record is assigned to that user.
Task worknoted for group	Notifies the group a service task record is assigned to when a user adds a work note.
Task closed for assignee	Notifies the user a service task record is assigned to when the record is closed.
Task opened for user	Notifies the user that opened a service task record when the record is created.

Email notifications created with new service categories (continued)

Name	Description
Task closed for user	Notifies the user that opened a service task record when the record is closed.
Task commented for user	Notifies the user that opened a service task record when a user adds a comment.

Forms created with new service categories

Name	Description
<department name> Task	The form for viewing request task records for the service category. By default, this form uses a layout that includes a formatter to display the questions for the service and the answers provided by the requesting user.

Service catalog categories

Name	Description
<service category name>	The default service catalog category for new services created within a service category.

Service Creator roles

The Service Creator application uses the specific roles.

To learn more about managing per-user subscriptions, see Managing per-user subscriptions in Subscription Management and contact your account representative.

Roles

Role Title [Name]	Description
`[service_category_user]` `[service_category_table_name_user]`	Accesses request records for a service category. The table name for the service category determines the name of the role. Users designated as the manager, editors, or service fulfillers for a service category automatically receive this role.
Catalog Administrator `[catalog_admin]`	Creates, edits, and publishes service categories and services, and creates and edits notifications including template notifications. Catalog administrators are primarily responsible for approving service category requests.
Catalog Manager `[catalog_manager]`	Creates, edits, and publishes services, and designates editors and service fulfillers. A user designated as the manager of a service category receives this role automatically.

Roles (continued)

Role Title [Name]	Description
Catalog Editor `[catalog_editor]`	Creates and edits services. A user designated as an editor of a service category receives this role automatically.

Manage a service

Using the Service Creator, department managers can request a new service category, designate editors and service fulfillers for that category, and create and publish services.

About this task

Editors create and modify services. Service fulfillers complete the tasks generated from service requests.

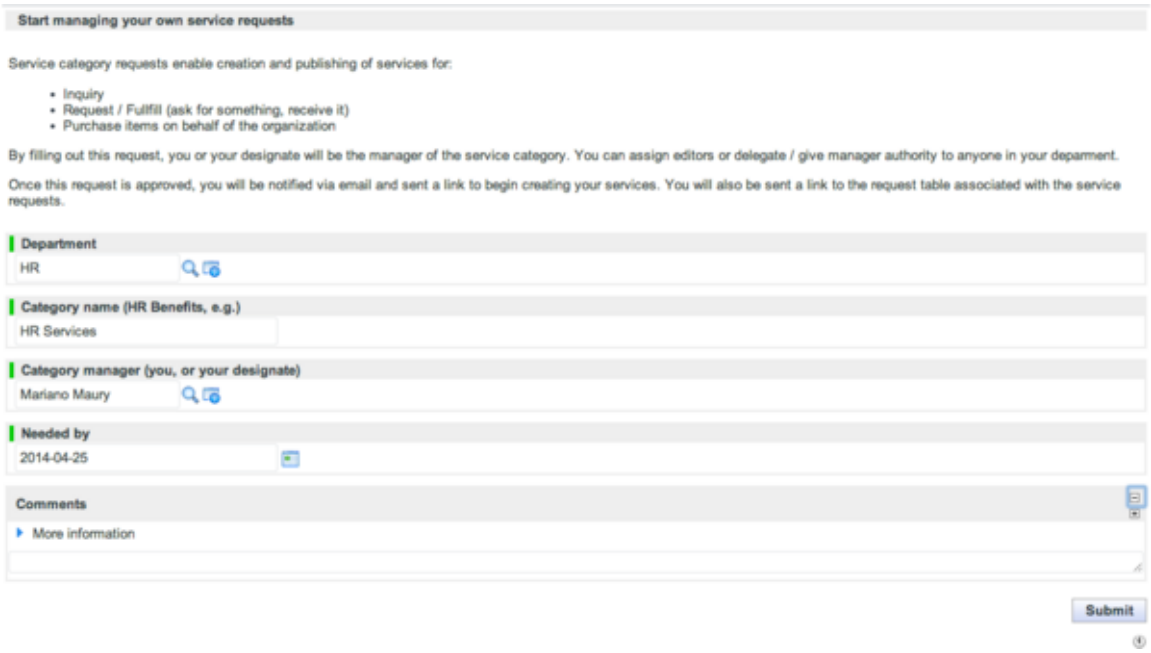
A service category request involves assigning a service category manager, which is typically the department manager who makes the request. After the request is submitted, a catalog administrator approves the request to publish the service category. When the category is published, the service category manager can assign service category editors and service fulfillers, and create services to offer in the service catalog.

To request a new service category:

Procedure

1. Navigate to **All** > **Self-Service** > **Service Catalog**.
2. Select the **Departmental Services** category.

   The *Departmental Services* category is part of the demo data available with service creator. If this category does not exist, a catalog administrator must add the *Service Category Request* catalog item to an existing category.
3. Select the **Service Category Request** item.
4. Change the default values, as necessary (see table).
5. Click **Submit**.



Managing Services

Field	Description
Department	Department this category request is for. By default this value is the department of the current user. Changing this value also changes the *Category name* and *Category manager* values.
Category name	Name for the new service category. By default, ServiceNow uses a name based on the *Department* value.
Category manager	Designated manager for the new service category. By default, ServiceNow uses the manager for the selected department.
Needed by	Date that the new service category should be available.
Comments	Additional comments describing the service category. This information appears as a journal entry on the Service Category form.

Designing services

Service creator includes an interface for designing services.

Using this interface, service category managers and editors can create and publish services, and edit service details.

All services must belong to a service category. If your department or group does not have an existing service category, you must create a new service category before you can design services for that category.

Add a template notification

Adding a template notification.

Procedure

1. Navigate to **All** > **Service Creator** > **Template Notifications**.
2. Click **New**.

3. In the *Send when* field, select **Event is fired**.
4. In the *Event name* field, select **ccrTemplate**.
5. Enter other notification details.
6. Click **Submit**.

   The new template notification creates a notification for all service categories published after that point.

Notification configurations

All service categories start with a set of associated notifications, such as the notification when a task to fulfill a service request is assigned.

Notifications defined in the **Service Creator** > **Template Notifications** module are copied when a user creates a new service category.

Template notifications are distinct from the notifications for the Service Creator application itself, such as the notification when a new service category is approved or rejected. Notifications for the Service Creator application are defined in **Service Creator** > **Notifications**.

A system administrator can add and delete template notifications.

Create the category and table

After the request has been submitted, a catalog administrator can approve or reject the request.

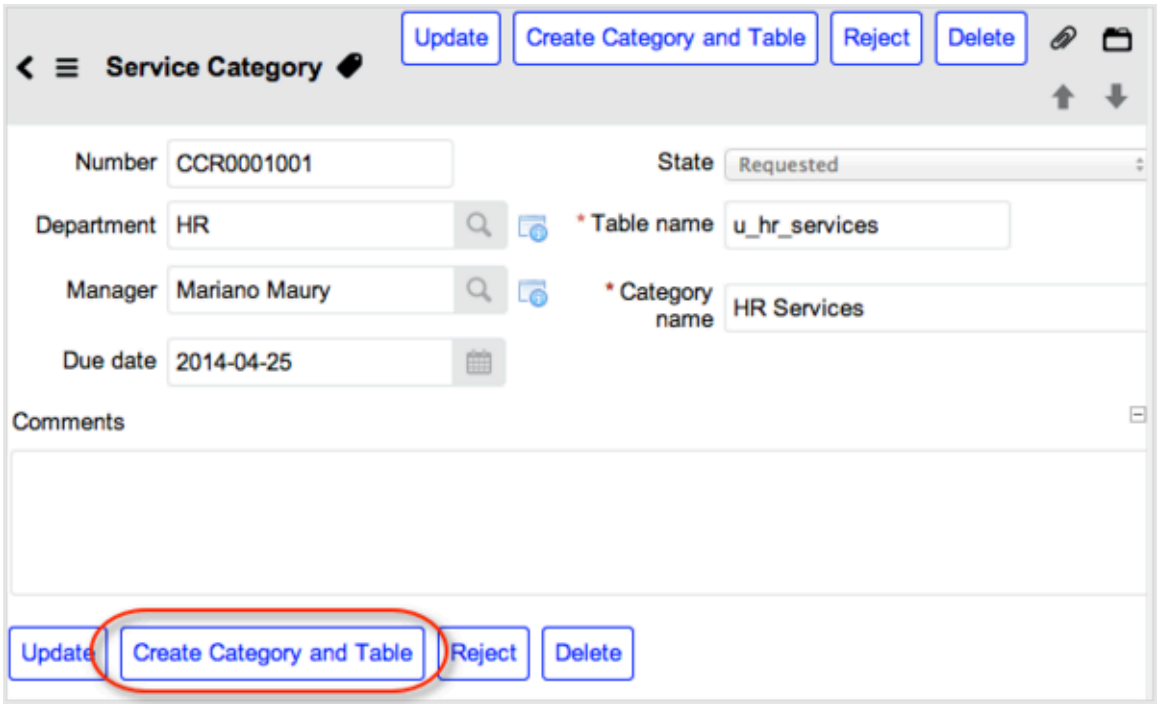
About this task

Approving the request creates a new table for the service category, adds an application to the application navigator using the *Category name* as the application label, and sets the *State* of the service category to *Published to Catalog*.

Procedure

1. Navigate to **All** > **Service Creator** > **Category Requests**.
2. Open a record with a *State* of *Requested*.
3. Review the requested service category. ServiceNow provides a suggested *Table name* based on the *Department*.
   If a service category exists with the specified category name or table name, a message appears under that field. Use a unique value for these fields.
4. Click **Create Category and Table** to approve the request or **Reject** to reject the request.

   If notifications are enabled for the instance, the service category *Manager* is notified of the approval or rejection.



After publishing the service category, you can access the new table by navigating to the new application in the application navigator, or by clicking the **View Task List** related link on the Service Category form.

Related topics

Manage a service

Delete a template notification

Deleting a template notification prevents new service categories from using the notification, but does not delete notifications for service categories that have already been created.

Procedure

1. Navigate to **All** > **Service Creator** > **Template Notifications**.
2. Select a notification record.
3. Click **Delete**.
4. Click **OK** to confirm.

Designate an editor

Editors can create and modify services within a service category.

About this task

Editors automatically receive the catalog_editor role.

The service category manager can designate editors for a published service category.

Procedure

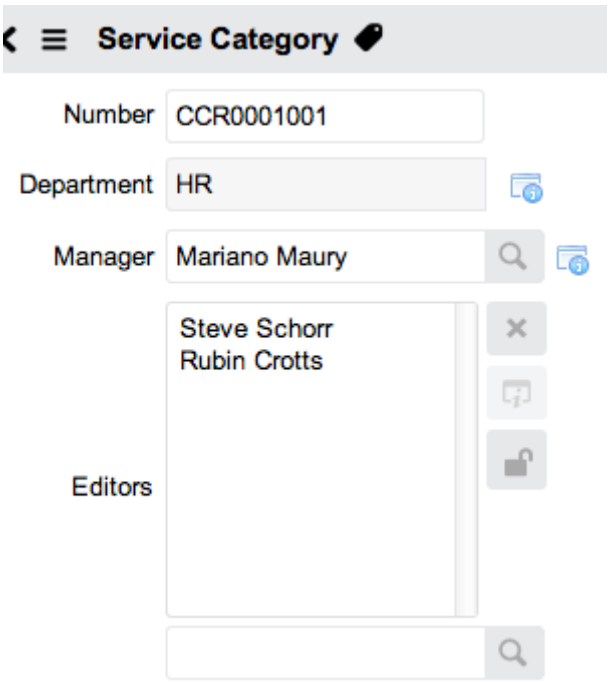
1. Navigate to **All** > **Service Creator** > **My Service Categories**.
2. Select a record with a *`State`* of *`Published to Catalog`*.
3. Click the lock icon beside the *`Editors`* field.

4. Select users to designate as editors using the reference lookup icon.

   Only users in the appropriate department are available for selection.

5. After adding all editors, click **Update**.

   Editors receive the Catalog Editor role.



Designate a service fulfiller

Service fulfillers can complete service requests submitted for a service category.

About this task

Service fulfillers can access applications for service categories they are assigned to, but cannot access the *Service Creator* application.

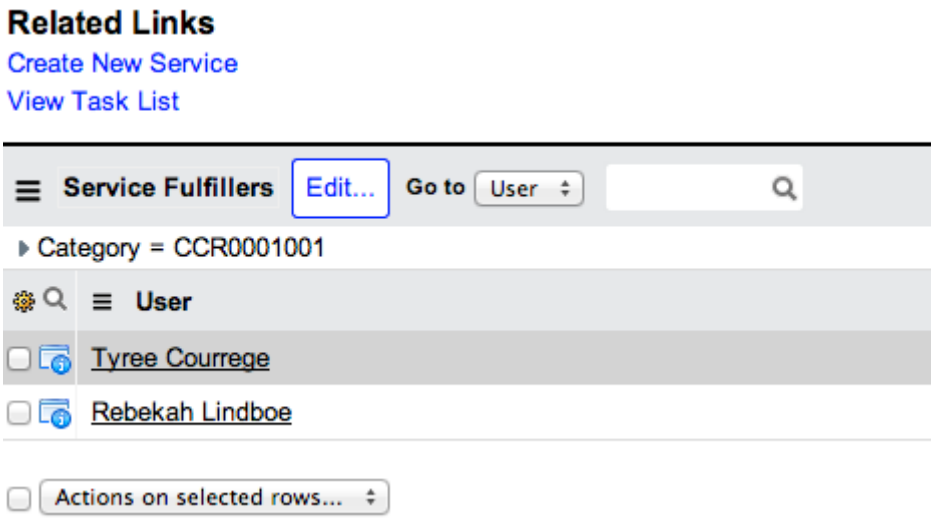
The *Service Fulfillers* related list on the Service Category form displays all users assigned as fulfillers for that service category. The service category manager can designate service fulfillers for a service category.

Procedure

1. Navigate to **All** > **Service Creator** > **My Service Categories**.
2. Select a service category with a *`State`* of *`Published to Catalog`*.
3. In the *`Service Fulfillers`* related list, click **Edit**.
4. Use the slushbucket to add the appropriate service fulfillers.

   Only users in the appropriate department are available for selection.

5. Click **Save**.



Fulfill a service request

End users can request published services through the service catalog.

About this task

When a user requests a service, the ServiceNow system creates a new task for that service category. Service fulfillers complete these tasks to fulfill the request.

New request tasks are automatically assigned to the group or user specified in the *Fulfillment Group* or *Fulfillment User* service setting. If no fulfillment group or user is set, new records are assigned to the service category manager.

Questions for a particular service and the answers entered by the requesting user appear in the *Variables* section on the fulfillment task record.

Procedure

1. Navigate to **All** > **<Your service application>** > **Assigned to me**.
2. Select a record.
3. Review the information presented.
4. Complete the task in accordance with department policies and procedures.
5. Set the *State* of the service request record to *Closed Complete*.
6. Click **Update**.

Publish a service

A service must be published to appear in the service catalog. When first created, new services appear in the Draft Services related list for the service category. Published services appear in the Services related list for the service category. The manager of a service category can publish draft services.

Procedure

1. Navigate to **All** > **Service Creator** > **My Service Categories**.
2. Select a service category with a State of *Published to Catalog*.

3. On the Service Category form, right-click a service in the **Draft Services** related list.
4. Select **Publish**.

Legacy - ServiceNow Studio

The legacy ServiceNow Studio provides an Integrated Development Environment (IDE)-like interface for application developers to work on custom applications in one centralized location. It offers a simple way to create, review, and update application files from a tabbed environment.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

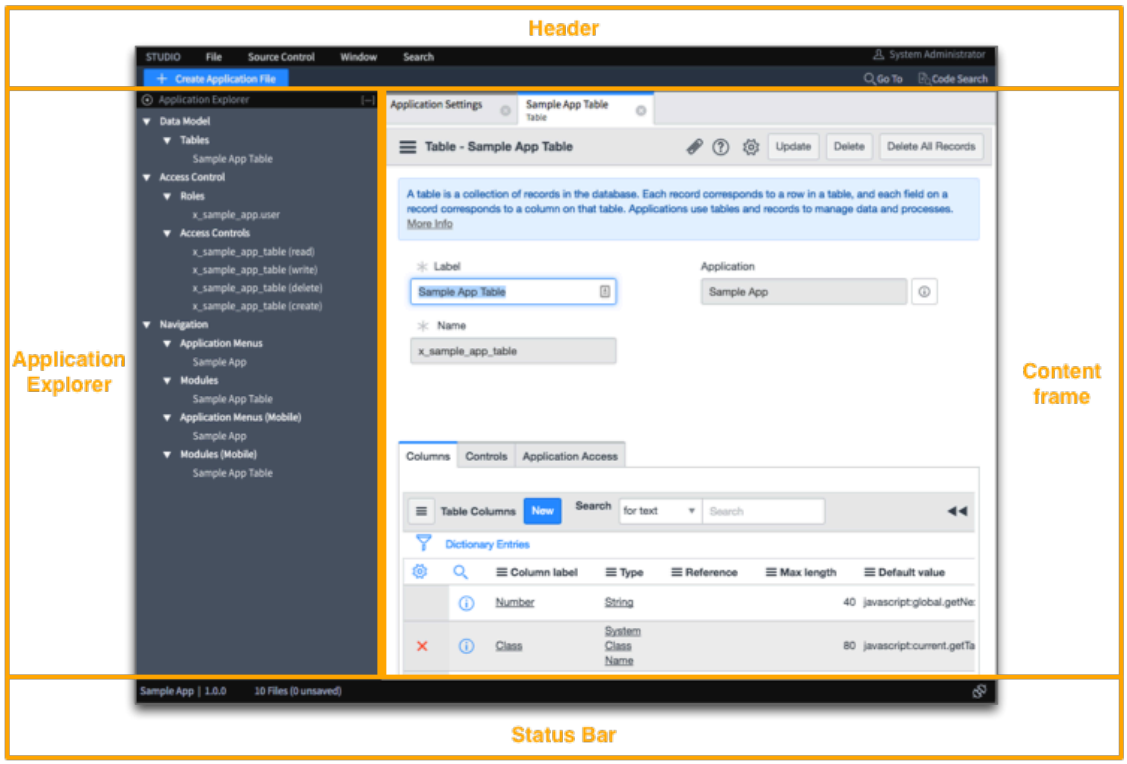
Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

The system opens the new ServiceNow Studio whenever you edit a custom application.

Capabilities

- Create an application and application artifacts.
- Perform code search.
- Integrate with source control.
- Create your company's customizations to store applications that belong to other organizations.
- Use Virtual Agent Designer to create and manage topics, which are blueprints for conversations between a virtual agent and a user. You can design topics that help your users resolve common work issues or guide them through self-service tasks.

Studio



With Studio, application developers can:

- See exactly what files comprise their application in the **Application Explorer**.
- Add new files to their application using a single **Create Application File** interface.
- Navigate to files using familiar search-by-name or by-type behavior with the **Go To** dialog.
- Find code both within and outside an application using the **Code Search** tool.
- Operate on multiple files at once using the tabbed interface.
- Operate on multiple applications at once using multiple studio windows.
- Publish their application to company instances or the ServiceNow Store.
- View information about their current application from the **Status Bar**.

Which builder should I use to create an app?

Types of builders

Want to build an app easily, without code?

Creator Studio specializes in helping you craft request-fulfillment applications without writing code. For example, an application to request office supplies by filling out a form, and someone approves or denies your request. For more information, see Exploring Creator Studio.

Need a more general app but still want low-code options?

App Engine Studio lets you build a broader range of apps than Creator Studio without being a programming pro. For more information, see Exploring App Engine Studio.

Are you a developer who wants more control in a centralized user interface?

Build apps smarter and deliver them faster with the new ServiceNow Studio. ServiceNow Studio empowers platform developers with a modern, unified environment for building on the ServiceNow AI Platform. ServiceNow Studio features streamlined navigation to applications and metadata, integrated low-code tools, efficient tracking and packaging of development work that accelerates development processes and enhances productivity. For more information, see Exploring ServiceNow Studio.

Are you a developer who wants to use industry-standard development tools and processes?

The ServiceNow IDE and ServiceNow SDK support developing applications in source code with ServiceNow Fluent, creating JavaScript modules, and using third-party libraries. ServiceNow Fluent is a domain-specific programming language for creating application metadata in code.

The ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform. The ServiceNow SDK uses Visual Studio Code Desktop locally. For more information, see Building applications in source code.

Working with the Studio UI

Parts of the Studio UI

UI element	Description
Header	Displays menus and controls.
File Menu	Contains a list of application-specific options. • **Create File** • **Import From Source Control** • **Create Application** • **Publish** • **Settings** • **Switch** • **Manage Developers** • **Launch Script Debugger**
Source Control Menu	Contains a list of source control options. • **Link To Source Control** • **Edit Repository Configuration** • **Apply Remote Changes** • **Commit Changes** • **Stash Local Changes**

Parts of the Studio UI (continued)

UI element	Description
	• **Switch Branch** • **Create Branch** • **Create Tag** • **Manage Stashes** • **View History**
Window Menu	Contains a list of tab management options. • **Close Current Tab** • **Close All Tabs** • **Close Other Tabs** • **Close Unmodified Tabs**
Search Menu	Contains a list of search options. • **Go To** • **Code Search**
User name	The header displays the name of current user.
Create Application File	Allows developers to add an application file to an application.
Go To	Search for application files by name or type.
Code Search	Search within application files for a text string. Search options include: • Restrict search to a particular table • Include all applications
Application Explorer	Displays a list of application files by type. Resize the Application Explorer to see more about application files or to provide more space for the content frame.
Collapse All	Collapses all nodes in the application explorer.
Expand All	Expand all nodes in the application explorer.
Data Model > Tables	A list of application tables. Click a table name to display and edit it in the content frame.
Access Control	A list of application access elements such as: • **Roles** • **Access Controls**

Parts of the Studio UI (continued)

UI element	Description
	Click a record name to display and edit it in the content frame.
Navigation	A list of application navigational elements such as: • **Application Menus** • **Modules** • **Application Menus (Mobile)** • **Modules (Mobile)** Click a record name to display and edit it in the content frame.
Content frame	Displays a detail form for each record in its own tabs.
Welcome to Studio	A list of keyboard shortcuts.
Tabs	Each tab contains a specific application file record identified by the record name and file type. Click a tab to display and edit the record. A tab with a blue circle icon indicates that the record contains unsaved changes.
Status Bar	Displays information about the application and the source control integration.
Application name	The status bar displays the name of the current application.
Application version	The status bar displays the current application version.
Total files	The status bar displays the total number of application files.
Unsaved files	The status bar displays the current number of application files with unsaved changes.
Source control integration status	The status bar displays an icon indicating the current status of the source control integration.

Contextual development environment

Legacy - Access ServiceNow Studio

Application developers access ServiceNow Studio to create, import, or open applications.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Role required: admin

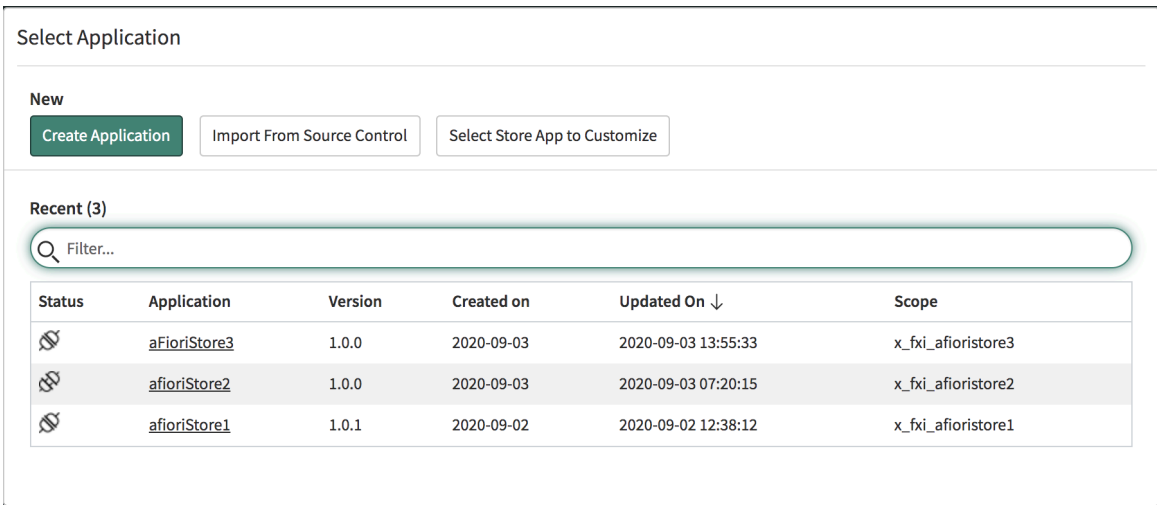
Procedure

1. Select the path available to your role.

Paths to Studio

User role	Action to open Studio
admin	Navigate to **All** > **System Applications** > **Studio**.

The Studio opens in a new browser tab and displays the Select Application modal dialog.

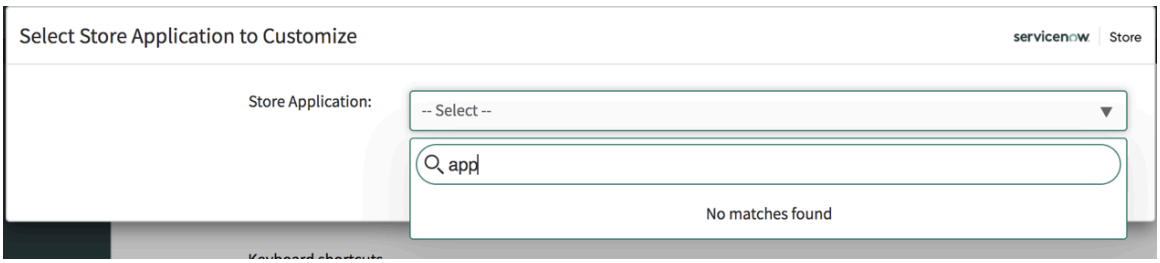


2. To create an application, click **Create Application**.
   The system displays a list of application creation options.
3. To import an existing application from source control, click **Import From Source Control** list.
   Studio opens **Import From Source Control**page.
4. To view an existing application, click the application name from the **Applications** list.

   The list also includes any store applications or scoped applications installed via plugins that are customized.

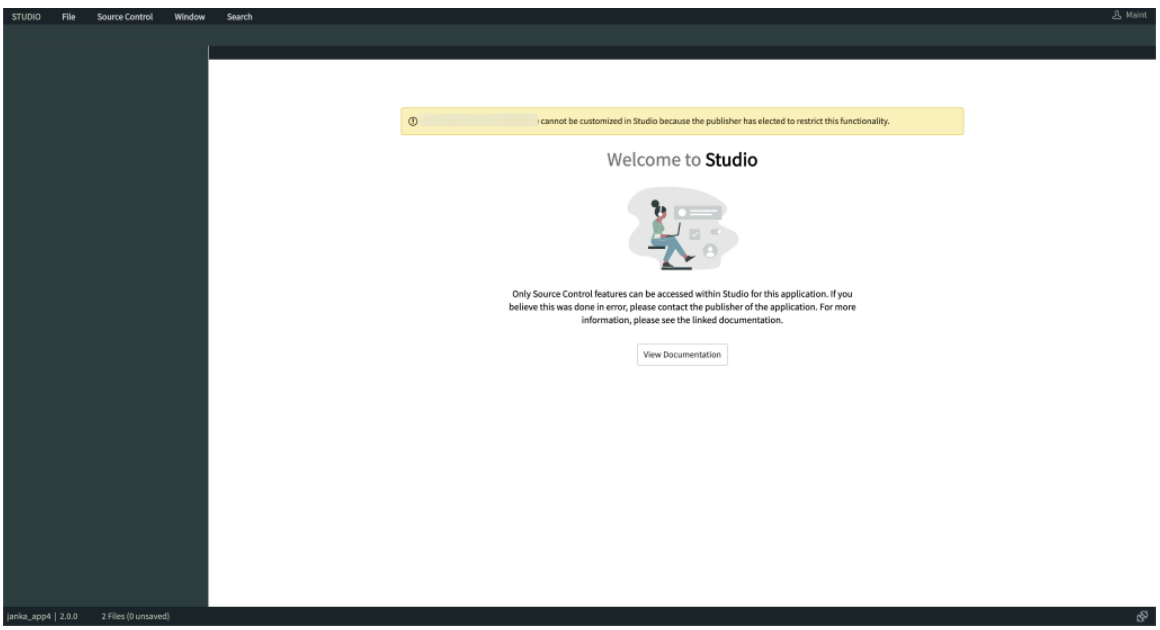
Note:
In a few scenarios for scoped applications installed via plugins, the **Name** field in the Store Applications (sys_store_app) table doesn't match the plugin name. To make sure you are choosing the correct application, search the Select Store Application list picker with the **Name** of the application mentioned in the sys_store_app. For example: The plugin **Agile - Scaled Agile Framework - Essential SAFe** creates the sys_store_app record with the name "SAFe". Therefore you would search the Select Store Application list picker with the word "SAFe".

5. To open an installed store application so you can create your company's application-customization for it, click **Select Store application** and select the store application from the list picker display.



Studio opens the selected application.

Note:
The linked icon indicates that there are uncommitted local changes in the application. The property is ignored for your company applications in development. The **Can Edit Application in Studio** property for a store application determines if the application can be edited in Studio. If set to false, you see a warning that you cannot edit the application in Studio. But you can open the application in Studio to use Source Control features or to publish its customizations to the application repository. The default is true for new applications. The application's owner can change the property value before releasing a new version.



Legacy - ServiceNow Studio keyboard shortcuts

ServiceNow Studio supports various keyboard shortcuts to manage and edit application files.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Studio keyboard shortcuts

Keyboard combination	Description
Windows: Control+Shift+O *Mac:* Command +Shift+O	**Go To**. Open any file in your application.
Windows: Control+Shift+C *Mac:* Command +Shift+C	**Create New**. Create an application file.
Windows: Control+Shift+F *Mac:* Command +Shift+F	**Code Search**. Search for any file or value.
Windows: Control+Shift+X *Mac:* Command +Shift+X	**Close Tab**. Close the current tab. If the tab contains unsaved changes, the system prompts the user to save them.

Legacy - ServiceNow Studio

Legacy - Add an application file to an application

Studio allows application developers to add new application files by type.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Role required: admin

This procedure requires creating a scoped application.

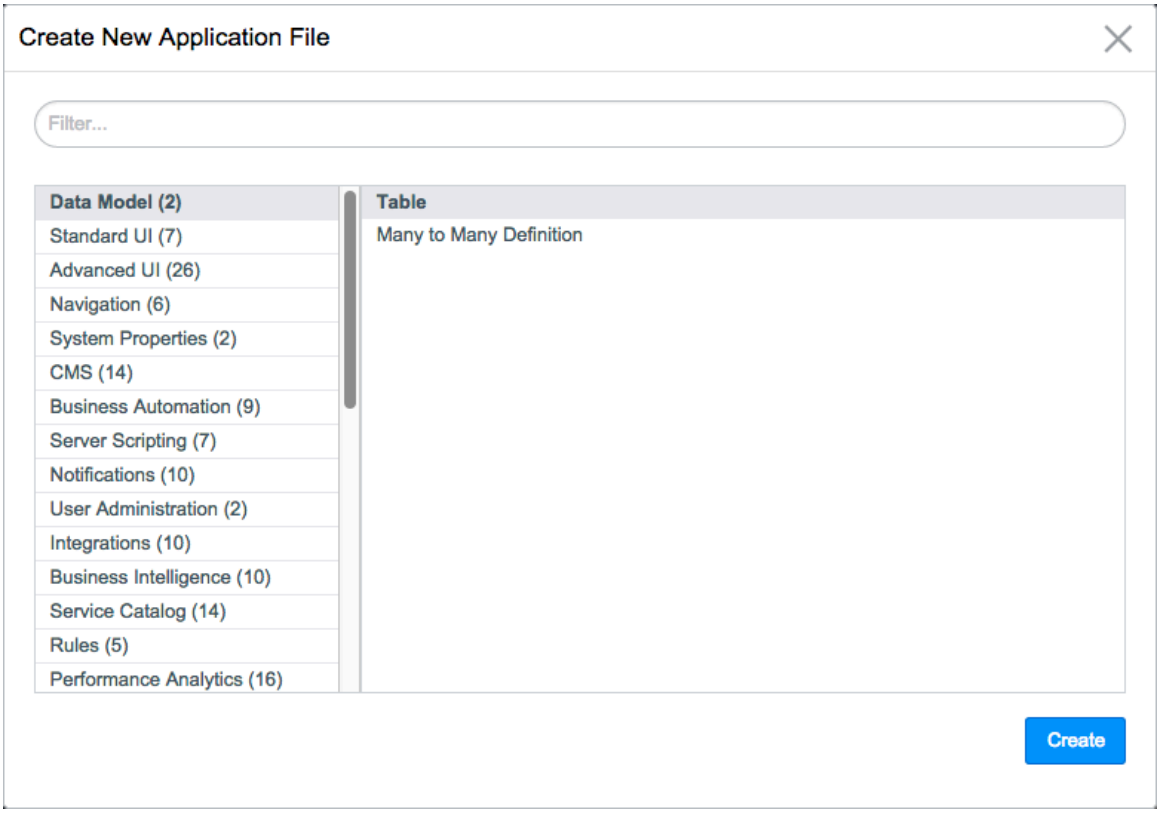
About this task
You can add application files to update the features of a custom application.

Procedure
1. Navigate to **All** > **System Applications** > **My Company Applications**.
2. From the **Develop** tab, click the **Edit** button next to the application you want to modify.
   The system opens the application in the Studio.
3. From the content frame, click **Create Application File**.
   You can also use a Studio keyboard shortcut.

Studio keyboard shortcut

Keyboard combination	Description
Windows: Control+Shift+C *Mac:* Command+Shift+C	**Create New**. Create an application file.

Studio opens the Create New Application File pop-up window.



Note:
Not all application file types will display in Studio. Some types of application files needs to created outside Studio, such as dashboards, even though they extend sys_metadata table.

4. Find the application file type you want to create.

Option	Description
Search by application file name	In the **Filter** entry field, enter the name of the application file.
Search by category	From the left pane, select a category name.

5. From the results pane, select the application file type you want to create.
6. Click **Create**.
   The system displays a blank form for the application file type in a new studio tab.

What to do next
Enter the necessary fields for the particular application file type you selected.

Application files

Legacy - Publish an application from ServiceNow Studio when linked to Source Control
You can publish a custom application from ServiceNow Studio when linked to Source Control.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Role required: admin

About this task
When you publish an application from ServiceNow Studio that is linked to Source Control, there is a different outcome than when you publish via the sys_app or sys_store_app **Publish** related link.

Procedure

1. When you select **Publish**, the sys_app or sys_app_customization record for the application is updated with the new version.
2. The current state of the application is committed to Source Control, including any untracked or uncommitted changes.
   The value of the **glide.sourcecontrol.default_commit_mode** property is ignored.
   This occurs because when the application is published, all the untracked and uncommitted changes are also published. Therefore, the state of the application in the Git repository matches what is published. See the Legacy - Commit changes topic for more information about the **glide.sourcecontrol.default_commit_mode** property.
3. A Source Control tag is created for the new version and the application is published.
   If needed, the sys_app record is updated with the new store correlation ID.

   Note:
   If your application is linked to Source Control and you publish a new version outside of Studio, a source control commit and tag are not created.

Legacy - Search for an application file by name or type

Application developers can use Studio to search for application files.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Role required: admin

This procedure requires creating a scoped application.

About this task
You can search for application files to add, remove, or update the features of a custom application.

Procedure

1. Navigate to **All** > **System Applications** > **Applications**.
2. From the **Develop** tab, click the **Edit** button next to the application you want to modify.
   The system opens the application in the Studio.
3. From the header, click **Go To**.
   You can also use a Studio keyboard shortcut.

   Studio keyboard shortcut

Keyboard combination	Description
Windows: Control+Shift+O *Mac:* Command+Shift+O	**Go To**. Open any file in your application.

   Studio opens the Go To window.
4. Enter a search string.

   Studio displays a list of matching application files as you type.
5. From the list of search results, click a record name.
   Studio opens the application file record in a new tab in the content frame.

Legacy - Search within application files

Studio allows application developers to search within application files for matching record values.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Role required: admin

This procedure requires creating a scoped application.

About this task

You can search within application files to add, remove, or update application file values.

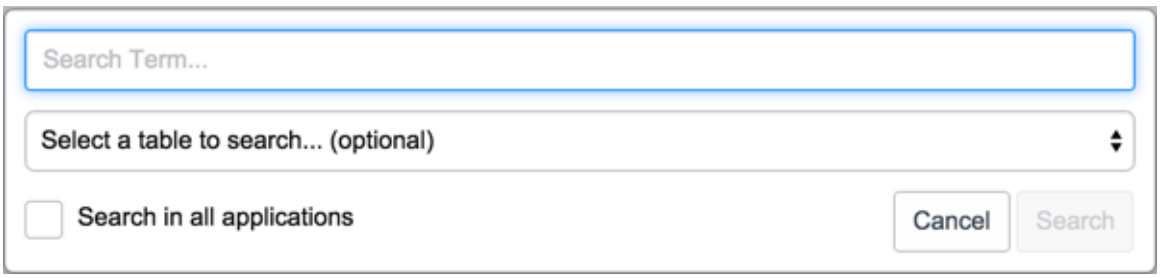
Procedure

1. Navigate to **All** > **System Applications** > **Applications**.
2. From the **Develop** tab, click the **Edit** button next to the application you want to modify.
   The system opens the application in the Studio.
3. From the header, click **Code Search**.
   You can also use a Studio keyboard shortcut.

   Studio keyboard shortcut

Keyboard combination	Description
Windows: Control+Shift+F *Mac:* Command+Shift+F	**Code Search**. Search for any file or value.

   Studio opens the Search pop-up window.
4. In **Search term**, enter a search string.

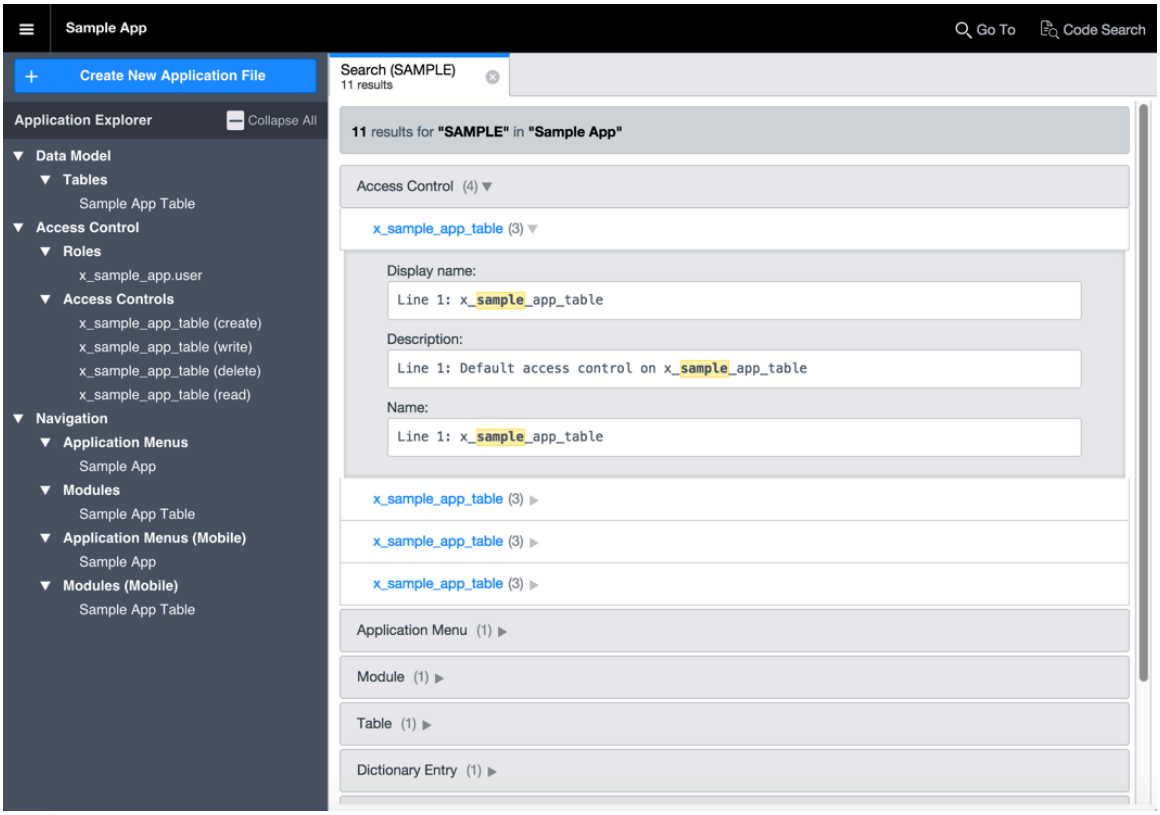


5. **Optional:** Select any additional search criteria.

Option	Description
Select a table to search	Search for matches only within the selected file type.
Search in all applications	Search for matches throughout the instance, not just within the current application.

   Note:
   Searches across all applications can take a long time.

6. Click **Search**.
   The Studio conducts a case-insensitive search of the application files you selected. While the search is running, Studio displays a search progress indicator. You can click the cancel icon to stop the search. When the search is complete, the system opens a new tab in the content frame to display the search results by application file type. Each application file type displays the number of matching search results.



7. From the search results tab, expand an application file type and click a record name.
   Studio opens the application file record in a new tab in the content frame.

Legacy - Update a custom application record

You can update a custom application record to add new features or change application functionality.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Role required: admin or a delegated developer role granting full access

About this task

You can only update applications in development on your local instance. You cannot edit applications downloaded from your company application repository or the ServiceNow Store.

Procedure

1. Navigate to **All** > **System Applications** > **Applications** > **Studio**.
2. Click the application name or the **Edit** button for the application you want to update.
   The system displays the application and application files in Studio.
3. Click **File** > **Settings**.

Studio opens a tab containing the Custom Application record for the current application.

4. Fill in the fields, as appropriate.

Custom Application form

Field	Description
Name	[Required] Enter a label for the application. Changing the name does not change any other field value derived from the application name such as the **Scope**, **Menu**, or **User role** fields.
Version	Enter version information for the application. Both the ServiceNow application repository and the store use this value to determine whether updates are available to your application users. **Note:** To publish the application in the ServiceNow Store, the version must conform to the application certification standards.
Application Scoping	
Scope	[Read Only] Displays the unique application scope set during the creation process. You can change this value only by deleting and recreating the application with a new value. For more information about the protections offered, see Application scope.
Application administration	Select whether to protect sensitive application data by restricting how users acquire application-specific roles. See Application administration.
Design and Runtime	
JavaScript Mode	The JavaScript standard that the application supports. Select **ECMAScript 2021 (ES12)** to support features in ECMAScript 12th edition or **ES5 Standards Mode** to support features in ECMAScript 5th edition. Select **Compatibility Mode** to support earlier ECMAScript editions. For more information, see Set the JavaScript mode for an application.
Runtime Access Tracking	Select how the application handles script access requests to resources in other applications. Select **None** to authorize all access requests to cross-scope resources without logging them. Select **Tracking** to log and authorize all access requests to cross-scope resources. Select **Enforcing** to log access requests to cross-scope resources but require an administrator to authorize each request.
Restrict Table Choices	Clear the option to allow the application to see tables from other application scopes. Select the option to restrict design choices to only tables in the same application.
Subscription Management	
Licensable	Specifies whether the application is tracked by the Subscription Management application.
Subscription requirement	Not applicable for ServiceNow customers who build custom applications for their own use. Used only by partners who sell and monitor the usage of resellable applications on the ServiceNow Store. Specifies whether the application requires a separate subscription (**Required**) or is monitored only.

Field	Description
Subscription model	Not applicable for ServiceNow customers who build custom applications for their own use. Used only by partners who sell and monitor the usage of resellable applications on the ServiceNow Store. Specifies how the Subscription Management application tracks usage. See Types of subscriptions in Subscription Management.
Primary Menu	
Menu	Select the application menu where you want to display modules. For more information about menus and modules, see Create an application menu.
End user access	
User role	Select the user role required to access the application menu. For more information about user roles, see Create a role Create a role.
Short description	Enter a description of the application purpose or usage.
Logo	Select the image the system displays in the applications list and ServiceNow Store.
Application Files	View configuration records associated with this application in platform feature tables.
Dependencies	View or add tables or applications on which this application depends. The system automatically adds records to this list when you extend tables or when another application creates application files for this application. Add script-based dependencies. See Dependencies for custom applications.
Cross scope privileges	View or create cross-scope privilege records to determine which script operations and targets the system allows to run. See Cross-scope privilege record.
Design Access	View or specify which other applications have design access to tables or records in this application. See Application design access record.

5. Click **Update**.

Legacy - Switch between applications

Application developers can switch between applications without leaving the Studio environment.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Before starting this procedure, you must create at least one custom application with its own application scope.

Role required: admin

About this task

The contextual development environment restricts some changes when the application files belong to another application. Switching to the application that owns the application files ensures that you change the proper application.

Procedure

1. Navigate to **All** > **App Options Menu** > **Switch Applications**.
   The system displays the list of applications.
2. Click the application you want to switch to.
   The system reloads Studio to display the selected application.

Legacy - Global application file management

Once you create a globally scoped application in the ServiceNow Studio, you can add existing globally scoped files to it, remove files from it, or move application files between global applications.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Legacy - Add a file from the global scope to a global application

Add existing globally scoped files into a selected global application. You can search for files in another globally scoped application by the update set name, table, or file name.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

The Global App File Management plugin must be activated.

Role required: admin

About this task

When you select an application in the application picker, application files are automatically assigned to it. You cannot move an application file into or out of a scoped application. See Application scope.

Procedure

1. Navigate to **All** > **System Applications** > **Applications** > **In Development**.
2. To the right of the application name, click **Edit in Studio**.
3. In Studio, click **File**, then select **Add Existing Files**.

4. Use any of the following options to find existing globally scoped application files that you can add into the current globally scoped application.

   Note:
   You can view up to 250 files at a time. If you want to view more files, perform another search with more specific search criteria.

5. Click **Continue** to list application files that are associated with the selected update set, table, or name.
   You can filter the results as needed.
   The system displays the filtered results but omits any files that are already associated with the current global application. The system displays the file type, application, when the file was last updated, and if it is a customized file.
6. Select the files that you want to add, and then click **Add**.
   The Confirm Changes dialog appears, stating that the files being moved are now considered customizable files and may appear on a skip list during an upgrade.
7. Click **Continue** to add the selected files.

   Note:
   The ability to add globally scoped files to globally scoped applications also allows you to move dictionary collection entries to a custom global scope. This action may result in unexpected cross-scope failures as the **sys_db_object** table and collection are not in the same scope anymore. The implication of this action is that CRUD operations (that are allowed based on sys_db_object application access and existent cross-scope privileges) would not be permitted without an obvious reason.

Result

The system moves the selected files to the selected application from the global scope, and flags them as customizable files. For example, if you select the sys_ui_policy file, the associated sys_ui_policy_actions file is also added to the selected application, and flagged as customizable. You see error messages when errors occur in the add process, or a confirmation when your files are successfully added to the globally scoped application.

Legacy - Remove a file from a global application

Remove selected files from the selected global application and return them to the previous global application that owned the file. If there is no previous owner, file is returned back to global scope. The removed files are still considered customized files.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

This option is only available if the Global Application File Management plugin is active.

Role required: admin or a delegated_developer role that grants full access.

Procedure

1. Navigate to **All** > **System Applications** > **My Company Applications** > **In Development**.
2. To the right of the application name, select **Edit in Studio**.
3. In Studio, select **File** > **Remove Files**.
   The system displays a list of the files in this global application.
4. Select the file that you want to remove from this application.
5. Click **Remove**.

Legacy - Move an application file between global applications

Move selected application files and their descendant files to a selected global application. When you select a global application, the selected application files are automatically assigned to it. You cannot move an application file into or out of a scoped application.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

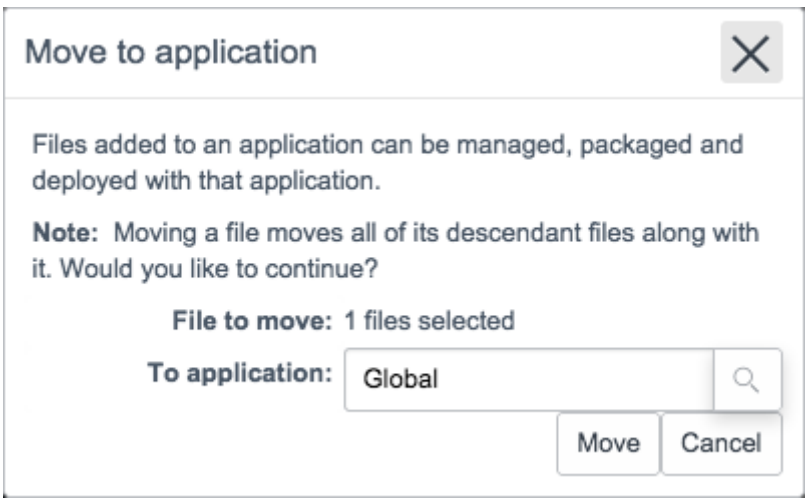
Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Roles required: admin or a delegated_developer role that grants full access.

This option is only available if the Global App File Management plugin is active.

Procedure

1. Navigate to the application file in a list or form view.
   For example, navigate to **All** > **System UI** > **UI Policies** to select UI policy files to move.
2. Select the check box beside each file you wish to move, and then select **Move to Application** in the **Actions on selected rows** choice list.
3. Select the global application.



4. Click **Move**.
   The selected application files and its descendant files are moved to the selected global application.

Legacy - Add multiple files from global update sets to a global application

Add multiple globally scoped application files at once from one or more global update sets to a new or existing global application.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Role required: admin

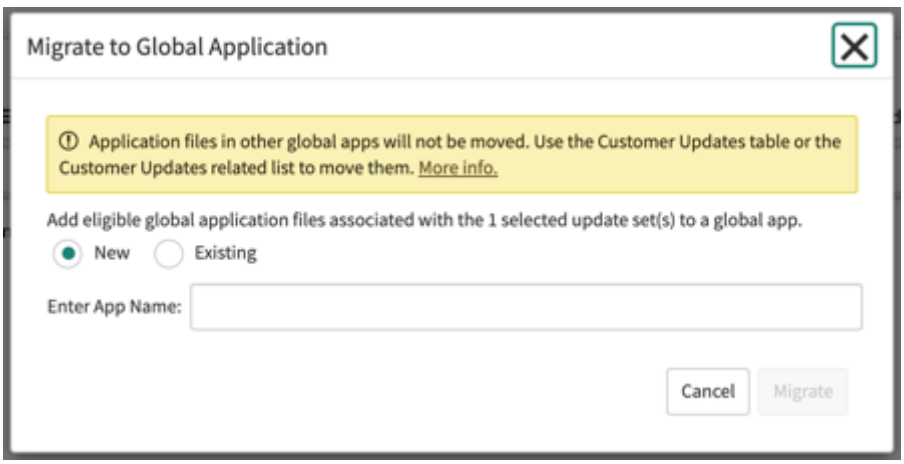
The Global App File Management plugin must be activated.

About this task

This feature is for customers who manage their customizations to globally scoped files via update sets. You can migrate these files in bulk to new or existing global applications. The global application can then leverage ServiceNow CICD tools which support only applications. Select multiple update sets to move globally scoped application files to a new or existing global application. All the eligible application files associated with the customer updates in those update sets will be moved. This operation moves only the application file as it is loaded on the instance. The payload in different customer updates to the same file is ignored.

Procedure

1. Navigate to **All** > **System Update Sets** > **Local Update Sets**.
2. Select the check box beside each update set you want to move, and then select **Migrate to Global Application** in the **Actions on selected rows** list.
3. Enter the name of a new global application or select an existing global application.



4. Select **Migrate**.

Note:
Selecting update sets to migrate does not move application files that are part of other global applications. Only files that are in the global scope are moved. To add files that are part of other global applications, see Legacy - Add multiple files from customer updates to a global application.

Trouble?

If an application file associated with an update was not moved, it could be because:

- The application file is not global.
- The application file is part of another global application.
- The application file was deleted.
- The application file is not eligible to move to another global application. For example, a `sys_app` file. \
- The application file is read-only.

Legacy - Add multiple files from customer updates to a global application

Add multiple globally scoped application files at once from one or more customer updates to a new or existing global application.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Role required: admin

The Global App File Management plugin must be activated.

To add global files that are part of other global applications, `glide.source_control.customize_files_in_other_global_apps` must be true.

About this task

This feature is for customers who manage their customizations to globally scoped files via update sets. You can migrate these files in bulk to new or existing global applications. The global application can then leverage ServiceNow CICD tools which support only applications. Select multiple customer updates to move globally scoped application files to a new or existing global application. All the eligible application files associated with the customer updates will be moved. This operation moves only the application file as it is loaded on the instance. The payload in different customer updates to the same file is ignored.

Procedure

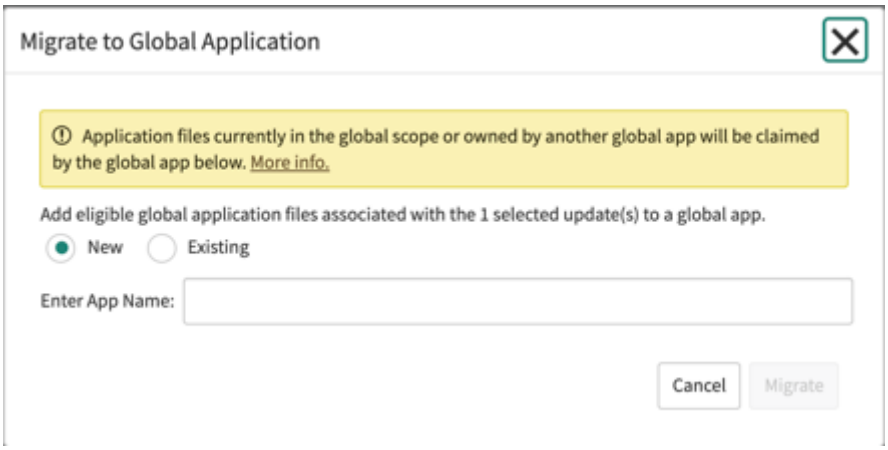
1. Navigate to **All** > **System Update Sets** > **Local Update Sets**, open an update set in Form view and go to its Customer Updates Related List.
   Or

Navigate to **System Maintenance** > **Customers Updates [sys_update_xml]** table and add updates from multiple update sets.

2. Select the check box beside each update you want to move, and then select **Migrate to Global Application** in the **Actions on selected rows** list.
3. Select **Migrate**.

> **Note:**
> To learn how to add multiple files from global update sets to a global application, see Legacy - Add multiple files from global update sets to a global application.

4. Enter the name of a new global application or select an existing global application.



Trouble?

If an application file associated with an update was not moved, it could be because:

- The application file is not global.
- The application file is part of another global application.
- The application file was deleted.
- The application file is not eligible to move to another global application. For example, a `sys_app` file.
- The application file is read-only.
- The application file is already associated to the global application being migrated to.

Legacy - Review claimed or skipped global files

Review files when one or more of your files has been skipped or claimed by another application.

> **Important:**
> Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.
>
> Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

During the development of a global application, warnings about skipped or claimed files may display on various progress screens. Skipped or claimed files can occur when the files in one application are claimed by other application(s).

These warnings display during the installation of an application from the Application or Git repositories or when you publish your application. When you see that your application files have been either skipped or claimed by another application, contact the team that owns the other application to determine the best course of action for both teams.

What your options are

Only one version can be loaded for production. The options are as follows.

- Decide with the other team from which application the file should be removed so that only one file is loaded for production.
- Use the Merge tool: If changes to files in both apps are needed in production, use the merge tool to pull the files into a new common application that serves both parties effectively.

To learn more see the Legacy - Resolve conflicts topic.

Legacy - Automatic recovery of draft records

Studio can maintain a version of any open existing record with unsaved changes. Users can recover unsaved changes when their user session ends unexpectedly due to network latency, session timeout, or service interruption.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

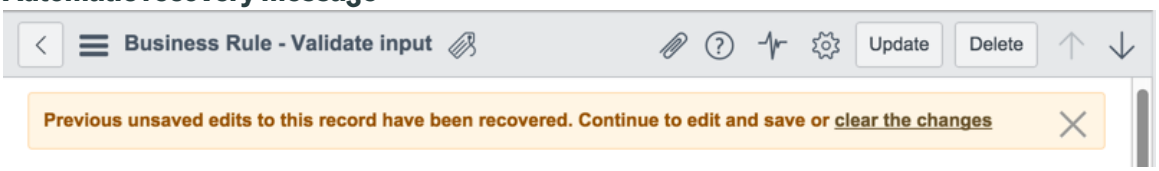
Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Automatic recovery only applies to:

- Records open in Studio. The system does not save all draft records.
- Changes made in desktop (non-mobile) browsers. The system does not save draft records from mobile browsers.
- Changes made to existing records. The system does not save draft changes to new records.
- Records containing unsaved changes that are the most recent update to the record. The system discards draft changes when another user has updated the same record.
- Records for tables that extend the Application File [sys_metadata] table.

After the user re-establishes a session, Studio displays a message for each record with recovered changes.

Automatic recovery message



For each recovered record, users can:

- Continue editing and save the record.
- Clear the changes from the recovery cache.

The system automatically clears changes from the recovery cache when a user:

- Saves the record. The system removes the saved record from the recovery cache.
- Confirms navigating away from a record without saving changes. The system removes the abandoned record from the recovery cache.
- Reaches the recovery cache limit of 5 MB of changes. The system removes the record with the oldest update date-time stamp.

By default, automatic recovery is enabled for all Application File [sys_metadata] tables while working from Studio.

Administrators can configure automatic recovery properties to:

- Disable or re-enable automatic recovery.
- Specify a list of field types to exclude from automatic recovery.

Users can enable or disable automatic recovery as a user preference.

User preferences

Legacy - Auto recovery properties

Administrators can configure how Studio handles the recovery of draft records by navigating to **Auto Recovery** > **Properties**.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Auto recovery properties

Property	Description
Enable Auto Recovery *glide.ui.auto.recovery*	By default, automatic recovery is enabled for all Application File [sys_metadata] tables while working from Studio. Set this property to disable automatic recovery of records.
Comma separated list of tables not supported for auto recovery *glide.ui.auto.recovery.unsupported.tables*	By default, automatic recovery is enabled for all Application File [sys_metadata] tables while working from Studio. Set this property

Auto recovery properties (continued)

Property	Description
	to exclude specific tables from automatic recovery.
Comma separated list of field types not supported for auto recovery *glide.ui.auto.recovery.unsupported.field.types*	By default, automatic recovery supports all field types. Set this property to exclude certain field types from automatic recovery.
Comma separated list of field types to exclude from auto recovery *glide.ui.auto.recovery.exclude.field.types*	By default, automatic recovery is enabled for all field types. Set this property to exclude certain field types from automatic recovery.

Legacy - Auto recovery dictionary attribute

Administrators can configure how the Studio handles the recovery of draft records with a dictionary attribute.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Auto recovery properties

Dictionary attribute	Description
Exclude Auto Recovery *exclude_auto_recovery*	Disables automatic recovery of draft records for this table.

Dictionary attributes

Legacy - Source Control integration

Enable application developers to integrate with a Git Source Control repository. Save and manage multiple versions of an application from a non-production instance.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Linking an application to Source Control enables all application developers on a non-production instance to:

- Import applications from a Git repository.
- Pull and apply remote changes from a Git repository.
- Commit all local changes on the instance to a Git repository.
- Create tags to permanently link to a given version of an application.
- Create branches to maintain multiple versions of an application simultaneously.

Integration requirements

To link an application to source control:

- The user must have the admin role.
- The non-production instance must have network access to the Git repository.
- Each application must be within its own Git repository.
- The repository user credentials must grant read and write access.

Note:
All application developers on the instance share a single set of credentials per repository.

Options available from ServiceNow Studio

After linking an application to Source Control, application developers can use ServiceNow Studio to manage the repository. From Studio, developers can:

- Edit the application repository credentials.
- Commit all local changes on the instance.
- Apply remote changes from the repository.
- Create a branch.
- Switch branches.
- Import an application from a remote repository.

It is not recommended to use Source Control to manage applications on a production instance, deploying to production may lead to unintended consequences, see Legacy - Production deployment tips. Instead, you can manage applications on a production instance using the application repository, an update set, or the ServiceNow Store. For more information about managing applications on a production instance, see Application sharing.

Options available from a Git repository

The ServiceNow platform offers limited support for modifying linked application files outside of an instance. From Git, developers can:

- Move application files to a different Git directory structure.
- Edit application files outside of ServiceNow Studio.

The system generates a properties text file called `sn_source_control.properties` at the root level of the repository. To move application files to a different Git directory structure, application developers can set the *`path`* parameter to specify the subfolder path containing their application files. For example, if you moved your application to the `src/app` subfolder, set the *`path`* to `path=src/app`.

The system generates a `checksum.txt` file in the Git repository to determine if any application files have been changed outside of Studio. When the checksum value from the file matches the current checksum value, the integration skips the validation and sanitization process. When the checksum values do not match, the integration validates and sanitizes the application files as part of the Source Control operation. The sanitization process:

- Creates upgrade log entries for each sanitization action taken.
- Removes unsupported folders and files from the repository.
- Aborts all Source Control operations when a system application file fails XML schema validation. For example, if a database dictionary record fails XML schema validation, the system aborts all operations.
- Skips the current Source Control operation when a non-system application file fails XML schema validation.

The Source Control integration sanitizes only content within the application path listed in the `sn_source_control.properties` file. Repository content outside the application path is ignored.

MID Server support

Use an existing MID Server to connect to a Source Control repository. Linking or importing an application through a MID Server enables access to repositories behind a firewall.

Configure MID server for source control integration

Configure a MID server for Source Control Integration to enable communication and the movement of data between a ServiceNow instance and external applications, data sources, and services.

- Add "bundle" extension to `glide.attachment.extensions` properties.
- If the MID Servers must go through a proxy to access the remote git repository, do as follows:
  - Add the following line to `agent\conf\wrapper-override.conf` file:
  - `wrapper.java.additionial.3=-Dhttps.proxyHost=<proxyHost>`
  - `wrapper.java.additionial.4=-Dhttps.proxyPort=<proxyPort>`
  - Restart the MID
  - Add a new entry in "MID Security Policy":
  - Name: <proxy host name>
  - Check "Active" only

Denoise source control commits

Skip unloading into XML files of noisy update fields for any metadata record in source control.

Legacy - Production deployment tips

When you develop customizations to applications on the ServiceNow® platform, you deploy them via the application repository to a production instance. This topic examines and provides cautions for the tradeoffs between installing an application from the application repository versus Git repository with source control.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Overview

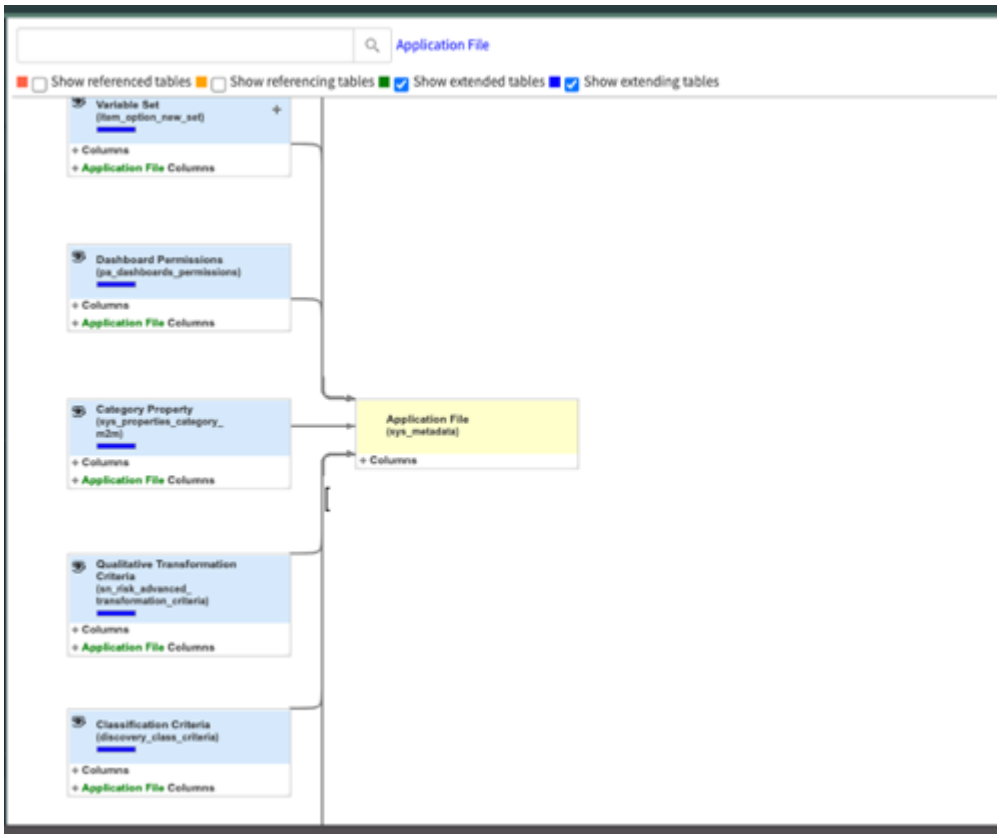
Technically, you can still "deploy" an application from a Git repository to a production instance using source control. This can have unintended consequences.

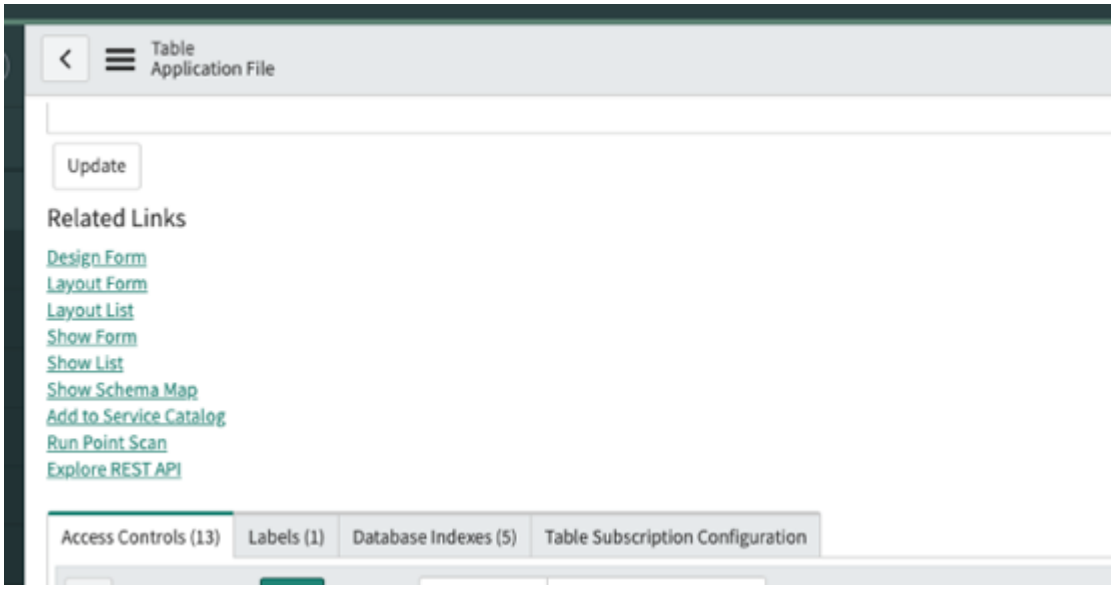
Glossary of terms

Term	Definition
Metadata or application files	The sys_metadata records that define configuration in ServiceNow and are packaged in an application. These records alter the behavior of the instance but do not contain data such as incident or CMDB records. (See Note below)
Scoped applications	ServiceNow applications that restrict allowing only updates and operations within the boundary of the scope. This mechanism is used for most new development.
Global applications	Global applications are developed in the legacy global scope. Work is often done in this scope to customize existing ServiceNow applications such as IT Service Management (ITSM).
Application repository	Applications are typically published here for deployment in production instances. Although the application repository has separate entitlement rules, it operates similarly to the ServiceNow Store.
ServiceNow Store	Repository for third-party (vendor) applications as well as ServiceNow published applications. Most customers do not publish to the Store, but often install applications from it.
Update sets	Standard method of packaging customizations for deployment in each successive instance. They contain the incremental collection of insertions, updates, and deletions.

Term	Definition
Legacy - Delta loading	The most efficient method of loading because it changes only from source control rather than earlier uninstall/reinstall methods.
Schema	Definition of tables and columns in the tables.
Rollback	Administrators can roll back the last installation of a selected application. A rollback removes all code, table, and file updates from the initial installation.

Note:
The **sys_metadata** table is the parent table of all application files in the ServiceNow platform using the table inheritance model. You can view summary information for metadata by visiting the parent table or tables that extend directly or indirectly as indicated by the Extends table(super_class) field on the Table(sys_db_object record). You can also see the whole schema by visiting the Table(sys_db_object) form for the **sys_metadata** table and selecting the **Show Schema Map** related link at the bottom of the form. The schema is large and so takes some time to render.





Installation location

When you install source control, it facilitates the ongoing development of a custom application. Therefore, the application is managed as an "In development" application in the Custom Application [sys_app] table rather than as an "Installed" application in the Store Application [sys_store_app] table. Both tables are extensions of sys_scope so they both provide the same protections and restrictions as the scope. So when you search for the installation of a source control deployed application, refer to the System Application [sys_app] table and the **in development** section of the Application Manager page.

You cannot have a sys_app record on the instance while deploying that same application from the ServiceNow Store or application repository. The two deployment models are mutually exclusive. If at any point the deployment model changes, the sys_app record must be converted to a sys_store_app record first. You can contact ServiceNow Support for help with performing that operation.

Delta loading

Prior to the ServiceNow Paris release, application installation from source control always removed and reinstalled the entire application when triggered, including the Apply Remote Changes function. With Legacy - Delta loading, now only the changes update, simplifying the process considerably.

The Delta loading process loads the changes from source control incrementally. When you apply remote changes, you don't drop existing tables or columns unless they were removed from the repository. This preserves the data for tables and fields that continued to be present.

Note:
The **glide.source_control.allow_delta_loading_in_scopedapp** property allows you to disable Delta loading in Paris; however, this will revert to the more destructive behavior of removing and reinstalling the application. Global applications in Paris always use Delta loading.

Below is a table of the different expected outcomes in an instance using Delta loading.

Application type	Install source	Schema present in package	Schema contains data	Claim by another app (Global)	Expected outcome for data and schema
Scoped	Application repository or Store	Yes	Yes/No	N/A	Preserved
Scoped	Application repository or Store	No	Yes/No	N/A	Preserved
Scoped	Source control	Yes	Yes/No	N/A	Preserved
Scoped	Source control	No	Yes/No	N/A	Removed
Global	Source control, Application repository, or Store	Yes	Yes/No	Yes/No	Preserved
		No	Yes	No	Preserved (1)
		No	No	Yes	Preserved (2)
	Source control	No	No	No	Removed (3)
	Application repository	No	No	No	Preserved

Note:

- While the database schema and the data are preserved, they will be moved into the default global application.
- While the database schema and the data are preserved, they will be moved into the global application which previously held claim to these files if installed. Otherwise, they will move into default global application.
- Applicable only on custom columns with **u_ prefix**. ServiceNow platform-authored columns are not dropped.

When switching branches in source control for a scoped application, use extreme caution in a production environment. If the target branch is missing schema elements found in the current branch, the related schema is dropped, destroying any data it contains. (Global applications do not drop schema when data is present.)

Just as with update sets, only a subset of the incremental changes needs to be applied with Delta loading. Unlike update sets, the application package represents the complete application. Files that are absent from the new package are deleted. This can alter functionality and delete data. Update sets and applications upgraded from the application repository or ServiceNow Store must have an explicit **DELETE** payload to remove a file or drop a schema.

If application files are being generated dynamically in any fashion, the next install/apply remote changes the operation of an application deletes those records. They are considered absent from the incoming application package. If you stash local changes, the application files may be recoverable by a stash commit, but if data is lost as a result of the changes, the data is not recovered.

Note:
Removing or suppressing sys_update_xml records prevents them from being removed by Delta loading; however, this action can have other severe or undesirable results.

Direct edits to the repository, especially to remove files, can have significant ramifications, including loss of data and cascading deletes. Perform this action with care.

Legacy - Author elective and customer updates

When you install an application from the application repository or ServiceNow® store, you can set a series of properties to define the behavior of delete and choice processing. These kinds of choices are called an "author-elective" feature.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Overview

You can find details on these properties in the Skipped records that occur during application installation topic. With these properties, you can opt in and out of deletes and choice updates depending on whether you are using your own or a third-party application.

When you install from source control, however, these records do not skip, except when a global application file is claimed by a different global application. Other than **com.glide.apps.include_my_deletes** and **com.glide.apps.include_global_deletes** that disable the processing of the author_elective_update folder altogether, those properties are not effective for source installed apps.

Note:
An “absent” file detected in Delta loading for source control is vastly different than a Delete payload housed inside the author_elective_update folder. Author_elective_update properties do not prevent Delta loading in source control from deleting the file.

Similarly, update sets protect customizations that you make in an instance against incoming changes that force a preview decision. Before you commit an update set, a preview must be run to attempt to detect collisions. You must address all preview problems before committing the changes. Source control may ask you to stash a local change, but the outcome of the installation is to load what is present in the source even if a change had been made locally.

Loading what is present in the source is challenging when properties must have different versions based on the target of the installation. For example, it’s difficult to resolve when a property containing an integration URL differs based on instance production role. The **is_private** flag is effective with a source control installation and does not overwrite the property if set, mitigating this concern.

Legacy - Roll back, back out, and uninstall

The application installation from the application repository is recorded for rollback, which means as an administrator, you can roll back the last installation of a selected application. When you roll back an application, you remove all code, table, and file updates from the initial installation.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Source control installations are not recorded for rollback, which means that the rollback feature to undo an application repository, store installation, or an in-family upgrade is not available for source control installations. They also cannot be uninstalled in the same sense that ServiceNow® Store applications can be (that is, with the option to retain tables and columns). They can be deleted by deleting the **sys_app** record. However, for scoped applications, this destroys the underlying schema and its data.

You cannot delete global applications until all application files are moved to another global application. Deleting a **sys_app** record for an application also creates **sys_update_xml** records with **DELETE** payloads. These payloads can generate skips if the same application is then installed via the application repository or ServiceNow Store.

To avoid these skips, the **sys_update_xml** records must be manually deleted before the application is installed from the application repository. Installing from source control also does not have the Back out option that update sets contain to remove a subset of new changes. That means that recoverability in this model is limited to installing a corrected version (older or newer) of the application on top of the current version. This action restores only metadata or configuration. Data lost as a result of a poor installation must be recovered from a database restore.

Legacy - Upgrade history

Upgrade history records and history line dispositions are generated as part of the source control installation providing a record of the install.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

The source control installation is more aggressive and generally doesn't skip unless there is a global claim or **is_private protection** on a property. Global applications also protect columns containing data, or those from the ServiceNow base installation, from being removed.

Legacy - Development considerations

When you are developing code, consider some of these suggestions for the most efficient performance.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Production instances shouldn't publish to the Git repository

To protect the integrity of production, you shouldn't push changes to publish to the Git repository from production even though technically you can open and commit changes in the application in ServiceNow® Studio. The "Can Edit Application in Studio" option can be disabled in production on the **sys_app** record. But it resets at the next source code operation that triggers an update (that is, when you apply remote changes or switch branches).

Dependencies are not installed when installing an application from the Git repository

Source-controlled applications do not automatically install or upgrade if they are listed as the dependency of your application. Instead, the customer must install or upgrade the source-controlled application on its own. The customer is also responsible for installing and upgrading the applications in the correct order.

Tight control on source control privileges in production

The source code operations are generally available to those with development privileges in the instance. Since production environments shouldn't have ongoing development, be sure to tightly control admin and delegated development privileges to avoid data loss and other serious consequences.

Legacy - Available source control operations

The source control integration primarily supports operations from Studio, but can also support some operations directly from the GIT repository.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Available source control operations

Operation	Description	Available from
Import from Source Control	Imports an application from the repository to the local instance.	Studio
Link to Source Control	Allows developers to manage application changes from a GIT repository.	Studio
Edit Repository Configuration	Updates the GIT repository user credentials.	Studio
Apply Remote Changes	Updates the local version of the application to match the repository version.	Studio

Available source control operations (continued)

Operation	Description	Available from
Commit Changes	Updates the repository version of the application to match the local version.	Studio
Stash Local Changes	Removes and saves local changes for later work.	Studio
Switch Branch	Updates the local version of the application to match the repository branch version.	Studio
Create Branch	Creates a branch in the repository to save a different version of the application.	• Studio • GIT repository
Create Tag	Creates a tag in the repository to link to a particular application version.	• Studio • GIT repository
Manage Stashes	Allows developers to apply or delete stashed changes.	Studio
Create repository	Creates a repository to store application changes	GIT repository
Create credentials	Creates credentials to the repository.	GIT repository
Grant access to repository	Provides read and write access to the repository tied to a specific set of credentials.	GIT repository
Source Control repository sync	Allows admins to apply remote changes from the Source Control repository, to resynchronize with the instance. **Note:** This operation is only available if Delta loading is being used for the repository. See Legacy - Delta loading.	Repository Configuration form

Legacy - Import application or application-customization from source control

Import an application or application-customization from a source control repository to continue developing it on this instance.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

- Role required: admin or source_control
  - Restrict permissions on the access token to allow read and write access to the Git repository.
  - The repository user credentials must grant read and write access.

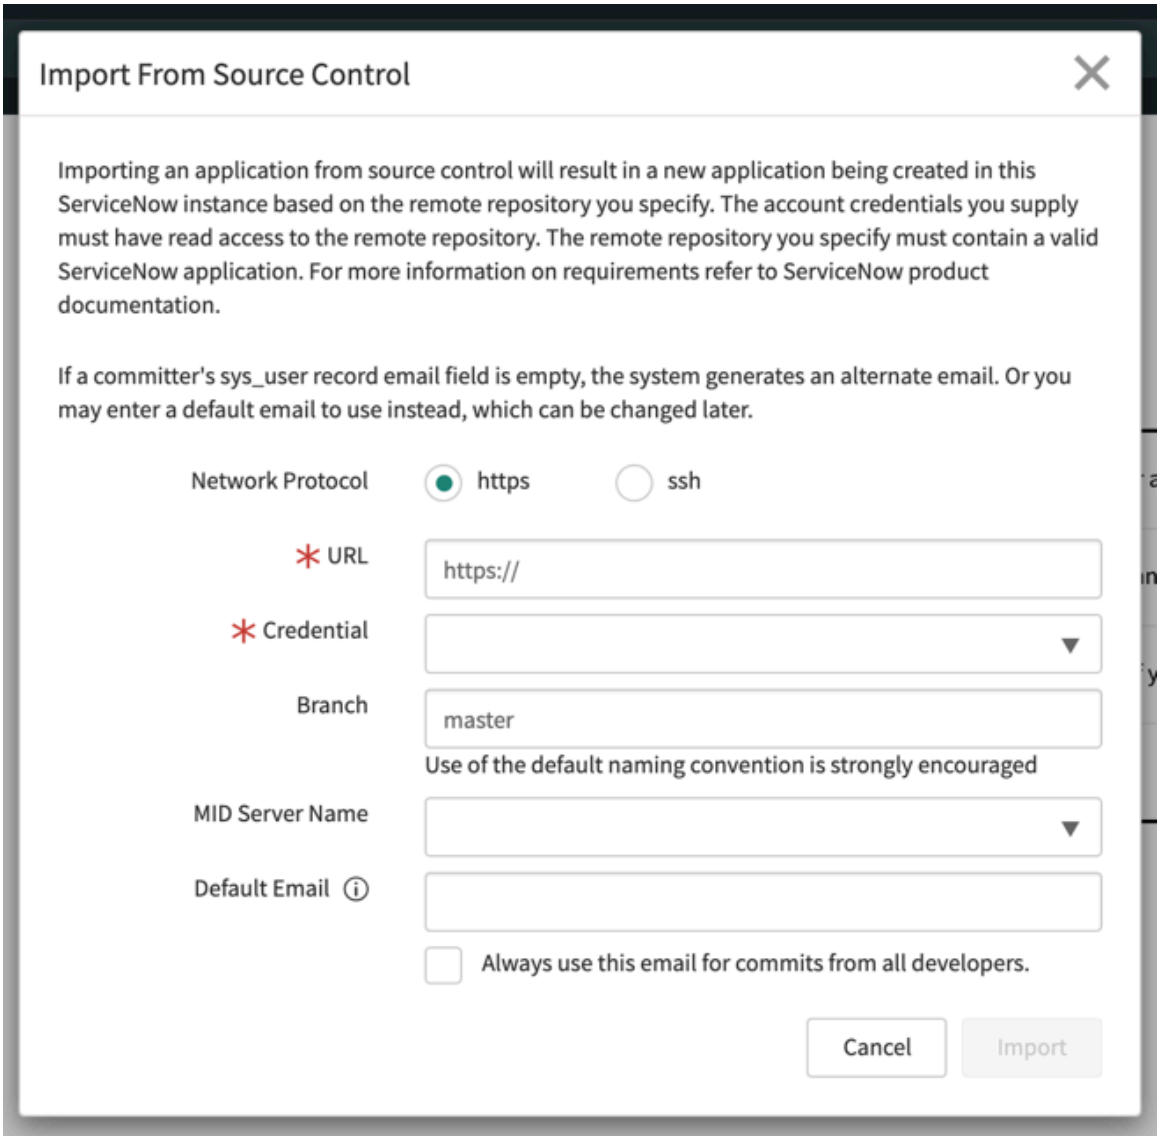
  For more information, see Link an application or application-customization to source control.
- Verify that the non-production instance has network access to the Git repository.
- Verify that the repository contains a valid application.
- Ensure that users add the email address to their respective Users Table (ServiceNow sys_user) record that they use in their commits to the Git repository.
- Learn more about application-customizations Managing application-customizations.

About this task

The source control integration does not support importing an application on a production instance. Instead install applications on a production instance from the application repository, an update set, or the ServiceNow Store.

Procedure

1. Navigate to **All** > **System Applications** > **Studio**.
   The system displays the Welcome to Studio page.
2. Click **Open Studio** > **Go**.
   The system opens Studio and the Switch Applications window.
3. Click **Import from Source Control**.
   Studio displays the Import from Source Control fields.



4. Enter the following field values.

Import from source control fields

Field	Description
Network protocol	Https or ssh credential type that enables secure channel data exchange.
URL	The URL to the Git repository where the application files reside. **Note:** If the Git repo URL for SSH provided by your Git server does not work, check with your Git server owner or provider for the correct URL. There may be additional specifications such as scheme protocol prefixes, port numbers, and so on, required for your Git repo URL to function.
Credential	Select the credential for your Git repository. (See Getting started with Credentials .)

Field	Description
	Note: If you select the ssh network protocol, enter a valid credential of the SSH Private Key type. If you select the https protocol, enter a valid credential of the Basic Auth Credentials type.
Branch	The repository branch to work on within the application. **Note:** The default branch is named after your instance. If you do not choose a name, the branch defaults to **master**.
MID Server Name	Select an existing MID Server to link to a Git repository stored behind your corporate firewall. **Note:** Use a separate MID Server to prevent conflicts with Discovery activities.
Default email	The committer email address is defined by the sys_user record if available. But if a committer's sys_user record email field is empty, the system generates an alternate email (username@instancename.service-now.com). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.

Note:
All application developers on the instance share the credential used to link a Git repository to an application.

5. Click **Import**.
   The system compares the checksum in the `checksum.txt` file to current checksum. When the checksum values match, the integration skips validation and imports the application. When the checksum values do not match, the integration first validates and sanitizes the application files before importing them.
6. Click **Select Application**.
   Studio displays the application as a new choice in the Switch Applications window.

What to do next

- Review the upgrade logs for any sanitization applied to application files during the import.
- Select the imported application to edit it.

Getting started with credentials

Legacy - Link an application or application-customization to source control

Linking an application or application-customization to source control allows application developers to manage changes from a Git repository.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

- Role required: admin
- Learn more about Managing application-customizations.
- Create a dedicated Git repository for the application. For increased security, enable multi-factor authentication for the Git repository.
- Generate an access token that the source control integration can use instead of a password and multi-factor authentication passkey. Search for personal access token on GitHub or GitLab.
- Restrict permissions on the access token to allow read and write access to the Git repository.
- Verify that the non-production instance has network access to the Git repository.
- Ensure that users add the email address to their respective Users Table (ServiceNow sys_user) records that they use in their commits to the Git repository.
- Learn more: Legacy - Migrate completed update set history to Source Control

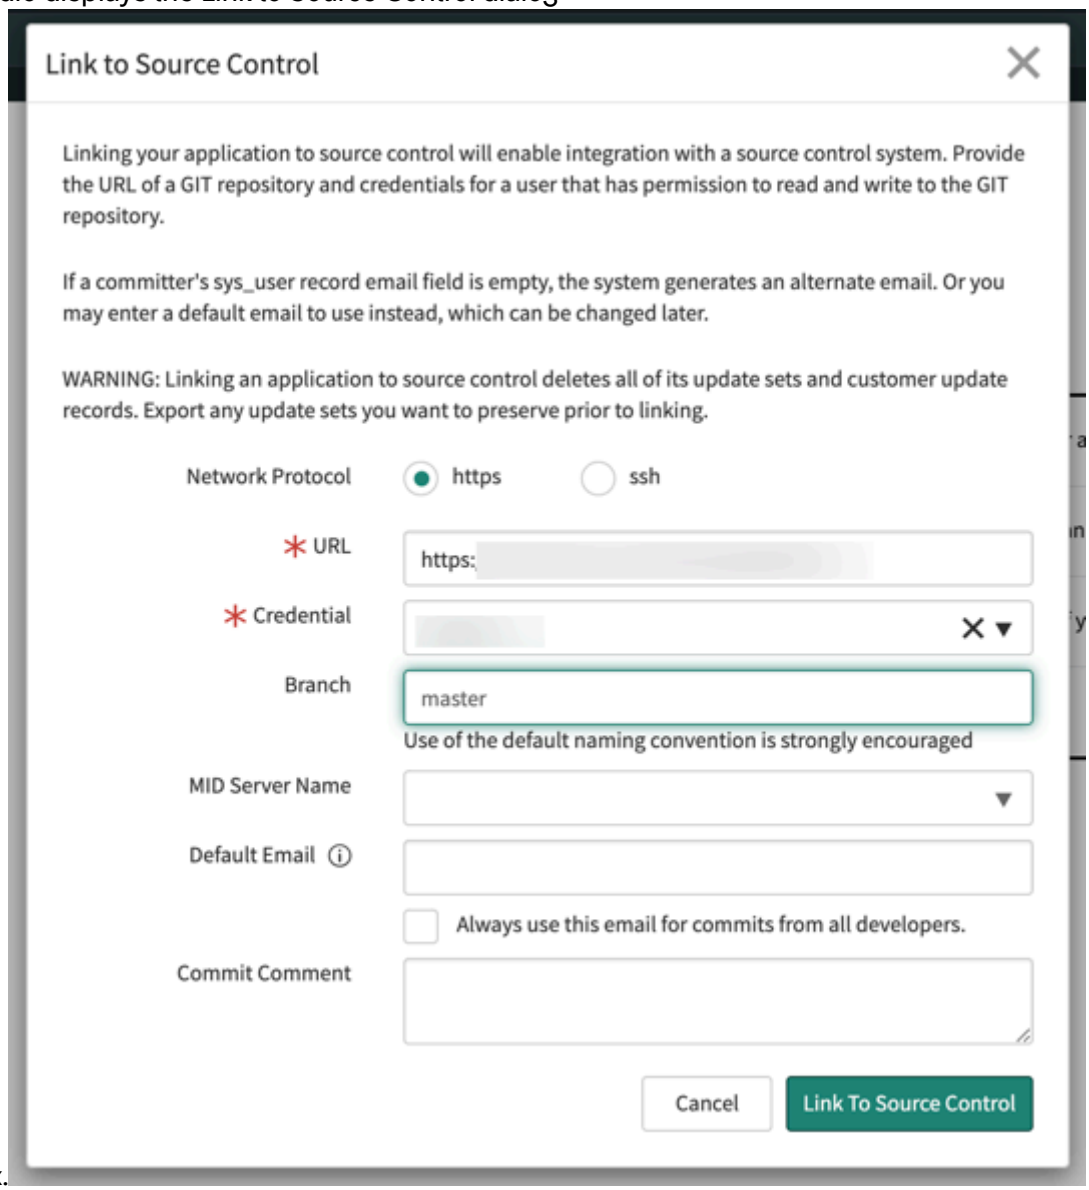
About this task

The source control integration does not support linking to an application or customization on a production instance. Instead, install applications on a production instance from the application repository, an update set, or the ServiceNow Store.

Procedure

1. Open the application you want to link to source control in Studio.
2. Navigate to **Source Control** > **Link to Source Control**.

Studio displays the Link to Source Control dialog box.



3. Enter the connection details for the Git repository.

Source control connection details

Field	Description
Network protocol	HTTPS or SSH credential type that enables secure channel data exchange.
URL	The URL to the Git repository where you want to save application files. For SSH protocol, use command to generate private key `ssh-keygen -t rsa -m PEM -b 4096 -C "email@address"`. **Note:** If the Git repo URL for SSH provided by your Git server does not work, check with your Git server owner or provider for the correct URL. There may be additional specifications such as scheme protocol prefixes, port numbers, and so on, required for your Git repo URL to function.

Field	Description
Credential	The credential to be used with the selected protocol. See Getting started with Credentials to learn more about creating credentials. **Note:** If you select the SSH network protocol, enter a valid credential of the SSH private key type. If you select the https protocol, enter a valid credential of the Basic Auth credentials type.
Branch	The repository branch to work on within the application.
MID Server Name	The name of the existing MID Server to link through. **Note:** Use a separate MID Server to prevent conflicts with Discovery activities. Be sure that the MID server user can create files to the sys_attachment table and that the table can accept files of the "bundle" type. Linking or importing an application through a MID Server enables access to repositories behind a firewall. See the Using MID Server with source control and MID Server topics to learn more
Default email	The committer email address is defined by the sys_user record if available. But if a committer's sys_user record email field is empty, the system generates an alternate email (username@instancename.service-now.com). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.
Commit Comment	An optional description of the repository or application.

Note:
All application developers on the instance share a single set of repository credentials.

4. Click **Submit**.
   The system validates the connection and user credentials and displays a success message.

   All application developers on the instance can use the linked Git repository to manage changes.

Getting started with credentials

Legacy - Using MID Server with source control

The ServiceNow® MID Server enables communication and the movement of data between a ServiceNow instance and external applications, data sources, and services.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

How bundle files work with MID Server

The **.bundle** file helps source control function with a MID Server. A bundle file is the way Git packages a local repository in a single file. This makes sharing or moving the repository simpler and more streamlined. The file is then sent to the MID Server, which passes it on to the remote repository.

The `outgoing.bundle` (commit operations) and `incoming.bundle` (apply remote changes) are attached to the MID Server attachment table [ecc_agent_attachment] for any request that goes to the MID Server. The `outgoing.bundle` is created on the instance while the `incoming.bundle` is created on the MID Server.

After an operation completes successfully, the bundle file is "promoted" into a `golden.bundle` that is attached to the Repository configuration table [sys_repo_config]. It's used to initialize the repository on a node that has not performed any Source Control operations yet.

The Auto Flush tool [sys_auto_flush] is a "table cleaner" that removes any `ecc_agent_attachment` record older than 30 days. This action removes the corresponding attachment as well.

The bundle files are kept on the MID Server and then saved to the Import directory on the MID Server.

On the MID Server, the bundle file is saved in the Import folder. This folder is under the user directory defined by the system property (user.dir), which users can configure. The bundle file is removed as part of the system flushing at the end of every operation.

Working with the MID Server

Note:
Source control operations can take more time for larger applications when using an MID server, as the entire app is bundled after an export and is dependant on the size of the app.

- Avoid conflicts with Discovery and create files for the system attachment [sys_attachment] table: MID Server
- Learn about system properties restrictions: Configure attachment system properties

Legacy - Migrate completed update set history to Source Control

When linking to Source Control, this feature allows application developers the choice of migrating the information in completed update sets to Source Control history.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Before migrating

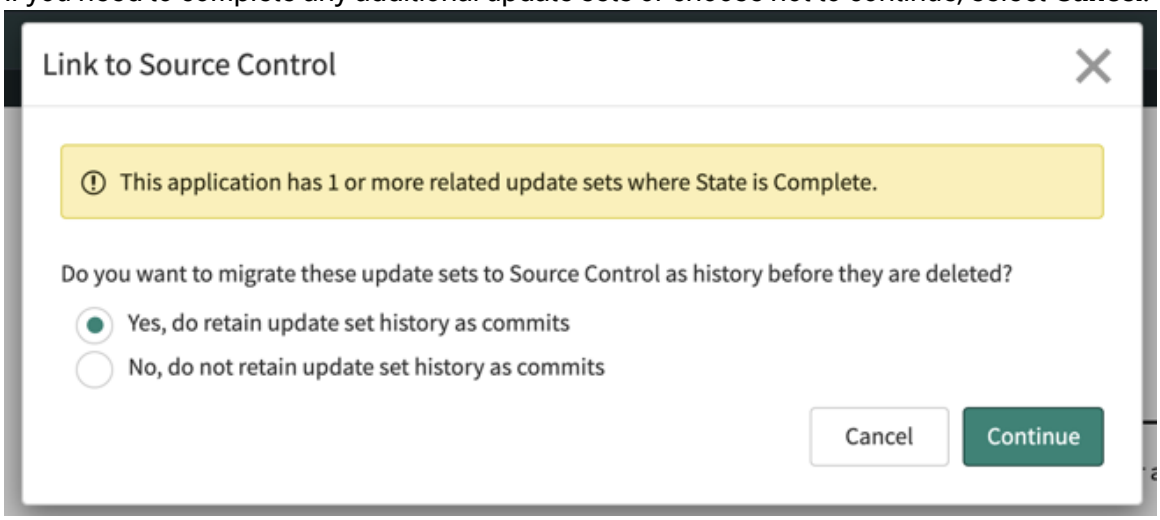
Make sure that you have fulfilled these criteria before attempting to migrate your update sets:

- Role required: admin
- Read the Legacy - Link an application or application-customization to source control topic
- Complete any update sets for your application that you want to export as Source Control history.
- Export the completed update set if you want to preserve it.

When you link an application to Source Control, the update sets and customer update records are deleted. After you link to Source Control, if the application has any completed update sets, you will be asked to make a choice in the dialog box below.

- If you select "Yes, do retain update set history as commits", the update set history is preserved as Source Control commits.
- If you select "No, do not retain update set history as commits," they are not preserved as commits.

Regardless of which option you select, if you select **Continue**, the **Link to Source Control** operation starts, and all completed update sets and all Customer Update records are deleted. If you need to complete any additional update sets or choose not to continue, select **Cancel**.



For every completed update set with updates to the application that you are linking to Source Control, commits are generated automatically by the system based on the sys_update_xml records in the update sets. The commits are ordered by the **sys_recorded_at** timestamp. For Global applications: Any **sys_update_xml** records that belong to the application and are part of a completed Global update set are captured as historical commits.

When the Link to Source Control operation is complete, the most recent commit is the current state of your application in its entirety. You can view historical commits in your Git repository or by clicking the Source Control menu option and selecting **View History**. Updates are separated into multiple commits:

- If there are updates for a file that are out of order between different update sets.
- If an update set contains multiple update records for a single file.

The commits for an update set are split into multiple commits ([Historical Commit 1], [Historical Commit 2]...) to represent each update. This is done so that each file has an ordered history of updates.

Warning:
Any commit prefixed by [Historical Commit] is generated solely to display its history. Do not attempt to check out these commits in the development process as they do not necessarily represent a stable snapshot of the application.

The **author_elective_update** folder is not created until the initial commit. That means that in the initial commit you might see files such as **sys_choice** files being renamed and moved from the update folder to the **author_elective_update** folder. Any files that are deleted from update sets in historical commits are deleted, and not moved to the **author_elective_update** folder as they would be for actual commits. During the initial commit, DELETE payloads are also created for any DELETE sys_update_xml records that were deleted as part of completed update sets.

Example commit message:

```
[Historical Commit 1] <Name of update set that this commit
 belongs to>
Description: <Description of update set that this commit belongs
 to>
Update Set was completed on / installed on <date>
Update Set was completed by <sys_user user_name > <sys_user
 email>
{
```

Additional values from sys_update_set record (see **Customization**section below)

```
}
{
```

Batch update set information (See the **Batch update sets** section below) }

Batch update sets

If an update set is part of a batch update set, that information is appended to the commit message in the following format, with the highest number being the Batch Base:

```
{
"1": {
"parent": "<name of parent update set>",
"description": "<description of parent update set>"
},
"2": {
"parent": " <name of parent 1's parent update set> ",
"description": " <description of parent 1's parent update set> "
}
}
```

Customization

You can add additional fields to include in the commit message by adding a **glide.source_control.historical_commit_fields** property. The value is a comma-separated list of fields the user wants to include from sys_update_set XML fields. Spaces and invalid or misspelled field names are ignored. This property is used for all applications that are linked to Source Control from the instance if the committer chooses to retain update set history.

Note:
If the value of a field references another table or sys_id, only the value of the field is added. For example: sys_id for a user instead of the name of the user.

XML example

```
▼<xml>
  ▼<sys_update_set>
      <application
      display_value="test_app2">a388a8735be720107c7899b8b681c7d8</application>
      <base_update_set/>
      <completed_by display_value="System
      Administrator">6816f79cc0a8016401c5a33be04be441</completed_by>
      <completed_on>2021-04-22 22:14:38</completed_on>
      <description>added a script include</description>
      <install_date/>
      <installed_from/>
      <is_default>false</is_default>
      <merged_to/>
      <name>update set 1</name>
      <origin_sys_id/>
      <parent/>
      <release_date/>
      <remote_sys_id/>
      <state>complete</state>
      <sys_created_by>admin</sys_created_by>
      <sys_created_on>2021-04-22 22:13:45</sys_created_on>
      <sys_id>6961f0f75be720107c7899b8b681c71f</sys_id>
      <sys_mod_count>1</sys_mod_count>
      <sys_updated_by>admin</sys_updated_by>
      <sys_updated_on>2021-04-22 22:14:38</sys_updated_on>
    </sys_update_set>
  </xml>
```

Value of the property

Result in commit message

[Historical Commit 1] update set 1

```
Description: added a script include
Update Set was completed on 2021-04-22 18:56:06
Update Set was completed by admin admin@example.com
{
  "sys_id": "5d278db35b2320107c7899b8b681c73d",
  "is_default": "false",
  "sys_created_by": "admin"
}
```

Legacy - Edit a Git repository configuration

You can edit a Git repository to change the network protocol selection, credentials or other field entries.

Before you begin

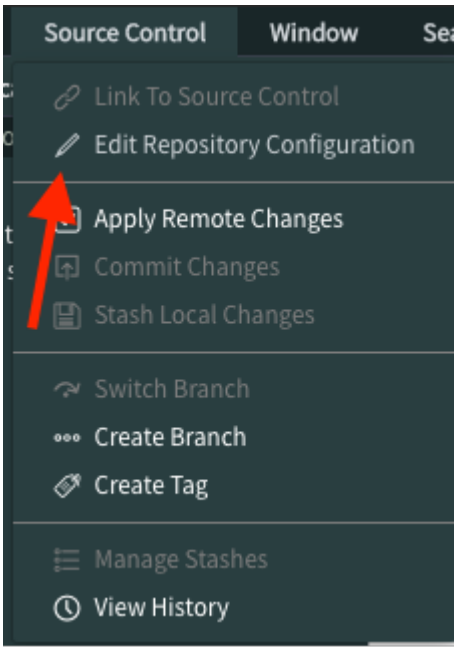
Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

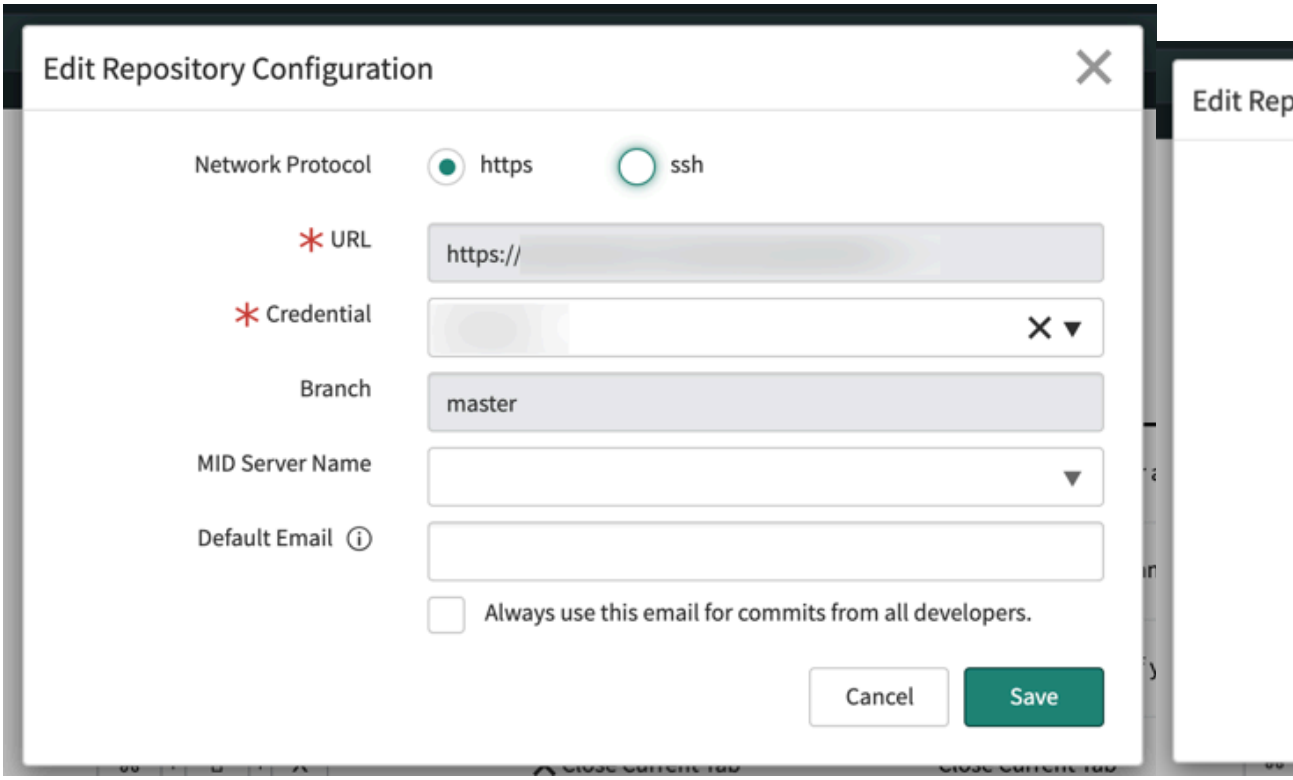
Role required: admin

Procedure

1. In Studio, select **Edit Repository Configuration**.



2. Choose **https** or **ssh** Network protocol and enter the URL address of your repository.



3. Change your credential or MID Server name if you wish.

   Note:
   If you have no MID server name, you can select a new one from the drop-down list. If you choose a new MID server, Legacy - Apply remote changes in the Source Control menu before making any further Source Control operations to avoid errors.

   For the default email field, the committer email address is defined by the sys_user record if available. But if a committer's sys_user record email field is empty, the system generates an alternate email (username@instancename.service-now.com). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.

4. Click **Save**.

Legacy - Apply remote changes

Application developers can pull changes from a linked GIT repository to apply remote changes to the local instance.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

- Role required: admin
- Legacy - Link an application or application-customization to source control

Procedure

Navigate to **All** > **Source Control** > **Apply Remote Changes**.
The following operations occur:

- The system fetches the most recent changes from the remote repository.
- The system applies the remote changes to the instance.
- The system identifies any change conflicts requiring resolution.

If there are conflicts, the system displays the **Resolve Conflicts** window.

Delta loading is enabled by default in sys properties so your data isn't removed. You can disable this feature if you want data automatically deleted.

Note:
After a Source Control **Apply Remote Changes** or other operation, you may encounter the error message: `Skipped loading file *.xml, cannot parse the xml document, found git merge conflicts tokens`. Make sure that the files in your application do not include values that the Git repository interprets as merge conflict tokens. While these aren't actual conflicts, you should remove them anyway. Examples of these values are:

```
>>>>>>>
```

```
=======
```

```
<<<<<<<
```

What to do next
Resolve any change conflicts.

Legacy - Commit changes

Application developers can commit their changes on the instance to the linked Git repository. You can either select a few changes to commit, or commit all changes on the instance at once.

Before you begin

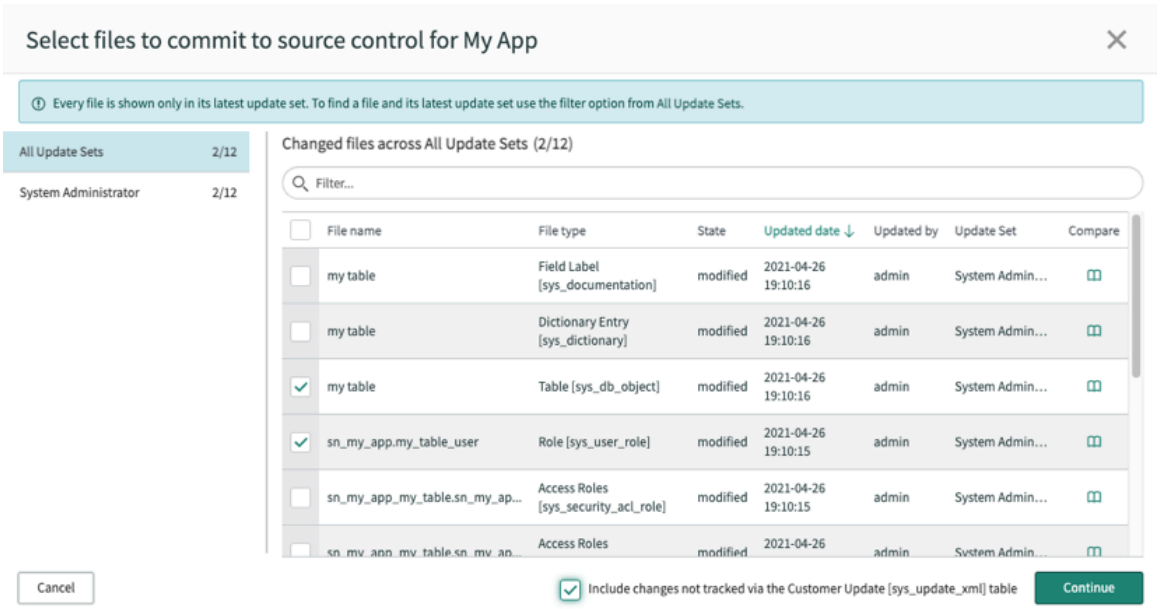
Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

- Role required: admin
- Legacy - Link an application or application-customization to source control

Procedure

1. Navigate to **All** > **Source Control** > **Commit Changes**.
   The system displays the **Select files to commit to source control** window. The file changes from all the updates sets display. By default, the file changes from the current update set display.



2. Select the file changes you wish to commit.
3. To include untracked changes, select the **Include changes not tracked via the Customer Update [sys_update_xml] table** check box.
   - The default for this check box is set via the **glide.sourcecontrol.default_commit_mode** property.
     - Property can be set to **include_untracked** or **exclude_untracked**.
     - The **include_untracked** mode commits the updates to the application that do not generate sys_update_xml records, as well as any user-selected updates.
     - The **exclude_untracked** mode commits only updates selected by the user in the **Select files to commit to source control** dialog.
   - The base system setting for the property is **exclude_untracked**.
   - Prior to the ServiceNow Rome release, only the **include_untracked** mode is used.

   To hide the check box and use the value of the **glide.sourcecontrol.default_commit_mode** property, create the **sn_devstudio.vcs.allow_commit_mode_selection** property and set it to false. Checking this check box may incur a performance penalty.

Note:

Commits always occur in **include_untracked** mode in the following cases:

- Linking to Source Control for the first time. (To learn more, see Legacy - Link an application or application-customization to source control.)
- Publishing an application that's linked to Source Control from ServiceNow Studio. (To learn more, see Legacy - Publish an application from ServiceNow Studio when linked to Source Control.)
- Selective commit mode is disabled.

4. Click **Continue**.
5. In **Commit comment**, enter a comment for the changes.
6. Click **Commit Files**.
   The following operations occur:
   - The system identifies all local changes.
   - The system commits all local changes to the remote repository.

Note:
For list of known files that don't have customer update records and are untracked, see Customer Updates table.

Legacy - Stash local changes

Application developers can remove and save changes locally to apply them later.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

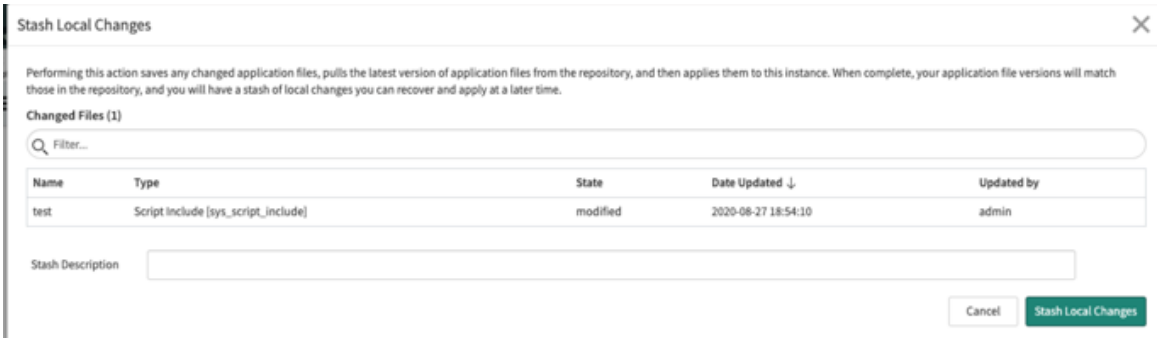
- Role required: admin
- Link an application to source control
- Change one or more application files

About this task

Stashing changes removes them from the current application and saves them for a developer to later apply or delete.

Procedure

1. From Studio, navigate to **Source Control** > **Stash Local Changes**.
   The system displays a list of locally changed files.
2. Enter your description.
3. Click **Stash Local Changes**.
   The system saves the current changes and displays a success message.



Note:
In the San Diego release onward, user information is preserved with each update during stashing. When the stash is applied, each update is restored in the respective user's in-progress local update set.

What to do next

- Close dialog
- Legacy - Manage stashes

To learn more see Getting started with credentials

Legacy - Switch branch

Application developers can switch to a different repository branch to work on another version of the application.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

- Role required: admin
- GIT repository with one or more available branches.

Procedure

1. Navigate to **All** > **Source Control** > **Switch Branch**.
   The system displays the Switch Branch window.
2. **Optional:** If there any local changes on the instance, you can save or discard them.

   Note:
   Use caution when discarding local changes. Since all application developers share repository credentials, there is no way to discard just one set of user changes. Note you cannot later restore discarded changes.

3. Select the branch you want to switch to.

4. Click **Switch Branch**.
   Studio updates the local application to match the branch version from repository.

Legacy - Create branch

Application developers can create a branch to work on a new version of an existing application.

Before you begin

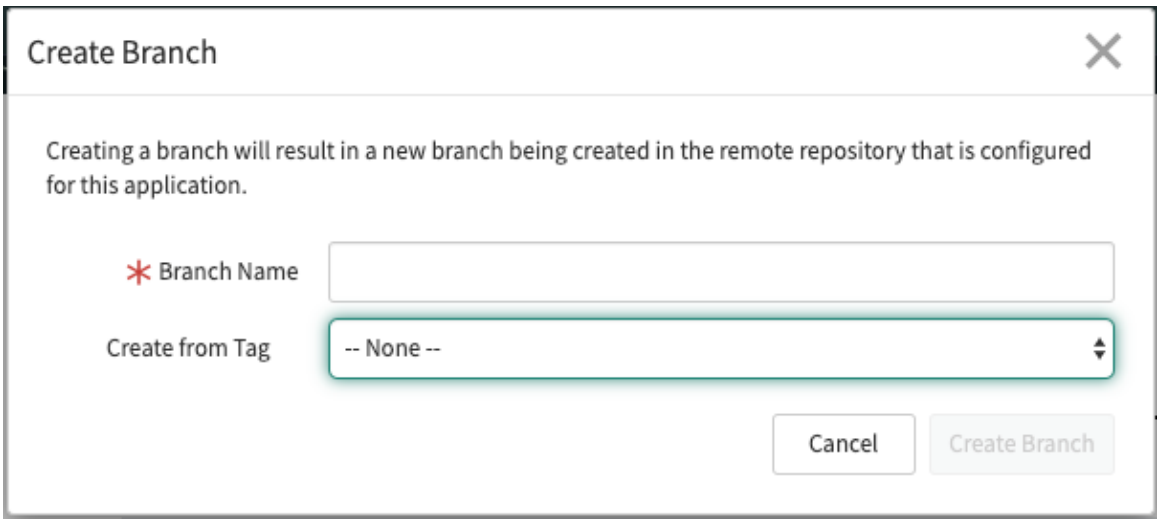
Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

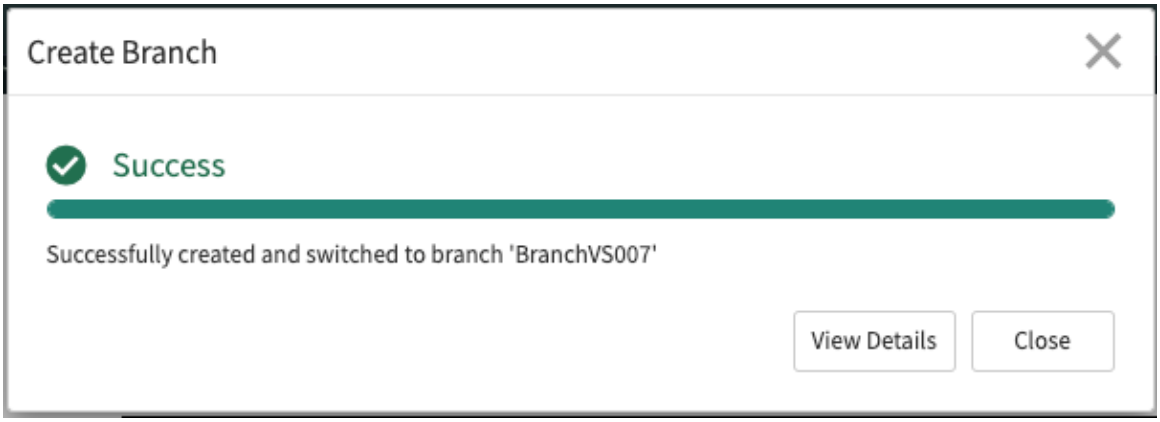
- Role required: admin or sn_group_creator.app_creator
- Legacy - Link an application or application-customization to source control

Procedure

1. Navigate to **All** > **Source Control** > **Create Branch**.
   Studio opens the Create Branch window.



2. Enter the **Branch Name**.
3. **Optional:** To create a branch from a tag, click the **Create from Tag**drop-down list and select an existing tag.
4. Click **Create Branch**.
   Studio creates the branch.



5. Click **Close**.

What to do next
Commit changes to the new branch.

Legacy - Set default branch

Set a default branch when you want to use a branch other than main for new changes or for your main development repository.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

- Role required: admin
- Legacy - Link an application or application-customization to source control

Procedure

1. Follow the steps to Add a system property .
2. Add the **glide.source_control.default_branch_name** property, and specify the default branch name of the GIT source control repository to work from (pull requests, code commits, etc.).

Result
Application developers' work is managed from and saved into the default branch if not otherwise specified. If not changed, this value defaults to sn_instances/<instance_name>.

Legacy - Manage stashes

Application developers can apply or delete stashed changes from Studio.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

- Role required: admin
- Link an application to source control.
- Stash one or more application file changes.

Procedure

1. From Studio, navigate to **Source Control** > **Manage Stashes**.
   The system displays a list of locally stashed changes.
2. Click the action next to the stash you want to manage.

Option	Description
Apply	Commits the stashed changes to the application and checks for conflicts.
Delete	Removes the stashed changes.
View	View the list of stashed changes.

Legacy - Resolve conflicts

Application developers can choose which application file version to use when applying remote or stashed changes.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

- Role required: admin
- Link an application to source control
- Apply a stashed change

About this task

Conflicts occur when there are multiple change versions of the same application file: one set of changes in the remote or stashed version and another set of changes in the local version. Studio requires developers resolve conflicts before applying remote or stashed changes.

Procedure

1. From Studio, apply remote or stash changes.
   If the system identifies a conflict, it displays the Resolve Conflicts dialog.
2. Select how to resolve the conflict.

Option	Description
Select an action	Apply or discard all stashed changes. Go to Step 3.
Manually merge changes	Individually select which changes to apply. Go to Step 6.

3. If you want to apply or discard all stashed changes, select an **Action**.

Option	Description
Take Stashed Changes	Applies the application file version from the stashed changes.
Discard Stashed Changes	Applies the application file version from the most recent pull from the repository.

4. Click **Apply Stashed Changes**.
   The system applies the selected changes.
5. Click **Close Dialog**.
6. If you want to merge the conflicting changes, click **Manually Apply**.
   The system displays a list of version differences by field.
7. Select the field values you want the merged application file to have.
8. Click **Save Merge**.
   The system applies the selected changes.

Legacy - View commit history

Application developers can view the commit history of applications linked to a source control repository.

Before you begin

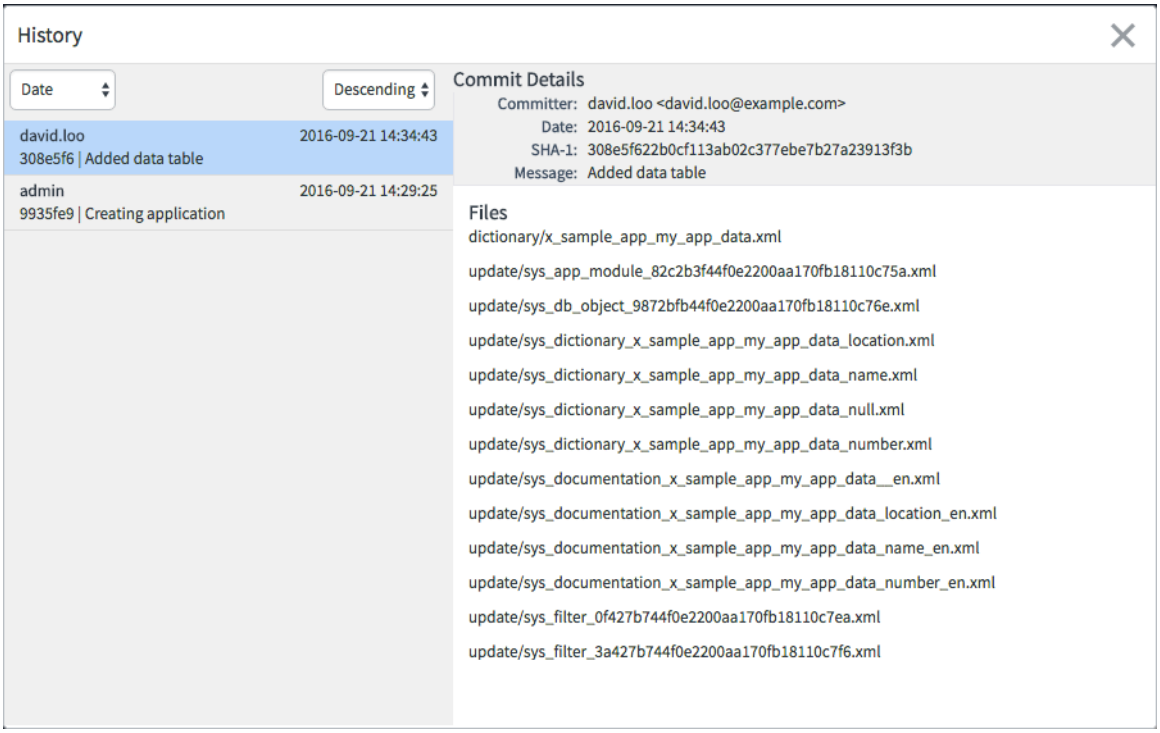
Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

- Role required: admin
- An existing link to a GIT repository

Procedure

1. Navigate to **All** > **Source Control** > **View History**.
   The system displays the History window.



2. Select the commit sort order type.

Option	Description
Date	Sort by commit date.
Committer	Sort by user name.

3. Select the sort order direction.

Option	Description
Descending	Sort dates from the most recent to oldest date. Sort user names reverse-alphabetically from Z to A.
Ascending	Sort dates from the oldest to most recent date. Sort user names alphabetically from A to Z.

   The system sorts commits by the selected sort order.

4. Select a commit.
   The system displays the commit details for the selected commit.
5. Review the commit details.

Commit Details

Field	Description
Committer	The user who committed the change.
Date	The date-time stamp of the commit.
SHA-1	The secure hash value identifying this commit in the repository.
Message	The commit message associated with this commit.
Files	The list of application files changed in this commit.

6. Close the History window.

Legacy - Move application files in a GIT repository

Move application files linked to source control to any folder of the repository. Allow application developers to store supporting content such as automated tests in the same repository as the applications they support.

Before you begin

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

- Legacy - Link an application or application-customization to source control
- Role required: Source control credentials with write access

About this task

Linking an application to source control generates a properties text file called `sn_source_control.properties` at the root level of the repository. The properties file specifies the folder containing the application files. The integration tracks changes to these application files by generating a `checksum.txt` file. When the checksum matches, the integration skips the validation and sanitization process. When the checksum does not match, the integration validates and sanitizes the application files as part of the source control operation. The integration ignores all repository content outside the application path.

Note:
You can set system properties **glide.source_control.checksum_required** to enable optional checksum validations and sanitizations and **glide.source_control.checksum_quick_install** to bypass sanitization steps on checksum matches. See Available system properties for more information.

Procedure

1. Login to source control repository linked to the application.
2. Create the destination folder where you will move the application files.

Example
For example, create the folders `src/app`.

3. Move the folder containing your application files to the destination folder.

Example
For example, move the folder `demo_my_app` to `src/app`.

4. Navigate to the root level of the repository.
5. Open the `sn_source_control.properties` text file in a text editor.
6. For the `path=` property, enter the folder path where you moved the application files.

Example
For example, enter `path=src/app`.

7. Save the properties file.

What to do next
Login to your instance and perform source control operations from Studio.

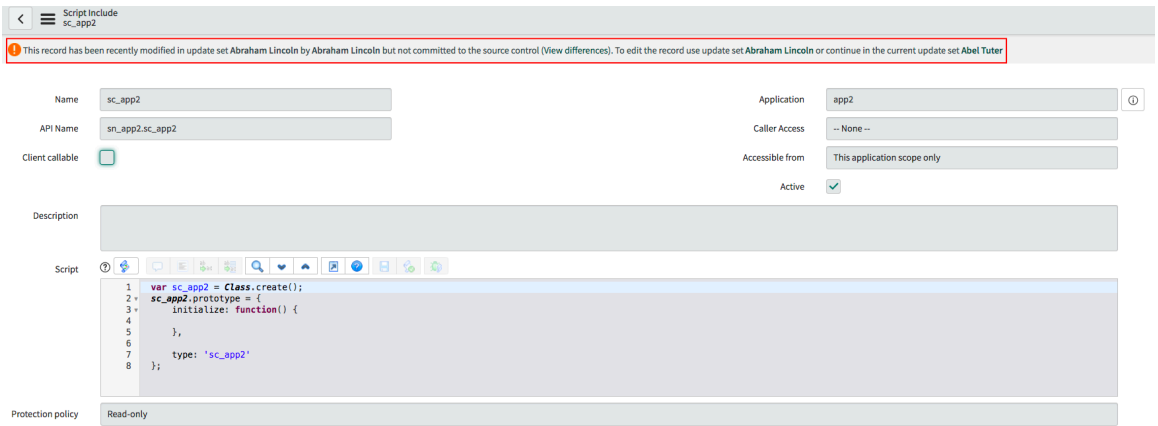
Legacy - Collision avoidance

Avoid modifying an application file across different update sets to ensure seamless experience during the commit process.

> **Important:**
> Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.
>
> Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

When the logged in user opens an application file that was modified in an update set different from the user's current update set for the corresponding application:

- Collision is detected in the application file and a warning message is displayed.
- Logged in user to prompted to choose an update set.
- Read-only protection policy is applied to the application file.



User can make changes to the application file only after selecting the required update set.

Note:
This feature is applicable to only those applications that are linked to GIT.

Enable or disable the collision avoidance feature using the *glide.ui.vcs.collision_avoidance* property in the System Property [sys_properties] table. By default, the feature is enabled. See Available system properties for more information.

When the feature is enabled, users can't work in the default update set of the application. If a user is assigned the default update set, a unique update set is created when the user logs in to the application for the first time after the collision avoidance feature is enabled. This new update set is specific to the user in current application.

Name of the update set specific to the logged in user is, User ID or user name based on the value specified for the *glide.ui.vcs.updateset_identifier* property in the System Property [sys_properties] table. See Available system properties for more information. By default, the update set name is set to user name of the logged in user. However, users can rename the update set.

Legacy - Delta loading

"Delta loading" is an optimized way to load an application from a Git repository.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

When you switch branches and apply remote changes, the Delta loading feature makes sure only changed updates load. Rather than having to perform a full uninstall and reinstall of the application, only the changes update. This speeds and eases the process for developers and does away with the need to use all branches during development. Data stored in tables is retained during these operations, lowering the need to load demo data back into the application after a reinstall or branch change operation.

Benefits of Delta loading

Time savings

Typically, the longest part of an application uninstall or reinstall is dropping and creating tables. Delta loading prevents that from occurring. Depending on the size of the application, not having to drop or create tables can significantly improve an operation's completion time.

Test and demo data retained

Tables that contain test and demo data are no longer deleted, so data is not lost. Developers can save time if they don't need to reimport demo data each time.

Cross-scope dependent references preserved

Items that are cross-scoped and share references are no longer lost when you apply changes. This used to occur when an item in scope B was associated to a parent item in scope A. Applying remote changes on scope A would delete the parent item and reinstall it, breaking the reference between both items, but not restoring that relationship. Delta loading prevents the uninstall, so the reference is not lost.

Recommended practice

Delta loading is enabled by default on all instances starting with the ServiceNow Paris release. The feature is designed to help in application development and receives continued support and upgrades.

Legacy - Denoise your source control commits

As a source control developer, you can merge the Git branches, without getting noise from the fields that are auto-updated by the system.

Important:
Starting with the Xanadu release, the legacy version of ServiceNow Studio is being prepared for future deprecation. It will be hidden and no longer activated on new instances but will continue to be supported. For details on the deprecation process, see the Deprecation Process [KB0867184] article in the Now Support Knowledge Base.

Try building and editing apps in the current version of ServiceNow Studio instead. For more information, see Building applications with ServiceNow Studio.

Overview

In Studio, the Source Control feature packages application files as XML payloads, when they are exported to Git repositories. When a user merges Git branches in a Git repository as part of the application development workflow, the user must resolve any conflicts in the XML files. These conflicts are typically in the fields that are system generated, like sys_updated_by, and represent non-user generated changes. The user must be careful when they are resolving conflicts in these fields because this process might create more noise.

Saver Exempt attribute

Features have been added in Source Control to de-noise the XML payloads, to assist the user in resolving the conflicts when the Git branches are merged.

By default, the system sets the saver_exempt attribute for certain fields in tables whose values are auto-generated by the system. For more information on the saver_exempt attribute, see Dictionary attributes.

The following table contains the saver_exempt values.

Saver Exempt attribute table

Fields	System Tables	saver_exempt values	Outcome expected
• sys_updated_on • sys_updated_by • sys_mod_count	• sys_metadata • sys_choice • sys_package • sys_app_customization • sys_claim • sys_package_dependency_m2m	exempt_vcs_only	The fields are not written to the corresponding XML representation of a record for the table during the packaging of the application for Git commits.
Sys_id	• sys_dictionary • sys_documentation • sys_choice	exempt_vcs_only	The sys_id field is not written in the XML representation of the record of three tables during the packaging

Saver Exempt attribute table (continued)

Fields	System Tables	saver_exempt values	Outcome expected
			of the application for Git commits.
Fields with loader_exempt=true		exempt_always	The fields that have loader_exempt set to **True** are not loaded in the instance. They are not written to the XML representation of the records in the tables during the packaging of the application for Git commits

Disabling the tracking property

An admin can disable the `glide.source_control.disable_tracking_of_update_fields` so that the fields do not display user-generated values.

Note:
The following fields are not written to XML during source control commits, and their values in the instance are loaded from a Git commit. If an admin wants the system to write these fields to XML and use the system-generated values for these fields, the admin can set the property `glide.source_control.disable_tracking_of_update_fields` to **False**.

The following fields are the system-generated values that the admin sees:

- sys_updated_by = commit user
- sys_updated_on = commit time
- sys_mod_count = zero

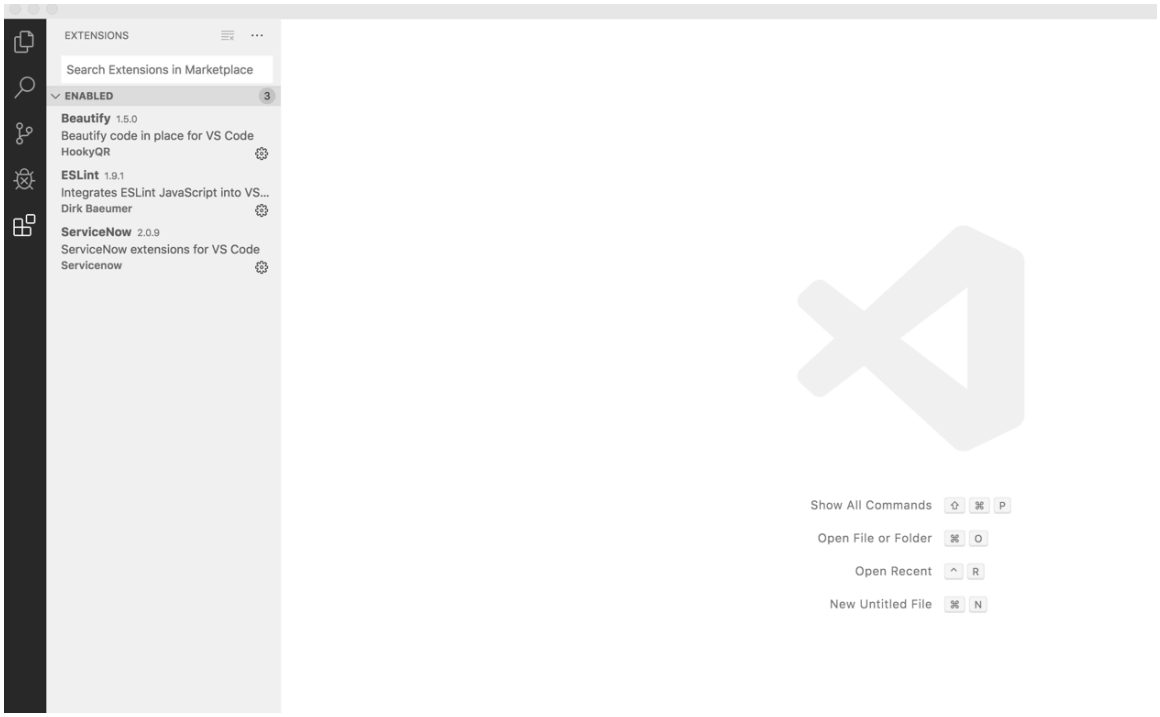
sys_id fields for tables

The sys_id field for tables are saved in the corresponding “dictionary/<tablename>.xml” so that they are not regenerated during the installation in the instance, other than when tables are created. The result is that the noise is reduced from all the XML files that reference the sys_id of the table or represent the sys_db_object record for this table.

ServiceNow Extensions for Visual Studio Code

Edit your ServiceNow applications in Visual Studio Code with the help of the ServiceNow Extensions for VS Code.

The ServiceNow Extensions for the VS Code editor enables you to edit applications within your ServiceNow instance.



Advantages of using Visual Studio Code

Edit your applications offline

Use Visual Studio Code to download and edit a local copy of your application. You can edit the application offline, and then synchronize again when your instance is available.

Use Visual Studio Code JavaScript features to reduce development time and improve code quality.

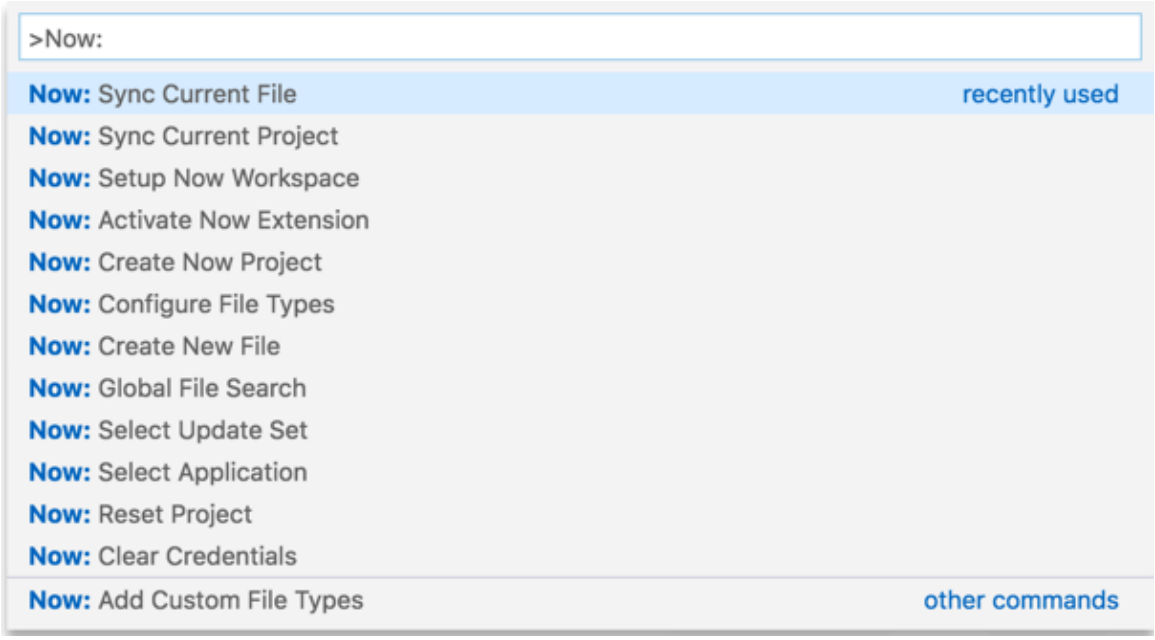
Visual Studio Code IntelliSense includes editing features such as code completion, code suggestions, and quick information. Use these tools to complete your coding tasks quickly and reduce errors. For more details on using IntelliSense in your applications, see IntelliSense in VS Code. The extension also supports Linting using ESLint. The same standard ESLint rules used in the ServiceNow instance are available.

Functions of ServiceNow Extensions for VS Code

The ServiceNow Extensions for VS Code extension includes tools for developing on the ServiceNow AI Platform.

The extension adds several functions to your Visual Studio Code (VS Code) implementation. You access these functions through the command palette.

Visual Studio Code command palette



Available functions in the ServiceNow extension for VS Code

Functionality	Description
Setup Now Workspace	Create the project folder to work with ServiceNow applications. For details on creating this workspace, see Set up a workspace in VS Code.
Activate Now Extension	Activates the ServiceNow extension. See Activate ServiceNow Extensions for VS Code.
Create Now Project	Import existing ServiceNow applications to a Visual Studio Code project. See Create a project in VS Code.
Sync Current Project	During development, synchronize all files between VS Code and the instance. See Synchronize the current project between a Visual Studio Code workspace and a ServiceNow instance.
Sync Current File	Synchronize the current file you are working on. See Sync the current file between a Visual Studio Code workspace and a ServiceNow instance.
Clear Credentials	Deletes the entered credentials in the Settings page. See Clear instance credentials in Visual Studio Code.
Reset Project	Sets project to its original state. See Reset a project in Visual Studio Code.
Configure File Types	Modify the options selected in the metadata. Metadata determines which elements of your application you want to synchronize with VS

Available functions in the ServiceNow extension for VS Code (continued)

Functionality	Description
	Code. See Import an application into Visual Studio Code.
Add Custom File Types	Add file types to your project using the Custom File Types wizard. See Add custom file types in Visual Studio Code.
Select Application	Switch between application within the workspace in VS code. See Import an application into Visual Studio Code.
Select Update Set	Select an update set. Changes synchronized to your instance are applied to the selected update set. For more information on update sets, see Import an application into Visual Studio Code.
Create New File	Create records in your application. For details, see Create a file in VS Code.
Global File Search	Find files within the instance. See Search files on your instance in VS Code.
Run Background Scripts	Run a background script on your instance. See Run background scripts using VS Code.
IntelliSense	An IntelliSense code-completion aid available for Glide APIs. See IntelliSense in VS Code.

Install ServiceNow Extensions for VS Code

Download and install ServiceNow extensions to begin editing your applications in VS Code.

Before you begin

Role required: none

In order to install ServiceNow Extensions for Visual Studio Code, you must have VS Code version 1.38.0 or later installed.

Procedure

1. Open VS Code and navigate to the **Extensions** tab by clicking the Extensions tab icon () or pressing Control+Shift+X on Windows or Command+Shift+X on MacOS.
2. In the Visual Studio Code Marketplace, enter `ServiceNow` or `ServiceNow Extensions` in the **Search Visual Studio Code Extensions** search box.
3. Select **ServiceNow Extensions for VS Code** in the search results and click **Install** to proceed with installation.
4. After the installation process completes, restart Visual Studio Code.
5. Navigate to **View** > **Command Palette** in Visual Studio Code.
   You can also use a keyboard shortcut (Control+Shift+P on Windows and Command+Shift+P on MacOS) to open the command palette.
6. Choose **Developer: Reload Window** from the list.

What to do next
Once you reload VS Code activate the ServiceNow extension.

Activate ServiceNow Extensions for VS Code

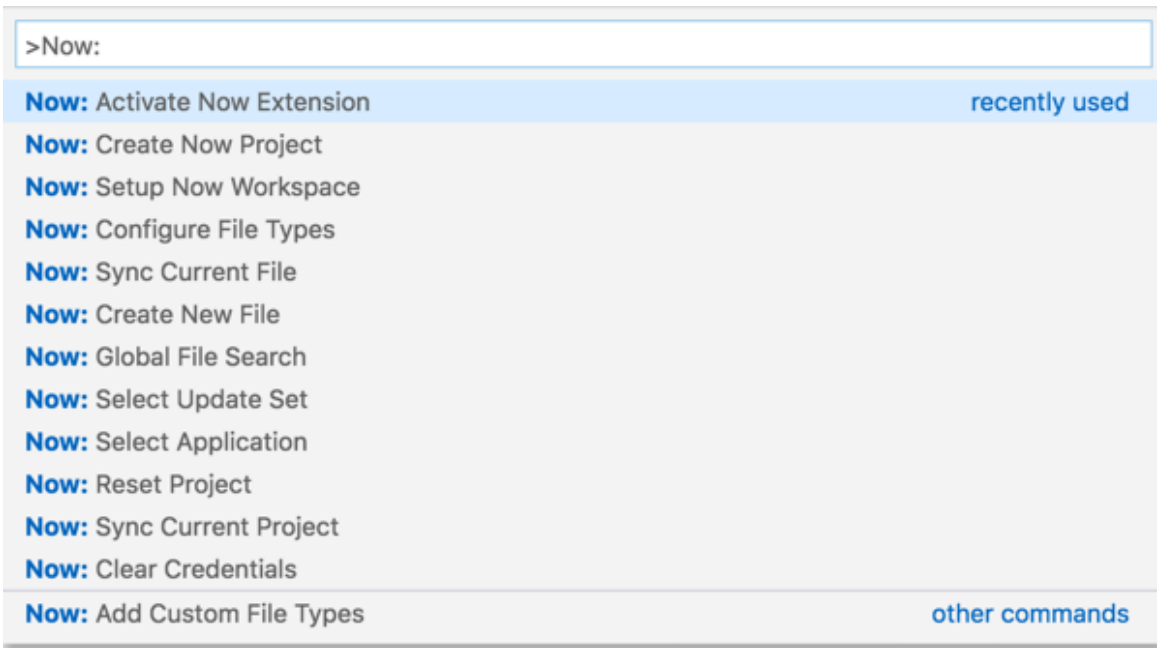
Activate the ServiceNow Extensions for VS Code to be able to edit applications within your ServiceNow instance.

Before you begin
Install ServiceNow Extensions for VS Code to activate the extension and begin editing your applications in VS code.

About this task
Activating the extension is the first step you must perform after installation of the extension to access its functionalities.

Procedure
1. Navigate to **All** > **View** > **Command Palette** to open the command palette.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette.
2. Choose **Now: Activate Now Extension** from the list.

Activate Now extension



The **Setup Workspace** link appears at the bottom of the VS Code IDE. After the extension is activated, Set up your workspace in VS Code to begin editing ServiceNow applications.

Set up a workspace in VS Code

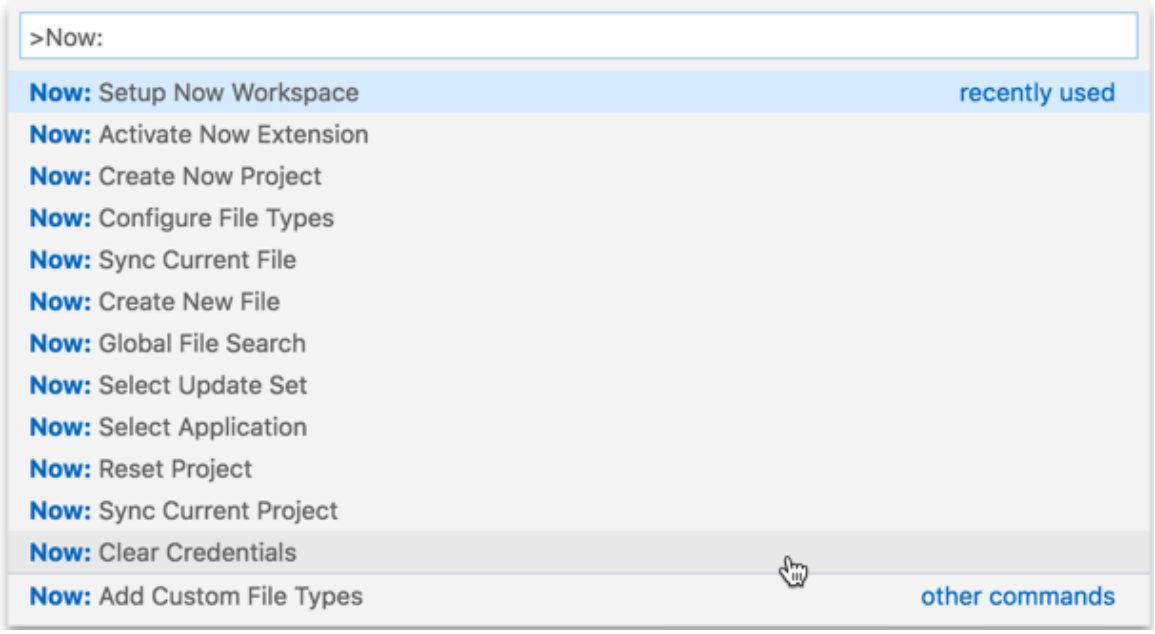
Using the ServiceNow Extensions for VS Code, create a project work folder to use as a workspace for ServiceNow applications.

Before you begin
Activate the workspace to access the functionalities of ServiceNow Extensions for VS Code. Role required: admin

Procedure

1. Click the **Setup Workspace** on the status bar at the bottom of the VS Code IDE.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette and choose **Now: Setup Now Workspace** from the list.

Setup Now Workspace command



2. Do any of the following actions.
   The workspace is created from the selected folder.

What to do next

Create a project in your workspace. You can create multiple projects of different project types within a workspace.

Create a project in VS Code

ServiceNow applications are contained within a project in the VS Code IDE. Import an application from your ServiceNow instance with the help of ServiceNow Extensions for VS Code.

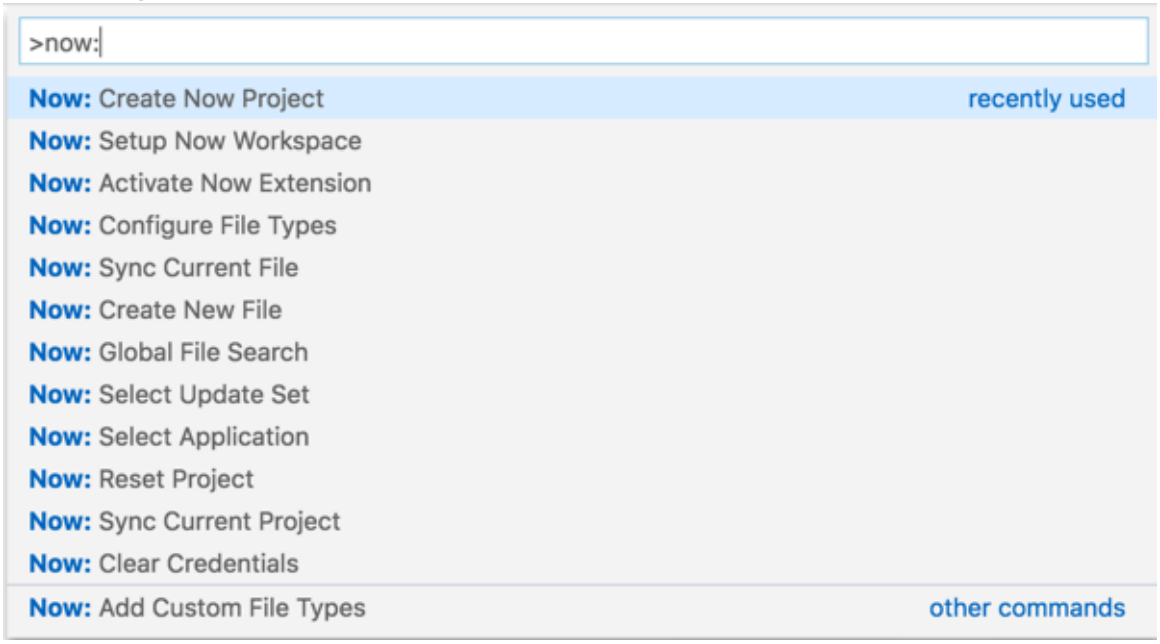
Before you begin

Setup your workspace to create a project and start editing your ServiceNow applications.

Procedure

1. Click **Create Project**in the status bar on the bottom of the VS Code IDE.

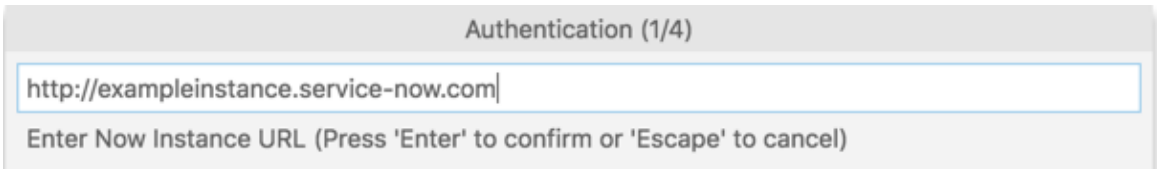
Create Project



You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette and choose **Now: Create Now Project** from the list.

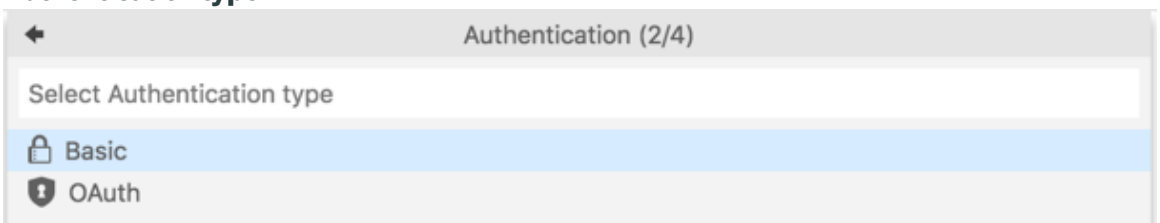
The **Create Project** wizard opens.

2. Enter the URL of the ServiceNow instance and press Enter to confirm.
Include the complete URL for your instance, for example, `https://example.service-now.com`



3. When prompted, select the Authentication type.

Authentication type



- To create a basic application, choose **Basic** and fill in the following fields, when prompted.

Basic application

Field	Description
User Name	Enter the User name of the ServiceNow instance URL.
Password	Enter the password of the ServiceNow instance URL.

Note:
The user account being used for authenticating must not contain the admin role.

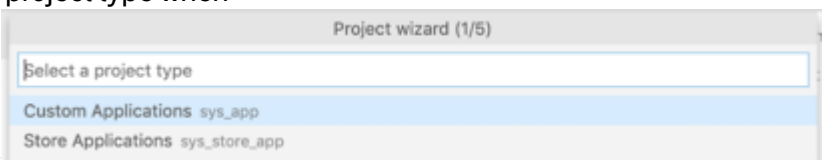
Project type

- To create an OAuth application, choose **OAuth** application and fill in the following fields, when prompted.

OAuth application

User Name	Enter the Username of the ServiceNow instance URL.
Password	Enter the password of the ServiceNow instance URL.
Client ID	Client ID is automatically generated by ServiceNow OAuth server.
Client secret	TClient secret for the OAuth application.

4. Select the project type when prompted.



Note:
You can enable the Packages and Plugins project types by enabling them from the Settings. Navigate to **Preferences** > **Settings** > **Extensions** > **Now** > **Project Settings** to enable them.

5. Select **Import Existing**.

Import an application into Visual Studio Code

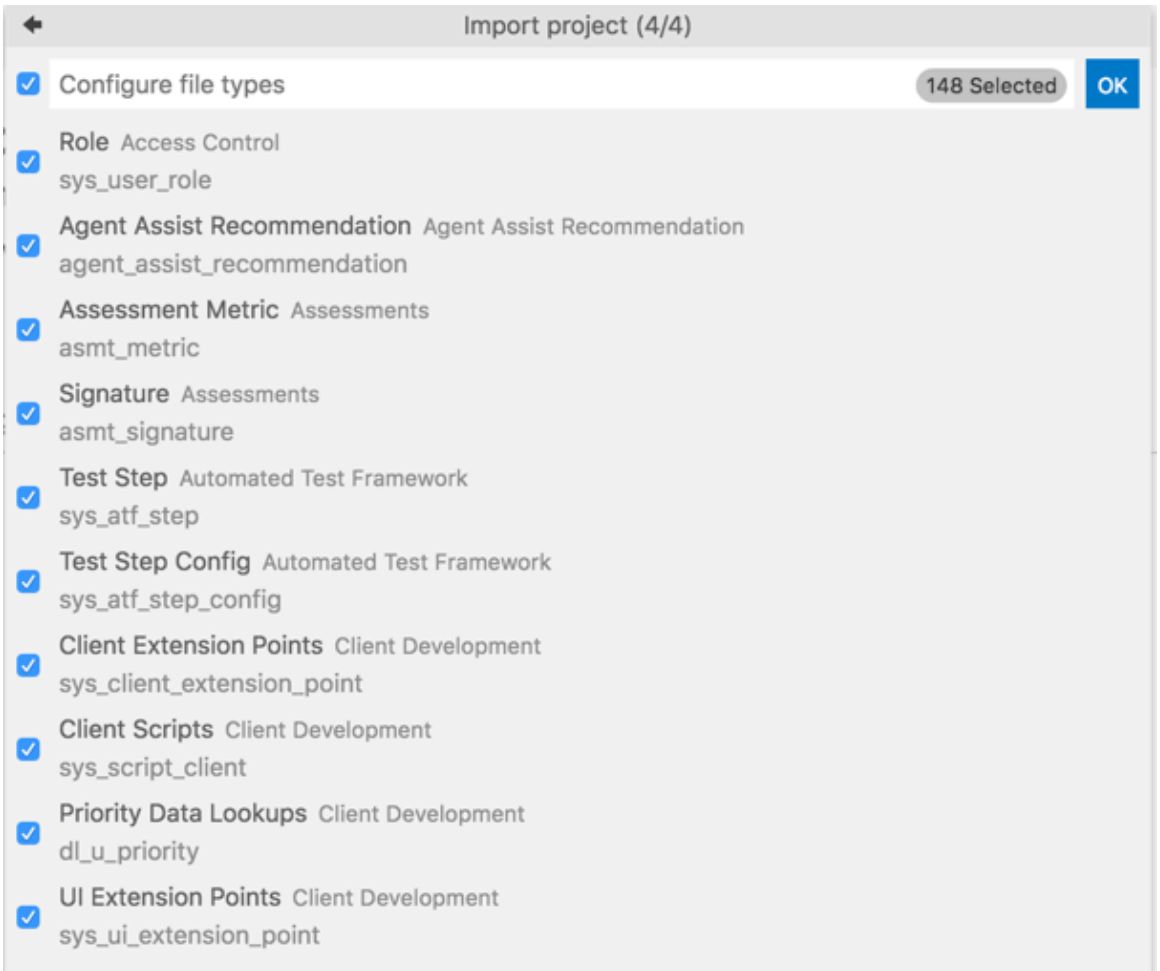
After you create a project, import an application from your instance into the project to begin editing.

Procedure

1. Visual Studio Code displays the list of applications available in your instance for the selected application type.

   The list of applications shows once the Manage Developers settings have been applied for the custom application intended to import. If the settings are left unchecked, applications will not be listed in the drop-down.

2. Select an application.
3. At the **Configure file types** prompt, click **OK** to select all file types.



By default, Visual Studio Code imports all the file types of your application. You can modify the selection of the file types while editing the application, by choosing **Now: Configure File Types** from the command palette and choosing the file types from the list.
Your ServiceNow application is imported into your workspace.

> **Note:**
> Even if your application exists on your instance, you must create a project for it in Visual Studio Code.

You can switch applications within the workspace by clicking the name of the application, for example, EmployeeApp in this case, in the status bar at the bottom of the VS code IDE or choosing **Now: Select Application** from the command palette and selecting the application name from the list. Similarly, you can modify the update set by clicking the current update set

icon, for example, EmployeeApp in this case, in the status bar at the bottom of the VS code IDE or by choosing **Now: Select Update Set** from the command pallet and selecting the name of the updateset.

Synchronization between Visual Studio Code and a ServiceNow instance

You can synchronize your applications between Visual Studio Code and your ServiceNow instance.

Synchronization

Changes made to your applications in Visual Studio Code are stored on your local file system only until you synchronise with your instance.

Synchronization accounts for the following changes:

- File modifications on the instance or in the local file system
- File creation on the instance or in the local file system
- File deletion on the instance or in the local file system

You can sync your currently selected record or all records in the current application.

Sync the current file between a Visual Studio Code workspace and a ServiceNow instance

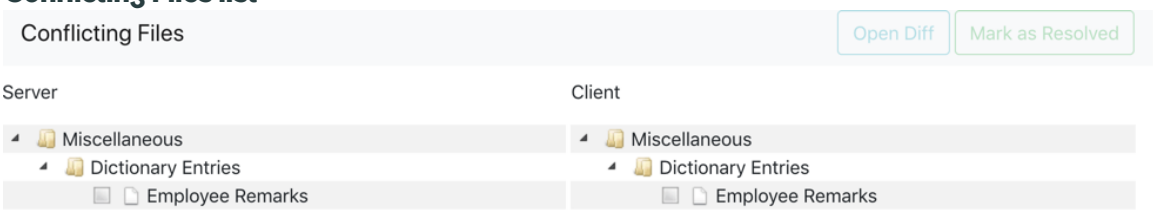
Identify conflicting files and merge or overwrite the changes, between the current file in your Visual Studio Code workspace and your instance.

Before you begin
Role required: admin

Procedure

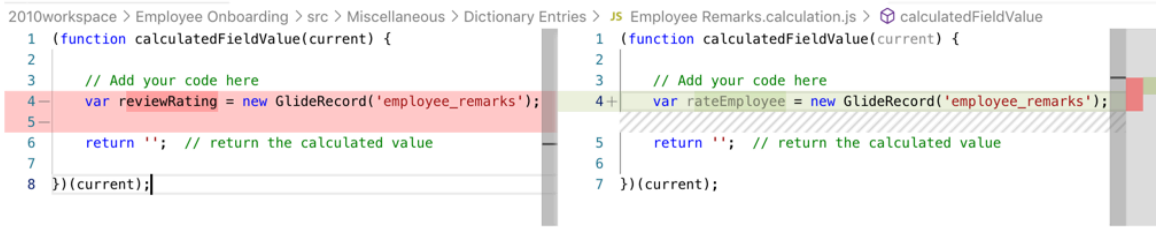
1. Click the **Sync** icon from the menu on the top-right corner of the Visual Studio Code IDE. You can also use a keyboard shortcut Control+Shift+P in Windows and Command+Shift+P in MacOS to open the command palette and choose **Now: Sync Current File** from the list.
   - If the changes occur either on the server or on the client, the extension synchronizes the file successfully without showing up any errors.
   - If there are no differences between the local and server versions, then the message **No changes detected** appears on the bottom of the page.
   - If the same file is modified both on the client and the server, then the system displays the conflicts in a **Conflicting Files** dialog box.
2. If a conflict list is displayed in a **Conflicting Files** dialog box, check the conflicts.
   - Compare the **Server** and **Client** version using the **Diff** window, and evaluate the changes.
   - Override the **Server** or **Client** changes.

Conflicting Files list



3. Check for the differences in the **Conflicting Files** list.

Conflicting changes display

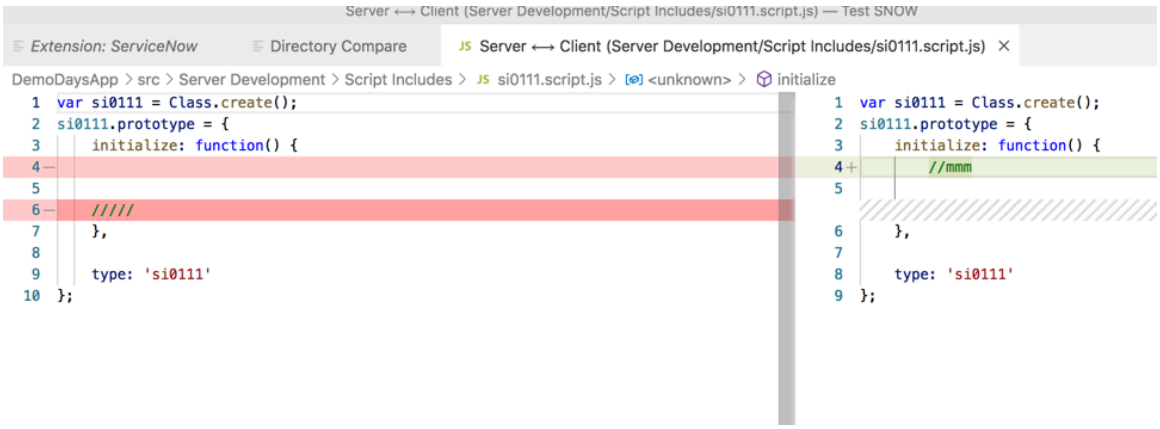


A dialog box displays the following options:

- Open Diff: Check for the differences between two versions and make the necessary changes.
- Mark Resolved: Resolve the differences and sync the versions.
- Overwrite Server: Choose if you want to override the server version with the client version.
- Overwrite Local: Choose **Override Local** to override the local version with the server version.

4. Click **Open Diff**.
   You can see two versions of the file with the differences highlighted.

Differences in client and server



5. Make changes to the server version from the client version and save the file.
6. Click **Mark as Resolved** under **Conflicting Files**.
   The changes are successfully synchronized upon the next synchronization. When the changes are merged successfully, the message **Sync completed successfully** appears at the bottom of the page.

Synchronize the current project between a Visual Studio Code workspace and a ServiceNow instance

Synchronize files between the Visual Studio Code workspace (client/local) and the instance (server) bi-directionally.

Before you begin

Create your projectand start editing your applications.

About this task

The changes made to the application files in the Visual Studio Code workspace are initially stored in the local file system. When you run the **Sync** command, the local changes made to the application files are sent to the server for persistence.

Procedure

1. Click **Sync** on the status bar on the bottom of the Visual Studio Code IDE.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette and choose **Now: Sync Current Project** from the list.

Sync current project

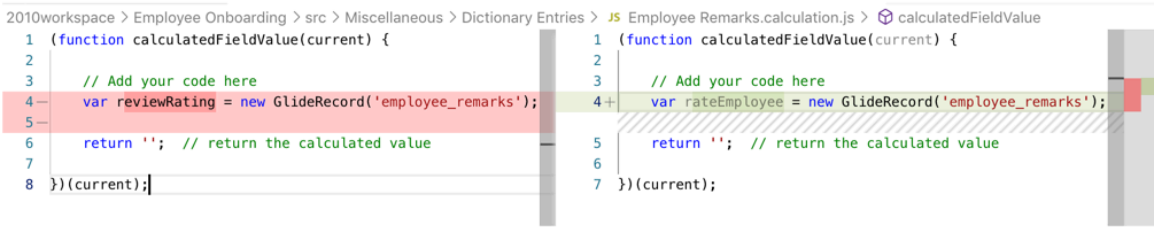
   - If the changes occur either on the server or on the client, the extension synchronizes the file successfully without showing up any errors.
   - If there are no differences between local and server versions, then the message **No changes detected** appears on the bottom of the page.
   - If the same file is modified both on client and server, then the system shows up the conflicts.

2. If a conflict list is displayed, right-click on the conflicting file to open the context menu and select from the context menu.
   Alternatively, select the file and click **Open Diff** menu from the top of the page.

Conflicting files display

   - Choose **Override Server** if you want to overwrite the server version with the client version
   - Choose **Override Local** to overwrite the client version with the server version.
   - Choose **Mark as resolved** to remove the flag indicating a conflict. The server version will be overwritten in the next synchronization.

Differences in client and server versions



3. Retain the desired changes in the client file and save.
4. Once you have resolved all file conflicts, click **Mark as Resolved** under **Conflicting Files**.
   The changes are synchronized on the next sync. When the changes are merged successfully, the message **Sync completed successfully** appears in the bottom of the page.

Note:
The files are checked for syntax errors at the beginning of synchronization process. Any errors found are presented in the problem tab at the bottom of the screen.

What to do next

All the changes are tagged to the update set in the status bar. When a project is loaded or selected, the default update set is displayed in the status bar. Click the update set picker to choose the current update set (valid until the IDE or project is closed). If you do not explicitly select an update set, all writes happen to the default update set.

Clear instance credentials in Visual Studio Code

Clear the stored credentials of the current project from the system. User credentials (instance URL, user name, password) of a project are stored in the operating system credentials vault so that the user does not need to log in each time.

About this task

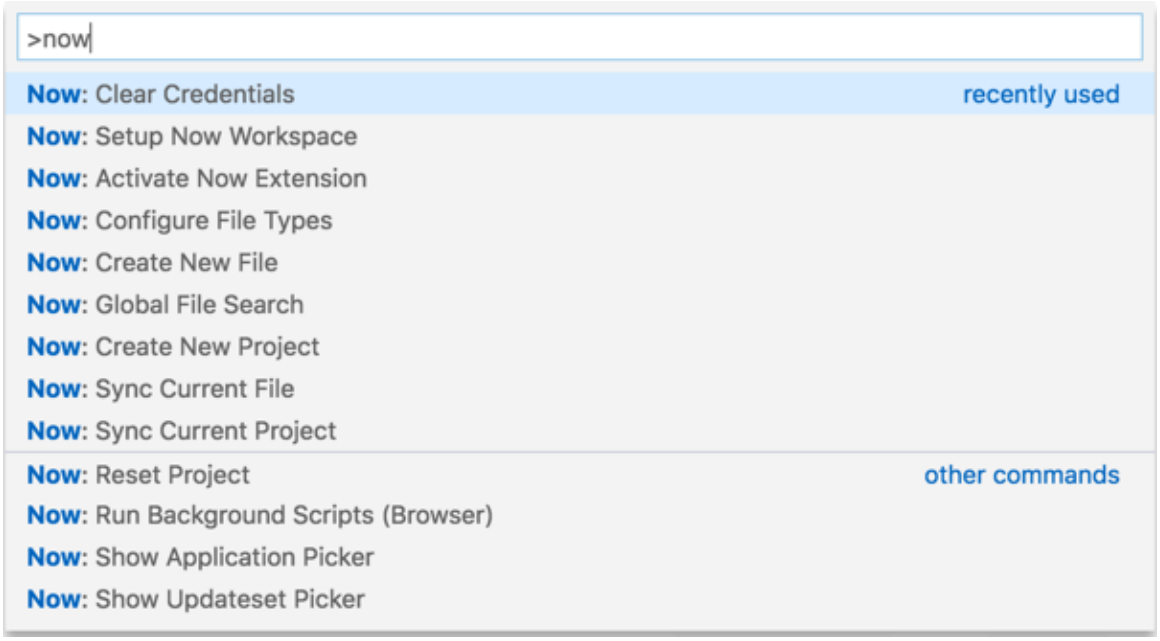
Once you clear credentials from the current instance, the ServiceNow Extensions for Visual Studio Code extension prompts for authentication the next time you open VS Code. You can continue working in the current session.

Note:
The password is not stored in the Visual Studio Code settings.

Procedure

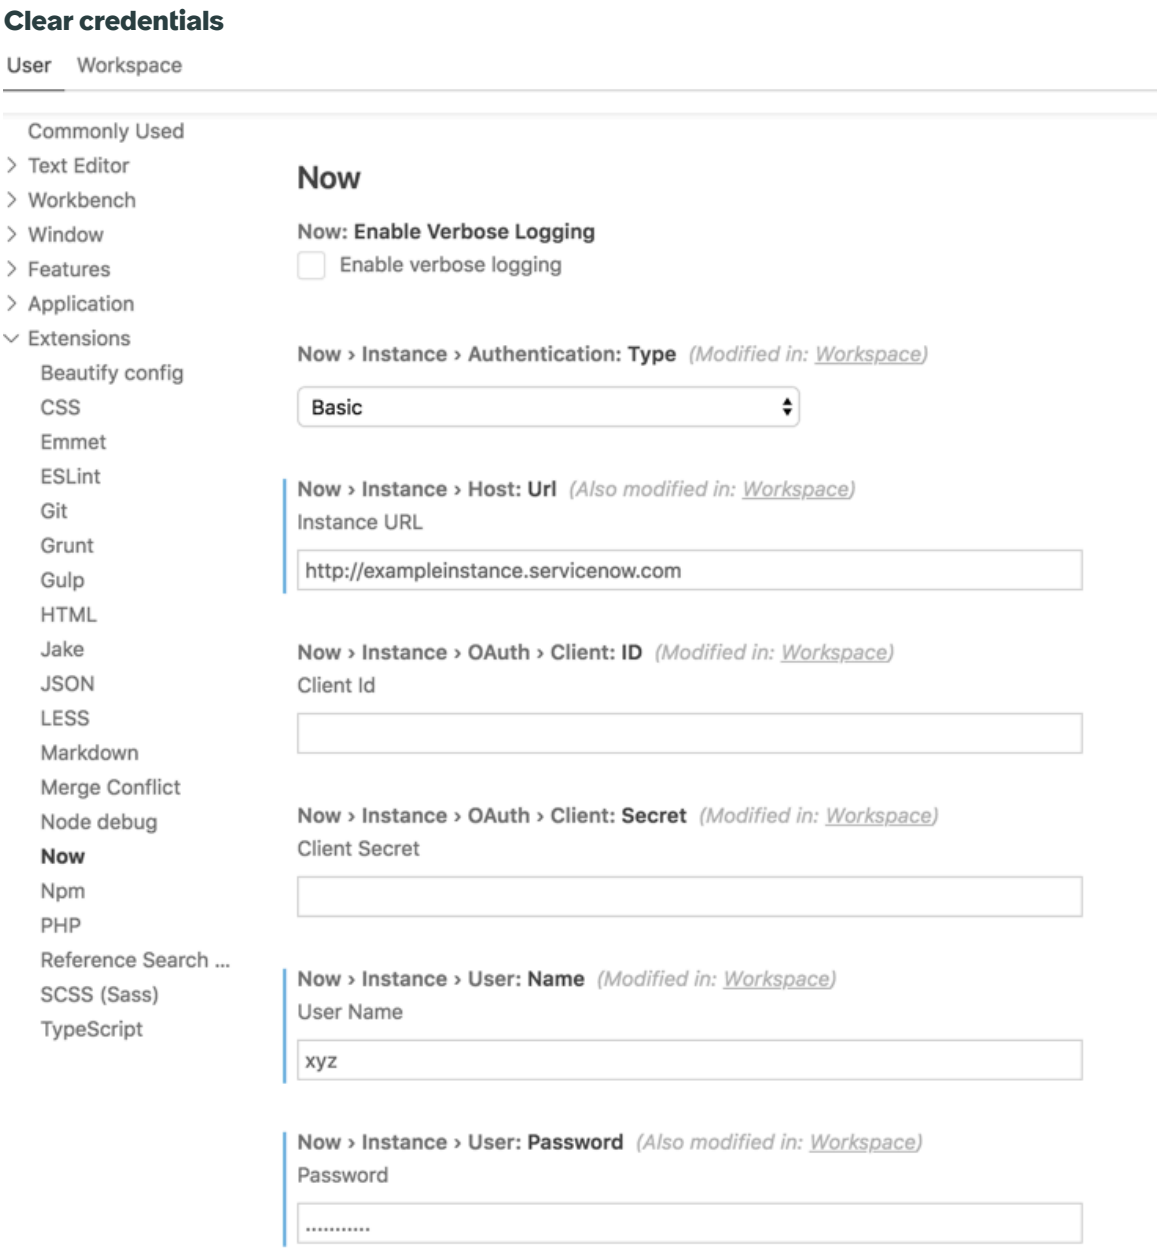
1. Navigate to **All** > **View** > **Command Palette**.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS to open the command palette.
2. Choose **Now: Clear Credentials** from the command palette.

Now: Clear credentials command



The credentials of the current project are cleared.

3. **Optional:** Navigate to **Code** > **Preferences** > **Settings** > **Workspace** > **Extensions** > **ServiceNow** to check whether the credentials and the instance URL have been deleted.



Note:
To re-enter your credentials, navigate to **Code Preferences Settings Workspace Extensions Now**. Enter your credentials in **Username** and **Password** fields.

Reset a project in Visual Studio Code

Reset the project to the state on the server by discarding all the local changes if you encounter any serious sync issues.

About this task

When you reset a project to its server state, all unsynchronized changes are lost.

Procedure

1. Navigate to **All** > **View** > **Command Palette** in.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette.

2. Choose **Now: Reset Project** from the drop-down list.
3. Click **Yes** in the dialog box.

Result
The project is reset to its original state.

Note:
This option should be used only when something goes wrong, for example, if the project is corrupted or you are facing sync issues.

Related topics

Create a project in VS Code

Add custom file types in Visual Studio Code

If you have work with file types other than the default types provided, you can add additional file types to your instance and edit them in ServiceNow extension for Visual Studio Code.

Before you begin
Role required: admin

Procedure
1. Create a new file type in your ServiceNow instance and inherit it from the application file.
2. Add custom columns of the type *`Script`* and *`String`*, and enter some data.
3. Navigate to **View** > **Command Palette** in Visual Studio Code.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette.
4. Choose **Now: Add Custom File Types** from the command palette.
   The command fetches all the existing tables in the current application and opens the **Add new file type** wizard.
5. Select the file type you created in your ServiceNow instance from the list.
6. At the Select tags prompt, select the tags you created in the instance.

   All tags are selected by default. Click a tag's check box to deselect it.

Select tags dialog box

The new file type is successfully added to the `app.config.json` file. You can also add the desired file types manually to the `app.config.json` file under your project. See the example below.

7. Absorb this new file type to the current project using the **Now: Configure File Types** command from the command palette.
8. Select the file type you created from the list of file types and click **OK**.
   The selected file type is ready for editing in the ServiceNow Extensions for Visual Studio Code extension.

Example:
The following is an example for app.config.json

```
"CustomFileTypes": {
        "sc_ic_aprvl_type_defn": {
            "superCoverName": "Miscellaneous",
            "coverName": "Approval Type Definition",
            "tags": {
                "approver_script": "js",
                "approver_html”: "html",
            }
        }
    }
}
```

- superCoverName is a name of the super parent directory (Should always pointtoMiscellaneous).
- coverName is a descriptive name of the table.
- sc_ic_aprvl_type_defn is a table identifier.
- tags represent the set of scriptable columns in the table
- approver_script is a name of the table column / xml tag
- js is an extension of the file (js | html | css | json)

Create a file in VS Code

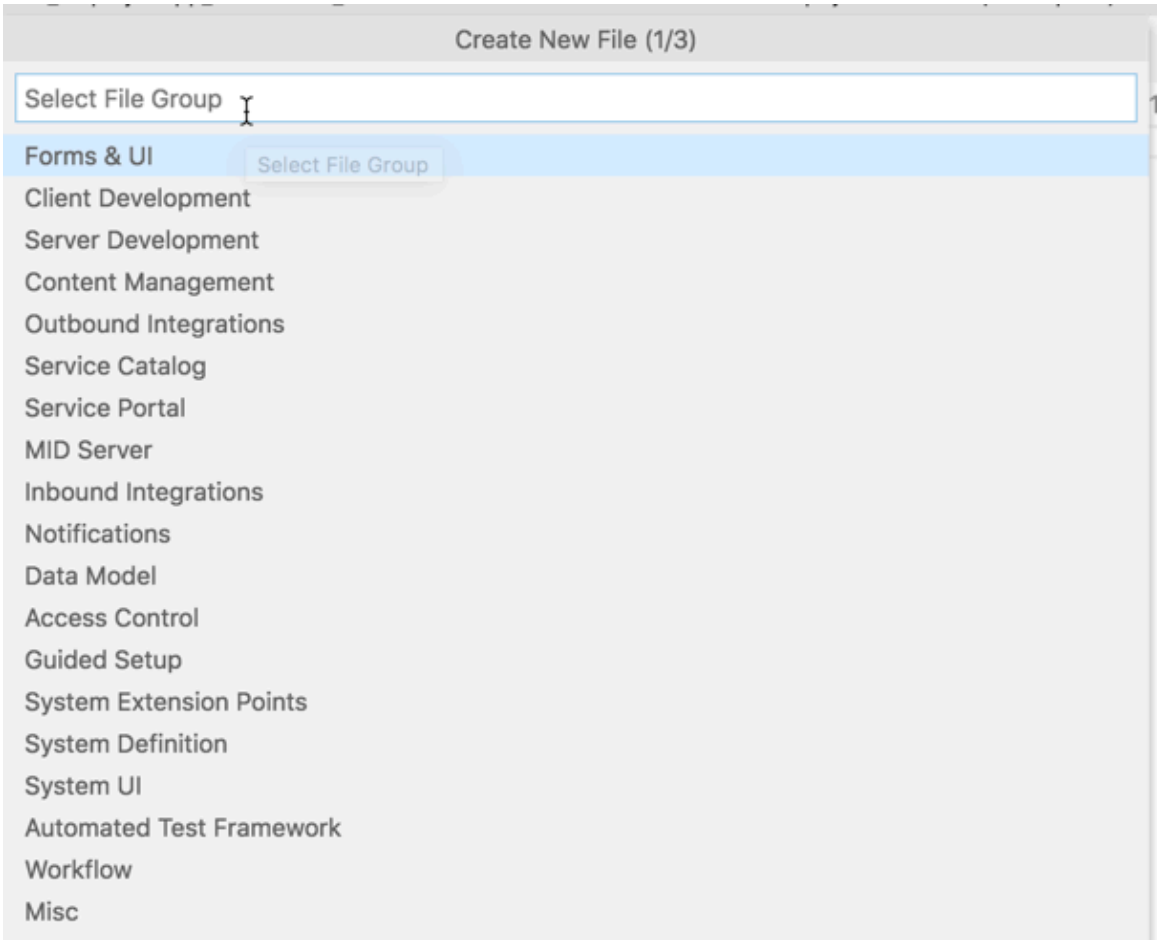
Use the ServiceNow extension to create a new file for your application with your project.

Before you begin
Import an application in your VS Code project to create a file within your project.

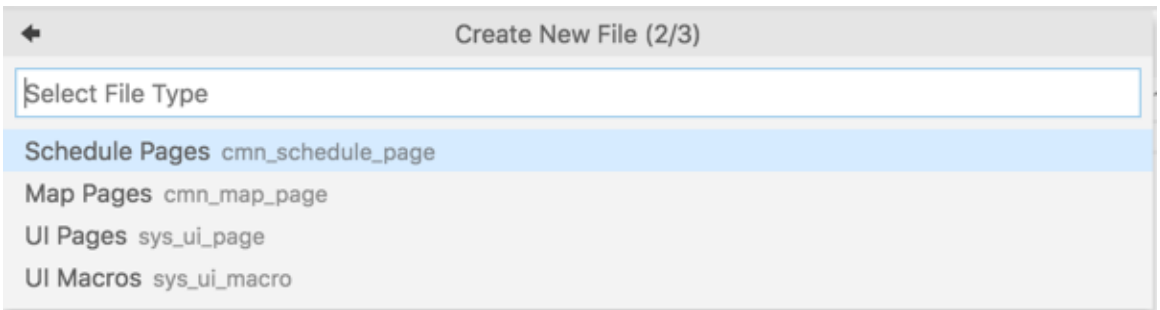
Procedure

1. Open the VS Code project containing your application.
2. Click the **Create File** (

) on the status bar on the bottom of the VSCode IDE.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette and choose **Now: Create New File** from the list.
3. Select the file group from Select File Group list.



4. Select the file type from the **Select File Type** list from the command palette at the top of the screen.



5. Enter a name for the file in the Create New File dialog box.
   The extension creates a file in your application on your local file system. The new file is added to your instance when you synchronize your workspace.

Search files on your instance in VS Code

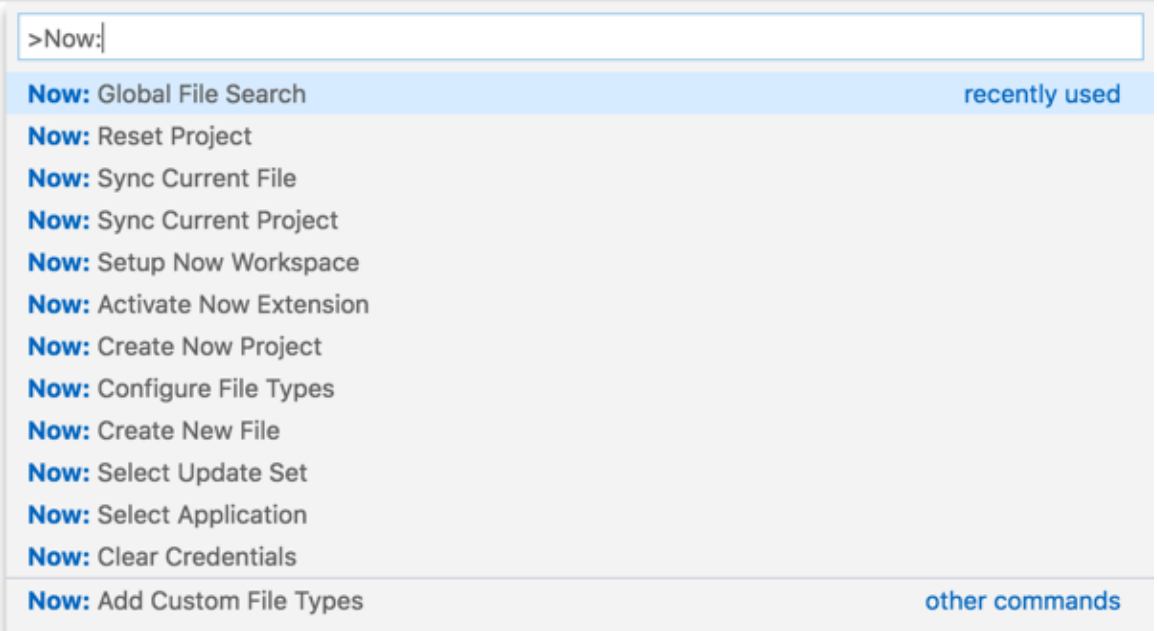
Search and download any script files on your instance using the ServiceNow Extensions for VS Code extension.

Before you begin
Role required: none

Procedure

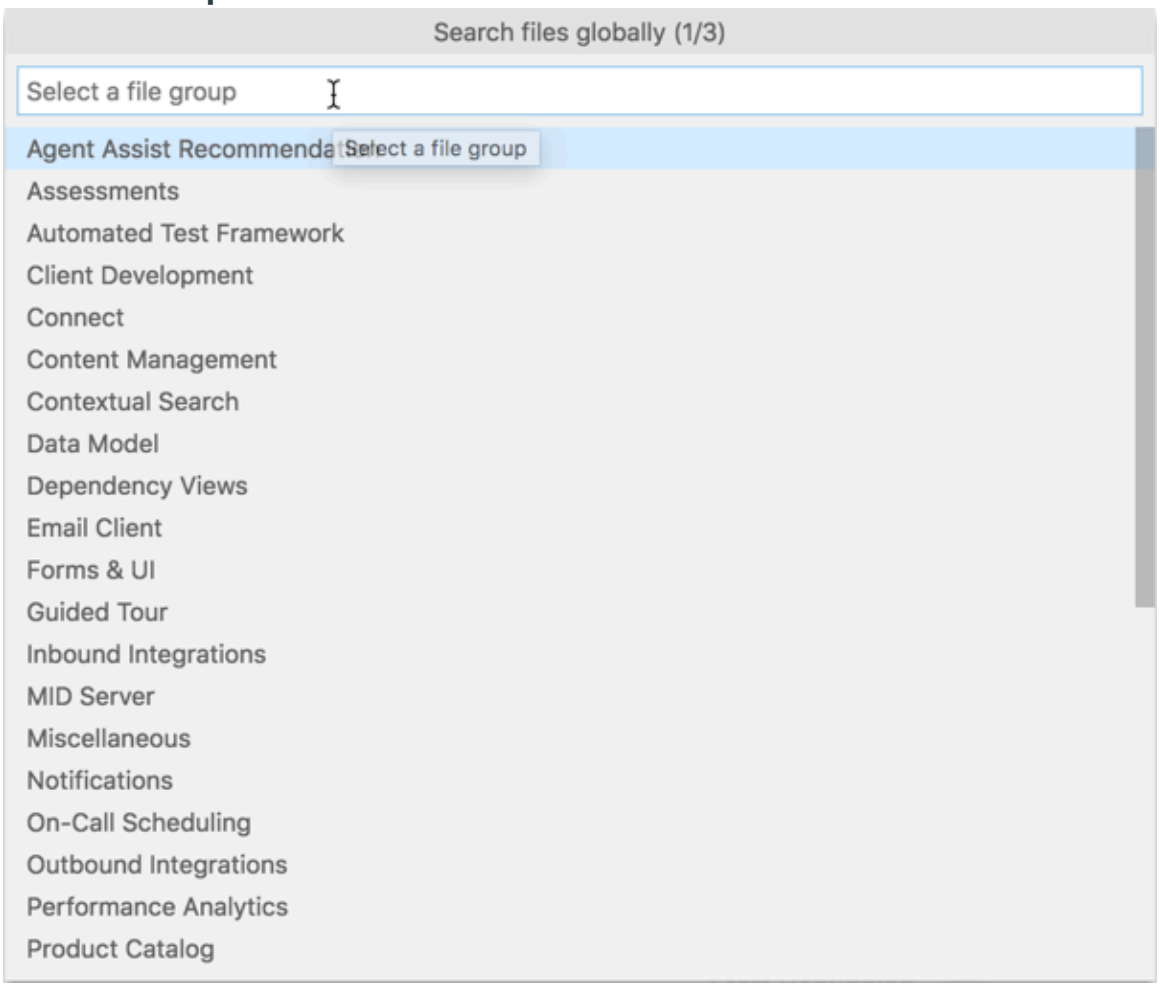
1. Open a project in VS Code containing your application.
2. Click the **File Search** on the status bar on the bottom of the VSCode IDE.
   You can also use a keyboard shortcut, Control+Shift+P in Windows or Command+Shift+P on MacOS, to open the command palette and choose **Now: Global Search** from the list.

Global File Search command



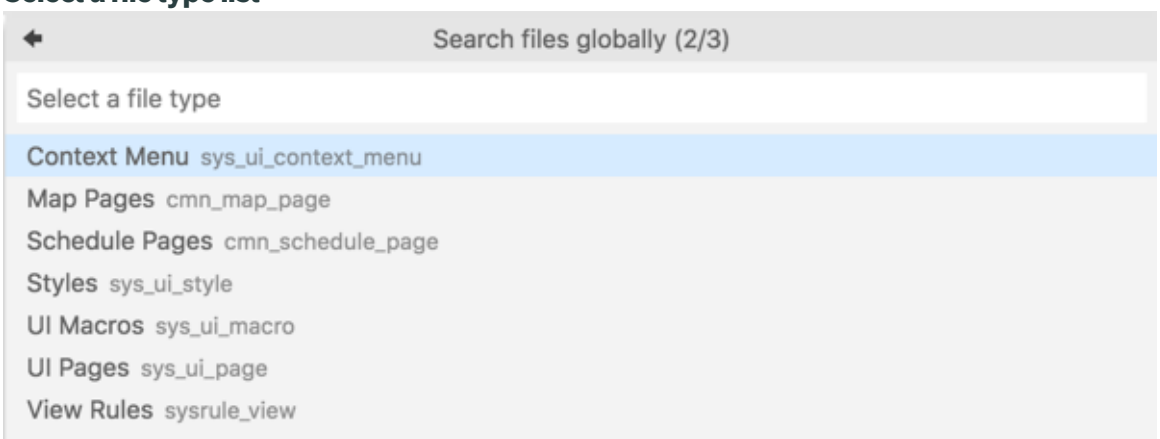
3. Select the file group from the **Select File Group** list in the command palette on the top of the screen.

Select File Group list



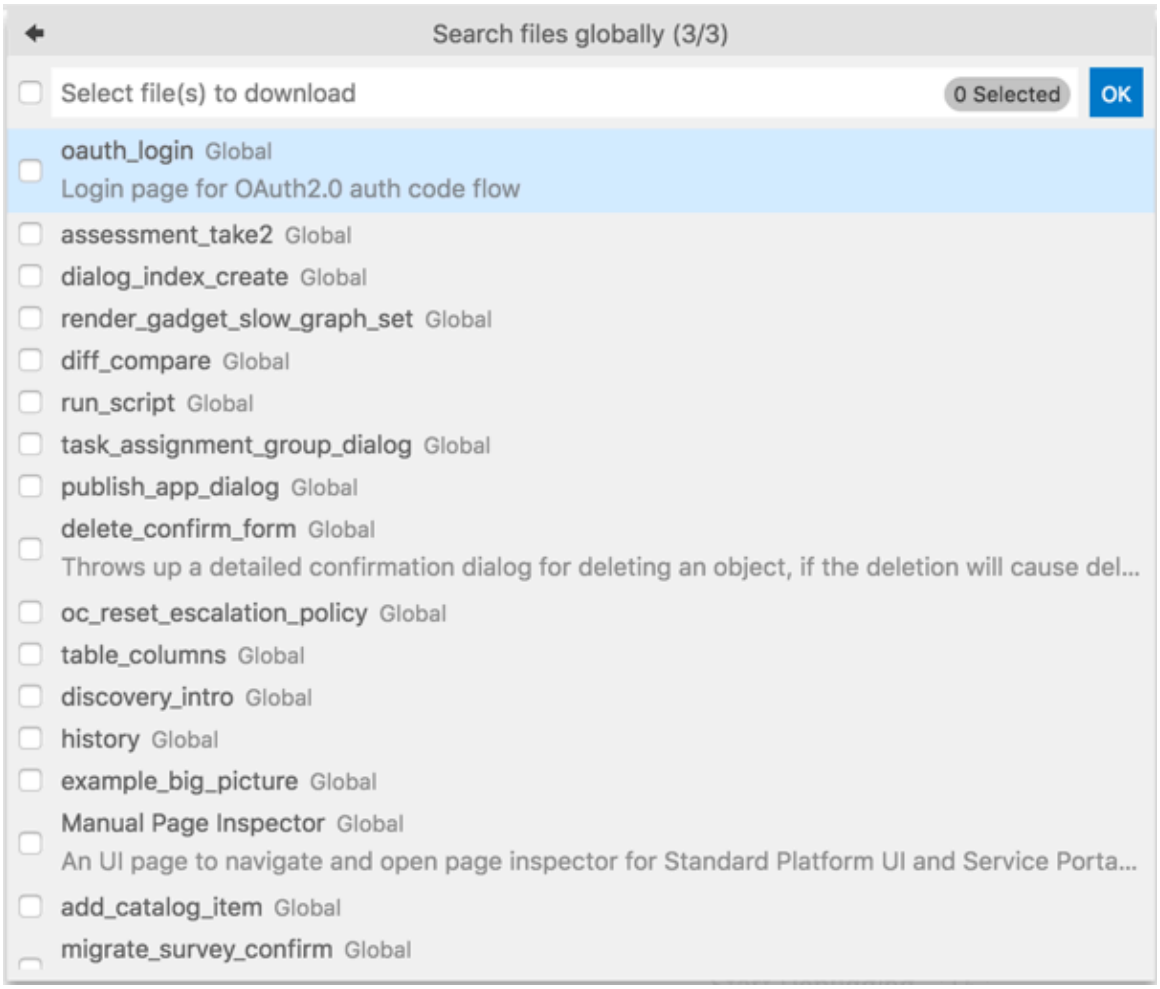
4. Select the file type from the Select a File Type list in the command palette on the top of the screen.

Select a file type list



5. Select files from the **Select files to download** list.

Select files to download list



You can select and download multiple files at a time.

The selected files are downloaded to the `scratch` folder of your application. You can edit the selected files.

6. View more than 10,000 results from your search:

   a. Open settings by selecting Control+, in Windows or Command+, on MacOS.

   b. Enter `now` into the search bar.

   c. Enter the number of records you want to see in the Fetch Records Max Limit settings.

Fetch Records Max Limit settings

Create a file in VS Code

Run background scripts using VS Code

Run scripts from your ServiceNow instance in VS Code using the ServiceNow Extensions for VS Code.

Before you begin

Role required: admin

Procedure

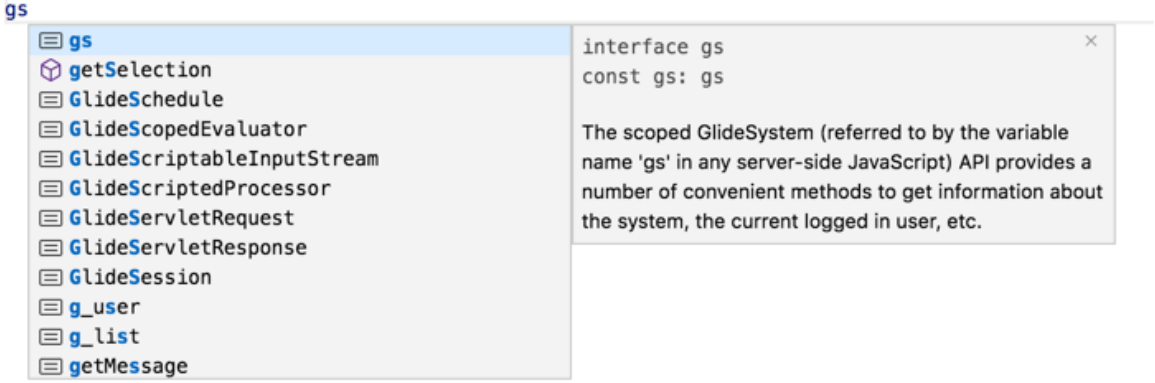
1. While writing the script in the VS Code IDE, select the script in the text file and right-click on the script.
2. Select **Run Background Script- Current** or **Run Background Script- Global** from the context menu.
   The background scripts runner tab opens in VS Code and shows the location where the script is executed in the server.

IntelliSense in VS Code

The IntelliSense code editing feature in the ServiceNow Extensions for VS Code extension provides intelligent code completions which provide auto-completion options to make writing code faster and more efficient.

When you start scripting in the VS Code, the IntelliSense feature shows auto-completion options suitable for your code context at the top of the list.

IntelliSense for GlideSystem



The auto-completion options available are:

- Auto-completion of methods and properties for client and server scripts.
- Auto-completion of methods and properties for standard JS APIs
- Auto-completion of Jelly tags and attributes.
- Code completion in commonly used standards.

The extension supports snippets (templates) for commonly used code patterns and loads snippets defined by the user in Macros table of the Syntax Editor on an instance. Snippets appear in IntelliSense when you type `#Space` along with other suggestions. Alternatively, snippets can also be inserted using the **Insert Snippet** command from the command palette in VS Code.

Telemetry in ServiceNow Extensions for VS Code

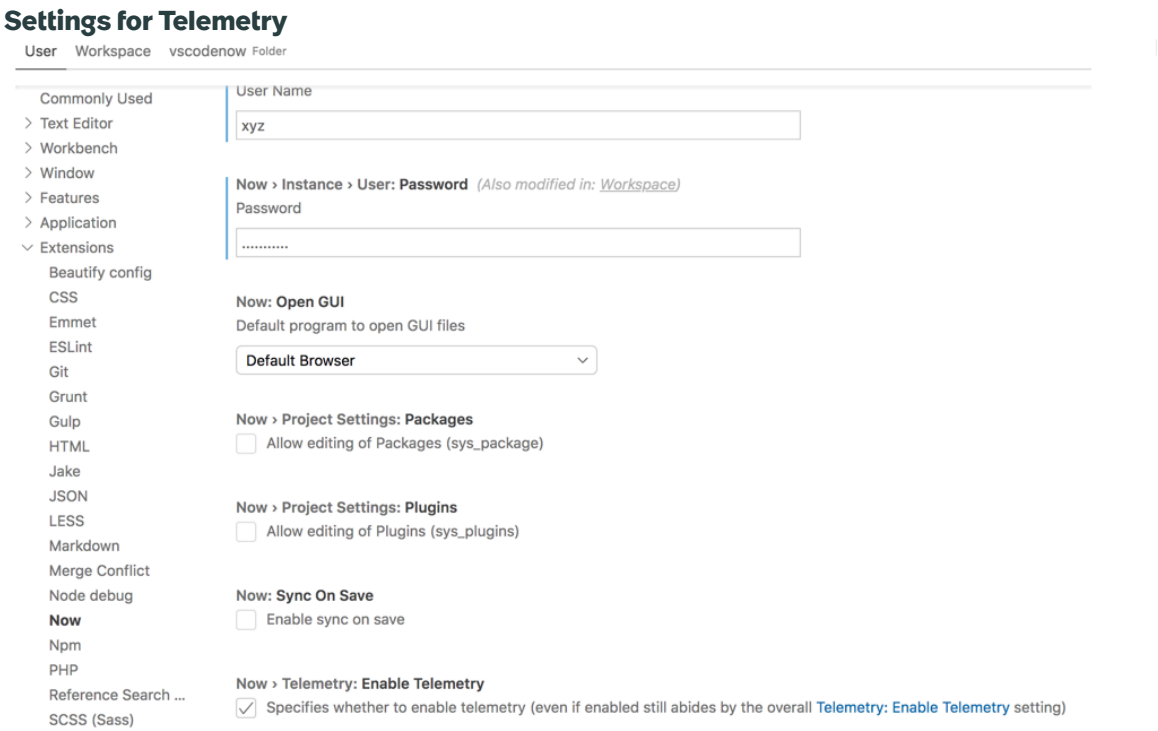
ServiceNow Extensions for VS Code collects information on its various usage patterns such as the commands run with the help of Now Telemetry.

Now Telemetry helps in the following

- Debug issues
- Analyse most used functions or features
- Capture user actions
- Improve the extension

Note:
Telemetry collects anonymous information related to usage and does not capture any personal information such as name and email ID of the users. Data is accessible to ServiceNow only and is not shared with anyone

Telemetry is enabled by default for the ServiceNow extension. If you do not wish to send usage data, you can set the `now.telemetry.enableTelemetry` user setting to false. Alternatively, select **File** (Windows) or **Code** (Mac) and navigate to **Preferences** > **Settings** > **Extensions** > **Now** and clear **Now Telemetry** check box to disable the feature.



Note:
The usage data will be sent until you disable the setting. The extension abides by the global telemetry setting `telemetry.enableTelemetry`. If that is set to false, Now telemetry is disabled.

Exploring professional development

ServiceNow provides a single mobile and web application development platform to quickly build business applications to power digital transformation. Learn how anyone can automate, extend, and build digital workflow apps across the enterprise with the ServiceNow AI Platform.

This content covers the application development stages to help developers easily build applications on the ServiceNow AI Platform.

- Plan your application development: Think through the application before building it.
- Build your application: Create and configure the application and its components.
- Validate app functionality: Perform functional testing and write test cases.
- Deploy your app: Move the application into production.

Plan your application development

The planning process is the most important step in building an application. Thinking through design and configuration before building has both immediate and long-term benefits for the application.

Fit for the ServiceNow AI Platform

Not every application idea is a good fit for the ServiceNow AI Platform. During the planning stage, consider what makes an application a good or a poor fit for the ServiceNow AI Platform. Keep the good fit characteristics in mind while planning the application.

Good fit	Poor fit
• Simple forms • Task management • Request management • Spreadsheet-driven processes • Repeatable processes • Third-party integrations • Orchestration of multiple systems • Single experience from functions in multiple systems • Web and mobile access to the same apps and data simultaneously	• Unstructured data • Unrepeatable processes • Content that needs graphics processing • Streaming audio or video • Highly customized user interface

Plan before you build

Essentially, an application is a digital program that supports user tasks. Some actions you take when building an application might be irreversible. Be aware of these actions and plan for them in advance.

Application scope

One of the first major decisions to make when creating an application is: Should the application be in a private scope or a global scope?

By default, applications are created in their own private application scope. Applications in a private application scope restrict access to their application artifacts so only application artifacts in the same scope have full access to create, modify, remove, or run application data. Scoped applications can use source control integration and delegated development. Globally scoped applications cannot use delegated development.

Create custom business applications in scope unless:

- The application has to delete global data.
- The application needs to change application access settings on multiple default tables to function.
- The application needs to access APIs only available in the global scope. Creating a globally scoped passthrough script include would not be enough for this requirement.

Note:
Globally scoped passthrough is a script include created in a global scope that is accessible from the private scope. The passthrough gives access to a global API that is not accessible by default from a private application scope.

For more information, see Application scope and Understanding Application Scope on the ServiceNow AI Platform (Whitepaper).

Instance selection

Proof of Concept (PoC) application builds can and should be built in a separate instance from a regular development instance. The instance can be a sandbox instance or a Personal Developer Instance (PDI) from the Developer Site. The PDI naming format is **dev12345.service-now.com**.

If using an instance with a different scope namespace, rebuild the PoC applications in the organization's development instance. Do not import the applications into the organization's development instance. The scoped namespace for the applications will not match the scoped namespace for the company's development instance.

Applications the organization intends to use (i.e. production apps) should be created in the organization's developer instance, so the application can follow the organization's testing and deployment process.

Naming decisions

The application name matters. ServiceNow suggests a scope based on the application's name. Application file names are appended to the scope to uniquely identify application resources in an instance. Scope is in the format: x_[company code]_[application_name] with a maximum of 18 characters. For example, an application name **Legal Request** has a suggested scope of **x_acme_legal_reque**.

All application files within the application inherit the scope, so carefully consider what the value should be. The application name can always be changed.

Manage app development

Govern app development on the ServiceNow AI Platform.

Source control

To enable simple, future proof collaboration for applications, use source control integration. Source control allows an organization to adopt industry standard tool sets while following modern application development and team management paradigms. See the Source Control Integration documentation for more information.

Source control platforms, such as GitLab and GitHub, align an organization with current and future best practice trends in ServiceNow application development and management. However, some organizations may not be ready to adopt the current source control integration.

- Branch merging is not currently supported.
- Corporate Git repositories behind a firewall cannot be directly integrated without additional firewall configuration.

Delegated development

Delegated Development allows designated users without the admin role to develop or deploy applications on the ServiceNow AI Platform. Users with the application-specific admin role or the system-level admin role can delegate application development to designated developers at the application level. Delegated developer roles have fewer privileges than admin roles but are still allowed to develop applications.

Note:
Delegated development is only available to privately scoped applications.

For more information about building applications, see Build My First Application.

Build your application

Build and define the data, design elements, and logic that make up your application.

Define and build the data model

After planning is complete, define and build the data model. Create one or more tables with fields, load the table with demo data, and verify access controls to the data.

Create an application

Create or open an application record.

- Create: If creating an application directly, use Guided App Creator to create the application. Guided App Creater allows you to create tables from spreadsheets, roles, and security rules. Design options are also available.
- Open: If developers do not have the admin role, the ServiceNow System Administrator needs to create the application and grant developers a delegated development role. Developers then use Studio to open the application for editing.

Note:
The application scope and table name are sometimes referred to as the internal names for these objects and cannot be changed once they are created. However, the application name and table label can be changed. Application users see the internal names in the URL only. If possible, internal names should always be consistent with what the user sees.

Build the data model

Create tables and fields on the tables to support the application's data model.

ServiceNow automatically adds five fields to each new table. The new fields contain auto-populated information about the table.

Fields added to every table

Field name	Database name	Description
Created by	sys_created_by	User who created the record.
Created	sys_created_on	Date/time when the record was created.

Fields added to every table (continued)

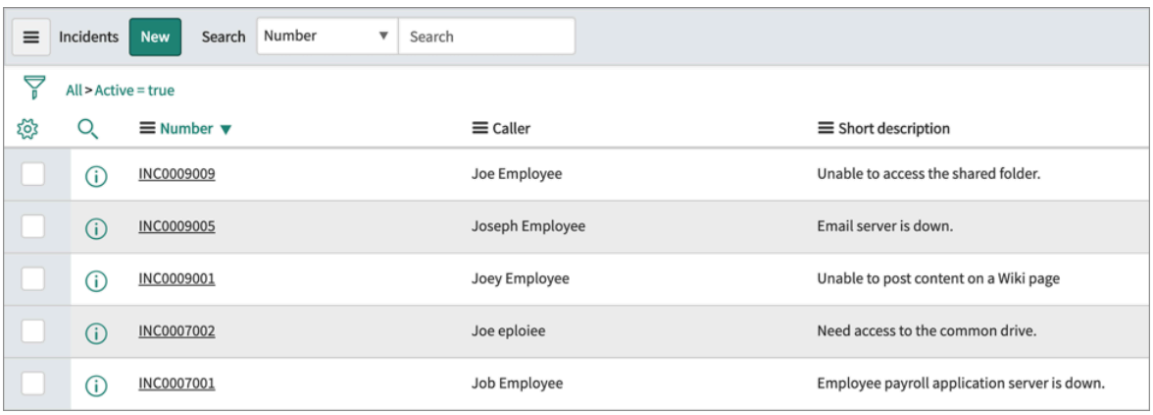
Field name	Database name	Description
Updated by	sys_updated_by	User who last updated the record.
Sys ID	sys_id	Unique identifier for the record. It is unique throughout the instance.
Updates	sys_mod_count	Numeric field that counts the number of updates to the record since record creation.

New tables can extend an existing table to inherit fields and functionality from the table being extended. Add to and modify the components of the extended table. The most commonly extended ServiceNow table is the task table. For more information, see When to create a new table vs. when to extend and Exploring ServiceNow AI Platform® tables.

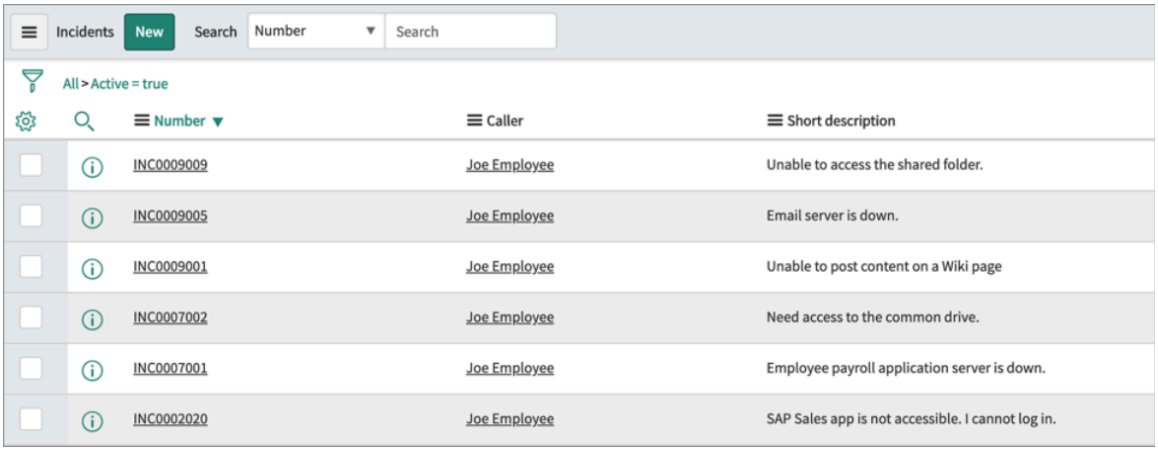
Add fields to the table to support the data model required by the application. ServiceNow has many different field types with built-in validation. Select the field type that best fits the field's data.

Note:
String (plain text) fields are the easiest to configure. However, because users can enter anything, string fields can result in bad and inconsistent data that is difficult to use.

In the example, a string field type is used for a user's name. Notice the Caller field is different for each Incident record, but the caller may be the same person. Do not use a string field type for a user's name in tables.



Instead, use a reference field type that references the User table instead of a String field. Users then need to select a single consistent record in the Caller field.



Reference fields ensure consistent data by normalizing date in another table in ServiceNow. ServiceNow has over 2000 baseline tables available to reference. The Appendix lists some commonly used tables for building an app.

While a reference field can normalize data, other fields can be used for specific types of data. The ServiceNow Documentation site has the complete list of Field types. Some common field types are:

Field type	Descriptions
Integer	Stores number values and can be used in calculations.
Currency	Holds a currency value and will show values in the currency of the logged in user.
Phone number	Includes validation and formatting for E164-compliant phone numbers.
Reference	Displays a record from another table and helps to normalize data.
Choice	Displays a select box with a predefined list of choices. Choice lists should include fewer than ten items.
Date	Stores a date value selected with a date picker. Use Date if you do not need a specific time.
Date/Time	Stores date and time values selected with a date and time picker. Use Date/Time to compare specific times or if the exact time is important.
String	Holds freeform text. Use String if no other field type matches the values stored in the field.

Note:
Field types should not be changed after a field is created.

Choice lists or reference fields

Choice lists and Reference fields both offer users a way to choose a value from a list. Choice lists are name/value pairs. Users select from the names and the field stores the value of the selected

choice. Scripts use the value. Add and remove name/value pairs from the choices to manage the list of options.

Reference fields point to a table. Manage choices in the table. The value stored in the reference field is the sys_id of the referenced record.

Choice lists do not require a reference table and are easier to configure than reference fields. Use Choice lists when the field has ten or fewer options and the options will not change. Consider using a reference field and table when:

- The field requires more than ten choices.
- The choices will regularly change.
- Someone other than an administrator needs to manage the choices.
- The value of the field has an impact on decision logic. For example, decision tables in Flow Designer.
- The data has multi-level dependencies between different fields that can lead to complex and unwieldy choice field combinations.
- The choices require more than a name/value pair. For example, referencing a user record gives the referencing table access to other user details, such as email and department.
- A table already exists that includes the data needed for the field.

When using reference fields, review the tables available in the instance to reference before creating a table. If creating a new table, check the list of exempt tables in section 2 of the Custom Table Guide. If appropriate, extend the new table from one of these.

Note:
Before creating new fields on an extended table, check for an existing field inherited from the base table that has a similar purpose. If a field is found, override the extended table's label.

Secure data

Data security is one of the most important and overlooked aspects of creating an application. ServiceNow automatically configures access control for a new or selected role during the table creation process. Only users with the role can access the table to read, create, write, and delete.

Use access control rules to configure table and column-level security in the ServiceNow AI Platform. To properly configure access to an application, developers should understand how access controls work and the order in which access controls are evaluated. Apply multiple access controls that together make an Access Control List (ACL).

Self-Paced Training: Securing Applications

Documentation: Access control list rules

When considering security:

- Protect tables, UI pages, property pages, and other content with the appropriate access controls and roles.
- Limit the use of GlideRecord queries in access control scripts. GlideRecord queries can affect performance.

Beginning with the Orlando Platform Subscription model, customers are charged by how many tables a user can access, regardless of whether the user does access the table. Configure ACLs to restrict access to a table to ensure that only the users that need access to a table can access the table.

Note:
Consider making any auto-populated fields read only. If the system is populating the data, a user should not be able to.

Alternately, secure data on the ServiceNow AI Platform with before-query Business Rules. Before-query Business Rules run before the database query and are limited to controlling read access to a record. Only use before-query Business Rules when necessary. Some considerations when deciding to use Access Controls or before-query Business Rules:

- GlideRecord queries will bypass read access controls on a table and will be restricted by before-query Business Rules on a table.
- When access controls restrict read access to records in a list, ServiceNow shows a message saying that access has been restricted for the records. With before-query Business Rules, the number of records in the list total matches the number of records shown to the user. The user receives no indication that some records have been hidden from the list.

Review the user query Business Rule on the User [sys_user] table for reference.

Note:
Before-query Business Rules do not take the place of ACLs. Denying users access to a table via before-query Business Rule will still count the table against the subscription model. Use Access Controls to prevent the table from being counted for the users in the Platform Subscription model.

Encryption

The ServiceNow AI Platform also provides various encryption solutions at the application tier, database tier, and hardware tier. Learn more in the Data Encryption Whitepaper.

Note:
Set up security before configuring any interfaces or business logic. Since security affects the data available to interfaces and business logic, waiting until the end of the application build process may cause rework and issues.

Manage data

With the data model (tables and fields) created and security set up, add data into the application's table(s).

Import sets

To populate tables in ServiceNow from an external platform, use import sets and transform maps. To retrieve data from an external source on a regular basis, use a scheduled import.

Self-Paced Training: Importing Data into ServiceNow

Guidelines for Import Set Performance:

- Break up large amounts of data into smaller sets for faster imports. Consider 100,000 rows to be a baseline and break up anything larger than that into sets of 100,000. For example, importing 10 sets of 100,000 will finish quicker than one set of 1,000,000 records. Also consider using Concurrent Imports with larger numbers of records.
- Importing large data sets simultaneously can put load on an instance. Stagger large imports so the imports do not overlap.
- If possible, deselect the Run business rules check box on the transform map table to avoid running Business Rules and other logic during an import. Consider using an onComplete

transform script to run business logic, such as calculations, at the end of an import rather than on each record as Business Rules do.

- Use default functionality for imports. Whenever possible, avoid writing custom scripts. For example, use the coalesce functionality rather than writing a custom coalesce script.
- Avoid GlideRecord queries in an import set.
- Make sure any fields configured to coalesce are indexed.
- If replacing a system with a requirement to import historical data, import only the historical data required for the application. Consider storing historical data in a data lake.

Inbound integrations

In addition to Import Sets, ServiceNow includes APIs to accept data from external platforms.

To push data directly into an application table from another system, use Web Service Import Sets instead of writing directly to application tables using the REST Table API or SOAP APIs.

To handle data transactions that are more complex than writing data to a table, such as sending an attachment or ordering a catalog item, review the available APIs to see if one exists that supports the required logic.

Use a Scripted REST API or Scripted SOAP Web Service to build REST or SOAP endpoints, respectively. Scripted REST API and Scripted SOAP Web Service endpoints can execute ServiceNow server-side code when the endpoint is consumed by an external system.

Self-Paced Training: REST Integrations

Create design elements

After the application's data model is created, secured, and populated with data, create the design elements to access that data.

Primary interfaces

The primary way for users to interact with a data model is through forms and lists or through mobile.

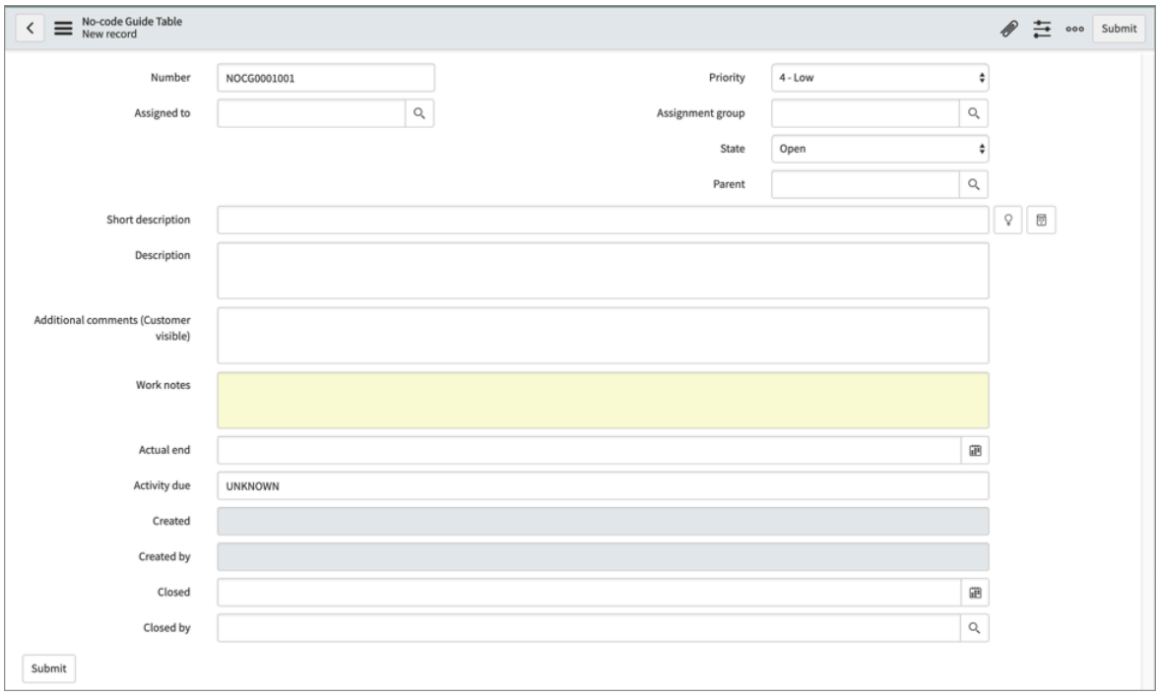
Forms and lists

The standard method of accessing data in ServiceNow is through the default forms and lists. A form displays information from one record in a data table and a list displays a set of records from a table. When configuring forms and lists:

1. Keep the number of fields on a form to a minimum. The more fields on a form, the longer the form takes to load resulting in a poor user experience. Use form views to create different sets of fields for different situations.
2. Use form sections to logically group fields together and to keep users from scrolling. The top section of the form should contain the fields that are always needed or used, while the other form sections contain less frequently utilized fields.
3. Make sure fields appear in the right order. For example, the start date field should always come right before an end date field.
4. Use seven or fewer columns in a default list. Users can add more by personalizing their lists.
5. Avoid using a reference field as the first item in the list view, because it is shown as hyperlinked text. Clicking on the reference field will redirect the user to the referenced record instead of the list record, resulting in a poor user experience.

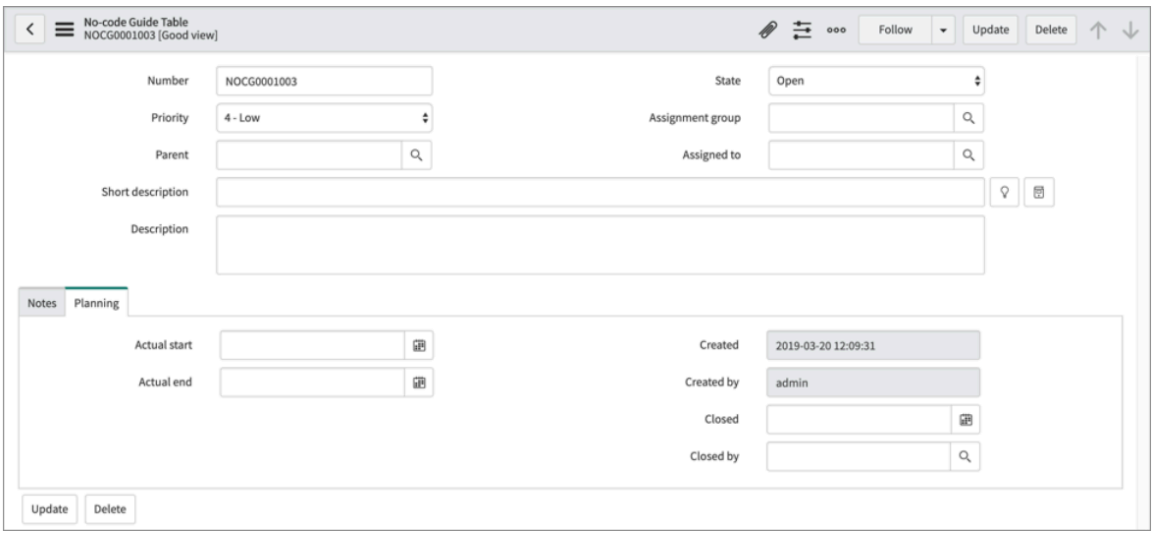
This example shows a poorly designed form.

- The form has no sections. Users need to scroll through the entire form to see all the fields.
- Similar fields are not grouped together. For example, Assignment group and Assigned to are on different sides of the form.



This example shows a well-designed form.

- Fields are grouped together logically.
- The form has been broken into sections for easier viewing and data entry.



Mobile

If users will interact with the application on their mobile devices and will need native iOS or Android functionality, such as geolocation or offline access to application data, use the ServiceNow Agent app. Use Studio to create a mobile application for the application.

Create applets in the mobile application. Applets are tiles within an application. Include a main screen, such as a map or a list, and various details screens, such as an activity stream or related lists. Applets should have focused experiences.

Note:
Individual applets can be secured by role as well as made available in offline mode.

Self-paced training: Mobile Applications

Other resources: Mobile Resources

Self service

Your application may need a way for end users to be able to access your data model, so there are self-service options available.

Service Portal

If the application has Requestor or Self-Service users, use Service Portal to provide a friendly web experience.

To give self-service users the ability to easily create application records from the Service Portal, create a record producer. A record producer can provide a better end-user experience than a regular form. Talk to your ServiceNow Administrator about the appropriate catalog and categorization to make the record producer accessible through the Service Portal.

Alternatively, create a Service Portal for your app if the following is true:

The application needs different branding, navigation, or user experience than an organization's current Service Portal.

OR

The organization does not have an existing Service Portal.

AND

The application needs more functionality than the default portals provide.

AND

The application requires a more customized user experience than the default forms and lists can provide.

OR

The application needs more control over branding and themes than the default interface provides.

Tip:
Do not try to reuse any existing service portal pages in an application. Create new pages and then reuse components in your pages, such as widgets and headers.

Widgets

Widgets are what define the portal content. The base system widgets provided with Service Portal can be used, or developers can build custom widgets to fit business needs.

Considerations for creating custom Service Portal widgets for an application:

- Start from an existing widget instead of creating a widget from scratch. To protect existing widgets from accidental modifications, all baseline widgets are read-only.
- When developing a widget, use the preview pane to quickly test the widget's behavior. Always test the widget on a portal page before releasing a widget to production.
- Use third-party debugging tools when debugging browser-based applications. For example, the ng-inspector Chrome extension for Angular JS.
- Avoid the use of $rootScope.$broadcast(). Instead, use $rootScope.$emit() to publish an event to the rootscope.
- Use widget options to make widgets more easily reusable. The widget option schema defines the user-configurable fields.
- For field types not supported in the option schema, create an extension table to store a custom widget option schema.
- Make use of Angular Providers, which are reusable components that can be injected into multiple widgets. To ensure quick loading widgets and a high performing portal, create Angular Providers instead of overloading your client controllers with persistent data and additional logic. With Angular Providers, you can maintain data for the lifetime of your Service Portal and reuse components and data objects across multiple widgets.

For more information, see Service Portal training.

Virtual Agent as an application design element

Consider Virtual Agent, ServiceNow's conversational bot platform. Use ServiceNow Virtual Agent (VA) to build and design bot conversations to help users quickly obtain information, make decisions, and perform common work tasks.

Some considerations when building VA conversation topics:

- If adding VA to a portal, create topics that focus on particular use cases rather than a broad topic.
- Read topics out loud to keep the topic from sounding too robotic or being too verbose.
- Do not try to design the whole interaction at once. Instead take an iterative approach when building the bot and test the conversation frequently.

For more information, see Virtual Agent.

Notifications

After the data model is defined and users are able to interact with the application, determine how the application should communicate with users. Configure notifications to alert users to important application related events, share application information in the knowledge base, and add translations to allow users to interact with the application in their native language.

The ServiceNow AI Platform can notify users by email, SMS text message, or push notifications.

Triggers: Event Driven Notifications vs Table Updates

Configure notifications to trigger based on updates to a table or based on an event. Use event-based triggering when triggering requirements cannot be easily implemented in the notification conditions or when the notification is triggered from a Workflow. Creating specific events also enables easier notification debugging.

Use the Notification activity in a workflow or the Send an email action in Flow Designer for simple notification use cases. For complex or critical notifications, trigger an event from a workflow or a Flow Designer flow and configure a notification to fire off that event.

Notification Content

ServiceNow notifications support static and dynamic content using email templates, email scripts, and notification variables.

Notification variables add dynamic information to the body of a notification, such as field values from the base record. The variables also support dot-walking, which allows field values from any related records to be included in the content without scripting.

For example, use the URI_REF variable to point to the record that originated the email.

Use email scripts or dot-walk from the base record to include dynamic content that is not available in the record. Use the mail script API to set notification details, such as the recipient and sender addresses, etc.

Note:
Scripts entered in the notification body using <mail_script> tags may not always work correctly. Always create email scripts at System Notifications > Email > Notification Email Script and include them in the notification body with ${mail_script:script_name}.

Create email templates for content used in multiple notifications. Adding the content to an email template enables administrators to create reusable content for the subject line and message body of email notifications.

Configure recipients

ServiceNow emails can be sent to users, groups, or individual email addresses. When sending to groups, check the **Include members** field on the group record for the notification to be sent to all members of the group in addition to the group email.

Subscription-based notifications - Select the **Subscribable** option on the notification to allow recipients to pick and choose the emails they want to receive.

For a subscription-based notification, the Mandatory option can be set to true for the recipients to receive the notification regardless of their individual preferences. Optionally, configure unsubscribe links in the outgoing email to allow users to remove themselves from the notification.

ServiceNow uses email watermarks to correctly process user responses to notifications. Email notifications automatically include watermarks unless the **Omit watermark** option is selected in the notification. Omit watermarks only when no email response is expected from the recipients.

The Troubleshooting Outbound Email knowledge base article provides troubleshooting steps for the most common notification issues. Log in to the HI portal (https://hi.service-now.com) to access the article.

Translations

When using one of the Internationalization plugins, most of the fields in the instance are automatically translated. However, customizations are not translated automatically, and need to be translated by hand. In this case, it is best to locate the individual untranslated strings, and insert those translations manually.

To implement a new language, activate the plugin for the new language. Then export the existing values from any of the Translation tables.

For example, export all **sys_choice** records. Provide the export to a translator to provide translations for the **Label** field in the provided file. The **Value** field should not change. Update the

Language value to the new language. Then, upload the translated values back to the **sys_choice** table.

> **Note:**
> To insert values, make sure you are setting all the necessary fields; table, element, language, label, value, and sequence. Set the dependent value and hint where applicable. This logic is the same for all translation tables.

For more information, see Language Internationalization Support

Overview of reporting and analytics for developers

Most applications that you create have some level of reporting requirements. Reports should be actionable to drive change.

"Reporting" generally refers to showing the data inside facts tables like Incident [incident]. You can also create key performance indicators (KPIs) to track changes in this data over time, through the Performance Analytics application.

Currently the ServiceNow AI Platform® is in transition between two user interfaces for showing this information:

- The older Core UI technology. This UI includes the Reporting application, which only shows data directly from tables, and PA Widgets, which show data from Performance Analytics indicators. Both reports and PA widgets can be placed on Core UI responsive dashboards. For more information, see Reporting, dashboards, and Performance Analytics in the Core UI.
- The newer Platform Analytics technology. This UI includes Data Visualizations, which let you report on data from any source. These visualizations can be placed on Platform Analytics dashboards, along with Platform Analytics filters. For more information, see Platform Analytics experience.

  All Platform Analytics objects are rooted in the Next Experience UI Framework and are available to developers. However, a non-developer can still build their own objects through the Platform Analytics experience, without using UI Builder. For more information, see Platform Analytics experience.

> **Note:**
> Although "reporting" is a general term, this documentation usually uses "report" and "reporting" to refer to the Core UI Reporting application and "visualization" or "visualize" to refer to Platform Analytics data visualizations, for disambiguation.

Follow these guidelines when building reports or data visualizations:

- Creating reports or visualizations on large tables can negatively impact performance. Be sure to filter by a date range or other limiting criteria rather than showing all records on the table.
- Grouping by fields that contain many possible values can negatively impact performance.
- If loading a report or visualization gives a Long running transaction timer message, consider adding more data filters to reduce the load time.
- If you need to export a report, data visualization, or dashboard on a regular basis, schedule the export and email.

In Platform Analytics, you have several possibilities for showing multiple data visualizations on one page:

- Create the data visualizations and the dashboards entirely inside the Platform Analytics experience. This approach does not require a developer role or special technical knowledge, and probably should be explored before you try a more complex solution.
- Create data visualization components in a generic UI Builder page, along with filters and other components. This approach gives you the most freedom as a developer, but also requires the most configuration.
- Create the data visualizations and the dashboards inside the Platform Analytics experience, but then place the dashboards inside UI Builder pages using the Dashboard page template. This approach lets you use the convenience of the Platform Analytics experience to create dashboards, data visualizations, and filters in your own experiences/workspaces. It also gives you the freedom to customize the page configuration partially. For more information, see Creating Platform Analytics pages in your own workspace.
- Create a technical dashboard and populate it inside UI Builder. This approach is almost the same as creating your own UI Builder page from scratch, but the dashboard is available in the dashboard library, has dashboard details, and can be shared like other dashboards. For more information, see Technical dashboards.

Build form and business logic

The next step in designing an application is to build logic. Logic includes form logic (what people can and cannot see/use on a form) and business logic (rules that govern what happens to data when it is entered).

Scripting and modifications

Before writing any code, be aware of the impact on upgrades and the adoption of new ServiceNow features. Particular care should be taken when modifying baseline artifacts and processes.

Consider the following before scripting:

- Assess the requirement. Is the logic critical to the functioning of the app?
- Determine if ServiceNow can be configured to fulfill the requirement without code.
- Leverage options, such as Flow Designer, Virtual Agent, and UI Policies to take advantage of platform capabilities without writing code.
- Low and no-code approaches to logic are easier to debug and upgrade.

Examples of when scripting is appropriate:

- Building Flow Designer actions
- Creating a Scripted REST API
- Creating logic for scoped applications in Script Includes
- Customizing and creating widgets for Service Portal

Evaluate the business requirement and consider a no-code route before using a scripted solution.

Be aware of ServiceNow enhancements. For example, in the orlando release, Virtual Agent conversations have more no-code options than London. Read release notes and other publications. Get certified and stay current with your certifications.

To better understand when to customize, review the Innovate at Scale Success Playbook on the Customer Success Center.

Modifying default behavior

In the past, one of the strategies used was to copy the artifact to update and to deactivate the original. The copy/deactivate approach is no longer recommended due to the following issues:

- Developers cannot tell if a deactivated artifact was upgraded without research.
- Two files, the original and the copy, need to be maintained. Maintenance doubles each time a customization is made.
- With each release, the customized record becomes older.
  - Customers do not receive the enhancements included in a new release.
  - A new release may rely on the original record being updated.
  - Developers may make more changes to compensate for the original record being inactive.

A script where only the **Active** flag is changed will be updated, but the script does not appear on the skipped list. With the copy and deactivate strategy, a developer has less visibility into customizations and cannot easily assess or revert to the baseline version.

Rather than copying and deactivating the original artifact, edit the artifact directly. The ServiceNow Upgrade Engine will add the latest version to the version history and report that the artifact was skipped. Developers can see a new version is available with the upgrade.

Form logic

Controlling what users see when they visit a form can increase productivity and responsiveness. For example, users should only see fields that are useful to them. Users may only need to see certain fields based on what is configured on the form. Apply form logic to control what is visible, read-only, and mandatory on a form.

The following question will help direct you to the right decision for when to control user access to information: Is this a suggestion or enforcement? A suggestion makes the form easier to complete whereas enforcement forces the user to do something in order to complete the form.

UI Policies are useful for conditional suggestionslike showing and hiding fields or adding field messages based on another field's value, while Data Policies and Business Rules are better suited for doing conditional enforcementlike making a field mandatory.

The best user experience is to utilize both suggestion and enforcement together.

For more information, see the UI Policy article in the Client-side Scripting Module.

Build UI Policies and Data Policies to handle client-side activities before scripting any client-side logic. Use of Client Scripts to validate user input and provide feedback while the user is completing the form.

Some general practices for client scripting are:

- Optimize for performance by using asynchronous GlideAjaxover client-side GlideRecordor multiple getReference()calls.
- Keep the isLoadingcheck in onChangeclient scripts.
- Keep the newValuecheck and add a newValue != oldValuecheck.
- Use all client-side scripts possible before making a server call with GlideAjax. Server roundtrips can impact performance.

Some client scripting practices to avoid are:

- Global Client Scripts or Global UI Scripts: Global scripts will run on every page load and introduce browser load delay.
- DOM Manipulation: Using document object model manipulation against default UI elements introduces upgrade risk and maintainability issues. The exception is using DOM manipulation against the DOM in pages authored in the same scoped application, like UI Pages or Service Portal widgets.

Business rules and script includes

Business rules are server-side actions that can be run during CRUD (Create, Read, Update, Delete) operations on instance records.

Some good practices when using Business Rules are:

- Keep Business Rules small and specific.
- Avoid modifying base system Business Rules.
- Use Script Includes instead of global Business Rules.
- Use scripting only when necessary.
- Store reusable script logic in a script include.
- Use queries to limit records processed within a Business rule.
- Avoid client-callable Business Rules to improve efficiency when running client scripts.
- Always use a condition with Business Rules to control when the Business Rule runs. Running Business Rules with conditions can also aid in debugging. Business Rules rarely run with no conditions.

Business Rules can be configured to run before or after a database operation. They can also be configured to run asynchronously and also before displaying a form or executing a query.

Value	Runs	When to Use	Example
Before	Synchronously before the database operation	Set or update values on the current object as part of the save operation. Validate and abort execution if required.	A developer wants to set the state of the current record based on another input in that record.
After	Synchronously after the database operation	Trigger events and notifications after the database update to access the previous object or to make something occur in sequence. Update related records other than the base table being updated to access the previous object or to make something occur in sequence.	A developer wants to cascade values from the current record down to child records.
Async	Asynchronously executed as a separate process after the database operation is completed	The process triggered by the rule may take a while to run. When the user who triggered the operation does not need the output right away. Trigger events, notifications, or related record updates when access to the previous values of the record or a specific sequence of actions is not required.	A developer needs to trigger an external process that may take a while or update a large number of records.
Display	Executed every time the	Used to make server-side objects available to client-side scripts.	A developer wants to write information

Value	Runs	When to Use	Example
	corresponding form is displayed		about a user associated with the current record to the g_scratchpad object to use in a client-side script.

Note:
current.update()should not be used in any Business Rules. Using current.update()triggers an additional database operation, which could cause duplicate notifications, recursive loops, etc.

Use Script Includes to store JavaScript functions and classes for use by server scripts. Each Script Include defines either an object class or a function that can be reused among any server-side scripts. For more information, see Script includes.

Store any code that might need to be used elsewhere in a Script Include. Call the Script Include from a Business Rule, UI Action, workflow script, Scripted REST API, etc. Instead of calling a Business Rule from a UI Action or a UI Action from a Scripted REST API, put the code in a Script Include and call the Script Include from both places.

Keeping functions in a Script Include allows testing of the function before deploying the function in other scripted areas, thus reducing overall development and testing time.

For more information, see Classic Business rules.

Flow Designer

Flow Designer is a ServiceNow AI Platform feature that enables rich process automation capabilities in a consolidated design environment. Flow Designer enables process owners to use natural language to automate approvals, tasks, notifications, and record operations without having to code.

Flow Designer and IntegrationHub

For any new process flow requirements, ServiceNow recommends using Flow Designer over the legacy workflow for almost all circumstances.

Flow Designer and Business Rules

You should use Flow Designer instead of Business Rules unless:

- Business logic needs to run in a specific sequence with other Business Rules. For example, new business logic needs to run after one Business Rule but before another.
- Logic needs to execute immediately before or after writing to the database in the same thread.
- The logic only calls a Script Include.

When designing a flow, follow these design principles:

- Single Purpose: Each flow should have a singular goal.
- Reusability: Design with reusable sub-flows in mind (approval is a great example).
- Clarity: The language and layout of a flow should make each action's purpose clear.

Start with a white board design of a business flow. Then build the flow action by action to align with the process. More than one flow may be required for a for a single process to keep to the design principles.

Use the following practices when working with Flow Designer:

- Use records, not SysIDs. Provide a guided experience with inline documentation.
- Learn how to use template objects to work with both static and dynamic inputs.
- Avoid passing around blobs of data unless absolutely necessary.
- Only pass information to a flow that the flow is going to use.

Use the following practices when working with Flow Designer Actions:

- Always create actions under the scope of the application's spoke, if applicable.
- Set access to Accessible from all scopes in actions to be able to reuse actions across other apps and scopes in the future.
- Set **Protection** to Read-only to avoid any unwanted edits to the actions by users.
- Make sure inputs have a specific type.
- Ensure that **Mandatory** is selected where required.
- If using a **choice** input type, use a default value.

Use the following practices when working with IntegrationHub:

- Create one spoke per integration system. Only put actions for a single system in a spoke.
- When creating the scoped app for the spoke, use a version naming convention that makes sense.
- Use a connection alias instead of an inline connection. The Base URL will be automatically extracted.
- Use connection attributes under the Alias to pass the version in a REST step giving future flexibility for versioning in the resource path.
- Use Save as Attachment to save the content in the response instead of creating another step to save the data.
- If the Alias is dynamic, make Alias one of the inputs and use the data pill to provide the Alias.

Use the following practices in Flow Designer and IntegrationHub for Error Handling:

- Create a Script Include to handle errors.
- Write short and understandable error messages.
- Incorporate all of the possible error messages the API returns.
- Ensure that the outputs from the integration step are validated before using them.
- Fail Early: If the inputs are not available, do not call the integration.

Self-Paced Training: Flow Designer

Self-Paced Training: IntegrationHub

Validate app functionality

As the application is built, validate that it works as expected.

Unit testing

Unit/Story testing ensures requirements specified in a story are validated before closing the story. A Story/Unit is a smallest testable portion of system or application that can be configured and executed.

When the configuration of the story is complete, developers need to unit test the features not only in the context of that particular story, but also other related stories that share components with the current story.

As a good practice, developers need to assign the story to process owner or designated stakeholder to validate the story configuration meets expected outcomes before closing the story.

ServiceNow's Automated Test Framework (ATF) is primarily meant for automating functional testing of applications but in few cases can be used to automate unit testing of configurations that involve Script Includes and Business Rules.

System testing

System testing is performed on a complete system when development is completed. Test the overall interaction of components and integrations with other applications within scope. System testing is performed by the QA/Testing team, but developers need to collaborate with the QA team and process owners to ensure test cases provide comprehensive coverage. Developers will be responsible for remediation of issues found during System Testing.

Automated Test Framework

Automated Test Framework (ATF) should be leveraged for automating functional system testing of ServiceNow applications to reduce testing time and costs and make testing repeatable and UI independent. When creating test cases, follow these guidelines.

When creating tests:

- Use parameterized testing to avoid duplicate test cases.
- Follow a Test naming standard.
  - `<app initial>: <functionality that is being tested>`
  - CSM: Resolve case
- Describe each test's use case in its description. For example: Sample that tests use case.
- Develop tests on a Development instance and promote/run the test on a Test instance.
- Clones wipe out tests. Use one of these options to preserve tests:
  - Bundle tests in a scoped app and upload the app to GIT.
  - Save tests before the clone.
  - Promote tests to prod instance, but DO NOT EXECUTE THE TESTS IN PROD.
- Create self-contained tests.
- Create new server-side or REST test steps any test steps are missing. For example: Email body verification.
- Use server-side test step whenever possible and when screenshots are not important.
- Start with the Impersonatestep.
- Be aware of browser throttling.
- Use the Test Logs and Test Transactions to troubleshoot test errors.

When creating test suites:

- Follow a test suite naming standard. For example: ITSM INT: Use cases.
- Describe the suite.
  - Test suite description: "This is a sample test suite to test plugin/application".
  - Provide any additional information possible in the description.
- Organize test suites by feature areas.

User acceptance testing

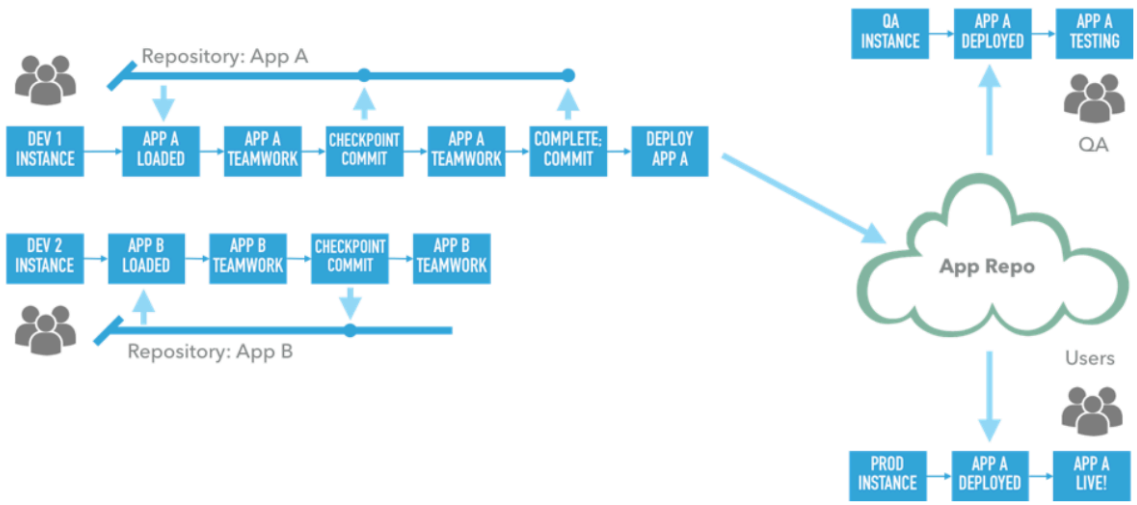
User Acceptance Testing (UAT) is a test conducted to evaluate the application's compliance with the business requirements and assess whether the application is acceptable for delivery. Users, customers, or other authorized stakeholders perform acceptance testing. Developers will be responsible for remediation of issues found during System Testing.

Deploy your app

Once the application is built and validated, the application needs to be moved to the production environment. Applications can be moved through an application repository or by using Update Sets. Applications should be deployed to test environments prior to moving to production.

Application Repository (App Repo)

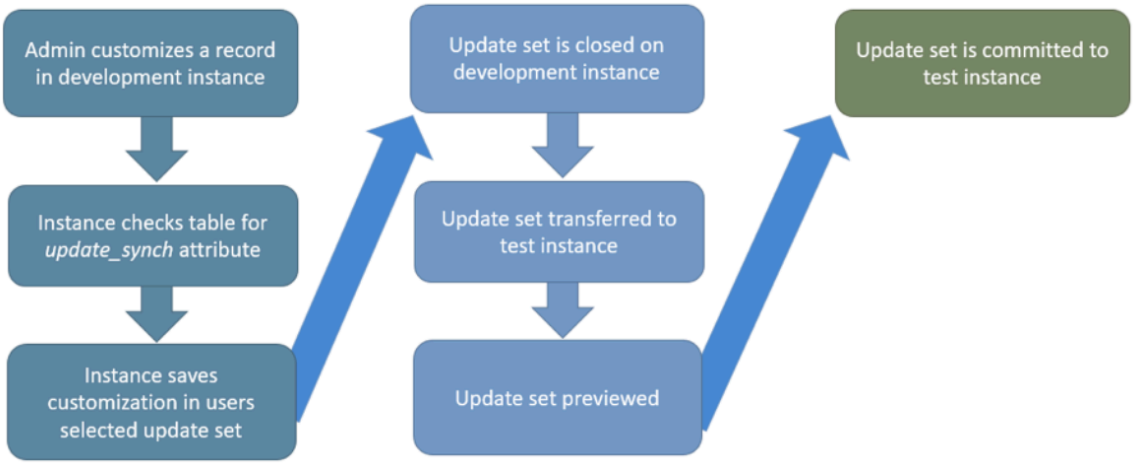
Publishing an application to the App Repo makes this version of the application available to all of an organization's ServiceNow instances. Use the App Repo to deploy an application to QA / Test instances (for testing) and finally to Production (Prod) instances.



For more information, see Publishing an application to the application repo, Install an application.

Update Sets

If the application repository cannot be used to deploy applications, use Update Sets instead. The diagram shows the best practice lifecycle of an Update Set to deploy a customization from the development instance to the test instance.



Practices that lead to a quality development and release process:

- Always move customizations from the bottom of the stack up.
  - Ensures down-stack instances match up-stack instances.
  - Customizations introduced mid-stack can be overwritten by future pushes from down-stack.
  - Common scenarios include:
    - Fixes need in test or prod – always push them from dev up
    - Common Prod admin customization, such as choice lists – always push updates from dev up
- Always review updates contained in an Update Set before transferring.
  - Look for updates associated with other development efforts and updates associated with testing.
  - Watch for system properties and integration end-points changes. Ex: pushing sys_properties change that directs all email to test email account
  - Move updates to a “scrap” Update Set rather than deleting the update.
- Always test after pushing to ensure that all desired customizations are captured and applied as expected.
- In situations with multiple, parallel releases, ensure communication and coordination between the development teams.
- Avoid experimenting on the development instance, because customizations can be captured accidentally and migrated by other team members.
- Do not capture development in the Default Update Set.

List all user Story numbers with a short description in the **Description** field of an Update Set. Include all manual steps that are required to deploy the Update Set.

Some typical examples of manual steps that are needed for a deployment that are not captured in an Update Set:

- Plugin activation.
- Transfer of tables that are not tracked in the Update Set (typically, starting with “x_” or “u_”).
- Creation of database indexes on the tables. The index creation is not tracked via Update Set and needs to be done manually.

Update Set management

Be sure the correct Update Set is selected when working on a story or a defect and check the records in the Update Set daily.

Do not manually move sys_update_xml records between Update Sets. The only exception is to move a record to the Default Update Set.

Update Sets capture configuration information but not task or process data. For example, Update Sets track Service Catalog item definitions and related configuration data like variables and variable choices. However, the orders (requests, items, catalog tasks) placed in testing are not tracked by Update Sets.

Be aware of Update Set DOs and DON'Ts:

- To remove a specific sys_update_xml record from the current Update Set, move the record to the Default Update Set and populate the **sys_update_set.comments** field of the record with the reason for moving the record to the Default Update Set.
- Never move customization records from one Update Set to another Update Set.
- Never delete an Update Set unless the Update Set has been merged successfully into a new Update Set.
- Always use data extracts or Import Sets to move data from one instance to other (and not Update Sets).

Update Set batching

Batch Update Sets to preview and commit Update Sets in bulk.

Dealing with multiple Update Sets can lead to problems, including committing Update Sets in the wrong order or inadvertently leaving out one or more sets. Avoid these problems by grouping completed Update Sets into a batch.

The system organizes Update Set batches into a hierarchy. One Update Set can act as the parent for multiple child Update Sets. A given set can be both a child and parent, enabling multiple-level hierarchies. One Update Set at the top level of the hierarchy acts as the base Update Set.

Previewing or committing the base Update Set previews or commits the entire batch. The system determines the processing order, and checks for collisions based on the dates the changes were recorded and on their sequential ancestry. Their ancestries are the specific instances in which the changes in the Update Sets took place.

Update set batching can be applied to releases, where an empty parent Update Set is created for the release, and actual Update Sets are included in the release as children.

Advantages of using Update Set batching are:

- Individual Update Sets can be removed from the release at the last moment.
- Batching is similar to merging, except batching allows updates to be removed.
- Batch Update Sets are easy to deploy. Only the Parent Update Set needs to be processed.

For more information, see System update sets.

What to do next

Now that the app is deployed, think about how to improve and enhance it. Here are some suggestions for determining where to go next:

- The people using the application day-to-day will be the best source of feedback. Talk to them about what new features or changes they would like to see.
- Determine if additional related process flows can be automated through Flow Designer.
- Determine if new IntegrationHub spokes can be leveraged for new integrations.

Builder library

The ServiceNow AI Platform provides a robust set of builder tools that enable you to quickly develop applications for your organization.

The following builder tools enable you to quickly design and build user experiences, interface components, data models, and more when developing applications on the ServiceNow AI Platform.

Builder tools

Tool	Description	Use case(s)
Exploring decision tables	**Configure application decision logic** Use decision tables to help resolve a complex decision that depends on multiple factors. Decision Builder enables developers to decouple decision logic from their code by creating and maintaining decision rules.	Determine a customer discount rate for a product given two inputs (number of units ordered, and whether or not it was paid for in cash).
Flow Template Builder	**Configure a standard template for specific app workflows** Flow Templates guide flow authors to create flows for common use cases. Use this builder to define flows, actions, and flow template variables.	Create a flow template to use as the basis for all request approvals within an IT application.
Integration with Performance Analytics	**Optimize processes through integration with Performance Analytics** Use Process Optimization with Performance Analytics to perform data extraction from an indicator and analyze processes associated with the KPIs, such as time to resolve.	Visualize the execution of processes or a customer journey, show insight into adoption, activity transitions, performance, and user experiences or identify bottlenecks and see their impact on your key performance indicators, enabling you to resolve root-cause issues.
Mobile App Builder	**Configure Mobile apps** The Mobile App Builder is a configuration tool to build and manage screens and records that make up workflows within	Streamline mobile configurations by organizing records in a hierarchical layout for quick access and reference, supporting hierarchical tree navigation, and enabling users to visualize how records relate to

Builder tools (continued)

Tool	Description	Use case(s)
	ServiceNow mobile apps. The organizational layout and navigation options in the Mobile App Builder facilitate a faster and more intuitive creation of ServiceNow mobile applications.	each other in the overall mobile app configuration.
Mobile Card Builder	**Configure and manage card templates to display information for mobile interfaces** Use Mobile Card Builder to create or modify card templates used in the ServiceNow mobile applications for iOS and Android. The ServiceNow mobile interface uses cards to display information about records on your instance.	Create cards for launcher screen record sections, calendar screens, form screens, Genius search results, list screens, and map screens.
NLU Workbench	**Configure Natural Language Understanding (NLU) models to interpret user-expressed intent** ServiceNow® Natural Language Understanding (NLU) provides an NLU Workbench and an NLU inference service that you can use to enable the system to learn and respond to human-expressed intent. By entering natural language examples into the system, you help it understand word meanings and contexts so it can infer user or system actions. NLU workbench is where you create, manage, and test NLU models. Use NLU models to apply ServiceNow® Natural Language Understanding on your instances. Create, manage, test, and publish NLU models with the NLU Workbench.	Configure a Virtual Agent Designer conversation flow to consume an NLU model so that agent chatbots can better understand user statements in the conversation.
Platform analytics for workspaces	**Configure performance analytics that capture historical trends in data through snapshots** Integrate data visualization and analytical functionality into the workspace experience. Subscribe to notifications about behavioral process changes. Explore KPIs and	Configure the ability for users to ask natural language questions and be shown the relevant analytics in a visualization, view any Next Experience dashboard that are owned by a user or shared with a user, create dashboards and data visualizations from workspace runtime, or drill down into KPIs,

Builder tools (continued)

Tool	Description	Use case(s)
	get answers and insights on Platform Analytics.	apply filters to slice data, or apply aggregations and statistical tools.
Reports	**Build and distribute reports that show the current state of instance data** ServiceNow® Reporting enables you to create and distribute reports that show the current state of instance data. Reporting functionality is available by default for all tables, except for system tables.	Show the number of open incidents at an organization that also displays the priority of each incident at a current point in time. A variety of different types of reports could be configured to show this information, including bar, pie, time series, multidimensional, scores, statistical, etc.
Service Portal Designer	**Create a self-service portal for your users** Service Portal enables you to build a mobile-friendly self-service experience for your users. It interacts with parts of the ServiceNow AI Platform, so users can access specific ServiceNow AI Platform features using Service Portal. This tool is used to create service portal pages to organize content, ensure responsive mobile optimization, and design meaningful portal user experiences for your customers. A page houses containers and rows, which then contain widgets. By manipulating the layout of the page, and the widgets within it, you can construct your desired user experience. Widgets are what define the content in your portal. You can use the base system widgets provided with Service Portal, clone and modify widgets, or develop custom widgets to fit your own needs.	Configure a mobile-friendly experience for a company's employees to engage with IT and request services like new emails, new employee computer setup, etc.
Table Builder	**Create application tables and table-related forms and configure display logic** Table Builder enables you to create, design, and administer tables and forms visually from a single user interface.	Create an online food order form in an food delivery application for customers. The form might capture the food ordered and related delivery options. The form would store and capture the information entered in a designated application data table that you configure for this purpose.

Builder tools (continued)

Tool	Description	Use case(s)
Themes in Theme Builder	**Customize themes and branding** Theme Builder enables you to tailor the visual experience for your users, helping to update the look and feel to be more like your brand. Next Experience extends the theming model used in UI Builder.	Configure a dark theme for your company's brand that makes use of a primary color and secondary color, specifies what color to use for screen elements like divider lines, and contains a new brand logo.
UI Builder	**Design application user Interfaces** UI Builder is a web user interface builder. Use UI Builder to build pages for workspaces or custom web experiences (generated by App Engine Studio) that use Next Experience Components and custom web components..	Create a new standard record page variant to show specific incident records, edit the standard record page to show a list of problems for a user, or build a landing page for a Next Experience app you are designing.
Virtual Agent Designer	**Design virtual agent conversation blueprints** The Virtual Agent Designer is a diagram tool for creating and managing topics, which are blueprints for conversations between a virtual agent and user. You can design topics that help your users resolve common work issues or guide them through self-service tasks.	Create and configure a conversation flow that enables end users to see the status of incidents they submitted and leave a comment in the incident.
Workspace Builder	**Create custom workspaces for your application** Workspace Builder is a streamlined, no-code environment that enables you to create a custom workspace from within App Engine Studio (AES) quickly and efficiently.	Configure a Service Desk workspace that will handle request and fulfillment of IT services within your organization.

Create custom components using ServiceNow CLI

Develop custom components using the Next Experience UI Framework and the ui-component extension.

Components are reusable building blocks that you use to create a custom user interface. The Next Experience Design System comes with a set of customizable components that you can drag into your custom UI. Develop your own components if you can't find what you need in the Next Experience Design System library.

To see the Next Experience Design System library, visit the ServiceNow® Developer Site.

Benefits of creating custom components

Developing custom components lets you:

- Personalize a UI according to your agent, customer, and company needs.
- Make your employees more effective and reduce context switching with quick access to important data and information.
- Accommodate your company's unique omni-channel environment using APIs to consolidate your data.

For example, you might want to create a component that displays the cases associated with an SLA, or that tracks the active chats in a particular queue. You can use the Next Experience UI Framework and the ui-component extension to develop the component you need, and access data from your platform using the Http Effect API. You can also query platform data using GraphQL by creating a custom schema. For more information, see Scripted GraphQL.

What to know before you begin

Before you start designing and building your component, make sure you have:

- Some general knowledge of web component concepts, development, and design.
- JavaScript knowledge to define the component behavior.
- Knowledge of Node Package Manager (npm).
- The most recent version of Node.js installed on your local machine. For more information, see, Node.js.
- The ServiceNow CLI installed on your machine.

Next Experience UI Framework

The Next Experience UI Framework is a JavaScript framework that lets you extend your apps and build web components that are reusable throughout your applications. Using the Next Experience UI Framework lets you:

- Create a single component to use in multiple places across your applications.
- Encapsulate the component's scope to prevent conflicts with other code.
- Add properties, slots, and actions to your component, allowing users to customize the component every time they use it in a Workspace.

For more information, see the ServiceNow® Developer Site.

ui-component extension and development flow

The ui-component extension is an extension to the ServiceNow CLI that lets you develop custom components using the Next Experience UI Framework. With the ui-component extension, you can:

- Create the set of files required to develop a component, or project scaffolding.
- Start a local development server to test your component.
- Build a component project and deploy it to a ServiceNow instance.

Application scope

When you deploy a Next Experience UI Framework component, it deploys into a scoped application on the instance. You can provide an application scope for the component to use as a namespace identifier. Use the namespace identifier guidelines for application development on the instance. For more information, see Application scope.

When reserving an application scope, follow these requirements:

- Maximum: 18 characters.
- Case: snake case.
- Format: `x_customerprefix_componentname`, where:
  - `customerprefix` is the value in the *`glide.appcreator.company.code`* system property on your instance.
  - `componentname` is the value provided in the component's `name` parameter when you created the project.

If you do not provide an application scope when creating your component project, the Now CLI creates one for you.

Alternatively, you can add a value to the `scopeName` parameter in the `now-ui.json` file. For more information, see Change a component's application scope.

Reference guide

To see the Now CLI reference guide, visit the Developer Site.

Set up your environment

Prepare your local environment by installing the Node.js JavaScript runtime environment, Node package manager (npm), and the ui-component extension. These tools enable you to develop and build components locally and deploy them to your instance.

Before you begin

The ui-component extension only supports these operating systems.

- Windows 10
- MacOS Yosemite and later
- Linux CentOS v7.5

Role required: none

Procedure

1. Install Node.js version 12.16.1 or greater.
   npm automatically installs as part of the Node.js package. Node.js is a JavaScript runtime environment that enables you to execute JavaScript locally. npm is the default JavaScript package manager for Node.js. For more information, see Node.js and npmjs.com.

2. Add the ui-component extension to the ServiceNow CLI.

   a. Open your system's command-line tool and execute this command.

   ```
   $ snc extension add --name ui-component
   ```

3. Verify the installation by running an extension command with the `--help` argument.

   ```
   $ snc ui-component --help
   ```

   The CLI displays a list of available commands. See Get help with ServiceNow CLI.

What to do next

Set up your project.

Related topics

Create custom components using ServiceNow CLI

ServiceNow CLI

Set up your project

Create the component project and the set of files required to develop a component. You can connect to your instance and create an application scope for your component, or you can reserve a scope to verify later.

Before you begin

Set up your environment.

Procedure

1. Create a folder for your project and point your system's command-line tool to the folder.
2. Create the component project and all the files required to build a component.

   a. From the folder you created, execute this command.

   ```
   $ snc ui-component project [--name name --description
    description --scope scope --offline]
   ```

   Pass in values for these arguments.

Name	Description
name	Required. The project name. Must be a valid and unique npm package name.
description	The project description to be available in the npm registry and the plugins list in your instance.
scope	Suggested application scope to assign to this project and its components. If provided, the instance validates the name. Use the namespace identifier guidelines for application development on the instance. For more information, see Application scope. Maximum: 18 characters. Case: snake case.

Name	Description
	Default: `x_customerprefix_componentname`, where: ▪ `customerprefix` is the value in the *`glide.appcreator.company.code`* system property on your instance. ▪ `componentname` is the value provided in the component's `name` parameter when you created the project. Alternatively, you can add a value to the `scopeName` parameter in the `now-ui.json` file. For more information, see Change a component's application scope.
offline	When true, creates and scaffolds a component while disconnected from your instance. Skips validation of the given scope name. Default: `false`.

Example

```
$ snc ui-component project --name @myorg/movie-quotes
 --description 'A web component that prints movie quotes.'
```

Example

```
$ snc ui-component project --name @myorg/hello-world --scope
 x_myorg_helloworld --offline
```

3. Run the following command to install the npm dependencies.

```
npm install
```

What to do next

Develop a component.

Related topics

Create custom components using ServiceNow CLI

Use a proxy server with ui-component extension

Use a proxy server with the Now CLI to define a separate data source for your component. When using a proxy server, the instance forwards Now CLI requests to the proxy server.

Before you begin

Set up your environment.

Procedure

1. In your component directory, open the `now-cli.json` file.
2. Update the `proxy` object.

```
{
 development: {
  proxy: {
   headers: {
    Authorization: "Basic <username:password>"
```

```
    },
    origin: "http://myinstance.servicenow.com",
    port: 3000,
    proxies: []
   }
  }
}
```

Update the following parameters with your proxy information.

Parameter	Description
development.proxy.headers	Headers to append to your proxied request.
development.proxy.headers.Authorization	Authentication header to add to the proxied request. Enter your Base 64-encoded username:password here.
development.proxy.origin	Host to open a proxy with (your instance host address).
development.proxy.port	The port the proxy runs on.
development.proxy.proxies	URL glob patterns to pass to the proxy server.

3. Save the file.

What to do next

Develop a component.

Related topics

Create custom components using ServiceNow CLI

Develop a component

Add your component code and test it using a local development server.

Before you begin

- Set up your environment
- Set up your project

About this task

For a tutorial on developing a counter component, visit the Developer Site.

Procedure

1. In your project directory, navigate to `src/<component-name>/index.js`.
   This is the primary code file for a component.
2. Add your component code.

Example

This example shows a sample Hello World component.

```
import {createCustomElement} from '@servicenow/ui-core';
import snabbdom from '@servicenow/ui-renderer-snabbdom';
import styles from './styles.scss';

const view = (state, {updateState}) => {
```

```
 return (
  <div>Hello World!</div>
 );
};

createCustomElement('hello-world', {
 renderer: {type: snabbdom},
 view,
 styles
});
```

To develop a component for Virtual Agent, add specific properties and actions to interact with the Virtual Agent client interface. The properties required depend on the type of component you are creating. For more information, see Develop a component for Virtual Agent for more information.

3. **Optional:** Add inner components.
   An inner component is a component included in another component. For example, a card component might include a separate button component. The button component becomes an inner component that you must import, install, and define in the card component project.

   a. Install the inner component package by executing the install command using your system's command-line tool:

   ```
   npm install @servicenow/<now-inner-button>
   ```

   b. Add an import statement to the top of your `index.js` file:

   ```
   import '@servicenow/<now-inner-button>';
   ```

   c. Use the inner component in your `index.js` file:

   ```
   <now-inner-button label="Click Me" />
   ```

   d. List the inner component in the `components.[component-name].innerComponents` array in the `now-ui.json` configuration file.

   Example

   ```
   {
     "components": {
       "now-chart-timeseries": {
         "innerComponents": [
           "now-inner-button"
         ],
   ```

4. Run the development server command to view your component in a test browser.

   ```
   $ snc ui-component develop [--entry entry --open --port port
    --host host]
   ```

   Pass in values for these arguments.

Name	Description
entry	Path to the test module in your component project.

Name	Description
	Default: `example/index.js`.
open	Opens the default browser and navigates to the test page. Default: false.
port	Port where the development server runs. Default: 8081.
host	Host address to use if you want your local development server to be accessible externally by others. Typically set to 0.0.0.0

Example

```
$ snc ui-component develop --entry example/hello.js --open
 --port 3000
```

What to do next

Deploy a component to an instance.

Related topics

Create custom components using ServiceNow CLI

Develop a component for Virtual Agent

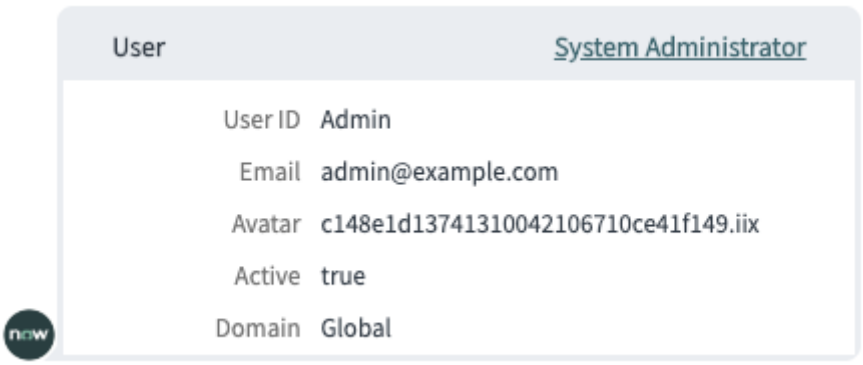
Create a custom Virtual Agent component to gather input or display information in the Virtual Agent client interface.

Types of Virtual Agent components

To develop a component for Virtual Agent, add specific properties and actions to interact with the Virtual Agent client interface. The properties required depend on the type of component you are creating.

Response component

A response component only provides information to the user, and does not gather input or handle user interaction. For example, a card control that does not require user input and is only in the conversation



once.

Add a property to your response component to handle the data sent by the Virtual Agent server.

Output component properties

Property	Description
controlData	Initial data that the Virtual Agent server sends to your component as the topic runs. Data type: JSON Object

Input component

An input component displays information and/or gathers user input. It includes the same property as the output component to handle data sent by the server, but has more possible states and requires user interaction.

Input component properties

Property	Description
controlData	Initial data that the Virtual Agent server sends to your component as the topic runs. Data type: JSON Object
responseValue	Data sent to the component from the user's response, either from the client directly, or from the server if there is a refresh. Only use in components that require user input. Data type: JSON Object
forceCloseControl	Flag that indicates whether the component can accept input. When true, the control closes and the user cannot interact with it. Monitor changes on the client to update this value. Only use in components that require user input. Data type: Boolean

Use this action to emit data from user interaction.

Input component actions

Action	Description
VA_CONTROL#ValueSent	Payload data from the client to send to the server. Only use in components that require user input. Data type: JSON Object

Input component states

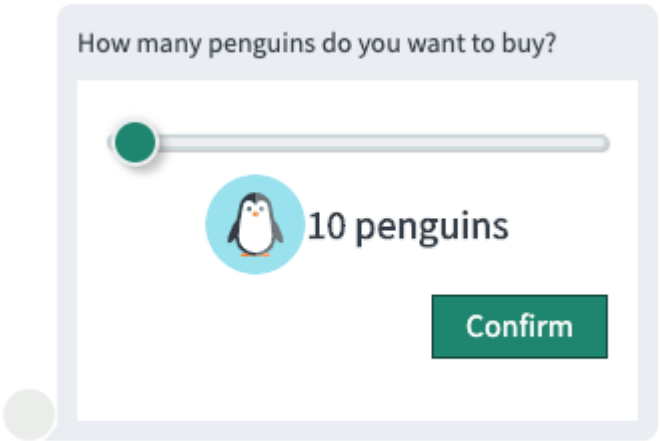
Because they accept data, input components must handle multiple states. The state flow is generally as follows:

1. Virtual Agent shows the custom component in the waiting for input state.
2. The user interacts with the component to provide input.

3. The component closes and sends the `responseValue` property to the server.
4. The server runs the server-side logic and sends the component with the user's input back to the client.

Waiting for Input

The initial state of a component waiting for user interaction. The `controlData` property is set, but the `forceControlClosed` property is false. This example shows a slider component in the waiting for input state.



In this example, if the user has not provided a `responseValue` and the control is not closed, the slider and the input button display.

```
const {controlClosed, sliderVal, sliderMin, sliderMax}
 = state;
return (<div class={{"slider-chat": true}}>
    {responseValue ? null :  <Fragment>
    <div class={{"slider-label": true}}>{label}</div>
    {controlClosed ? null : <Fragment>
        <div class={{"slider-container": true}}>
                    <input on-change={onSliderChange}
 type="range" min={sliderMin} max={sliderMax}
 value={sliderVal} class={{"slider": true}} />
            <div class={{"slider-value": true}}>
                    {unitIcon &&
                     <div class={{"unit-icon":
 true}}><img src={unitIcon} /></div>
                     }
                     {sliderVal} {unitName}
                </div>
        <div class={{"button-container":true}}>
            <now-button variant="primary"
 label={buttonText || 'Confirm'} />
         </div></div></Fragment>}
```

Handling Input

In the previous example, the slider uses a `now-button` component, which the user clicks to confirm input and send it to the server. When the user clicks the button, the VA_CONTROL#VALUE_SENT action fires with the `responseValue` payload.

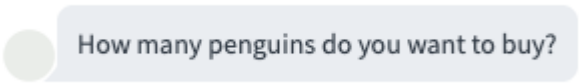
```
'NOW_BUTTON#CLICKED': (data) => {
    const {updateState, dispatch, state: {sliderVal}} =
 data;
    updateState({controlClosed: true});
    dispatch('VA_CONTROL#VALUE_SENT', {
        value: {
            sliderVal
        }
    });
}
```

Closed

A component that is closed can no longer accept user input. Components are generally closed because:

- The user responded to the component. The component closes and the conversation continues.
- The user ended the chat. The server does not wait for a response.

For example, the slider component only renders the original prompt when in the closed state.



Sending response

After the user responds, the control is rendered again on the user's side of the conversation with the value of the `responseValue` property.

For example, the slider control uses this snippet to render the response.

```
{responseValue && <div className="response-container
 slider-value">
   {unitIcon &&
   <div className="unit-icon"><img
 src={unitIcon} /></div>
   }
   {returnVal} {unitName}
</div>}
```

Adding the component to Virtual Agent Designer

After developing the component and deploying it to your instance, add it to Virtual Agent Designer using a custom control and definition. For more information, see Virtual Agent custom controls.

Add properties to communicate with Virtual Agent

To develop a component for Virtual Agent, add specific properties and actions to interact with the Virtual Agent client interface. The properties required depend on the type of component you are creating.

Before you begin

- Set up your environment
- Set up your project
- Develop a component

Procedure

1. In your component code, add the Virtual Agent properties to interact with the Virtual Agent client interface.

Virtual Agent component properties

Property	Description
controlData	Initial data that the Virtual Agent server sends to your component as the topic runs. Data type: JSON Object
responseValue	Data sent to the component from the user's response, either from the client directly, or from the server if there is a refresh. Only use in components that require user input. Data type: JSON Object
forceCloseControl	Flag that indicates whether the component can accept input. When true, the control closes and the user cannot interact with it. Monitor changes on the client to update this value. Only use in components that require user input. Data type: Boolean

2. If creating an input component, use the `VA_CONTROL#VALUE_SENT` action to send user values to the server.

Virtual Agent component actions

Action	Description
VA_CONTROL#VALUE_SENT	Send data from the client to send to the server. Only use in components that require user input. Data type: JSON Object

What to do next

Test a component for Virtual Agent and Deploy a component to an instance.

Related topics

Create custom components using ServiceNow CLI

Test a component for Virtual Agent

Test your Virtual Agent custom component before deploying it to your instance.

Before you begin

- Set up your environment
- Set up your project
- Develop a component
- Add properties to communicate with Virtual Agent

Role required: virtual_agent_admin or admin

About this task

Virtual Agent components must be tested within the Virtual Agent client chat to ensure that the component responds correctly to user input. You can set properties in your component project to test your component in a mock Virtual Agent test client tool.

Procedure

1. Add a dependency on the test client tool to your component project.
   a. Open the `<component-name>/package.json` file in your component project.
   b. Add `"@servicenow/sdk-ci": "1.0.8"` and `"@servicenow/library-translate": "^18.0.0"` to the `devDependencies` object.

   Example

   Here is an example `package.json` file with the correct dependencies.

```
"dependencies": {
    "@servicenow/ui-renderer-snabbdom": "xanadu",
    "@servicenow/library-translate": "^18.0.0",
    "@servicenow/now-button": "xanadu",
    "@servicenow/now-dropdown": "xanadu",
    "@servicenow/sass-generic": "xanadu",
    "@servicenow/cli-archetype": "xanadu",
    "@servicenow/sdk-ci": "1.0.8"
}
```

2. Add sample properties to use as the initial state of the component in your test.
   a. Add a `<component-name>/example/sampleProps.json` file with initial properties to render in your test.

   Example

   Here is an example `sampleProps.json` file with initial properties set for a slider component.

```
{
 "label": "How many penguins do you want to buy?",
 "defaultValue": 10,
 "sliderMin": 20,
```

```
 "sliderMax": 80,
 "unitName": "penguins",
 "unitIcon":
 "https://image.flaticon.com/icons/svg/141/141836.svg"
}
```

3. Update the `example.js` file to open the component through the test client tool using the sample properties that you created.

   a. Open the `<component-name>/example/element.js` file in your component project.

   b. Add statements to import `@servicenow/sdk-ci` and the sample properties file you created.

   c. Add the following statement, replacing `<component-name>` with your component's name to create the test tool with initial data from your sample properties.

```
const el =
 document.createElement('tool-ci-custom-control-tester');
el.componentTagName="<component-name>";
el.initialExampleData=sampleProps;
document.body.appendChild(el);
```

Example

Here is an example `example.js` file that opens the component using the test client tool.

```
import '../src/now-chat-control-slider';

import '@servicenow/sdk-ci';

import sampleProps from './sampleProps.json';

const el =
 document.createElement('tool-ci-custom-control-tester');
el.componentTagName="<component-name>";
el.initialExampleData=sampleProps;
document.body.appendChild(el);
```

4. Run the development server command to view your component in a test browser.

```
$ snc ui-component develop [--entry entry --open --port port
 --host host]
```

Pass in values for these parameters.

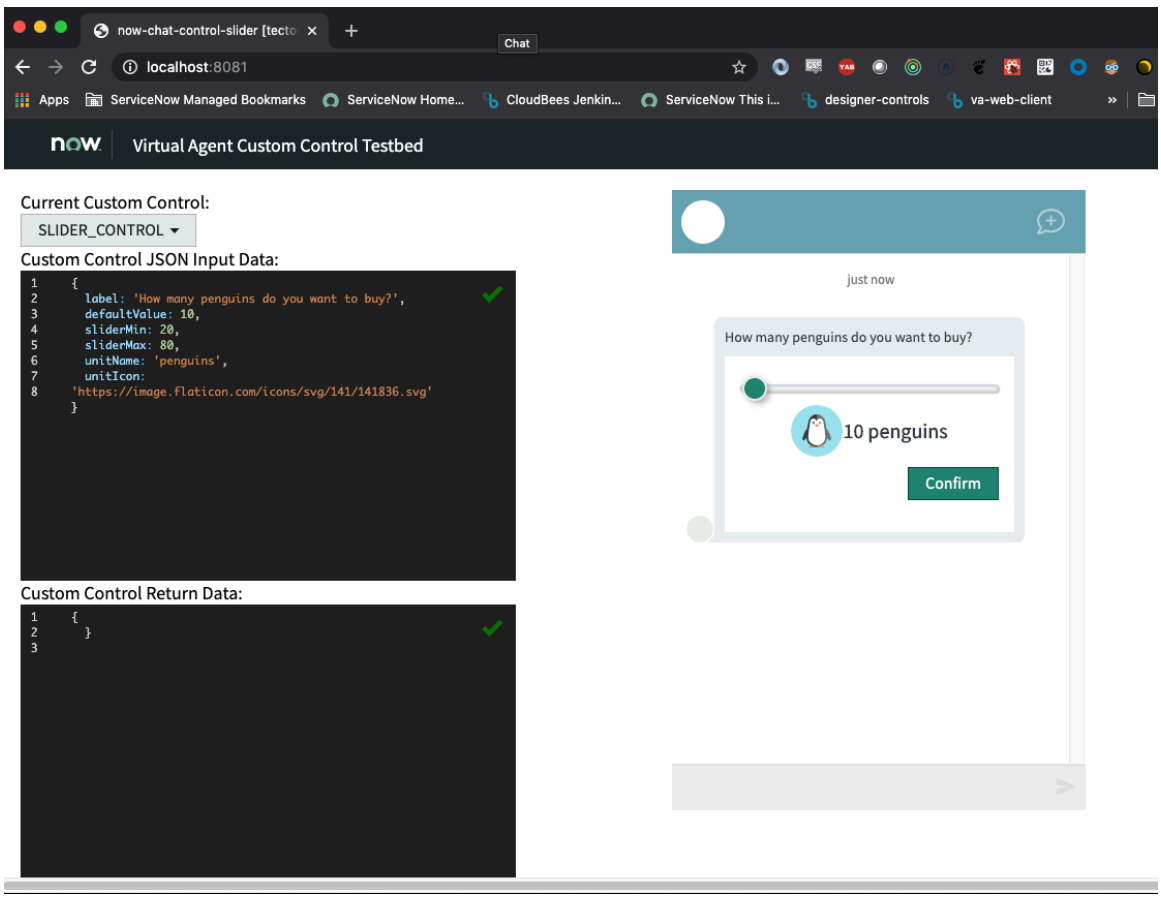
Name	Description
entry	Path to the test module in your component project. Default: `example/index.js`.
open	Opens the default browser and navigates to the test page. Default: false.
port	Port where the development server runs.

Name	Description
	Default: 8081.
host	Host address to use if you want your local development server to be accessible externally by others. Typically set to 0 . 0 . 0 . 0

Example

```
$ snc ui-component develop --entry example/hello.js --open
 --port 3000
```

The component opens in the test client tool. You can see the initial data provided in the **Custom Control JSON Input Data** field and the component's output in the **Custom Control Return Data** field.



What to do next

If your component is working as expected, deploy it to your instance. See Deploy a component to an instance.

After developing the component and deploying it to your instance, add it to Virtual Agent Designer using a custom control and definition. For more information, see Virtual Agent custom controls.

Related topics

Create custom components using ServiceNow CLI

Add a component to Agent Workspace

Use custom components to create a custom Workspace interface to fulfill the specific need of your company's agents.

Communicating with customers through multiple channels can be time consuming. To be efficient in these omni-channel interactions, your agents need a single view of customer information to reduce context switching between multiple tools. By developing custom components for Workspace, your team can bring communications from multiple channels into one interface.

Adding components to a Workspace

Once deployed to your instance, you can add components to Workspace in these ways.

Add a component to a Workspace modal

Use a UI action to launch a custom component in a modal so an agent doesn't have to navigate to a different screen to accomplish a task. For more information, see Render a component in a modal.

Add a component to a Workspace landing page using UI Builder

Use the UI Builder to create custom landing pages for your agents. UI Builder is a drag-and-drop tool that lets you visually arrange workspace components. For more information, see Configuring Configurable Workspace.

Configure properties in the `now-ui.json` file to use deployed components in the UI Builder. For instructions, see the ServiceNow Developer Site.

Add a component to a Workspace record view

You can add custom or standard components to the component area in the Workspace record view. For more information, see Forms.

Add a component to UI Builder

Set properties in a configuration file to add your component to the UI Builder in your instance.

Before you begin

- Set up your environment
- Set up your project
- Develop a component

Procedure

1. In your project directory, open `now-ui.json`.
2. Add the `components.[component-name].uiBuilder` object to the file.
   This object adds the component to the UI Builder.

   This object includes these key-value pairs:

Key	Data type	Description
components.[component-name].uiBuilder	Object	Object that adds the component to UI Builder.
components.[component-name].uiBuilder.label	String	Required. The display name of the component in UI Builder.

Key	Data type	Description
components.[component-name].uiBuilder.icon	String	Required. The name of the icon that appears in UI Builder.
components.[component-name].uiBuilder.description	String	Required. A short description of the functionality of the component.

Example

```
{
  "components": {
    "card": {
      "uiBuilder": {
        "label" : "Card",
        "icon" : "chat-fill",
        "description" : "A visual card format for a record.",
        "associatedTypes": ["global.core"]
      },
```

3. If your component includes properties, add the `components.[component-name].properties` array to the file.
This adds the properties as configuration options for the component in UI Builder.

   This object includes these key-value pairs:

Key	Data type	Description
components.[component-name].properties	Array <Object>	An array of objects that includes all the properties of the component and all relevant information about those properties.
components.[component-name].properties[].name	String	Name of the property in your component's code.
components.[component-name].properties[].label	String	Display name of the property to display in UI Builder, if applicable.
components.[component-name].properties[].description	String	A short description of what the property does or how to use it.
components.[component-name].properties[].readOnly	Boolean	When true, prevents a user from configuring the property in UI Builder. Default: false.
components.[component-name].properties[].required	Boolean	When true, the user must configure the property. Default: false.
components.[component-name].properties[].defaultValue	String	The default value when the user does not provide one.
components.[component-name].properties[].associatedTypes	Array	Describes where in the UI Builder toolbox the component appears. Value must be `"global.core"`.

Key	Data type	Description
components.[component-name].properties[].typeMetadata	Object	Extra configuration data that some data types require, such as reference properties and choice lists.

Example

```
{
  "components": {
    "properties": [
      {
   "name": "backgroundColor",
   "label": "Background Color",
   "description": "Background Color",
   "readOnly": false,
   "required": false,
   "defaultValue": "lightgray"
      },
      {
         "name": "cardType",
   "label": "Type of card",
   "description": "Type of card",
   "readOnly": false,
   "required": false,
   "defaultValue": ""
      }
   ]
```

4. Save the file.

What to do next

Deploy a component to an instance.

Related topics

Create custom components using ServiceNow CLI

Deploy a component to an instance

Deploy your component to display in your instance as an application plugin.

Before you begin

- Set up your environment
- Set up your project
- Develop a component

Procedure

Deploy the component to your instance.

a. Open your system's command-line tool and execute this command.

```
$ snc ui-component deploy [--open --force]
```

Pass in values for these arguments.

Name	Description
open	When true, opens the default browser and navigates to UI Builder in your instance. Default: false
force	Deploys component changes and overwrites any existing component records. Default: false.

Example

```
$ snc ui-component deploy --open
```

What to do next

Navigate to your instance and add your component to a modal or a landing page in Agent Workspace, or to Virtual Agent. For Agent Workspace, see rendering a Now component in a modal or creating custom landing pages for workspaces. For Virtual Agent, see Virtual Agent custom controls.

Related topics

Create custom components using ServiceNow CLI

Change a component's application scope

Change a component's application scope if you encounter scope issues when deploying your component to an instance. For example, you may have set an application scope that is already in use or invalid while creating a component in offline mode.

Before you begin

- Set up your environment
- Set up your project
- Role required: none

About this task

Procedure

1. In your project directory, open `now-ui.json`.
2. Update the `scopeName` key with the desired scope name.

   Use the namespace identifier guidelines for application development on the instance. For more information, see Application scope.

   When reserving an application scope, follow these requirements:

   - Maximum: 18 characters.
   - Case: snake case.

Example

```
"scopeName": "x_customerprefix_componentname"
```

3. Deploy your component.
   See Deploy a component to an instance.

AI limitations

This application uses artificial intelligence (AI) and machine learning, which are rapidly evolving fields of study that generate predictions based on patterns in data. As a result, this application may not always produce accurate, complete, or appropriate information. Further, there is no guarantee that this application has been fully trained or tested for your use case. To mitigate these issues, it is your responsibility to test and evaluate your use of this application for accuracy, harm, and appropriateness for your use case, employ human oversight of output, and refrain from relying solely on AI-generated outputs for decision-making purposes. This is especially important if you choose to deploy this application in areas with consequential impacts such as healthcare, finance, legal, employment, security, or infrastructure. You agree to abide by ServiceNow's AI Acceptable Use Policy, which may be updated by ServiceNow.

Data processing

This application requires data to be transferred from ServiceNow customers' individual instances to a centralized ServiceNow environment, which may be located in a different data center region from the one where your instance is, and potentially to a third-party cloud provider, such as Microsoft Azure. This data is handled per ServiceNow's internal policies and procedures, including our policies available through our CORE Compliance Portal.

Data collection

ServiceNow collects and uses the inputs, outputs, and edits to outputs of this application to develop and improve ServiceNow technologies including ServiceNow models and AI products. In addition, this application will collect information about scripts (and associated script records) in which Now Assist for code generation is called. Customers can opt out of future data collection at any time, as described in the Now Assist Opt-Out page.

For more information, see the Now Assist documentation.

Exploring UI generation

Learn about how AI-generated experiences can empower developers building on the ServiceNow AI Platform.

Experience generation overview

With experience generation, you provide text describing the experience you want and Now Assist will create a fully functional starter experience for you.

Experience generation workflow

To generate an experience, you describe the table, chart type, and navigation your users will be working with. For best results, include as much detail as possible.

1. The user describes the desired experience and triggers experience generation.
2. The user reviews the AI-Generated experience and either accepts or rejects it.
   - If the user accepts it, the experience is saved and the user can begin working with the experience.
   - If the user rejects it, the experience is not saved, and the user can make changes to the experience description to achieve the desired outcome.

General guidelines experience generation

Use these general guidelines for experience generation to get better experiences.

Writing prompts

Write clear and specific but concise prompts

Describe the table and navigation your users will be working with. For best results, include as much detail as possible.

Experiment with different prompts

As you refine and experiment, the Now LLM Service uses this feedback to learn and improve.

- Try adding a specific title for your desired experience.
- Try including navigation details.
- Keep track of your prompts, including any modifications, and instructions for generating prompts to meet your specifications. This tracking enables easy regeneration of past results for comparative analysis.

Example prompts for experience generation

Strong prompt	Weak prompt	Notes
Create a Tabbed experience called, "Incident Management" to help track Incidents by Priority.	Track incidents.	Includes experience title details.
Create a Breadcrumb style experience called, "Change Request Tracking" that uses a Pie chart to group Change Requests by State.	Change request pie chart.	Includes navigation details.
Create a Tabbed experience to allow user to see Requested Items trending by Created Date in a Line Chart.	Requested items.	Includes chart details.
Create a Breadcrumb navigation experience called, "Task Tracker" with a Bar chart	Task tracker bar chart.	Includes Grouped by details.

Example prompts for experience generation (continued)

Strong prompt	Weak prompt	Notes
showing Tasks in a Bar Chart Grouped By Assigned to.		

Reviewing generated experience

Review experience

Implement strict and detailed reviews of the AI-generated experience to determine its accuracy, efficiency, and how well it adheres to your standards.

Configuring UI generation

Configure and install UI generation.

Install UI generation

Install the ServiceNow® Now Assist for Creator application from the ServiceNow Store to get Now Assist for UI generation.

Before you begin

- Review the Now Assist for Creator application listing in the ServiceNow Store for information on dependencies, licensing or subscription requirements, and release compatibility. Now Assist for Creator installs the Now Assist for UI generation application.

Role required: admin

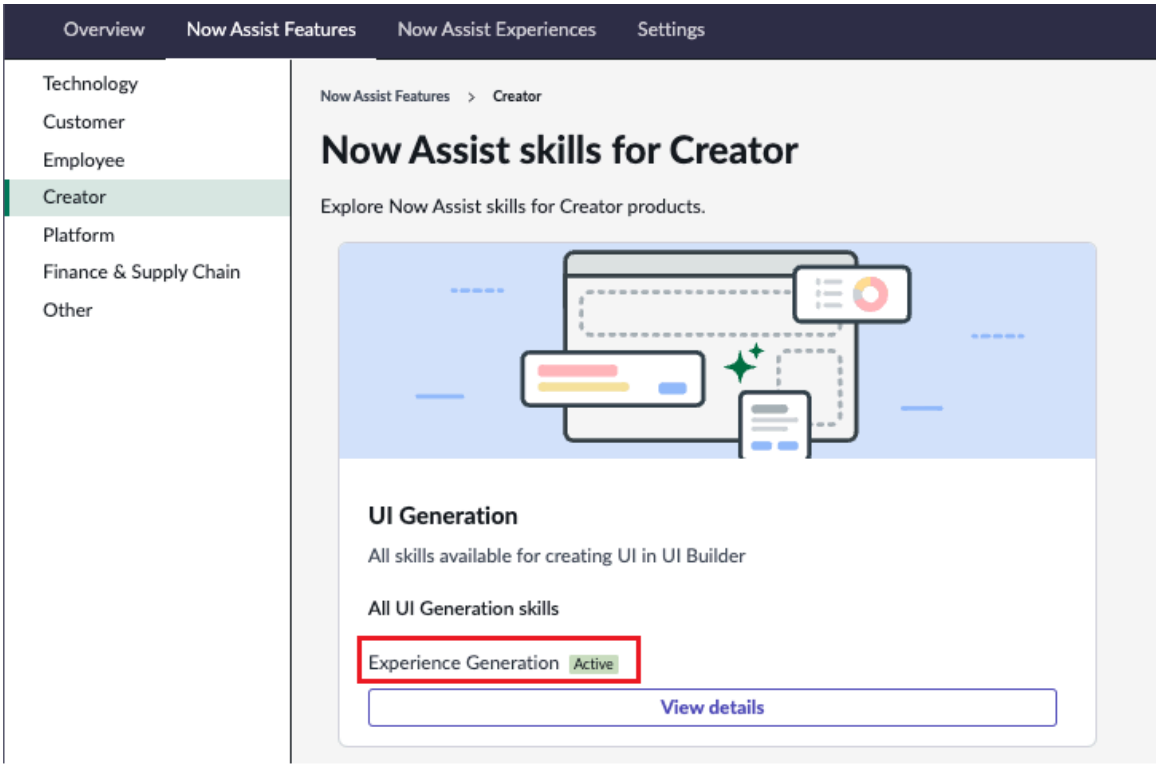
Procedure

1. From the Now Assist for Creator application page on the ServiceNow Store, select **Request App**.
2. After approval has been granted, on your instance, navigate to **All** > **System Applications** > **All Available Applications** > **All**.
3. Using the search bar, search for the Now Assist for Creator application (sn_now_creator).
4. Select **Install**.
5. Verify that Now Assist for Creator is installed:

   a. Navigate to **All** > *Now Assist Admin* > **Features**.

   b. In the workflow list, select **Creator**.

c. On the UI Generation card, verify that the Experience Generation skill is active.



For more information about Now Assist Admin, see Now Assist.

What to do next

Grant the now.assist.creator role to each user you want to use UI generation.

Related topics

Install Now Assist for Creator

Using UI generation

Quickly generate multi-page experiences using natural language with Now Assist.

When UI generation is enabled, the option to create an AI-Generated experience (✨) appears in the UI Builder dialog.

Developers must be assigned now.assist.creator role to use UI generation.

Experience generation

Use experience generation to create a multi-page experience using natural language with Now Assist.

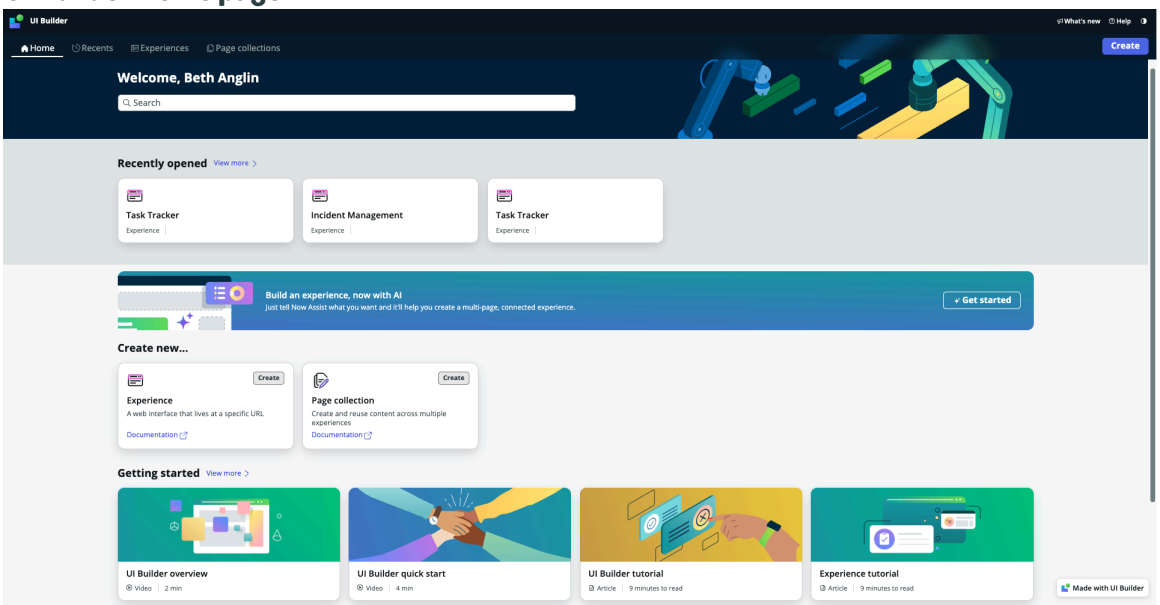
Before you begin

Role required: now.assist.creator

Procedure

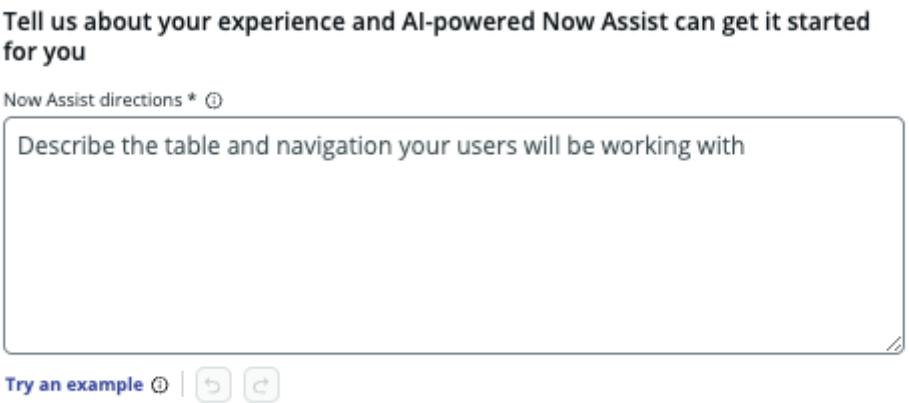
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.

UI Builder Home page



2. From the UI Builder Home page, select **Create**.
3. Select **AI-Generated experience**.

Create an experience form



4. In the **Create an experience form**, enter a description of the experience you would like to generate.

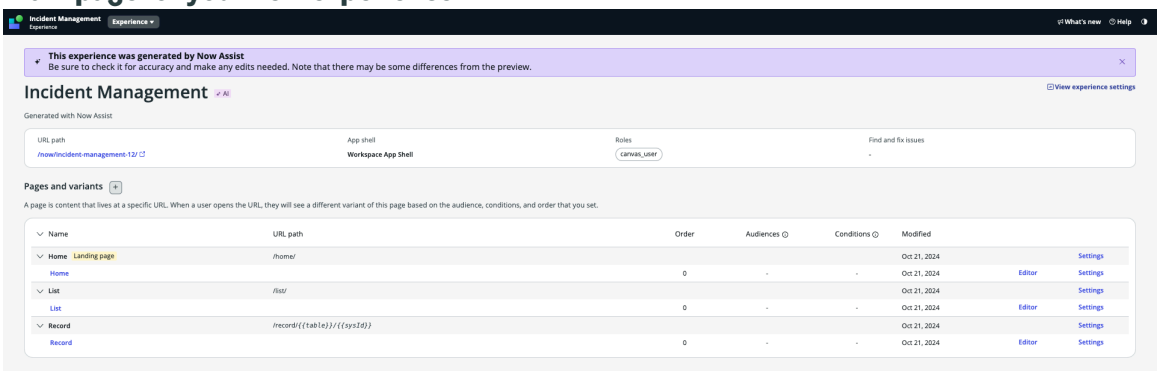
> **Tip:**
> Select **Try an example** to insert different experience examples to see what good Now Assist directions include.

5. Select **Generate preview**.

6. Review the experience and complete one of the following steps:
   - To proceed in creating your experience, select **Save and edit experience**.
   - To create a new experience, reword your description and select **Regenerate preview**.

   When you select **Save and edit experience**, the experience settings page indicates the UI was generated with Now Assist.
7. Review the main page for your new experience.

Main page for your new experience



Note:
In addition to the name of your new experience, the screen includes the URL, app shell, and the roles of users who can view the experience. Any pages or variants you create for the experience appear in the **Pages and variants** section.

UI generation reference

Reference topics provide additional information about configuration properties, roles, and more.

UI generation roles

The following roles are installed for use with UI generation.

To learn more about managing per-user subscriptions, see Managing per-user subscriptions in Subscription Management and contact your account representative.

Now Assist Creator [now.assist.creator]

Create experiences using AI-powered UI generation.

Groups

This role is assigned to no groups by default.

Contains Roles

This role contains no roles.

Elevated

This role is not an elevated role.

Special considerations

None

UI generation properties

You can adjust how UI generation functions on an instance using several advanced properties.

Note:
To open the System Properties [sys_properties] table, enter `sys_properties.list` in the navigation filter.

Decision Tables

Use decision tables to decouple decision logic from your code by creating and maintaining decision rules.

Important:
Try creating decision tables in Workflow Studio instead. Workflow Studio integrates workflow authoring, configuring, and monitoring into a single page experience. For more information, see Create decision tables in Workflow Studio.

Use decisions tables to help you reach outcomes that depend on multiple factors. In these tables, each factor is a decision input. For example, if you are trying to make a decision about car insurance coverage, your inputs might include the location where the insured person lives, the age and accident history of the insured person, the car make, the car model, and the car year. This logic can save time and present a more organized, readable format than using a script. Decision tables provide a single point where you can create, view, and modify decisions.

To interact with Decision Tables in script, use the DecisionTableAPI - Scoped, Global.

Components of a decision

Decision Table [sys_decision] records

Decision table records represent a single decision. In this record, you specify which table you want to use for your answers. This record also contains related lists where you can create your decision inputs and decisions.

Decision inputs [sys_decision_input] records

Decision input records represent your inputs that are used to obtain answers in a decision. These inputs can include a variety of types, including strings, references, true/false inputs, and dates. Each decision input has a specified input type and can be assigned a default value.

Decision [sys_decision_question] records

Each decision record represents a decision that is based on your inputs. Use the condition builder on the decision record form to create a condition that is based on the inputs for this decision. Then, you can select an answer record for this decision. The answer record can be any record from the table that you have defined in the Decision Table record. You can select the same answer record for more than one decision.

Answer [sys_decision_multi_result_element] records

Answer records represent answers that are reached using different decision input values. Answers records can be records on any table, but you need to choose the table when creating your Decision Table record. You could, for example, use the sys_choice table to use existing choice records. From the example about insurance coverage, you could create a table where each record contains details about the levels of insurance coverage.

Decision tables in the classic environment

In the classic environment, you can develop a table to use for your decision answer records. You then associate an answer record to each decision on your decision table. This answer record is returned when the decision is reached based on your inputs.

Note:
Workflow Studio decision tables provide a new intuitive interface to create decision tables. For more information, see Workflow Studio.

Create a decision table to resolve complex decisions

Create a decision table to help you resolve a complex decision that depends on multiple factors.

Before you begin

Role required: decision_table_admin

Procedure

1. Create or select a table to use for your decision answer records.
   You will associate an answer record to each decision on your decision table in later steps. This answer record is returned when that decision is reached based on your inputs. For information on creating a table, see Create a table.
2. Ensure that one field on the table that you use for your decision records has been set as the display value.

   This field is used as a label when you display decision answers in Workflow Studio.

   You can use an existing table or create a new table to use for your decision records.
3. Create a record on this table to each answer in your decision.
   If you have modified an existing table, you may need to customize the form to show the new fields that you have added.
4. Create a decision table record.

   a. Navigate to **System Definition** > **Decision Tables**, and select **New**.

   b. On the form, fill in the fields.

   Decision Table form

Field	Description
Name	Descriptive label for this decision.
Application	Application scope of this decision. This field defaults to the current scope.
Answer table	Table that this decision uses for answer records. Select the table that you created in the previous steps.
Accessible From	Option to limit the availability of this decision to the current scope. Select **All application scopes** or **This application scope only**.

   c. Right-click the form header and select **Save**.
   The form refreshes with the Decision Inputs and Decisions related lists.
5. Create decision input records.

a. In the Decision Inputs related list, select **New**.

b. On the form, fill in the fields.

Decision Input form

Field	Description
Name	Name of the decision that is associated to this decision input. This field is automatically populated.
Application	Application scope of this decision input. This field defaults to the current scope.
Type	Type of data that is used for this input. When you use this decision in a flow, you can only use data pills that match this type.
Active	Check box to activate this input. This field is selected by default.
Label	Descriptive label for this input.
Read only	Check box to make this decision input read-only.
Column name	Column name for this input. This field is automatically populated when you give the **Label** field a value.
Mandatory	Check box to make this decision input mandatory.
Display	Check box to indicates that this decision input is the display value for reference fields.
Choice	Select a method for users to see a list of suggested values: ▪ List menu without -- None -- ▪ List menu with -- None -- ▪ Suggestion field type If a choice is used, define your choices in the Choices related list at the bottom of the form.
Default Value	Default value for this input.

c. Select **Submit**.
Your changes are saved and the decision table record reopens.

6. Create decision records.

a. In the Decisions related list, select **New**.

b. On the form, fill in the fields.

Decision form

Field	Description
Label	Descriptive label for this decision table.
Application	Application scope of this decision. This field defaults to the current scope.
Order	Order in which the flow evaluates decisions. The order can be important in flows that use the **First decision that matches** option and ends after the first match is found.
Answer	Answer that is used when the conditions in this decision are met.
Default Answer	Check box to enable this decision as the default for your decision table.
Condition	Conditions that are needed to reach this decision. The fields available for your condition are the Decision inputs that are associated with this decision table.

c. Select **Submit**.
Your changes are saved and the decision table record reopens.

What to do next

With Workflow Studio, you can add your decision to the **Make a decision** flow logic. For more information about the **Make a decision** flow logic, see Make a decision flow logic.

Table Builder

Table Builder enables you to create, design, and administer tables and forms visually from a single user interface.

Announcements

The Table Builder for App Engine application has been combined with the standalone Table Builder application. Some features such as schema view, spreadsheet view, flows, and PDF extractor that previously were only available in the Table Builder for App Engine application are now available in Table Builder.

Exploring Table Builder

Learn about Table Builder features that enable you to design tables, forms, and flows visually using a single user interface.

Learn more about Table Builder	Additional ServiceNow resources
You can use Table Builder to configure form elements such as layouts, fields, field configuration, and UI policies.	  Table Builder: Creating a custom order form

Key features

Table Builder includes these key features:

- Edit tables by adding additional fields or changing existing field properties for a particular application or globally.
- Visually customize form views by using a simple drag-and-drop editor interface. You can add and arrange sections, fields, and annotations as needed from a table that you select.
- Configure UI Policies for your forms from one interface or view these other related policies and rules:
  - Access control rules
  - Client scripts
  - Business rules
  - Workspace view rules
- Preview your forms throughout the editing process so that you can be sure that any changes function well in your environment.
- Integrate with App Engine Studio to promote a unified experience for designing your forms and managing data.

Accessing Table Builder

You can access Table Builder in several ways.

Launching Table Builder from App Engine Studio

Table Builder can be currently accessed from within App Engine Studio.

See Editing data in App Engine Studio for instructions on editing application data.

1. Open an application in App Engine Studio.

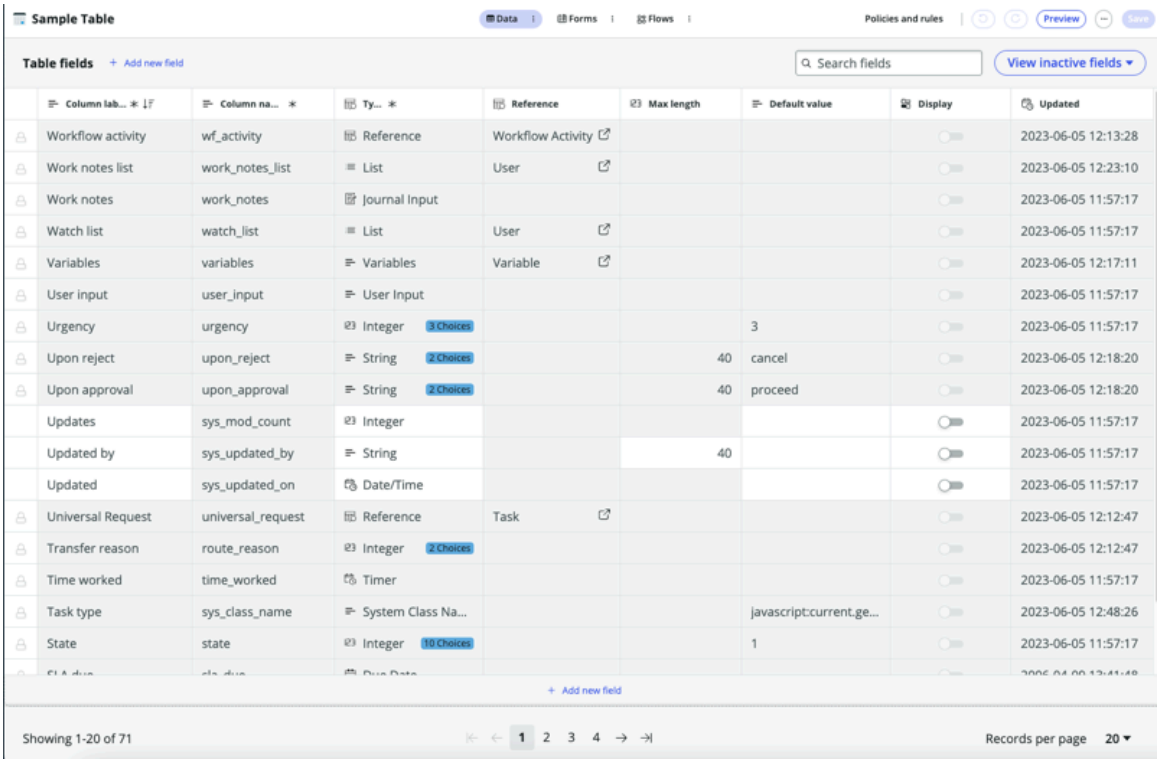
   Note:
   A data table must first be present in the application so that you can access Table Builder.

2. From the application home, select the menu icon (•••) next to a table, and then select **Edit**.

   Table Builder opens with the **Data** tab selected as shown in the following example.

Note:
To edit form views for the selected data table, navigate to the **Forms** tab.

Data tab



Launching Table Builder from UI Builder

Table Builder can be accessed from within UI Builder by clicking **Edit form view** at the bottom of the Config panel, for a selected form object.

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**, and then select a form component on a page.

   See Work with components in UI Builder for more information on adding components.

2. Click **Edit form view** at the bottom of the Configuration pane.

Table Builder opens with the **Forms** tab selected, where you can customize your form views for the selected table. To edit table data, navigate to the **Data** tab as shown in the following example.

Forms tab

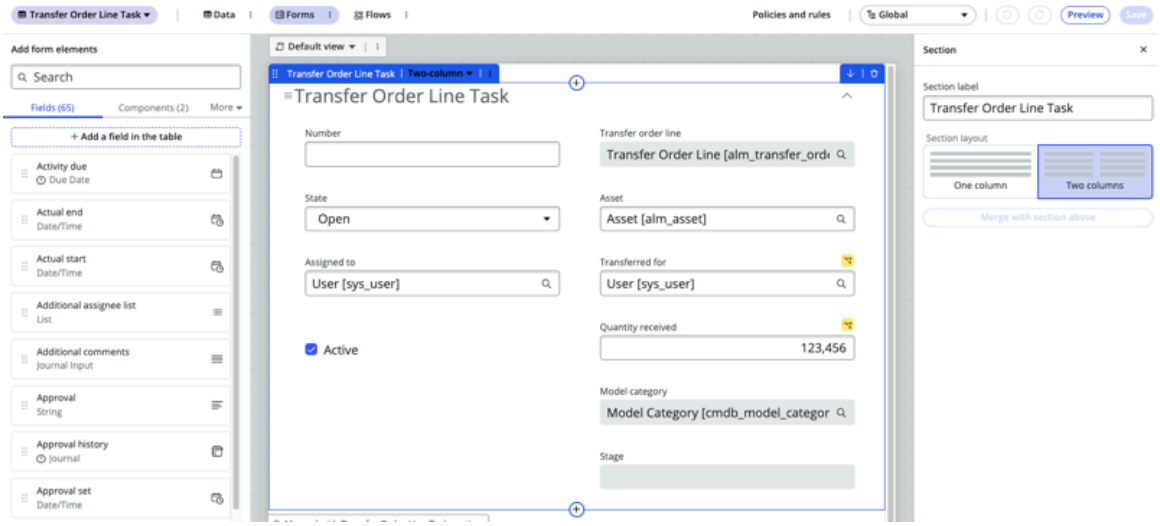


Table Builder permissions

To use Table Builder, you must either be an administrator, or have the following role permissions in ServiceNow AI Platform, or have relevant AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Table Builder permissions

Permission	Access
Personalize Form (personalize_form)	• Required to access **Forms** tab. • Required to customize fields on the form. • Does not grant dictionary access. • Does not grant Policies and Rules access. • Does not grant Tables access.
Personalize Dictionary (personalize_dictionary)	• Required to access **Data** tab. • Required to access field configuration. • Required to change dictionary fields. • Does not grant Policies and Rules access.
Personalize Rules (personalize_rules)	Enables access to the **Policies and Rules** tab.
Personalize Choice	Allows a user to configure choices for a field.

Table Builder permissions (continued)

Permission	Access
(personalize_choices)	
Flow Designer (flow_designer)	Required to access the **Flows** tab. Allows a user to configure flows. To work with Table Builder flows, you must also have personalize_form and personalize_dictionary permissions (or related delegated developer permissions).

Accessing Form Builder

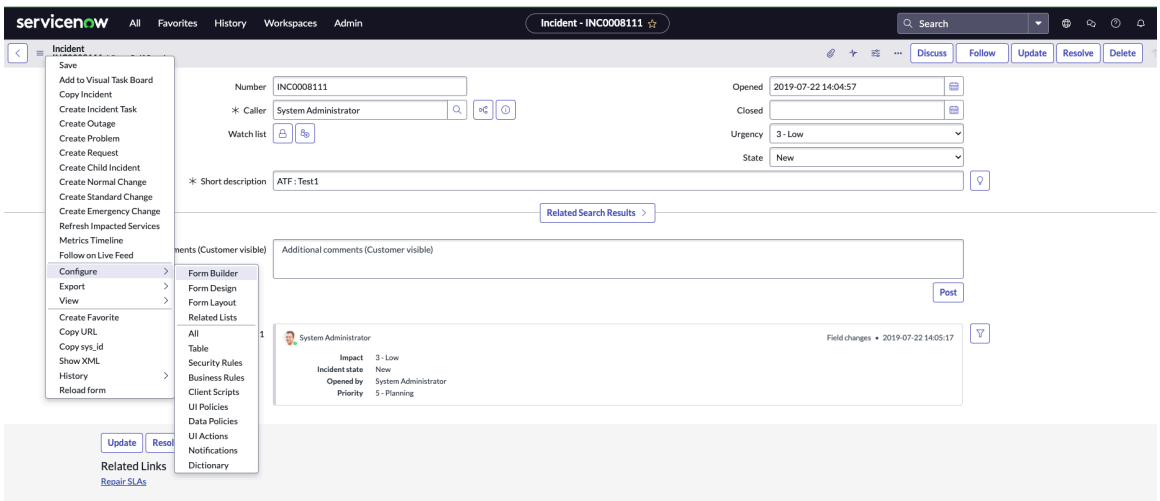
Form Builder is an application that is accessed most often through Table Builder on the **Forms** tab. You can also access Form Builder through the ServiceNow AI Platform® and the **Related Links** section of any table.

Accessing Form Builder from Table Builder

In Table Builder, access Form Builder on the **Forms** tab. For more information, see Forms in Table Builder.

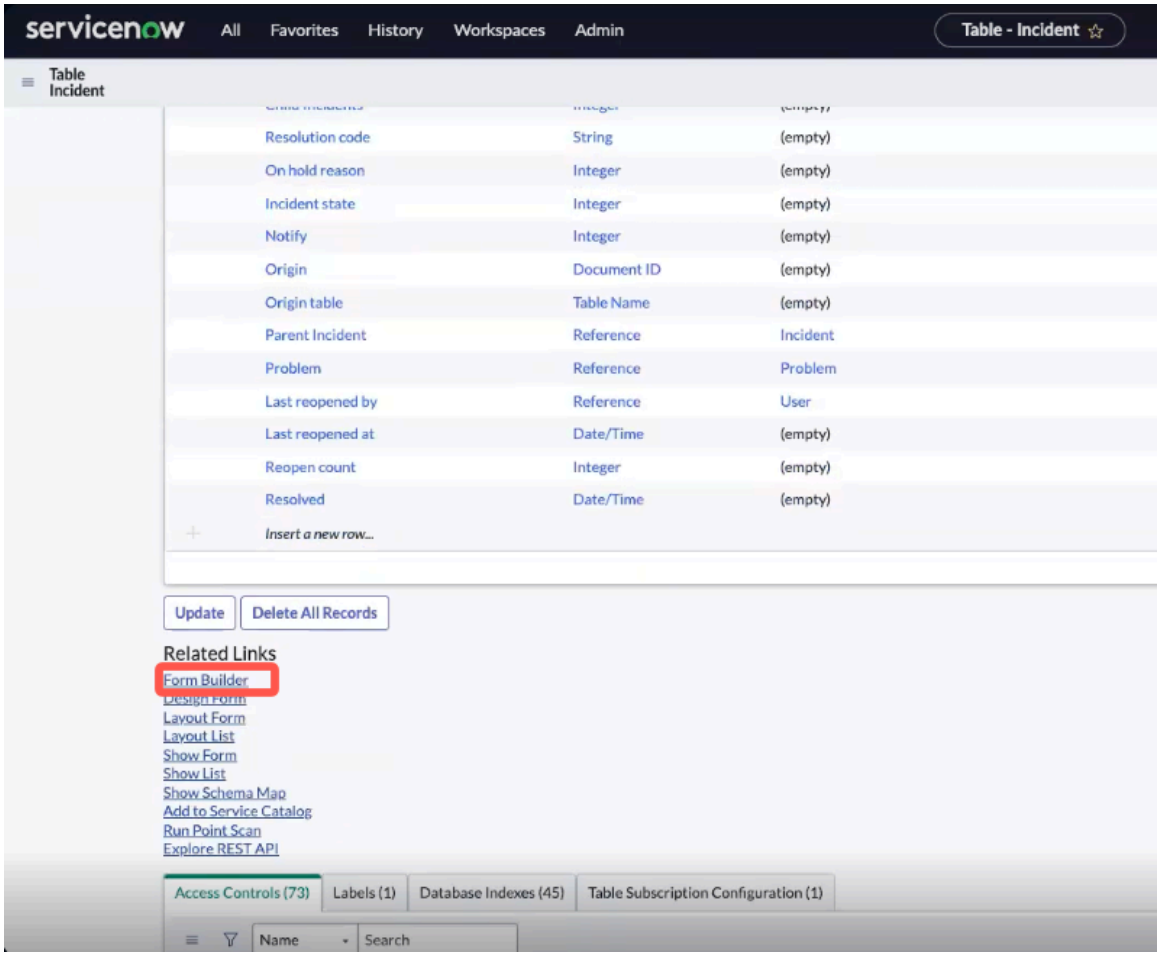
Accessing Form Builder from the ServiceNow AI Platform

Customize any ServiceNow AI Platform record or form using Form Builder. On the form context menu, select **Configure**, and then select **Form Builder**.



Accessing Form Builder from Related Links

You can also access Form Builder from the Related Links section of any table. Open Form Builder to make edits to the form that you use to populate records for that table.



Accessing Form Builder from UI Builder

You can access Form Builder directly from the UI Builder stage. Move your cursor to a form component that has a set **Table** value and **View** value, then select the **Edit Form** button. Your changes appear on the form after closing Form Builder.

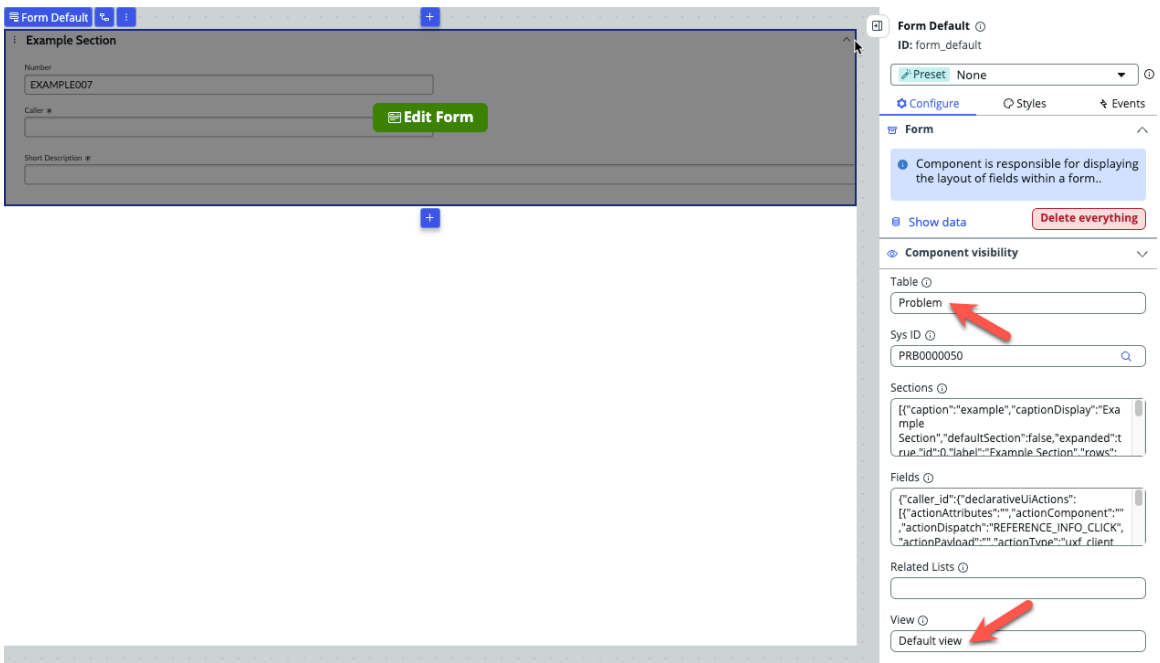


Table Builder workflow and navigation

You can start using Table Builder to manage your data tables, forms, or flows by reviewing this high-level workflow.

Learn about the high-level actions that you perform when you are using Table Builder.

Basic workflow

The following table outlines the basic actions that you take when working in Table Builder.

Basic workflow

Action	Description
Choosing a table or form to work with	To choose a data table or form to work with, launch Table Builder as instructed in Accessing Table Builder and choose the table or form to work with. **Note:** While using Table Builder in App Engine Studio, the table selected here is chosen when you click on a table in your app. However, if Table Builder is launched from UI Builder, you can choose a new table to work with from the drop-down list that displays the name of your currently selected table.
Selecting a domain and application scope	Select a domain and application scope to work within from Table Builder navigation. **Note:** While using Table Builder in App Engine Studio, the application scope selected is the app you are working in. However, if Table Builder is launched from UI Builder, you can choose an application scope to work with from the drop-down list in the top right side of your screen (e.g., Global). See Domain separation and Table Builder and Using an application scope with Table Builder.
Modifying table properties	Select **Data** tab to edit table properties directly. For more information, see Data in Table Builder.
Customizing form views	Select **Forms** tab to create and customize new views or configure the form elements for a selected view. For more information, see Forms in Table Builder.
Configuring policies and rules	Select **Policies and rules** tab to configure and control how data is displayed for your form views.

Basic workflow (continued)

Action	Description
	For more information, see Policies and rules in Table Builder.
Previewing a form and managing your changes	At any point in the process, you can preview the changes you've made by selecting **Preview**. For more information, see Preview your form. Save your form view changes at any point in the process by clicking **Save**. Your form view is ready and can be accessed by other applications in the ServiceNow AI Platform. **Note:** To undo ( ) or reapply ( ) changes you make, select the Undo or Redo icons at the top of your screen.

Navigational elements

The following table shows and describes the basic navigational elements shown in Table Builder.

Basic navigation elements

Navigational element	Description
Table selection list (Problem)	Choose an option to customize the policies and rules, table properties, fields, or form views for the selected table.
Select domain list (global)	Choose an option to customize the policies and rules, table properties, fields, or form views within the selected domain (for example, the Global domain).
Select scope list (Global)	Choose an option to customize the policies and rules, table properties, fields, or form views within the selected application scope (for example, the Global application scope).
Undo ( ) Redo ( )	Select the undo ( ) or redo ( ) icons in the navigation bar to revert to a previous editing state.
Advanced table properties menu ( )	Choose an option: • **Advanced view** to manage the advanced properties in the selected table. For more information, see Table administration. • **Form designer** to launch the selected table in Form Designer. For more information, see Using the Form Designer. • **Delete table** to delete the selected table.

Basic navigation elements (continued)

Navigational element	Description
	Note: This option only appears on the Data tab.
Preview (Preview)	Select **Preview** to review the selected form as how it is displayed in the ServiceNow AI Platform. For more information on previewing, see Preview your form.
Save (Save)	Select **Save** to commit your changes to your selection.
Search fields and filter options ( )	Use the search box to filter the list of field columns by keyword or use the **Filter options** list to show inactive fields or to hide extended fields from the list (if a table has been extended from an existing table).
PDF extractor ( )	If a PDF is associated with the selected data table, select this element to launch the PDF extractor tool and view the PDF. See Use a PDF to create data tables.

Domain separation and Table Builder

Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Standard*

The support level is Standard but has some exceptions or special conditions.

- Includes all aspects of **Basic** level support.
- Business logic: The service provider (SP) creates or modifies processes per customer. The use cases reflect proper use of the application by multiple SP customers in a single instance.
- The instance owner must be able to configure minimum viable product (MVP) business logic and data parameters. This configuration is done per tenant, as expected for the specific application.

Sample use case: An admin must be able to make comments required when a record closes for one tenant, but not for another.

For more information on support levels, see Application support for domain separation.

Overview

Table Builder enables developers to configure the layout and logic for each form view for tables in their application. When launched from UI Builder, Table Builder supports domain separation, which is the ServiceNow instance-wide multi-tenant architecture.

Note:
Domain separation is supported for Table Builder when it is launched from UI Builder. Domain separation is not supported when launching Table Builder from App Engine Studio.

Table Builder enables developers in domain-separated environments to create forms while they are in the same browser window. Domain separation in Table Builder works similarly to an application scope that helps administrators to create or edit in a multi-tenant environment.

Standardization is the key principle to maintaining a stable, healthy, and scalable ServiceNow instance, where domain separation is installed. By having standardization, you have a common configuration that most of the instance operates by. When an instance has hundreds or thousands of domains, managing them successfully requires rigorous governance. Domain-specific configurations should be done only if they are deemed necessary by the instance owners. Most instances should follow the common instance configuration to provide a more uniform experience across the instance. It also lets instance owners minimize the code sprawl that slows the adoption of new ServiceNow features that are included as part of the release upgrades.

How domain separation works in Table Builder

Table Builder enables developers to switch the session domain to create domain overrides to the form layout, section layout, and form logic. System dictionary record changes (such as field metadata for a field label) do not require domain overrides. Form layout changes require domain overrides to both the form record and the section when the change is performed at a lower domain. When creating a domain override, section labels can't be edited prior to saving the override.

Note:
UI policies can have overrides at lower domains, as well. An override indicator appears on the UI policy.

In the global domain, a developer can expand the domain scope to see all form views from different domains. Developers can see all form views and views with overrides that are indicated with an icon.

Note:
Single section form records do not have a *sys_ui_forms* record attached to it. Instead, these records only have an attached *sys_ui_section* record until a second section is created. If a single section form has existing domain overrides, and the developer adds another section to the form, the existing domain overrides will break.

Domain separation for service providers

Using an application scope with Table Builder

Selecting an application from the application scope list in Table Builder enables you to customize form views for the users of the selected application in the ServiceNow AI Platform.

Application scoping protects applications by identifying and restricting access to application files and data. As an administrator, you can specify what parts of an application are accessible to other applications, which helps to protect data and application files. In Table Builder, you and your developers can set an application scope when you are working with a table or form.

Changing the scope in Table Builder also changes the scope in the ServiceNow AI Platform®, and changing the scope in the ServiceNow AI Platform® will change the scope in Table Builder.

When you are creating a form, you must be aware of the scope that you are working in. Choose the correct application scope for a table, form, or policy. The **Select scope** list is near the **Select Domain** list. The scope defaults to the scope that the user is in within the ServiceNow AI Platform®. If your users change to a different scope while in a page, they are notified that they are in a different application scope from the one that the form was created in.

Using Table Builder

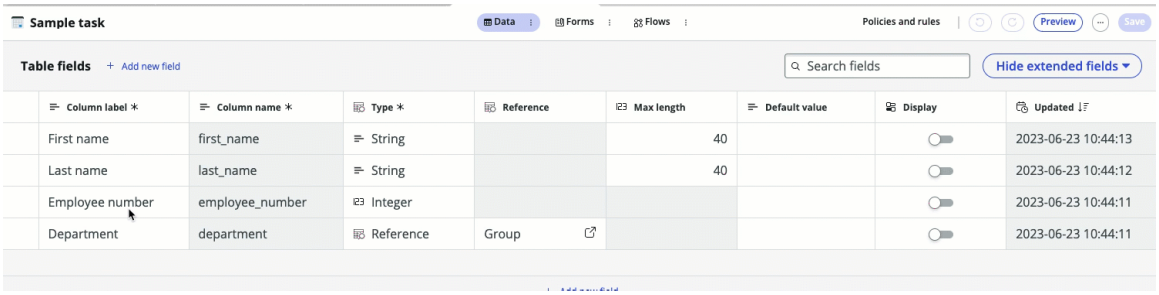
Use Table Builder, to design and customize tables, forms, and form elements for users from a single interface without needing to navigate between existing ServiceNow AI Platform tools.

Data in Table Builder

With Table Builder, you can modify the table properties and manage the fields that are available for a selected data table.

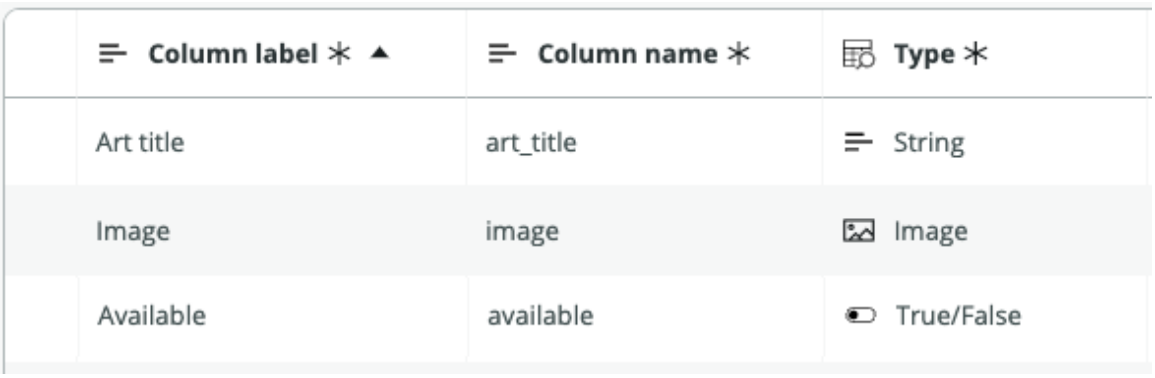
Table Builder is a tool for editing data tables. You edit a table on the **Data** tab by editing the columns of the table.

Table Builder

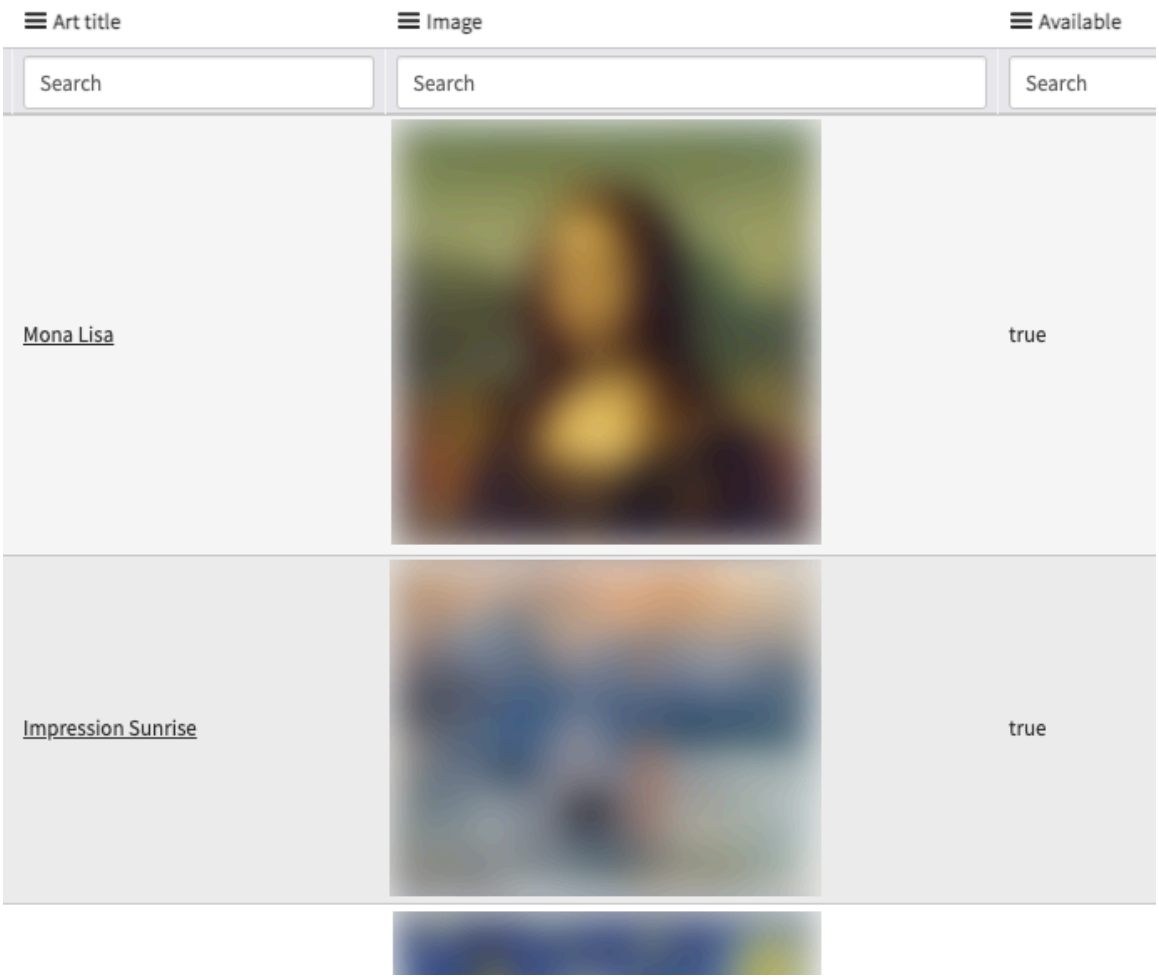


In Table Builder, each table column is represented as a row. For example, "Art title," "Image," and "Available" appear as column headers on the actual table. However, when you edit the columns in Table Builder, they appear as rows.

Example: Columns in Table Builder



Example: Actual data table shown with two records



To easily find a specific table column to edit in the default Fields view, type the column name into the search box at the top right. As you type, the list of columns below is filtered to match the entered keyword.

Note:
Use the **Filter options** list to show inactive fields or to hide extended fields from the list (if a table has been extended from an existing table).

Search for a table column

As you edit the table columns in Table Builder, think of each row as a field on a form. For example, if you change a column label, use a label that describes the data that you expect the user to enter in the form field. Change the column type to support this kind of form entry.

Modify table properties and table structure in **Fields** view, where you can perform the following actions:

- Add a new column to a table. See Add a table column in Table Builder.
- Delete a table column. See Delete a table column in Table Builder.
- Edit table properties. See Edit table properties in Table Builder.

- Change a column label. See Change a column label in Table Builder.
- Change a column name. See Changing a table column name in Table Builder.
- Change a column type. See Change a column type in Table Builder.
- Add a default value to a table. See Add a default value to a table column in Table Builder.
- Select a column as table display name. See Select a column as the table display value in Table Builder.
- Delete a table. See Delete a table in Table Builder.

Work with table structure and your data records in spreadsheet format within **Spreadsheet** view, where you can perform the following actions:

Note:
This feature is only available if your licensing entitles you to "exclusive low code capability" and you have Table Builder for App Engine installed. Contact your Solutions consultant for more information.

- Add a new data record. See Add a new data record.
- Edit individual data records. See Edit individual data records.
- Sort your data records. See Sort your data records.
- Filter your data records. See Filter your data records.
- Edit column field properties. See Edit column field properties.
- Add new columns. See Add new columns.
- Duplicate an existing column. See Duplicate an existing column.
- Reorder columns. See Reorder columns.
- Set column visibility. See Set column visibility.
- Pin columns. See Pin columns.
- Delete a table column. See Delete columns.

You can also view the table relationships for your table in **Schema** view. See Schema view in Table Builder.

Note:
This feature is only available if your licensing entitles you to "exclusive low code capability" and you have Table Builder for App Engine installed. Contact your Solutions consultant for more information.

Spreadsheet view in Table Builder

Use **Spreadsheet** view in Table Builder to work with your application data records and data structure in a spreadsheet format.

Overview

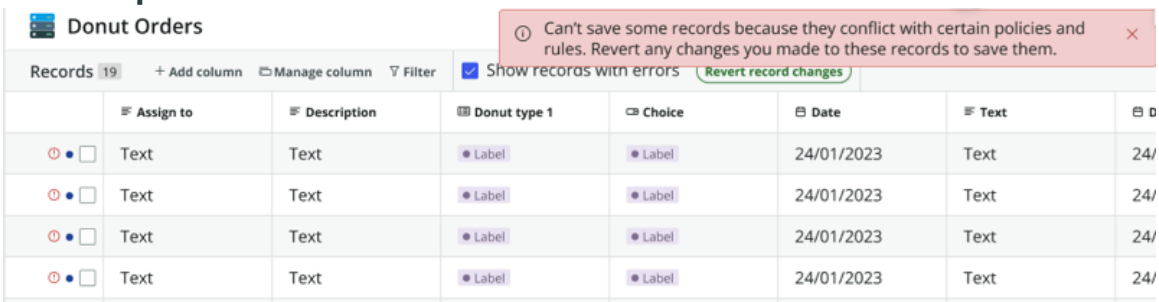
Spreadsheet view in Table Builder, enables you to review your application tables and their accompanying data in a familiar spreadsheet format. You can add columns, delete columns, and change column properties as well as review and update individual data records within those columns from a single screen.

Saving data records in Spreadsheet view

Sometimes errors occur when trying to save data records (i.e., data conflicting with applicable policies or business rules). When this happens, a warning popup displays along with a filtered list of errored data records.

Correct the data in each record individually, or select **Revert record changes** to revert any changes you made to the errored records.

Errors in Spreadsheet view



Use the following procedures to edit table field structure and any imported data records for a selected table using **Spreadsheet** view in Table Builder

Add a new data record

Add a new data record within Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

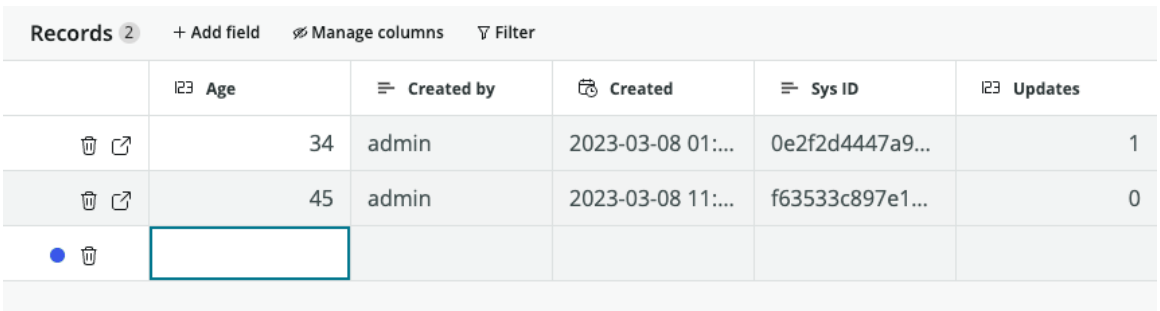
Procedure

1. Navigate to the **Data** tab.

> **Note:**
> Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Select the **Add new record** icon ( ).

Add new record



3. Make your changes to the data record.
4. Select **Save**.
   See Saving data records in Spreadsheet viewfor details on troubleshooting errors.

Edit individual data records

Edit individual data records within Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

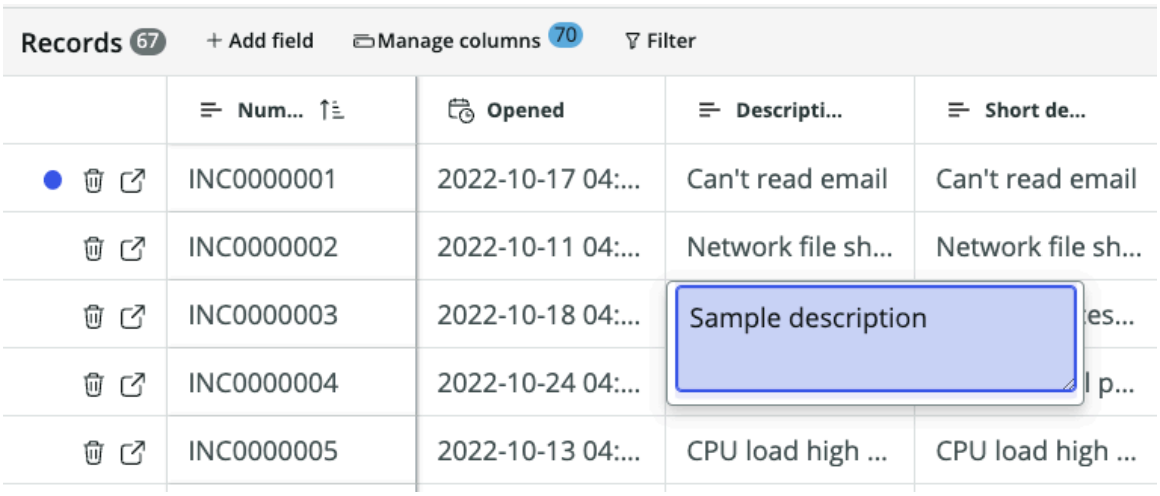
Procedure

1. Navigate to the **Data** tab.

   Note:
   Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Click into any editable data record field to launch the data for editing.

   Edit a field



3. Make your changes to the data.
4. Select **Save**.
   See Saving data records in Spreadsheet viewfor details on troubleshooting errors.

Sort your data records

Sort your data records by a specific field column within Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

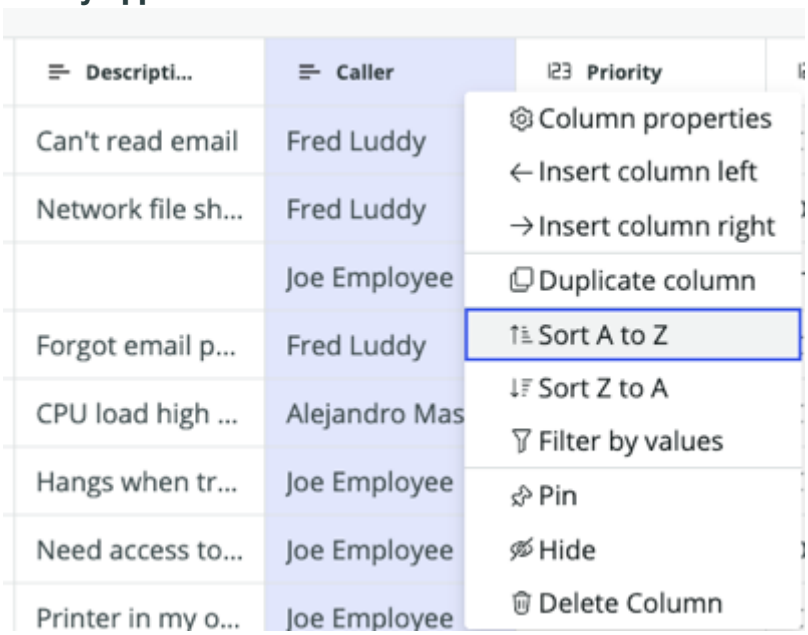
Procedure

1. Navigate to the **Data** tab.

   Note:
   Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Hover over a column header that contains the data by which you would like to sort the list of records, and then select the **Additional actions** icon ( ) to launch a column-specific list of actions (e.g., sort records by Approval Date in ascending order).
3. Select from the following options to choose whether to sort the data for the column in ascending or descending order.
   - Sort A to Z or Sort Oldest to Newest (ascending order)
   - Sort Z to A or Sort Newest to Oldest (descending order)

Sort by Approval Date



The list of records will then display in the order you chose.

Show matching data records

Show a filtered list of data records that contain matching data for a selected field within Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

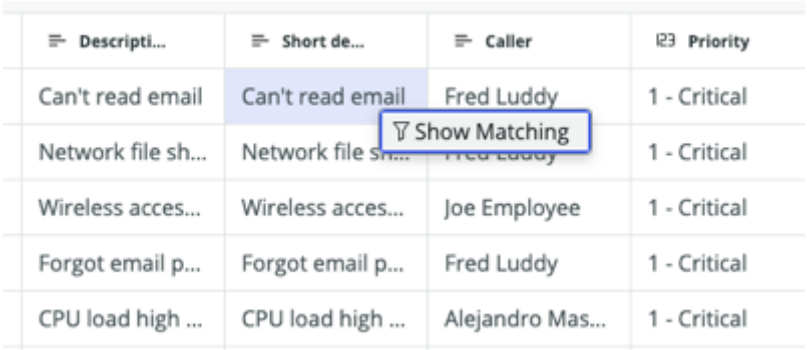
Procedure

1. Navigate to the **Data** tab.

> **Note:**
> Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Select and hold (or right-click) the data record in a cell to create a filtered list of records that contain the matching data, (e.g., show all records where **Short description** is "Can't read email".).

Show matching data records



A filtered list of records with matching data displays and a new filter query is added and accessible when you click the **Filter** button at the top of the grid.

Note:
To remove the filtering you just added, select the **Filter** button, and then delete the new filter condition from the list. See Filter your data records.

Filter your data records

Display only the data records you want to see in your list by setting up a conditional query within Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Data** tab.

   Note:
   Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Select **Filter** above the spreadsheet to launch a filter query.
   You can also select **Filter by value** from a specific column's **Additional actions** menu ( ) to pre-select that column's data for your query.

   Note:
   When a number appears to the right of the **Filter** button, it means that there are existing filters set for the view.

   The Filter window displays (along with any filter criteria that has already been set). In this case, an existing filter is set to display records where **Age** is 35.

Filter data

3. Enter your filtering query to specify which data records you want to display.
   - Select the **New condition set** button to enter a new filter condition which is connected by an OR statement.
   - Select the **or** or **and** buttons to extend the existing filter set with the desired boolean.
   - Select the **Delete** icon to remove a filter condition row.
4. Select **Apply** to apply the filter condition to your view.
   The filtered list of records will then display based on the criteria you chose.

Edit column field properties

Edit field properties such as the field label, type, attributes, and default values within Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

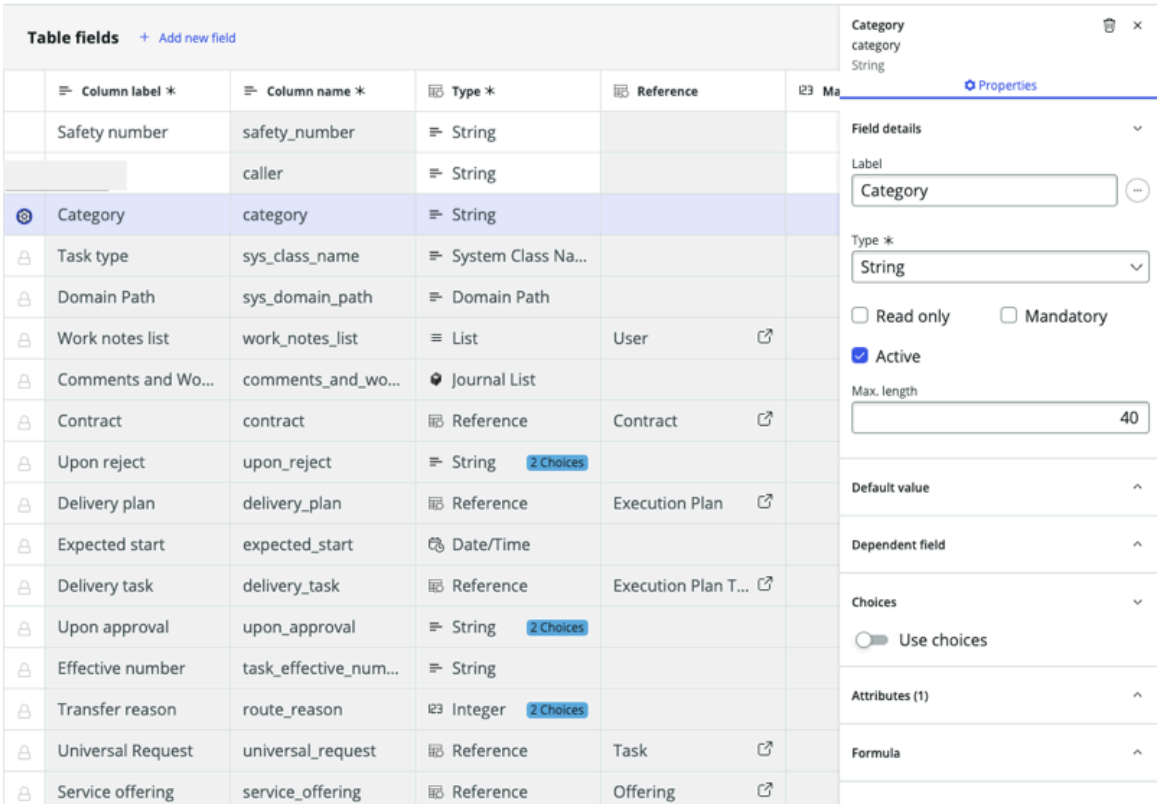
Procedure

1. Navigate to the **Data** tab.

   Note:
   Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Hover over the desired column header, and then select the **Additional actions** icon ( ) to launch a column-specific list of actions.
3. Select **Column properties**.
   The Properties pane displays for the selected field column.

Properties pane



4. Edit the desired field property for the column.
   See Field configuration in Table Builder for more information on field properties.
5. Select **Save**.

Add new columns

Add new field columns to a selected table within Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Data** tab.

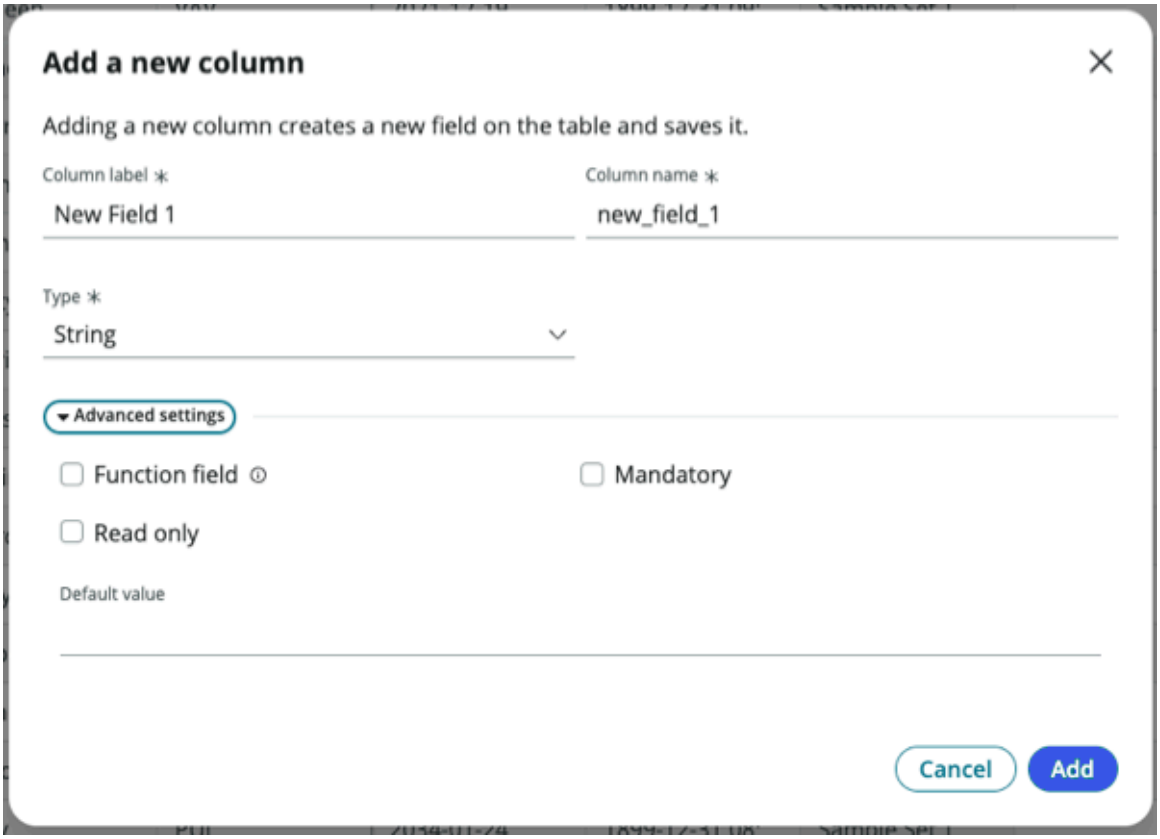
   Note:
   Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Select the **+ Add field** button.

   Note:
   You can also select the **Additional actions** icon ( ) to launch a column-specific list of actions, and then select **Insert column left** or **Insert column right** to insert the new column in a specific place within the table.

   The Add a new column window displays.

Add new column



3. Enter the following information for your new field column.

4. **Optional:** Select **Advanced settings** to expand it and enter any additional properties for your new field column.

5. Select **Add** to add the new field column to your table.

Duplicate an existing column

Duplicate an existing field column within a table shown in Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

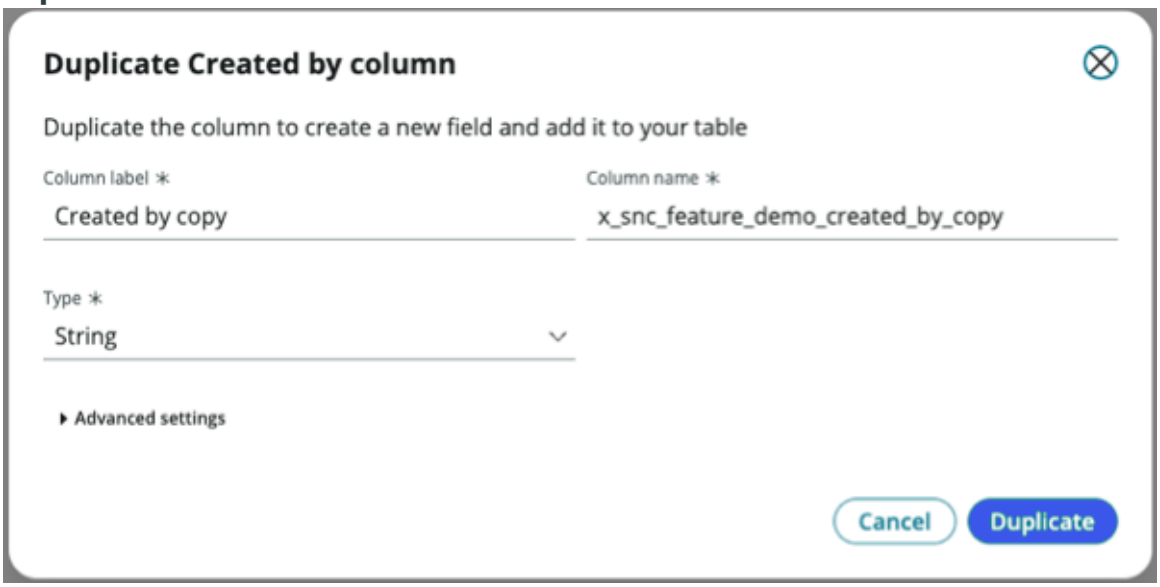
1. Navigate to the **Data** tab.

   Note:
   Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Hover over the header for the column to duplicate, and then select the **Additional actions** icon ( ) to launch a column-specific list of actions.
3. Select **Duplicate column**from the menu.

The text "copy" is automatically appended to the existing column label.

Duplicate column



4. Edit the **Column label** to the desired display name for the duplicated field column.
5. Edit the **Type** for the field column as desired.

   See Field types.
6. Select **Duplicate**.
   A new column displays in the view.

Reorder columns

Change the order in which your columns are displayed within Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

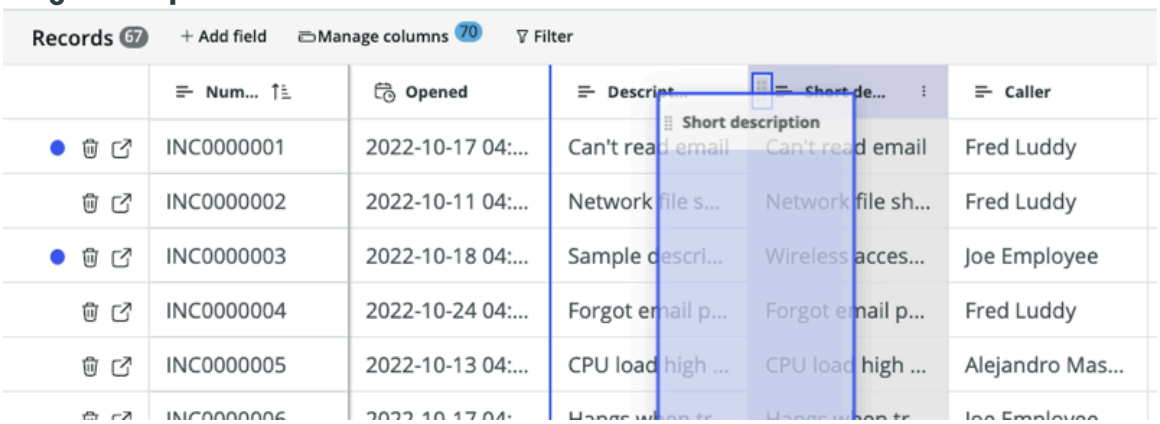
Procedure

1. Navigate to the **Data** tab.

   Note:
   Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Click to select the **Column handle** icon ( ) for a column and then drag the column to the desired locations in the table.

Drag and drop columns



Note:
If your table contains many table columns, select the **Manage columns** menu to view a compact list of column names, and then visually drag and drop within this list to order your table columns.

Set column visibility

Choose whether to hide or show specific field columns within Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Data** tab.

Note:
Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Choose one of the following options.

Note:
A number displays to the right of the **Manage columns** button to show how many columns are active in the view.

Pin columns

Pin specific columns to always display on the left when you scroll to the right in a table with a large number of field columns within Table Builder **Spreadsheet** view. Pinned columns are saved for each individual user, not globally. The next time a user logs in, any columns they pinned will be shown.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Data** tab.

   Note:
   Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Choose one of the following options to pin or unpin a field column.

   Note:
   You can also view which columns are pinned in the view by clicking the **Manage columns** button. Pinned columns will have a pin icon displayed next to the right of the listed column.

Delete columns

Delete a field column for a selected table within Table Builder **Spreadsheet** view.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Data** tab.

   Note:
   Spreadsheet view displays by default. You can also access Spreadsheet view from the Additional actions menu ( ).

2. Hover over a column header you want to delete, and then select the **Additional actions** icon ( ) to launch a column-specific list of actions (e.g., sort records by Approval Date in ascending order).
3. Select **Delete column**.
   A confirmation window displays.
4. Select **Delete** to delete the field column from your table.

   Note:
   If there are data records stored for the column you want to delete, you will not be able to delete the column until you have removed the records stored for this field.

Fields view in Table Builder

Modify the table properties and manage the table fields by using the default Fields view on the **Data** tab in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

Use the following procedures to edit tables using **Fields** view in Table Builder.

Add a table column in Table Builder

Store more information in a table record by adding a table column.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

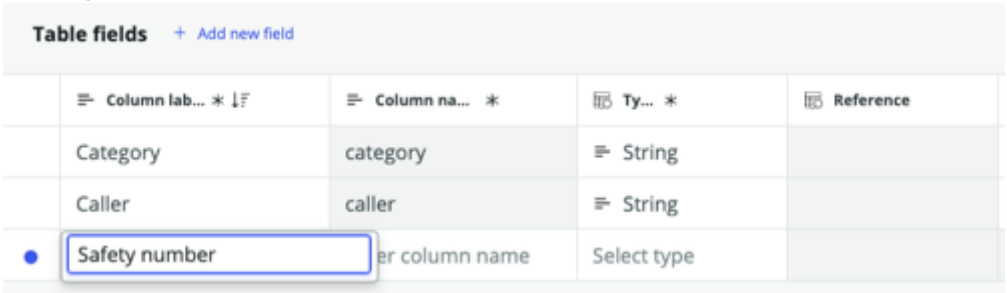
Procedure

1. Navigate to the **Data** tab.

   Note:
   Fields view displays by default. You can also access the Fields view from the Additional actions menu ( ).

2. Select **+ Add new field**.
3. On the resulting blank row, fill in the desired properties for the new data table column.

Adding a new field to a table



4. Select **Save**.

Result

If you preview the table, you can see the new column that was added to your table. For more information on previewing a table, see Preview your data in Table Builder.

Delete a table column in Table Builder

Delete a column from your table using Table Builder.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Data** tab.

   Note:
   Fields view displays by default. You can also access the Fields view from the Additional actions menu ( ).

2. Next to the table field row you want to delete, hover over the leftmost column, and select the Open side panel icon ( ).

3. At the top right corner of the side panel, select the trash icon ( ) to delete the field.

   Note:
   Your table includes several default columns (including Created and Updated), that you can't delete. Also, you can't delete columns that are extended from another table or columns where data records are already present. To delete the column, you must first delete the existing data.

4. Select **Delete** in the confirmation dialog.

Result

If you preview the table, you can see that the table column is no longer used in the table. For more information on previewing a table, see Preview your data in Table Builder.

Change a column label in Table Builder

Modify the label that uniquely identifies the data that is stored in it to users.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

About this task

A column label is the text that's visible to your users when they're reading or updating application data. For example, if you create a form for requesters to fill in, each column label appears as a form field label.

Use a column label that describes the specific information that you expect users to enter. For example, to prompt a user to add comments, you would use the column label "Comments" instead of "Text".

Procedure

1. Navigate to the **Data** tab.

   Note:
   Fields view displays by default. You can also access the Fields view from the Additional actions menu ( ).

2. Change a column label in the Column label column, by updating the text in the corresponding row.

   For example, to change the label of the "Office location" column, you would select the cell that says "Office location" and enter a different label.

The column label updates automatically after you select another cell.

3. Select **Save**.

Changing a table column name in Table Builder

Change the database name for the column. You may opt to change the column name manually if a reviewer finds that the column name in the database was causing issues in testing.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

About this task

Note:
You can't change the column name for existing fields that have information in them saved already.

A column name is the text that an administrator uses to track column data in the database. A column name is created automatically after you enter a column label. In Table Builder, if you change the column label, the column name also changes automatically.

Procedure

1. Navigate to the **Data** tab.

   Note:
   Fields view displays by default. You can also access the Fields view from the Additional actions menu ( ).

2. Change the column name in the Column name column by updating the text in the corresponding row.

   For example, to change the name of the "Office location" column, you would select the cell that says u_office_location and enter a different name.

   The column name updates automatically after you select another cell.

3. Select **Save**.

Change a column type in Table Builder

Change the type of field that will store information for rows in a table column. For example, if your table is tracking dates, you would want to select the Date column type.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Data** tab.

   Note:
   Fields view displays by default. You can also access the Fields view from the Additional actions menu ( ).

2. Select a cell and clear the text from the **Type** column.

3. From the list, select a column type.

   You can search the list by entering new text. For example, to find all the string types, you would enter `string`.

4. If required, define the column type with more information.

   For example, if you select **Choice**, define the list of choices that users can select from.

   The column type updates automatically after you select another cell.

5. Select **Save**.

Edit field properties in Table Builder

Edit field properties such as the field label, type, and default values in Table Builder.

Before you begin

Launch Table Builder. For more information, see Accessing Table Builder.

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Data** tab.

   Note:
   Fields view displays by default. You can also access the Fields view from the Additional actions menu ( ).

2. Select a field you want to modify in the table.

   For information about basic field properties, see Field Configuration.

3. Next to the field you want to edit, hover over the leftmost column, and select the Open side panel icon ( ).

4. Make your changes to the field properties.

   For information about modifying a field's UI policies, see Modify a UI policy in Table Builder.

   Note:
   The **Config** tab on the right stays open even if you switch between the **Data** and **Forms** tabs.

5. Select **Save**.

Add a default value to a table column in Table Builder

Define the default value to populate a table column automatically after a user creates a record.

Before you begin

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Data** tab.

   Note:
   Fields view displays by default. You can also access the Fields view from the Additional actions menu ( ).

2. Add the default value of a column in the **Default value** column by updating the content in the corresponding row.

   You define the default value by selecting a cell and then entering the value. The value that you enter depends on the column type. For example, if the column requires a choice, you would select one of the choices that you defined in the Type column.

   The column name updates automatically after you select another cell.

3. Select **Save**.

Select a column as the table display value in Table Builder

Select a column value that will be displayed in the reference fields of other tables. For example, the Opened by column of the task table could refer to a specific column in the user table so it can display a user name.

Before you begin
Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

About this task
A reference field shows the display value of the table to which it is referring. For example, the Opened by column of the task table refers to the user table. Because the display value of the user table is the user name, the **Opened by** field shows something like "Beth Anglin" or "Joe Employee". When you select a display value, choose the table column that would act as an appropriate title for individual records.

Only one column can act as the display value for a table.

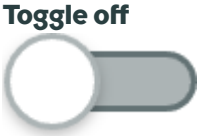
Procedure

1. Navigate to the **Data** tab.

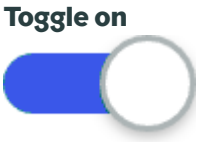
   Note:
   Fields view displays by default. You can also access the Fields view from the Additional actions menu ( ).

2. Check that all selections are cleared from the **Display** column.
   To clear a selection, toggle off the switch as shown in the following example.

   Toggle off

3. From the Display column, select one row to act as the table display value.
   To select a row, toggle on the switch as shown in the following example.



4. Select **Save**.

Schema view in Table Builder

Use **Schema** view in Table Builder to explore data relationships for your application data.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

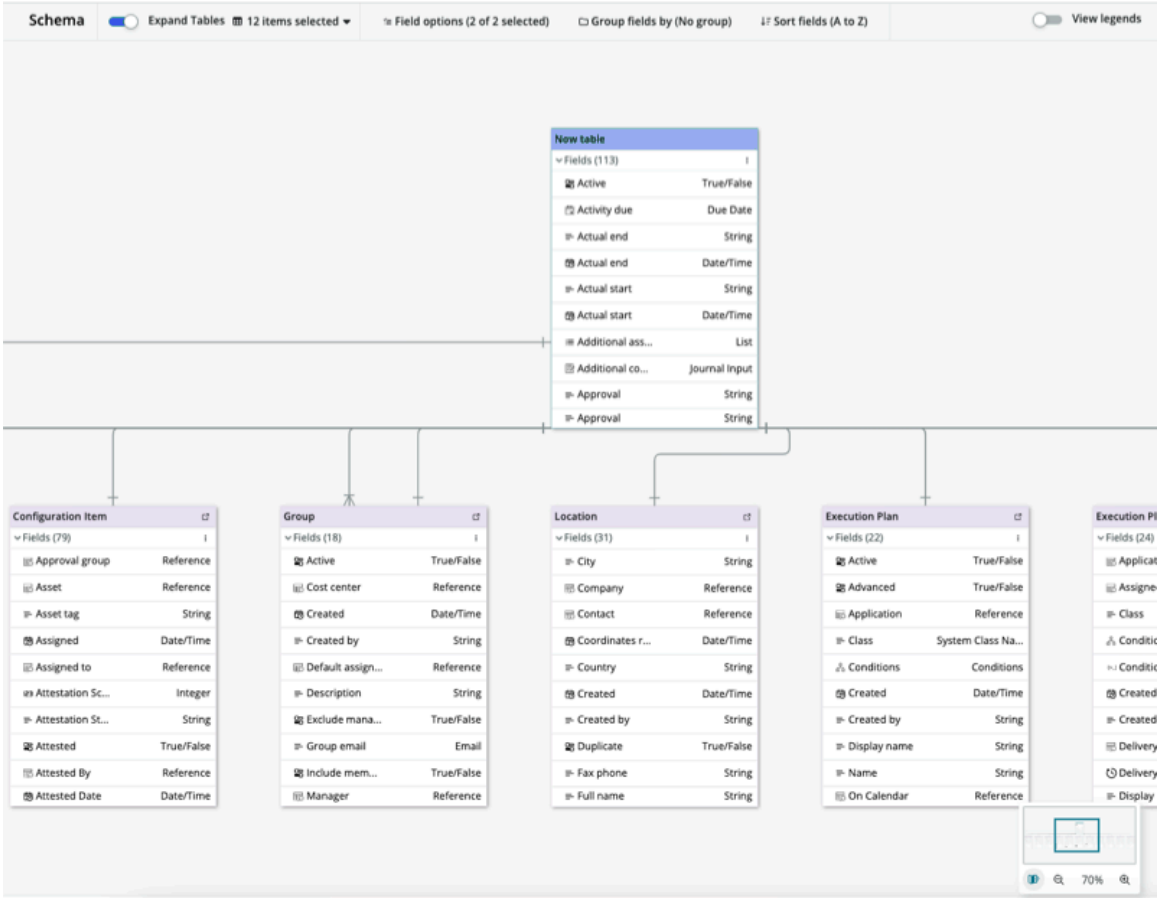
Procedure

1. Navigate to the **Data** tab.

   Note:
   Spreadsheet view displays by default.

2. **Optional:** Select **Schema** from the additional actions menu ( ) to access Schema view.
   A visual depiction of the table and its relationships to other tables displays on the screen.

Schema view



3. Navigate through the schema diagram by dragging the canvas with your mouse.
4. You can perform the following additional actions on this read-only screen.

Option	Description
Navigation overview controls	Select the **Overview toggle** icon ( ) in the lower right corner to toggle the navigational overview controls on or off. This navigational control enables you to perform the following actions: ○ When the schema diagram is zoomed in, you can drag the rectangle showing your view around by clicking and dragging it to focus it on the part of the diagram you want to review. ○ Select the **Zoom in** icon ( ) to zoom in. ○ Select the **Zoom out** icon ( ) to zoom out.
Show / hide table fields	The **Expand tables** toggle is toggled on by de fault to show all the fields within the displayed schema tables. To hide the fields within the displayed schema tables, select **Expand ta bles** to toggle it off.
Show / hide tables	Use the **Items selected** menu to view a list of application and non-application tables that

Option	Description
	are displayed in the schema diagram. You can select the table name to remove the selection checkmark, which hides the table from dis playing in the diagram. To show the table, se lect the table name again to toggle the check mark back on.
Set field options	Use the **Field options** menu to control how fields display in the schema diagram. ○ Select **Extended fields** to display extended fields within schema tables. ○ Select **Field type** to show the type of field for each field displayed in the schema ta bles.
Group fields	Use the **Group fields by** menu to group fields within the displayed tables (e.g., grouping fields by type). Choose from the following grouping options: ○ No group ○ Extended ○ Reference ○ Type
Sort fields	Use the **Sort fields** menu to sort fields within the displayed tables. Choose from the follow ing sorting options: ○ Alphabetically (A to Z) ○ Alphabetically (Z to A)
View legends	Select **View legends** to view information for in terpreting the displayed schema diagram.
Table-specific options	Select the **Additional options** icon (⋮) for a ta ble to control how fields in the selected table are displayed, grouped, and/or sorted similar to the top-level options described above.
View in Table Builder	Select the **View Table** icon (↗) to view the se lected table in Table Builder.

Preview your data in Table Builder

See what your table looks like after you've edited the table columns.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Role required: none

About this task

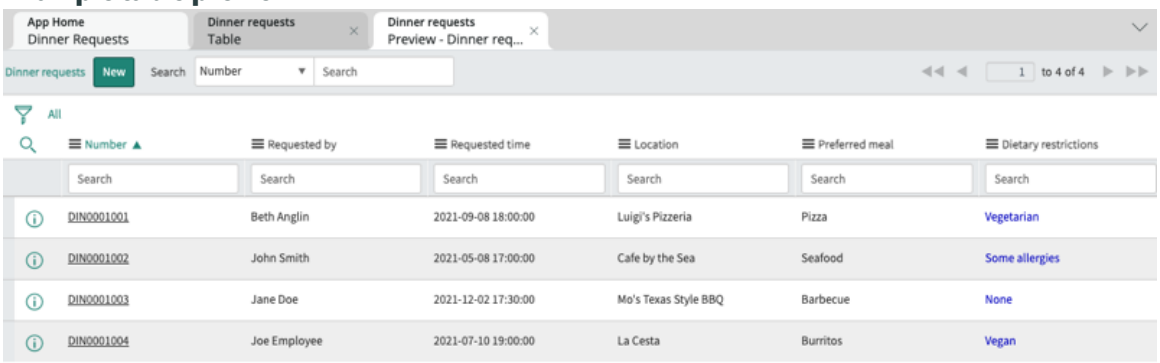
Each row in Table Builder represents a column from your table. Previewing the table enables you to see what the columns look like in their proper place. You can also test the experience of creating records on your table.

Note:
The table which you are editing must have at least one role that is associated to it or preview is disabled.

Procedure

1. On the **Data** tab, select **Preview**.
2. From the new tab, review the table preview as shown in the following example.

Example table preview



What to do next

If your table doesn't work as expected, continue editing in Table Builder. Then, preview the table again.

Delete a table in Table Builder

Delete a table from your application so that it no longer appears in the app dashboard.

Before you begin

Note:
Parent tables can't be deleted until all existing child tables are deleted.

Role required: Users must have canDelete access to **sys_db_object** or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Data** tab.
2. Select the menu icon (•••), and then select **Delete Table**.
3. In the dialog box, enter `delete` and then select **Delete**.
4. Select **Save**.

Result

The table is no longer available in the app dashboard.

Edit table properties in Table Builder

Change table properties such as the table label or other settings so that you can make a table extensible or add record numbers by using Table Builder.

Before you begin
Role required: none

> **Note:**
> User must have canWrite access to *sys_db_object* or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

About this task
By editing table properties, you can relabel your table, make your table extensible, or add record numbers. You can also set application access settings.

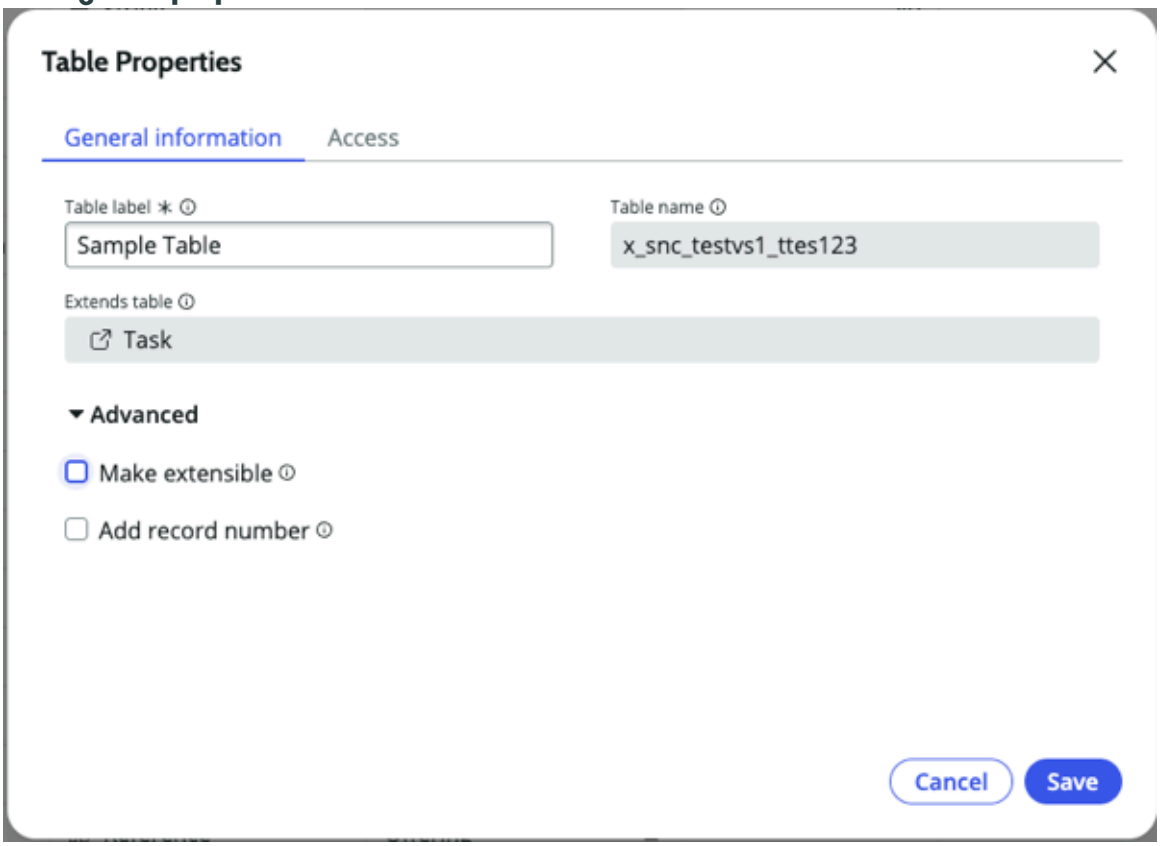
Making a table extensible means that you are enabling new tables to share columns from your table. For example, if you created an "Office location" column in your table, you can allow new tables to use the "Office location" column also. For more information on table extensions, see Table extension and classes.

Adding record numbers means that a tracking number is created automatically for each new table entry. For example, a new entry to the Travel Requests table would get a record number like TRV1234567. You can use this number to find table records more easily.

Application access settings determine whether script objects from other applications can access the table in your application. You can give these script objects access to read, create, update, or delete records on your table. Alternatively, you can disable access to your table from other applications. For more information on the application access controls, see Table design and runtime settings.

Procedure
1. Navigate to the **Data** tab.
2. Select **Properties**.
3. In the dialog box that appears, update the table properties as shown in the following example. For more information on these properties, see Table properties.

Editing table properties



4. To close the dialog box, select **Save**.
5. Select **Save**.

Forms in Table Builder

On the **Forms** tab in Table Builder, you can visually create, configure, and customize the different form views for your users using the form editor. The views that you define contain the elements that appear when a user opens that form or list.

Overview

A form view defines the elements that appear to a user when the user opens a form or list. Each form has a default view, but you may want to create several different form views for different groups of users.

In Table Builder, you can customize multiple views for a form for the different users who input data or view the form. You can also customize the default form view for everyone.

Explore the following major areas when you configure a form or list:

- Form view selection
- All form views list
- Form layout
- Form fields
- Form annotations

- Formatters
- Embedded lists

Basic form navigation

The **Forms** tab consists of the following four major areas:

- Top navigation menu
- Add form elements panel
- Form editor
- Configuration panel

The following table contains a list of some of the other basic navigational elements within the **Forms** tab in Table Builder.

Navigational elements in the Forms tab

Navigational element	Description
Forms additional actions list ()	The Additional actions list (vertical ellipsis) on the **Forms** tab provides a quick way to perform any of the following actions: • Add a new form view • Duplicate the selected form view • Configure a related list • Configure a UI action • Navigate to a filterable, sortable list of all form views by selecting **All form views**. See All form views list. Changes to the form made in the editor are committed to the selected view. **Note:** The additional actions menu (vertical ellipsis) is visible only when forms are accessed throughServiceNow Studio or App Engine Studio, not throughServiceNow AI Platform.
Form view list ()	Select a form view from this list or use the Additional actions menu (vertical ellipsis) to add a view. Changes to the form made in the editor are committed to the selected view.
PDF extractor ()	If a PDF is associated with the selected data table, select this element to launch the PDF extractor tool and view the PDF. See Use a PDF to create data tables.

Navigational elements in the Forms tab (continued)

Navigational element	Description
	Note: This feature is only available if your licensing entitles you to "exclusive low code capability" and you have Table Builder for App Engine installed. Contact your Solutions consultant for more information.
Form element search bar ()	Enter keywords here to filter the list of form elements.
Multiple selection check box 	When you point to a form element in the Add form elements panel, you can select this option if you want to select and drag multiple fields to the form editor at once.
Add form element icon ( )	When you point to a form element or section, select this icon to add a new section or element above or below the existing element.
Move element icon ( )	When you point to a form element, this icon displays on the left edge. Select this icon, and then drag the element to move it to the desired location.
Delete form element icon ( )	When you point to a form element in the editor, you can select this icon to remove it from the form view.
Move section arrow icon ( )	When you select a form section, you can select the up or down arrow to move it up or down on the form view.
Delete section icon ( )	When you select a form section, you can select this icon to remove the section from the form view.
Open panel icon ( ) Close panel icon ( )	Selecting the Open panel icon expands the panel to the right. Selecting the Close panel icon collapse it.

Form view selection

Select a form view to work with from the form view list in the form editor.

Note:
You can also select a form view from the Additional actions menu on the **Forms** tab.

See Choose a form view in Table Builder.

All form views list

Select **All form views** from the Additional actions menu to the right of the **Forms** tab to browse a filterable list of form view cards (vertical ellipsis). This page allows you to create complex filtering and sorting if you have a great deal of form views to navigate.

You have the following options for finding a desired form view if you have a large list of them.

All form views list

Option	Steps
Search	Type a keyword in the **Search** box. The list of cards will be filtered as you type.
Sort form views	Select an option from the sorting list to sort the form view cards. • Form name (a to z) • Form name (z to a) • Updated by (a to z) • Updated by (z to a) • Updated (recent to last) - Default option • Updated (last to recent)
Filter forms by setting up filter criteria	**1.** Select the filter icon ( ). **2.** Add your filter condition criteria including any AND/OR logic. **3.** To add additional conditions, select **+ New condition set**. **4.** Select **Apply**.

Form layout (sections)

A view is composed of sections that group the data elements that you want displayed.

You can add multiple sections and change the layout of each section into one or two columns. A section is where you can group the data elements that you want to display for a form view. These elements include form fields, annotations, formatters, and embedded lists.

See Customize your form layout in Table Builder.

Form fields

When you select a table in Table Builder, the available fields are displayed in the form elements panel. You can create fields for the table or configure the fields and their properties.

By dragging these fields into the form editor, you can then visually arrange these fields on the form view you have selected.

See Add fields to a form layout in Table Builder.

See Modify field properties in Table Builder form editor.

Form annotations

A form annotation is an additional piece of information on a form, such as a line or paragraph of text.

For example, you may want to add instructional text for a particular section on the form. By using Table Builder, you can add a form annotation to the view that displays on-screen instructions on how a user should enter information.

See Create form annotations in Table Builder.

Formatters

A **Formatter** is a read-only element in a form that displays additional information about the selected table record. Unlike fields, formatters are not editable.

See Formatters.

By using Table Builder, you can visually drag any of the displayed formatters onto the form editor and arrange them.

See Add formatters in Table Builder.

Embedded lists

You can use an embedded list to display the data for a selected related list on a form. A related list shows the records in the tables that have relationships to the current record. For example, for a form view that references a Problem table, you might want to display a list of locations that are impacted by a selected problem.

With Table Builder, you can visually drag a list from the **Embedded Lists** tab of the form elements panel onto the form editor, and then arrange them.

By adding an embedded list to a form, you enable your users to view or edit the related list without needing to navigate away from the form. Changes to the data in the list are saved when the user saves the form.

See Add embedded lists in Table Builder.

Choose a form view in Table Builder

Choose existing views, duplicate views, or create entirely new views for form users in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

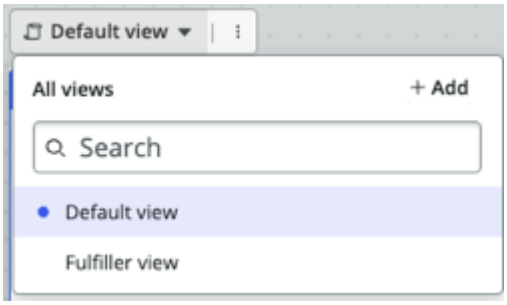
Note:
To understand how to approach customizing your forms, review Table Builder workflow and navigation.

Role required: personalize_form or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Forms** tab in Table Builder.
   The "Default view" is selected.

   View list

2. You can modify the default view selected by using the View list or select another view.
   You can also add a view or choose one the other form view actions from the Additional actions menu.

   Additional actions menu

   
   - Add a new view to customize by clicking **Add new form view** from the view list or by selecting an option from the Additional actions (⋮) menu.
   - Duplicate an existing view to customize by selecting a view and then choosing **Duplicate this form view** from the Additional actions (⋮ menu.
   - Configure a related list for the selected form view by selecting this option from the Additional actions (⋮) menu.

   Note:
   You can also choose a view from the Additional actions list to the right of the **Forms** tab or navigate to the **All form views** list to filter and sort a large list of form views. See All form views list.

3. With the view selected, you can modify the form view in the following ways:
   - Add fields to your form. See Add fields to a form layout in Table Builder.
   - Customize the layout of your form (sections). For more information, see Customize your form layout in Table Builder.
   - Add non-field elements that display data on your form. For more information, see Add formatters in Table Builder.

- Add instructional text or other text to your form. For more information, see Create form annotations in Table Builder.
- Add related lists to your form. For more information, see Add embedded lists in Table Builder.

Note:
To customize the elements that display on a form, see Forms in Table Builder.

Customize your form layout in Table Builder

Visually design the look of the forms your users see by customizing form views in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Note:
To understand how to approach customizing your forms, review Table Builder workflow and navigation.

Role required: personalize_form or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Forms** tab in Table Builder.
2. Choose a view to work with.
   For detailed information on how to choose a view for a form, see Choose a form view in Table Builder.
3. Customize the form layout that displays in the form editor by performing the following actions.
4. To rearrange the sections within the form, in the section header, select the section and then drag it to the desired location on the form or use the up and down arrow icons.
5. Select **Save**.

Add fields to a form layout in Table Builder

Visually add and arrange fields within a form layout to create a form that matches your requirements using Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Note:
To understand how to approach customizing your forms, review Table Builder workflow and navigation.

Role required: personalize_form or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

About this task

Procedure

1. Navigate to the **Forms** tab in Table Builder.
2. Choose a view to work with.
   For detailed information on how to choose a view for a form, see Choose a form view in Table Builder.
3. To display a list of the existing fields for the selected table, in the add form elements panel, select **Fields**.

   Note:
   You can also launch the Add form elements panel by selecting the Add (+) icon above any existing element in the form editor.

4. Customize the fields that display on the selected form view by performing one of the following actions.

   Note:
   Certain field types are only supported in Core UI. Fields are flagged with an exclamation icon (!) to indicate an unsupported type.

5. Select **Save**.

Modify field properties in Table Builder form editor

Modify basic field properties for the fields that display for users in a form view from within the **Forms** tab in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Note:
To understand how to approach customizing your forms, review Table Builder workflow and navigation.

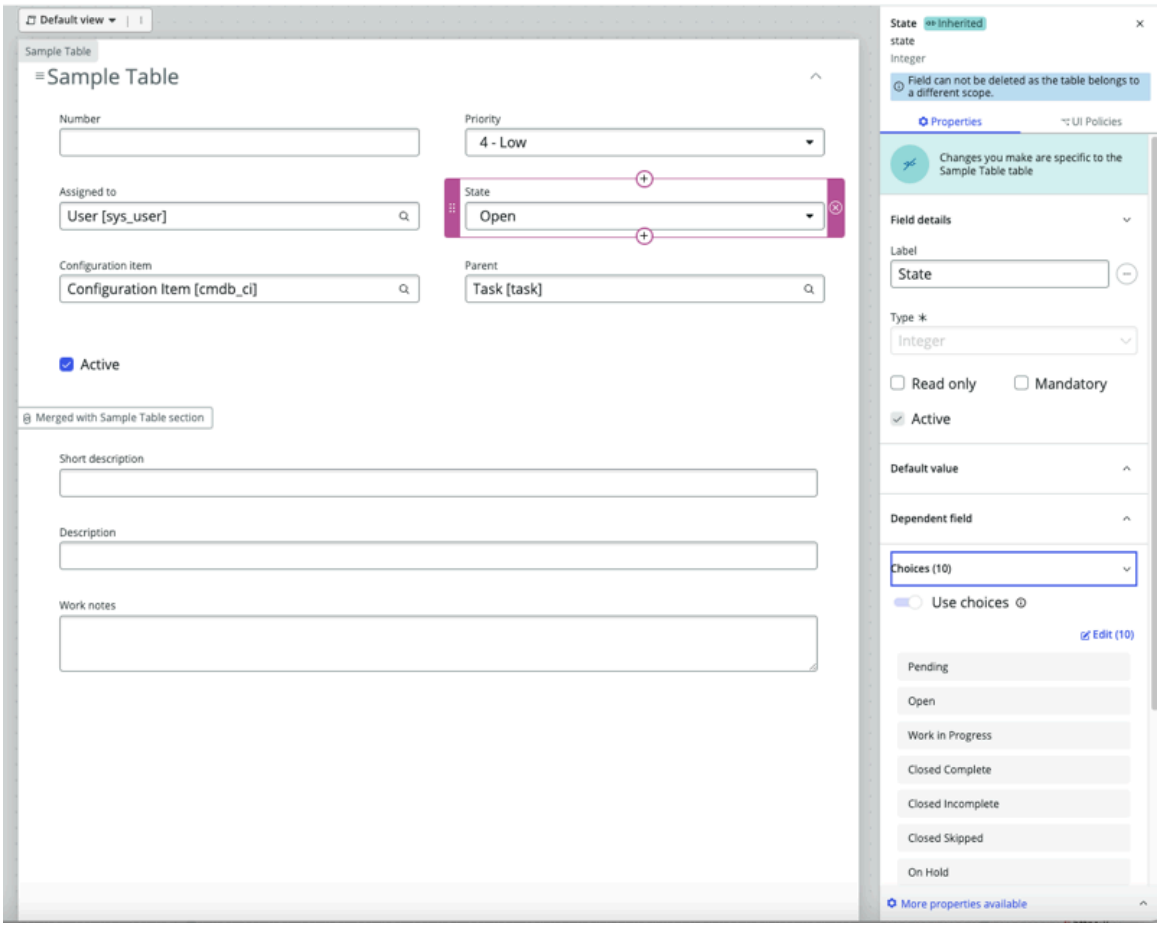
Role required: personalize_form or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. On the **Forms** tab, choose a view to work with.
   For detailed information on how to choose a view for a form, see Choose a form view in Table Builder.
2. In the form editor, select a field to highlight it.

The following example shows that the panel on the right displays the **Properties** tab. This tab shows the basic properties of the selected field.

Properties tab



3. Edit the basic field properties as needed for the selected field.
   The sections displayed vary depending on the field type. For a description about these fields, see Field configuration in Table Builder.

   Note:
   Below the **Properties** tab, select **More properties available** to launch the full dictionary entry for the selected field.

4. To view any UI policies that are set up for the selected field and make edits to that field, select the **UI Policies** tab.
   For more information about the policies and properties, see Policies and rules properties in Table Builder.
5. Select **Save**.

Create form annotations in Table Builder

Add instructional text and other design elements to your forms by using form annotations in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Note:
To understand how to approach customizing your forms, review Table Builder workflow and navigation.

Role required: personalize_form or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

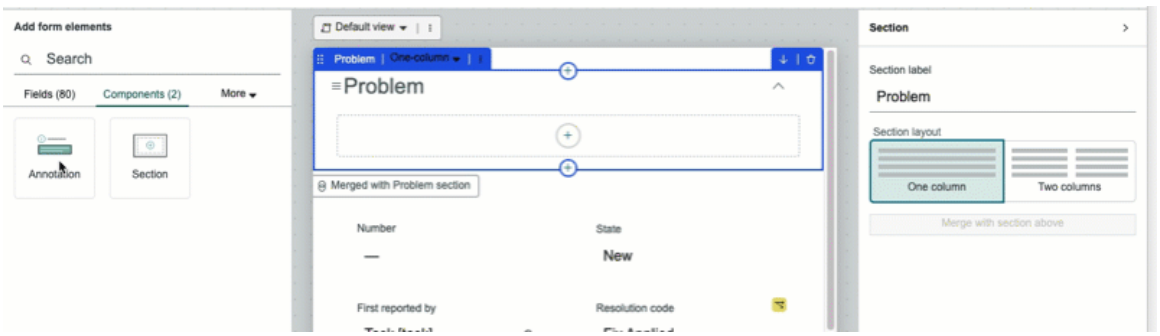
Procedure

1. Navigate to the **Forms** tab in Table Builder.
2. Choose a view to work with.
   For detailed information on how to choose a view for a form, see Choose a form view in Table Builder.
3. To display a list of the available components that you can add to your form view, in the Add form elements panel, select **Components**.

   Note:
   You can also launch the Add form elements panel by clicking the Add (+) icon above an existing element in the form editor.

4. Select the **Annotation** elements, and then drag it to the location in the form editor where you'd like to position the annotation text as shown in the following example.

   Add annotation

5. Select the **Annotation type**.
6. Select an option for **Annotation text**.
7. Enter the desired annotation text in the field that displays in the Annotation panel.
8. Select **Save**.

Add formatters in Table Builder

You can add form elements that display non-field information to users by adding a formatter in Table Builder. For example, you may want to display a **Comments** field where users can add comments to a displayed form.

Before you begin

Note:
Formatters are only supported in Core UI and earlier.

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Note:
To understand how to approach customizing your forms, review Table Builder workflow and navigation.

Role required: personalize_form or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Forms** tab in Table Builder.
2. Choose a view to work with.
   For detailed information on how to choose a view for a form, see Choose a form view in Table Builder.
3. To display a list of the available components that you can add to your form view, in the Add form elements panel, select **Formatters**.

   Note:
   You can also launch the Add form elements panel by clicking the Add (+) icon above an existing element in the form editor.

4. Select a formatter, and then drag it to the location in the form editor where you'd like to place it.

   Note:
   Formatters in forms are only supported in Core UI and earlier interfaces.

   For information on how you can add a formatter to a form, see Formatters.
5. Select **Save**.

Add embedded lists in Table Builder

Add an embedded list using Table Builder to display data for a selected related list on your form. A related list shows the records in the tables that have relationships to the current record. For example, for a form view that references a Problem table, you might want to display a list of locations that are impacted by a selected problem.

Before you begin

Note:
Embedded lists are only supported in Core UI and earlier.

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Note:
To understand how to approach customizing your forms, review Table Builder workflow and navigation.

Role required: personalize_form or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to the **Forms** tab in Table Builder.
2. Choose a view to work with.
   For detailed information on how to choose a view for a form, see Choose a form view in Table Builder.
3. To display a list of the embedded lists that you can add to your form view, in the Add form elements panel, select **Embedded lists**.

   Note:
   You can also launch the Add form elements panel by clicking the Add (+) icon above an existing element in the form editor.

4. Select an embedded list, and then drag it to the location in the form editor where you'd like to place it.

   Note:
   Embedded lists in forms are only supported in Core UI and earlier interfaces.

   For information on how you can add an embedded list to a form, see Embed a list within a form.
5. Select **Save**.

Preview your form

Previewing and saving your form in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Note:
To understand how to approach customizing your forms, review Table Builder workflow and navigation.

Role required: personalize_form or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

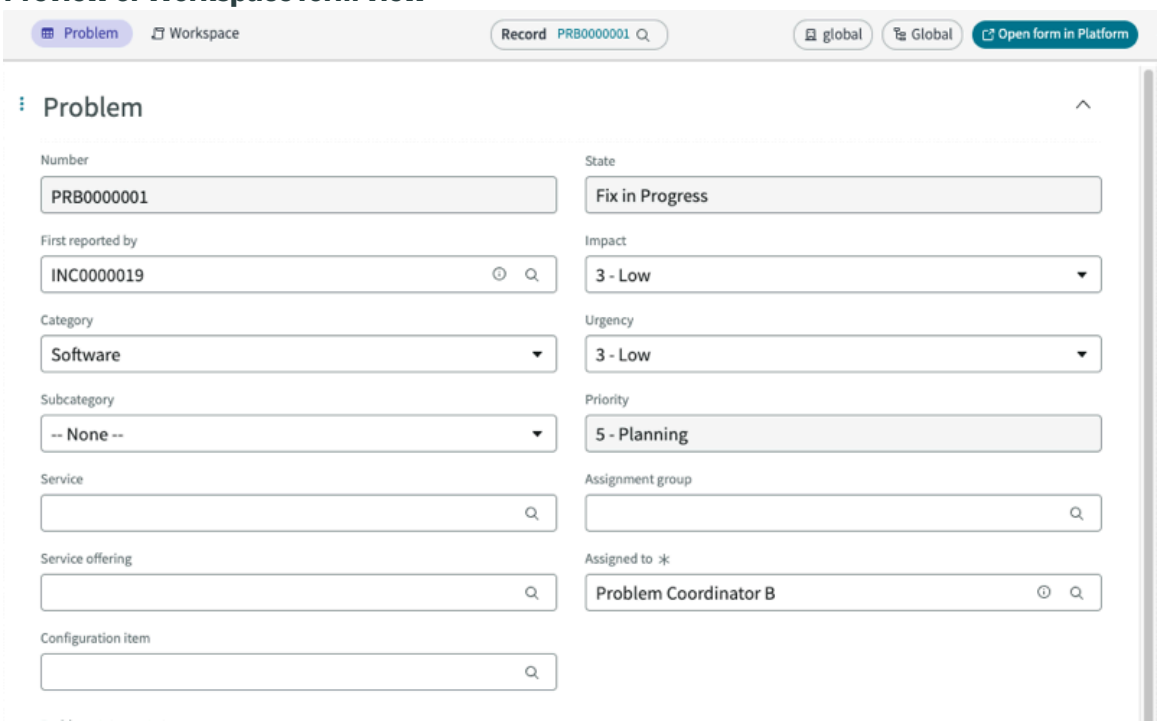
Procedure

1. Access Table Builder.
   - For information on viewing forms, see Launching Table Builder from UI Builder.
2. Select the **Forms** tab.
3. Select a form view.
4. Customize the form view as desired.
5. Save your changes by selecting **Save**.

> **Note:**
> Once you save your changes, you cannot undo them using the Undo function. The Undo icon ( ) is grayed out.

6. Select **Preview** to review your saved changes.
   The Preview window displays a record for your form. The Workspace form view is shown in the example.

Preview of Workspace form view



7. You can perform any of the following actions as you review your changes to better understand how your form will display for users.
   - When previewing a form, you can search for a new record to populate your form with by clicking the New record icon ( ). This will also let you add a new record if none exist so you can really see what the form will look like.
   - When previewing a form, you can open the form in the ServiceNow AI Platform by clicking the Open form in Platform icon (Open form in Platform).
8. When you are finished reviewing, close the browser window.

Policies and rules in Table Builder

Policies and rules define how information appears to users based on role and entries, as well as who can access tables and forms built in Table Builder.

Sections for working with policies and rules

The **Policies and rules** tab in Table Builder has several sections, but you can edit only UI policies within Table Builder. The other sections are read-only and contain links to manage their content in other parts of the ServiceNow AI Platform.

Administrative UI policy and rules sections

Section	Description	Editable within Table Builder
UI Policies	Dynamically change the behavior of information on a form and control custom process flows for tasks.	Yes.
Access control rules	Control access to the specified resource based on role, condition, and script criteria being met.	No.
Client Scripts	Create scripts that control how form fields appear based on defined criteria.	No.
Business Rules	Create business rules to accomplish tasks like automatically changing values in form fields when certain conditions are met.	No.
Workspace view rules	Define rules to control how users view workspaces based on criteria.	No.

To manage a rule or policy script outside of Table Builder, select for the entry. Or, you can view the full list of rules and scripts outside of Table Builder by selecting the **Full list** link for each section of the **Policies and rules** tab:

- **Full ACL list**
- **Full client scripts list**
- **Full business rule list**
- **Full workspace view rules list**

UI policies for tables and forms

Configure UI policies to adjust how forms appear based on roles and user input.

For example, you can use UI policies to make a field on a form read-only or required or hide certain fields depending on a user's role. Basic UI policies do not require any scripting. For more advanced actions, use the **Run scripts** option.

You can also use client scripts to perform all these actions, but for faster load times use UI policies when possible.

Create a UI policy in Table Builder

Configure UI policies in Table Builder to adjust how forms appear based on roles and user input.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

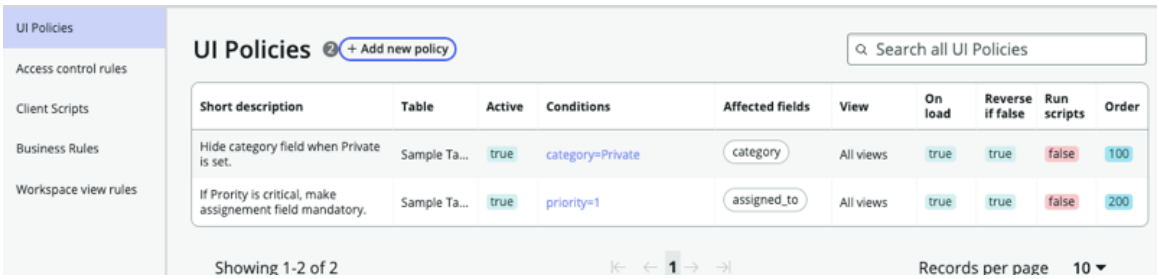
Role required: personalize_rules or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

About this task

You can create and edit UI policies only for applications that you own. For more information on application scope, see Domain separation and Table Builder.

Procedure

1. On the Table Builder screen, choose a table to work with.
2. Select the **Policies and rules** tab.
   Alternatively, you can add a UI policy for a field directly in the **Forms** tab of Table Builder in the right pane that appears when you select a field.
3. Select the UI Policies section to display a list of UI policies.
4. Select the **Add new policy** link to display the policy details.
   - If the link is inactive, you must change the scope that you're working with on the **Forms** tab.
   - If a field has policy and appears in the view, the active icon appears on the top corner of the field as shown in the following example.



5. On the form, fill in the fields for the Policy details section.
   For more information on field definitions, see Policies and rules properties in Table Builder.
6. In the When these conditions are met section, specify the conditions that, if fulfilled, cause the UI policy to be applied using the condition builder.
   To add multiple sets of conditions, select **New condition set**.
7. In the Do the following section, create field actions that should be performed when the conditions are met.
8. To finish adding the policy, select **Add UI policy**.

Result

After you add the UI policy, you can configure scripts and the related list actions for it. For more information on client scripts and UI policies, see Client scripts for UI policies.

Modify a UI policy in Table Builder

Edit UI policies to change how forms appear based on roles and user input in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Role required: personalize_rules or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

About this task

You can create and edit UI policies only for applications that you own. For more information on application scope, see Domain separation and Table Builder.

Procedure

1. In the UI policies section, on the **Policies and rules** tab, select the policy that you want to edit. You can also edit a field's UI policy directly in the form by selecting it in the **UI policies** tab of the right pane that appears when you select a field.
2. Change the UI policy fields and attributes as needed.
   For more information on field definitions, see Policies and rules properties in Table Builder.
3. Click **Update UI policy**.

Flows in Table Builder

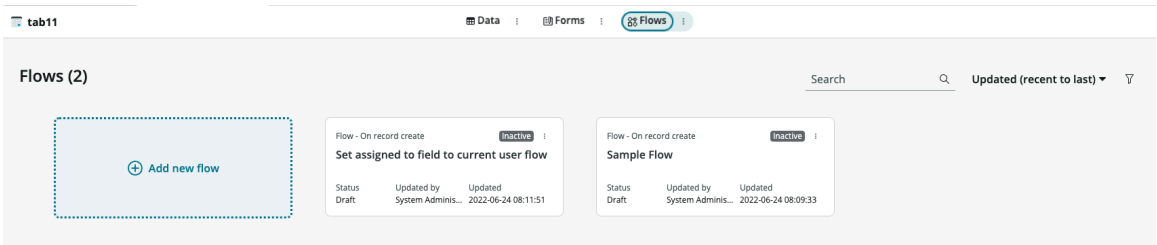
You can use the Workflow Studio functionality that is integrated within Table Builder to manage your table's record-based flows. You can manage these flows by using the **Flows** tab.

Workflow Studio is a ServiceNow AI Platform® feature that enables process owners to automate work. Build multi-step flows from reusable components without having to code.

The **Flows** tab within Table Builder is where you can view and work with record-based flows for a selected data table (that is, actions that are triggered when a table record is created or updated or both).

Flows tab

The following diagram shows flow cards in Table Builder.



Find a record-based flow

Use the **Flows** tab in Table Builder to search and filter a list of flows that are triggered when selected table records are updated, created, or both.

Before you begin

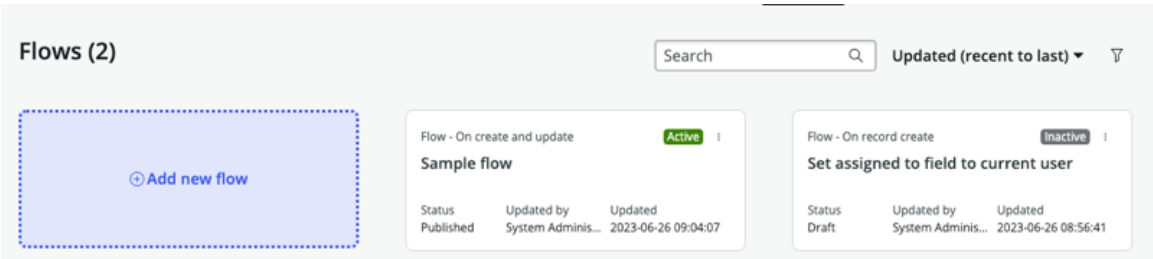
- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Role required: personalize_forms, personalize_dictionary, and flow_designer permissions (or relevant AES user role and delegated developer permissions). For more information, see Delegate developers using AES.

Procedure

1. Launch Table Builder as described in Accessing Table Builder.
2. Select the **Flows** tab.
   The flows triggered by the selected table are listed as flow cards.

Flow cards list



3. Filter or search the list of flow cards as needed to find the desired flow.

Find the desired flow card

Option	Steps
Search text	Type a keyword in the **Search** box. The list of cards will be filtered as you type.
Sort flows	Select an option from the sorting list to sort the flow cards. **a.** Flow name (a to z) **b.** Flow name (z to a) **c.** Updated by (a to z) **d.** Updated by (z to a) **e.** Updated (recent to last) - Default option **f.** Updated (last to recent)
Filter flows by setting up filter criteria	**a.** Select the filter icon ( ). **b.** Add your filter condition criteria including any AND/OR logic. **c.** To add additional conditions, select **+ New condition set**. **d.** Select **Apply**.

What to do next

- Select the flow card to edit your new flow using Workflow Studio. See Modify a record-based flow.
- Create a new record-based flow from an existing one. See Copy a record-based flow.
- Delete the flow. See Delete a record-based flow.

Add a record-based flow

Add flows that are triggered when a table record is updated, created, or both updated and created by using the **Flows** tab in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Role required: personalize_forms, personalize_dictionary, and flow_designer permissions (or relevant AES user role and delegated developer permissions). For more information, see Delegate developers using AES.

Procedure

1. Launch Table Builder as described in Accessing Table Builder.
2. Select the **Flows** tab.
3. Select the **Add new flow** button.
4. On the New Flow form, fill in the following fields for your new flow.

New Flow form

Field	Description
Name	Name to uniquely identify your flow. The system computes the internal name of the flow from the name.
Description	Description of your flow.

5. **Optional:** To enter advanced options for your flow, select **Show advanced options** on the New Flow form.

Advanced options

Field	Description
Protection	Option that you can select if the flow is read-only. You can only select a value when you create the flow in an application scope that you own.
Run as	(Optional) Option to specify the user that runs the flow. You can select the system user or the user who initiates the session. Select the user who initiates the session option when updates should come from the user who triggered the flow. For example, use this option when you want the incident record comments to come from the user who started

Field	Description
	the flow. Settings for the Run as option in a flow don't apply to child subflows. To create a flow that can run with a personal OAuth token, select the user who initiates the session option. If the user who is running the flow has a personal OAuth token, the flow runs with that token. For more information about creating a personal OAuth token, see OAuth 2.0 credentials. When flows run as the user who initiates the session, the system limits the flow actions by user access control list (ACL) restrictions. Ensure that security restrictions don't prevent users who trigger the flow from performing flow actions. Flows that are run by the initiating user also respect user-specific settings, such as the date/time formats. **Note:** Inbound email flows ignore this setting and always run as the user who initiates the session. To test access controls for an inbound email flow, impersonate a typical inbound email user and manually trigger the flow.
Run with roles	Roles that the flow runs with. This option is only available when **Run as** is set to **user who initiates the session**.

6. Select **Continue**.
7. Choose the event that your flow will be triggered by.

Option	Description
When the record is created	Create a flow that is triggered when a record in the selected table is created.
When the record is updated	Create a flow that is triggered when a record in the selected table is updated.
When the record is created or updated	Create a flow that is triggered when a record in the selected table is created or updated.

The flow that you just created is displayed in the flow diagramming view. See Flow diagramming view.

8. Select **Add node**, and then select one of the following options to modify your flow:

Option	Description
Action	Select the desired action. Workflow Studio includes Workflow Studio actions that are available to flows and subflows. Alternatively, a user with the action_designer role can create additional actions to add to flows. The Integration Hub and Spokes plugins install additional actions. To add draft actions from the More Actions menu, set **Show draft actions** to **true**. To view spokes that are available in the ServiceNow Store, set **Show store spokes** to **true** from the More Actions menu.

Option	Description
	Note: Under **Not Installed Spokes**, the system displays spokes that are available in the ServiceNow Store based on compatibility with the ServiceNow version and application dependency on Workflow Studio.
Flow Logic	Select an option to specify conditional or repeated operations.
Subflow	Select a published subflow and define the input values. In addition to adding a subflow as a flow action, you can enable the **Show triggered flows** option from the More Actions menu to select an activated flow and define the required inputs. Running a triggered flow ignores its trigger conditions and runs all actions.

Note:
Alternately, you may toggle the Workflow Studio default view from the view selector, and then select **Add an Action, Flow Logic, or Subflow** in that view of Workflow Studio. For more information, see Flow diagramming view.

9. Continue modifying your flow in Workflow Studio.

Note:
For detailed information on how to work with flows for your application, see Create a flow.

10. Select **Save**.
Workflow Studio saves a draft of the flow, trigger, and actions.

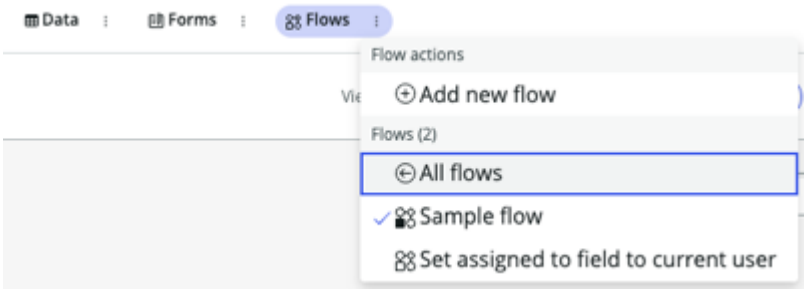
What to do next

Test your flow until you're ready to activate it. For more information on testing and editing flows, see Activate a flow.

Note:
Your application can trigger only activated flows. For detailed information on how to design, test, and activate flows for your application, see Flows in Workflow Studio.

To return to the comprehensive list of flows related to the selected table after editing a flow, select the Additional actions (⋮) menu to the right of the **Flows** tab, and then select **All flows** as shown in the following example.

All flows



Modify a record-based flow

Edit flows that are triggered when table records that you select are updated, created, or both updated and created by using the **Flows** tab in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Role required: personalize_forms, personalize_dictionary, and flow_designer permissions (or relevant AES user role and delegated developer permissions). For more information, see Delegate developers using AES.

About this task

The **Flows** tab in Table Builder provides a list of flows that are triggered by record changes to a table and enables you to manage them from the record table that triggers the workflow.

Procedure

1. Launch Table Builder as described in Accessing Table Builder.
2. Select the **Flows** tab.
   The available flows that are triggered by the table are listed as flow cards.
3. Filter or search the list of flow cards as needed to find the desired flow.
   See Find a record-based flow.
4. Select a flow card to open the flow for editing.
5. Edit the record-based flow by using Workflow Studio.
   For detailed information on how to work with flows for your application, see Create a flow.

   Note:
   To return to the list of flow cards that are related to the table, select the Additional actions (⋮) menu to the right of the **Flows** tab, and then select **All flows**.

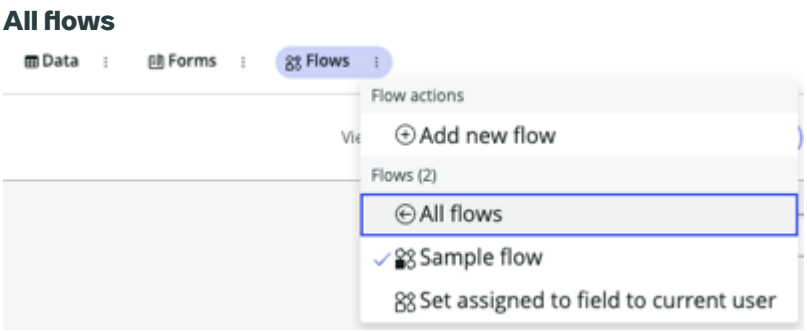
6. Select **Save**.

What to do next

Test your flow until you're ready to activate it. For more information on testing and editing flows, see Activate a flow.

Note:
Your application can trigger only activated flows. For detailed information on how to design, test, and activate flows for your application, see Flows in Workflow Studio.

To return to the list of flows related to the table that you selected after you edited a flow, select the Additional actions (⋮) menu to the right of the **Flows** tab, and then select **All flows** as shown in the following example.



Delete a record-based flow

Delete a record-based flow by using the **Flows** tab in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Role required: personalize_forms, personalize_dictionary, and flow_designer permissions (or relevant AES user role and delegated developer permissions). For more information, see Delegate developers using AES.

Procedure

1. Launch Table Builder as described in Accessing Table Builder.
2. Select the **Flows** tab.
   The available flows that are triggered by the table are listed as flow cards.
3. Filter or search the list of flow cards as needed to find the desired flow.
   See Find a record-based flow.
4. Select the Additional actions (⋮) menu in the top-right corner of the flow that you want to delete, and then select **Delete** from the list of options.
5. In the delete confirmation window, enter DELETE, and then select **Delete**.
6. Select **Save**.

Copy a record-based flow

Create a new record-based flow from an existing flow by using the **Flows** tab in Table Builder.

Before you begin

- Launch Table Builder. For more information, see Accessing Table Builder.
- (Optional) Choose a domain to work within (if not global). For more information, see Domain separation and Table Builder.
- (Optional) Choose an application scope to work within (if not global). For more information, see Using an application scope with Table Builder.

Role required: personalize_forms, personalize_dictionary, and flow_designer permissions (or relevant AES user role and delegated developer permissions). For more information, see Delegate developers using AES.

Procedure

1. Launch Table Builder as described in Accessing Table Builder.
2. Select the **Flows** tab.
   The available flows that are triggered by the table are listed as flow cards.
3. Filter or search the list of flow cards as needed to find the desired flow.
   See Find a record-based flow.
4. Select the Additional actions (⋮) menu in the top-right corner of the flow that you want to delete, and then select **Copy** from the list of options.
5. In the Create a copy of the flow window that appears, enter a name for the new flow that you want to create from the existing flow, and then select **Copy**.
6. Edit your new flow by using Workflow Studio.
   For detailed information on how to work with flows for your application, see Create a flow.
7. Select **Save**.

Note:

To return to the list of flows after editing a flow, select the Additional actions (⋮) menu to the right of the **Flows** tab, and then select **All flows**.

Table Builder reference

Reference topics provide additional information about the form and table elements you can configure using Table Builder.

Table properties in Table Builder

Various table and table column properties can be modified by using Table Builder.

Table column properties

The following table shows descriptions of the properties that you can modify for the columns in a data table.

Table column properties

Field	Description
Column label	Unique label for the column.
Column name	Database name for the column.
Type	Type of information that the column contains. For example, to contain plain text in the column, select **String**. Depending on the type that you select, fill in the additional fields to further define the table column. For example, if you select **String**, define the character limit of the string input. Or, if you select **Choice**, define the choices that users can choose from. See Field types.
Reference	Table that is associated with the column. This field applies only if the column type is **Reference**.
Max length	Maximum number of characters that users can enter in the field.

Table column properties (continued)

Field	Description
Default value	Value that populates the field automatically after a new record is created.
Display	Option to set the column as the display value for the table. A reference field shows the display value of the table to which it is referring. For example, the **Opened by** column of the task table refers to the user table. Because the display value of the user table is the user name, the **Opened by** field shows something like **Beth Anglin** or **Joe Employee**. When you select a display value, choose the table column that would act as an appropriate title for individual records. Only one column can act as the display value for a table.

Table properties

The following table shows the descriptions of the properties that you can modify for a selected data table.

Table properties

Option	Procedure
Change the table label	In the General information tab, update the **Table label** field.
Make the table extensible	1. In the General information tab, select **Advanced**. 2. Select the **Make extensible** check box.
Add record numbers	1. In the General information tab, select **Advanced**. 2. Select the **Add record number** check box. 3. Define the record numbers by updating the **Prefix**, **Starting number**, and **Number of digits** fields.
Accessible from	1. Open the **Access** tab. 2. In the **Accessible From** field, select **All Application Scopes** or **This Application Scope Only**.

Table properties (continued)

Option	Procedure
Application access controls	1. Open the **Access** tab. 2. In the **Application Access Controls** field, select Read, Create, Update, and/or Delete selection boxes to specify the desired level of access for the table.

Field configuration in Table Builder

You can configure the basic field properties for any field within Table Builder.

Field details

The Field details section lets you configure the basic field elements for the selected field in the form editor.

To see field type descriptions and learn more about what field types you can use, see Field types.

To understand the basic field properties and learn more about adding and customizing a field in a table, see Add and customize a field in a table.

The following table shows field descriptions for the Field details section.

Field details

Field	Description
Label	Name of the field that is displayed for form users.
Active	Option that you can select to make a field active so that form users can view it. Deselecting **Active** inactivates a field. When **Active** is not selected, the field will not display in the form editor. To reactivate a field, hover to the left of the field column in the **Data** tab and select the Open side panel icon [⚙]. Select **Active** and save changes.
Read only	Option that you can select so that the field is not editable by the form users.
Mandatory	Option that you can select so that the data that your users enter in the field is required before they can save their changes to the form.
Configure Label details menu (⋯)	Properties for a field label:

Field details (continued)

Field	Description
	• **Tooltip** property that is displayed when a user points to the field. • **Plural** property that indicates if multiple instances of a field exist, your user should enter the plural form of the label (for example, the plural of cat is cats) • **URL** property that indicates if the field label links to some other location, your user should enter the URL here.

Default value

The default value automatically fills in the field on the empty form for a new record, or fills in the field later (if the field is empty) when your user submits the new record. You can specify the default values as either a constant or use a script to generate them.

To learn how to define a default value for the fields, see Specify a default field value.

The following table shows field descriptions for the Default value section.

Default value

Field	Description
Use dynamic default	Property that displays the **Dynamic default value** field where you can set the default value that is displayed for the field.
Default value	String or number that represents the default value of the field.
Dynamic default value	Keywords that can be entered in the search field. Your user can then select a field that contains the desired default value for the field.

Function definition

A function field generates a value that is based on the simple computations of other fields and constants.

This section is displayed in the editor when you are creating a field and you select **Function field** in the Advanced properties section.

For information on defining function fields, see Function field.

The following table shows field descriptions for the Function definition section.

Function definition

Field	Description
Function Definition	Function expression that generates the desired value for the field.

Reference

A reference qualifier restricts the records that are available for reference fields.

For information on defining reference fields, see Reference field type.

The following table shows field descriptions for the Reference section.

Reference fields

Field	Description
Reference	Data table that the selected field references.
Use reference qualifier	Qualifier options: • **Simple** option that enables your users to build a simple conditional expression. Your user can select the **Edit Conditions** button below the **Reference qualifier** field. • **Advanced** option that enables your user to build an advanced conditional expression by using the **Reference qualifier** field. The advanced reference qualifiers enable your user to define an inline encrypted query string or JavaScript (actual code or the name of an existing script include or business rule) filter in the **Reference qualifier** field. • **Dynamic** option that enables your users to build a conditional expression for the selected reference field by using the **Reference qualifier** field. Dynamic reference qualifiers enable your users to use a dynamic filter to run a query against a reference field to filter the returned data set.
Reference qualifier	Referenced qualifier that is based on your user's selection for the **Use reference qualifier** field.
Edit conditions	Hyperlink to launch a pop-up window where your user can enter a simple conditional expression for the **Reference qualifier** field.

Dependent field

A choice or reference field can be declared dependent on another field on the same table. Dependent fields limit their available values based on the value in the dependent field.

Using dependent fields turns on choices. The available choices for your field rely on the value that a user chooses for the dependent field.

For information on defining field dependencies, see Make a field dependent.

The following table shows field descriptions for the Dependent fields section.

Dependent fields

Field	Description
Use dependent field	Field dependency that you can activate for the selected field.
Select dependent field	List where you select a different field on the form that can then be used to control which choices that are displayed to users in the form field you are configuring.

Choices

A choice list is a type of field that lets the user select from a pre-defined set of choices. You can define the available choices and customize the behavior and appearance of your choice lists. For information about the choice list configuration, see Choice list field type.

In the Choices section of the Config panel, select **Use choices**, and then select **Edit** or the **+Add** icon to customize the available choices for the selected field.

The following table shows field descriptions in the Choices section.

Choice properties

Field	Description
Label	Text that is displayed to your users for the choice in the list.
Value	Value for the choice field.
Dependent value	Value that you map in the selected Dependent field to the entered choice.
Domain	Domain that the choice resides in.
Active	Option to display the choice as a selection. Inactive choices do not display for users.
Options	Option that enables you to select **Use the choices from another field** to duplicate the displayed choices for this field from the choices in another selected field.
Show choices as	Options that control how a list of choices displays for users of your form.

Choice properties (continued)

Field	Description
	• **Dropdown** option. You must set a default value for the field. **Note:** If no default is set, then **None** automatically becomes the default value and is shown in the choice list to users. • **Dropdown with --None-- choice** option. **None** becomes the default value. • **Suggestions (Core UI only)** option. Choices are displayed as suggestions.
Filter	Option to filter the choice list. Select **Show inactive choices** to view all choices (including inactive ones).

Attributes

A dictionary attribute alters the behavior of the table or element that the dictionary record describes. You can add or modify the dictionary attributes. For information about dictionary attributes, see Dictionary attributes.

In the Attributes section of the Config panel, select **Edit** or **+Add** to customize the available attributes for the selected field.

The following table shows field descriptions for the Attributes section.

Attribute properties

Field	Description
Attribute	Option list of available attributes. Select an option from the list of available attributes. To review the list of available attributes, see Dictionary attributes.
Value	Attribute value that you can set to alter the field behavior that is described by the dictionary record.

Formula

A formula allows you to calculate the value of a column without writing a script. You can use one of the predefined formulas or combine two are more formulas to calculate the column value. For information on the predefined formulas and examples, see Formulas.

In the Formula section, select **Edit** or **+ Add** to edit or add a formula.

Formula properties

Field	Description
Formula editor	A text-editor like interface that allows you to enter and edit formulas.

Formulas for column values in Table Builder

You can use a predefined function and create a formula to calculate the value of a column without writing a script. Use a predefined function or create a nested formula by using the existing predefined functions to calculate the column value type.

Supported operators

The following comparison operators are supported only for number type values.

- = (Equal to)
- <> (Not equal to)
- > (Greater than)
- < (Less than)
- >= (Greater than or equal to)
- <= (Less than or equal to)

Simple math functions

Use simple math functions to perform basic mathematical calculations on numeric value columns.

AVERAGE

Returns the average value of the arguments.

Syntax	Input	Output
AVERAGE(argument 1, argument 2, ... argument n)	Numeric value, function call, or variable	Numeric value

Examples:

- Function: AVERAGE(1,2,3)

  The result is 2.

- Formula: AVERAGE(LENGTH(first_name), LENGTH(last_name))

  The result is the average value of the number of characters in the first_name column and last_name column.

DIVIDE

Returns the final quotient value after consecutively dividing the first argument with the next argument until the function reaches the last argument.

Syntax	Input	Output
DIVIDE(argument 1, argument 2 ... argument n)	Numeric value, function call, or variable	Numeric value

Examples:

- Function: DIVIDE(10,20, 0.25, 10)

  The result is 0.2.

- Formula: DIVIDE(LENGTH(full_name),2)

  The result is the number of characters in the full_name column divided by 2.

INDEXMATCH

Retrieves the first not null value from the specified set of arguments.

Syntax	Input	Output
INDEXMATCH(argument 1, argument 2 , ... argument n)	String, numeric value, function call, or variable.	Numeric value

Example:

Function: INDEXMATCH("","" ",2,"string")

The result is 2.

MAX

Returns the highest value in the specified arguments.

Syntax	Input	Output
MAX(argument 1, argument 2, ... argument n)	Numeric value, function call, or variable	Numeric value

Examples:

- Function: MAX(1, -5, 20, 6)

  The result is 20.

- Formula: MAX(LENGTH(first_name), LENGTH(last_name))

  The result is the number of characters in the first_name column or last_name column whichever is the highest.

MIN

Returns the lowest value in the specified arguments.

Syntax	Input	Output
MIN(argument 1, argument 2, ... argument n)	Numeric value, function call, or variable	Numeric value

Examples:

- Function: MIN(1, -5, 20, 6)

  The result is -5.

- Formula: MIN(LENGTH(first_name), LENGTH(last_name))

  The result is the number of characters in the first_name column or last_name column whichever is the lowest.

MULTIPLY

Returns the total multiplied value of the arguments.

Syntax	Input	Output
MULTIPLY (argument 1, argument 2, ... argument n)	Numeric value, function call, or variable	Numeric value

Examples:

- Function: MULTIPLY(12, 4)

  The result is 48.

- Formula: MULTIPLY(order, 2)

  The result is the order column value multiplied by 2.

POWER

Returns the result of the base value raised to the power of the exponent value.

Syntax	Input	Output
POWER(argument 1, argument 2)	argument 1 is base and argument 2 is exponent. • base: number or variable • exponent: number or variable	Number

Examples:

- Function: POWER(3,2)

  The result is 9.

- Formula: POWER(LENGTH(full_name),2)

  The result is the number of characters in the full_name column to the power of 2.

SUBTRACT

Returns the result value after consecutively subtracting the next available argument from the earlier argument until the function reaches last argument.

Syntax	Input	Output
SUBTRACT(argument 1, argument 2 ... argument n)	Numeric value, function call, or variable	Numeric value

Examples:

- Function: SUBTRACT(1.15, 0.02, 0.45, -0.85)

  The result is 1.53.

- Formula: SUBTRACT(LENGTH(full_name), LENGTH(first_name))

  The result is the number of characters from the full_name column minus the number of characters from the first_name column.

SUM

Returns the sum of all the arguments.

Syntax	Input	Output
SUM(argument 1,argument 2, ... argument n)	Numeric value, function call, or variable	Numeric value

Examples:

- Function: SUM(0.03, -0.02, 1)

  The result is 1.01.

- Formula: SUM(LENGTH(first_name), LENGTH(last_name))

  The result is the total number of characters in the first_name column plus the total number of characters in the last_name column.

COUNTIF

Returns the number of arguments that match the specified criteria within the specified set of arguments.

Syntax	Input	Output
COUNTIF(argument 1, argument 2, argument n-1, criteria)	• argument 1 ... argument n: String, numeric value, function call, or variable. • criteria: Criteria that evaluates the specified	Numeric value

Syntax	Input	Output
	set of arguments. String, numeric value, function call, or variable.	

Example:

Function: COUNTIF(2,3,2,"string",2)

The result is 2.

MODE

Returns the most frequently repeating value in the specified set of arguments.

Syntax	Input	Output
MODE(argument 1,argument 2, ... argument n)	Numeric value, function call, or variable	Numeric value

Example:

Function: MODE(1, 2, 2, 3, 3, 3)

The result is 3.

String functions

Use string functions to reformat or perform calculations on string column values.

CONCATENATE

Joins one or more input strings into a single string.

Syntax	Input	Output
CONCATENATE(string 1, string 2, ... string n)	String, function call, or variable	String

Examples:

- Function: CONCATENATE(first_name, ".", last_name, "@", LOWERCASE(example), ".com")

  The result is the concatenated value <first_name_value>.<last_name_value>@example.com. In this example, <first_name_value> and <last_name_value> are placeholders.

- Function: CONCATENATE(first_name, " ", last_name)

  The result is the concatenated string of first_name column value and last_name column value separated by a white space.

ISBLANK

Finds white spaces or blank values in the string and returns true if there are any.

Syntax	Input	Output
ISBLANK(argument)	String or value	True or false

Examples:

- Function: ISBLANK(“example_string”)

  The result is false.

- Function: ISBLANK(full_name)

  The result is true only when there are empty spaces in the full_name column. Otherwise, the result is false.

LENGTH

Returns the total number of characters in the input string.

Syntax	Input	Output
LENGTH(argument)	String value, function call, or variable	Numeric value

Examples:

- Function: LENGTH("example_string")

  The result is 14.

- Function: LENGTH(full_name)

  The result is the total number of characters in the full_name column value.

LOWERCASE

Converts the input string to all lowercase characters.

Syntax	Input	Output
LOWERCASE(argument)	String, function call, or variable	String in lowercase

Examples:

- Function: LOWERCASE(“ExamPle inpuT stRing”)

  The result is example input string.

- Function: LOWERCASE(sys_created_by)

  The result is the lower case string of the sys_created_by column value.

REPLACE

Replaces the characters in the source string with the characters in the target string.

Syntax	Input	Output
REPLACE(source_string, target_string, replacement_string)	• source_string: String, function call, or variable • target_string: String, function call, or variable • replacement_string: String, function call, or variable	String

Examples:

- Function: REPLACE(“Pepperoni Pizza”, “Pepperoni”, “Cheese”)

  The result string is Cheese Pizza.

- Function: REPLACE("abe.tuter@example.com", "example", company_name)

  The result string is abe.tuter@<company_name>.com. In this example, <company_name>is a place holder.

TITLECASE

Converts the input string to all title case characters.

Syntax	Input	Output
TITLECASE(argument)	String, function call, or variable	String in title case

Examples:

- Function: TITLECASE("example string")

  The result is Example String.

- Function: TITLECASE(full_name)

  The result is the full name column value in the title case.

UPPERCASE

Converts the input string to all uppercase characters.

Syntax	Input	Output
UPPERCASE(argument)	String value, function call, or variable	String in uppercase

Examples:

- Function: UPPERCASE("eXamPle sTring")

  The result is EXAMPLE STRING.

- Function: UPPERCASE(state)

  The result is the State column value in upper case.

FIND

Searches for the first occurrence of a substring within a string and returns the position of the first occurrence.

Note:
This function is case sensitive.

Syntax	Input	Output
FIND(search_string, source_string, from_index)	• search_string: Substring, function call, or variable. • source_string: Main string, function call, or variable. • from_index: Index position in the main string from where the search should start. Numeric value, function call, or variable.	Numeric value (integer). When the substring does not exist in the main string, -1 is returned.

Example:

Function: FIND("morning", "Good morning")

The result is 5.

SEARCH

Searches for a substring within a string and returns the position of the first occurrence of the substring.

Note:
This function is case insensitive.

Syntax	Input	Output
SEARCH(search_string, source_string, from_index)	• search_string: Substring, function call, or variable. • source_string: Main string, function call, or variable. • from_index: Index position in the main string from where the search should start. Numeric value, function call, or variable.	Numeric value (integer). When the substring does not exist in the main string, -1 is returned.

Examples:

- SEARCH("Morning", "Good morning")

  The result is 5.

- SEARCH("World","Hello world!")

  The result is -1.

SUBSTRING

Retrieves a substring from a string at the specified index position and for the specified length.

Syntax	Input	Output
SUBSTRING(source_string, start_index, length)	• source_string: String, function call, or variable. • start_index: Position in the string from where the substring is extracted. Numeric value, function call, or variable. • length: Length of the substring that should be extracted.	String

Example:

SUBSTRING("Hello, Good Morning", 7, 4)

The result substring is 'Good'.

Date and time functions

Use date and time functions to calculate or reformat the date and time column values.

NOW

Returns the current date and time of the instance in ISO format (YYYY-MM-DD hh:mm:ss).

Syntax	Input	Output
NOW()	No arguments are required for this function	ISO format of current date and time

Example:

Function: NOW()

The result is the current date and time in ISO format.

TODAY

Returns the current date with time offset to start of the day in ISO format in UTC time zone.

Syntax	Input	Output
TODAY()	No arguments are required for this function	Current date with time offset to start of the day in ISO format.

Example:

Function: TODAY()

The result is the current date and start time of the day in ISO format.

TIMEDIFF

Evaluates the time duration difference between two dates.

Syntax	Input	Output
TIMEDIFF(argument1, argument2)	Date in ISO format (YYYY-MM-DD hh:mm:ss) as string or variable	Duration

Examples:

- Function: TIMEDIFF("2021-05-02 9:10:12", "2021-04-07 6:2:23")

  The result is 25 03:07:49.

- Formula: TIMEDIFF(sys_created_on, NOW())

  The result is the time duration difference between the sys_created_on date and the current date of the system.

DATEDIF

Evaluates the difference between the two dates in days, months, or years.

Syntax	Input	Output
DATEDIF(start_date, end_date, date_difference_unit)	• start_date: Date in ISO format (YYYY-MM-DD or YYYY-MM-DD hh:mm:ss) as string or variable. • end_date: Date in ISO format (YYYY-MM-DD or YYYY-MM-DD hh:mm:ss) as string or variable. • date_difference_unit: Character String and either "Y","M", or "D" in lowercase or uppercase. Default is "D".	Numeric duration value based on the specified date difference unit.

Example:

Function: DATEDIF("2021-05-02 9:10:12", "2021-05-05 6:2:23 ","d")

The result is 3.

DATE

Creates a date from the specified individual year, month, and day values. The created date is in Coordinated Universal Time (UTC) time zone.

Syntax	Input	Output
DATE(year,month,day)	• year: Numeric value, variable or function. • month: Numeric value, variable or function. • day: Numeric value, variable or function.	Date in ISO format (YYYY-MM-DD hh:mm:ss)

Example:

Function: DATE(2021,5,2)

The result is 2021-05-02 00:00:00.

DAY

Retrieves the numerical day component from the specified date.

Syntax	Input	Output
DAY(date)	Date in ISO format (YYYY-MM-DD or YYYY-MM-DD hh:mm:ss) as string, variable, or function.	Numeric value (integer). The values range from 1 through 31.

Examples:

- Function: DAY("2021-05-029:10:12")

  The result is 2.

- Function: DAY(NOW())

  The result will be the day component of the current date and time.

MONTH

Retrieves the numerical month component from the specified date.

Syntax	Input	Output
MONTH(date)	date: Date in ISO format (YYYY-MM-DD or YYYY-MM-	Numeric value (integer). The values range from 1(January) through 12(December).

Syntax	Input	Output
	DD hh:mm:ss) as string or variable.	

Examples:

- Function: MONTH("2021-05-02 9:10:12")

  The result is 5.

- Function: DAY(NOW())

  The result will be the month component of the current date and time.

YEAR

Retrieves the year component from the specified date.

Syntax	Input	Output
YEAR(date)	Date in ISO format (YYYY-MM-DD or YYYY-MM-DD hh:mm:ss) as string, variable, or function.	Numeric value (integer)

Examples:

- Function: YEAR("2021-05-02 9:10:12")

  The result is 2021.

- Function: YEAR(NOW())

  The result will be the year component of the current date and time.

WEEKDAY

Returns the numerical day of the week for the specified date. The day range is 1 (Sunday) through 7 (Saturday).

Syntax	Input	Output
WEEKDAY(date)	date: Date in ISO format (YYYY-MM-DD or YYYY-MM-DD hh:mm:ss) as string or variable.	Numeric value (integer)

Example:

Function: WEEKDAY("2021-05-02 9:10:12")

The result is 1.

TEXT

Retrieves the specific date components in a date in string format.

Syntax	Input	Output
TEXT(date, format_text)	• date: Date in ISO format (YYYY-MM-DD or YYYY-MM-DD hh:mm:ss) as string, variable. • format_text: Date components as string or variable that are to be extracted.	String

Example:

TEXT("2022-08-17 9:10:12","yyyy-MM")

The result is 2022-08.

DATEVALUE

Converts a date in text format into a date in ISO format.

Syntax	Input	Output
DATEVALUE(date_text)	date_text: Date stored as text must be in YYYY-MM-DD format.	Date in ISO format (YYYY-MM-DD hh:mm:ss) as string.

Example:

Function: DATEVALUE("2021-05-02")

The result is 2021-05-02 00:00:00.

WORKDAY

Returns the nearest working day for the specified input date by excluding the specified holidays and weekends before or after the specified n number of days.

Syntax	Input	Output
WORKDAY(start_date, days, holiday 1,holiday 2, ..., holiday n)	• start_date: Date in ISO format (YYYY-MM-DD or YYYY-MM-DD hh:mm:ss) as string or variable. • days: Number of days as a numeric value, string, or function. • holiday 1...holiday n (Optional): Date in ISO	Date in ISO format (YYYY-MM-DD hh:mm:ss) as string.

Syntax	Input	Output
	format (YYYY-MM-DD or YYYY-MM-DD hh:mm:ss) as string or variable.	

Example:

Function: WORKDAY("2022-08-17 9:10:12",2)

The result is 2022-08-19 00:00:00.

NETWORKDAYS

Calculates the number of working days between two dates by excluding weekends and specified holiday dates. Number of working days includes the start date and end date.

Syntax	Input	Output
NETWORKDAYS(start_date,end_date,holiday 1,holiday 2, ... holiday n)	• start_date: Date in ISO format (YYYY-MM-DD or YYYY-MM-DD hh:mm:ss) as string or variable. • end_date: Date in ISO format (YYYY-MM-DD or YYYY-MM-DD hh:mm:ss) as string or variable. • holiday 1,holiday 2, ... holiday n (optional) : List of holidays that should be excluded while calculating working days.	Numeric value (integer)

Example:

Function: NETWORKDAYS("2022-08-17 20:10:12","2022-08-19 9: 10:12")

The result is 3.

Logical functions

Use logical functions to perform logical operations on column values.

AND

Performs a logical AND operation on the arguments.

Syntax	Input	Output
AND(argument 1, argument 2)	String, function call, or variable	True or false

Examples:

- Function: AND(2>3, 4<5)

  The result is false.

- Formula: AND(LENGTH(sys_created_by)>25, LENGTH(sys_updated_by)>25)

  The result is true only when the number of characters in both the sys_created_by and sys_updated_by columns are greater than 25. Otherwise, the result is false.

IF

Executes the specified statements based on the Boolean output of the conditional expression.

Syntax	Input	Output
IF(<conditional_expression>, <do_this_when_true>, <do this_when_false>)	• conditional_expression: Logical conditional expression, function call, or variable **Note:** Logical comparison of strings is not supported in the conditional expression. • do_this_when_true: String, numeric value, function call, or variable that is returned when the condition evaluates to true • do_this_when_false: String, numeric value, function call, or variable that is returned when the condition evaluates to false	String, numeric value, function call, or variable based on the Boolean output of the conditional expression.

Examples:

- Function: IF(number_of_incidents >= 5, "High", "Medium")

  If the number of incidents is greater than 5, the string ‘High’ is returned. In other cases, the string ‘Medium’ is returned.

- Function: IF(LENGTH(full_name) > 100, "Number of characters exceed the limit", "Number of characters within the limit")

  If the number of characters for the full_name column is above 100, the string 'Number of characters exceed the limit' is returned. Otherwise, the string 'Number of characters within the limit' is returned.

OR

Performs logical OR operation on the arguments.

Syntax	Input	Output
OR(argument 1, argument 2)	Conditional expression, function call, or variable	True or false

Examples:

- Function: OR(2>3,4<5)

  The result is true.

- Formula: OR(LENGTH(first_name)>25, LENGTH(last_name)<25)

  The result is true when the number of characters in the first_name column is greater than 25 or the number characters in the last_name column is less than 25. Otherwise, the result is false.

IFERROR

Evaluates expression 1 and returns the expression 1 value when there are no errors in the expression 1. When an error occurs while evaluating expression 1, expression 2 is evaluated and expression 2 value is returned.

Syntax	Input	Output
IFERROR(expression 1, expression 2)	• expression 1: Arithmetic, Logical expression, function call, String, numeric value or variable. • expression 2: Arithmetic, Logical expression, function call, String, numeric value or variable.	Result of expression 1 when there are no errors in expression 1. Otherwise, result of expression 2.

Example:

Function: IFERROR(MULTIPLY(snr_factor, signal), MULTIPLY(default_factor, signal))

If the snr_factor value is a valid number, the multiplied value of snr_factor with signal is returned. If the snr_factor value is not a valid number, the multiplied value of default_factor value with signal is returned.

Add a formula to a column in Table Builder

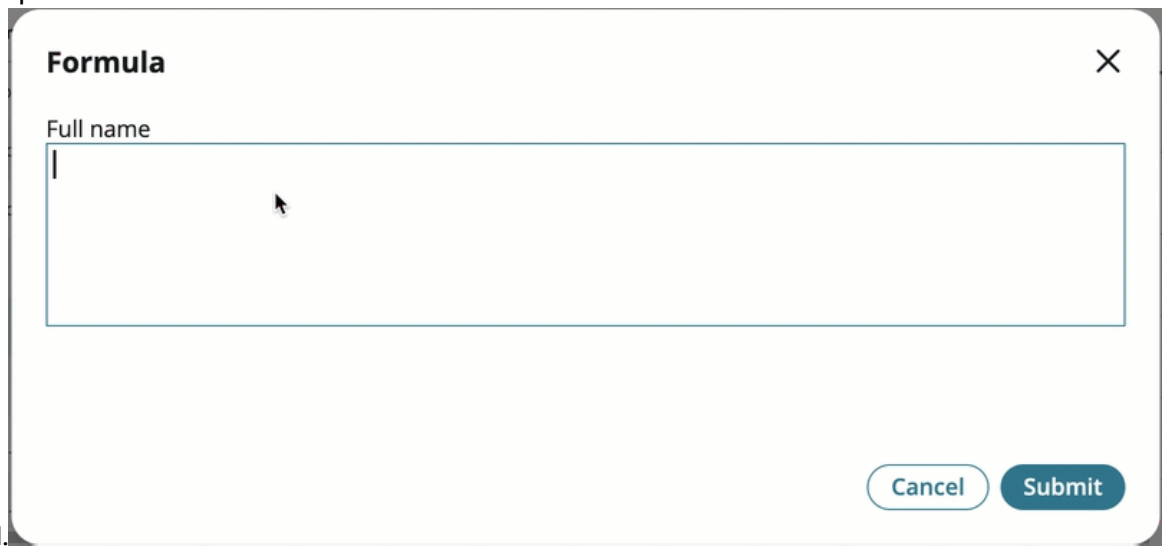
Use a predefined function or create a formula to calculate a value for a column without writing a script in Table Builder. You can use two or more functions to create a formula according to your requirements.

Before you begin

- The scope of the table should be within the scope of the application. Otherwise, you cannot add a formula to a column in the table that is outside the scope of the app.
- Role required: personalize_dictionary or AES user role and delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. From the **Data** or **Forms** tabs, click the Open side panel icon ( ) for a column.
2. In the **Config** tab of **Formula** section, click **+ Add**.
3. Enter a predefined function or a formula in the **Formula editor** modal.



For example, to concatenate the First name column value with the Last name column value and populate the Full name column value, enter CONCATENATE(`first_name,last_name`). For more information about available predefined functions and example formulas, see Formulas for column values in Table Builder

For syntax guidance and examples, click the function in the auto-suggestion that appears as you begin typing.

Note:
You cannot add a formula for unsupported columns, columns that are function fields, and the columns that already have script as the calculated value type.

4. Click **Submit**.

Result
The formula is validated and added to the column if it doesn't have any errors.

Policies and rules properties in Table Builder

You can configure the basic field policies and rules for any field that you work with in Table Builder.

UI Policies

The UI Policies section enables you to configure how forms appear based on roles and user input.

To understand the basic field properties, see Create a UI policy in Table Builder.

The following table shows the field descriptions for the Policy details section when adding or editing a UI policy.

Policy details

Field	Description
Short description	Short summary of the UI policy.
Table	Data table that the policy applies to.
Domain	Domain that the choice resides in.
Order	Sequence for processing, from the lowest number to the highest number. If two policies conflict, the UI policy with the higher number runs. For inherited UI policies, the extended (child) table's UI policies run first. Then, the base table UI policies run, both from the lowest to the highest specified value.
Active	Status of the UI policy. Only active UI policies are applied.
Apply to all views/Apply to view [Advanced settings]	Option for specifying whether the UI policy applies to all form views or specific views. For more information on form views, see View management.
On load [Advanced settings]	Option for specifying that the UI policy behavior should be performed OnLoad as well as when the form changes. Check or clear the UI policy **On load** check box to control whether it runs every time a form is loaded and conditions are satisfied. In the following example, an administrator does not want an incident to enter the **Awaiting user info** state unless the user provides an explanation to the customer. The administrator creates a UI policy with the following settings: • In the When these conditions are met section, adds the condition **[State] [is] [Awaiting user info]** and clears the **On load** check box. The UI policy applies only when the state is changed to **Awaiting user info**. • In the UI Policy Actions list, creates a record that makes the **Additional comments** field required when the condition is met.
Reverse if false [Advanced settings]	Option for specifying that the UI policy action should be reversed when the conditions of its UI policy evaluate to false. When the conditions are true, actions are taken and when they change back to false, the actions are reversed (undone).

Policy details (continued)

Field	Description
Inherit [Advanced settings]	Option for specifying whether extended tables inherit this UI policy. When a child table has an inherited UI policy from its parent table, the UI policy on the child table always runs first, regardless of the **Order** of the UI policies. In the following example: • A child table has a UI policy with the**Order** value **500** that shows the **Urgency** field when its conditions are met. • Its parent table has a UI policy with the same conditions that hides the **Urgency** field. The parent table UI policy has the **Order** value **100**. • Although the parent table **Order** field has a lower value, the child UI policy runs first and then the parent UI policy runs. When the conditions are met, the **Urgency** field is hidden.

The following table shows field descriptions for the When these conditions are met section when adding or editing a UI policy.

When these conditions are met

Field	Description
Condition set	Conditions that, if fulfilled, cause the UI policy to be applied. Conditions are built with the condition builder by using logic statements. To set conditions using a script, use a client script instead. Conditions are only rechecked if a user manually changes a field on a form. If the change is made by a UI action, context menu action, or through the list editor, it is not evaluated.

The following table shows field descriptions for the Do the following section when adding or editing a UI policy.

Do the following

Field	Description
Field name	Field on the selected table to which the UI policy performs an action if conditions are met.

Do the following (continued)

Field	Description
	Note: If the specified field is not on the form, the UI policy performs the action on the variable with the same name.
Mandatory	List for specifying how the UI policy affects the required state of the field. The choices are the following: • **Leave alone** • **True** • **False**
Visible	List for specifying how the UI policy affects the visible state of the field, that is, whether it appears. The choices are the following: • **Leave alone** • **True** • **False**
Read only	List for specifying how the UI policy affects the read-only state of the field. The choices are the following: • **Leave alone** • **True** • **False**
Clear the field value	Option to clear the specified field if the conditions are met.

Access control rules

The Access control rules section enables you to configure access to the specified resource based on role, condition, and script criteria being met.

The following table shows field descriptions for the Access control rules section.

Field	Description
Name	Names each user who has permission to access the form or data. • Enter the names as firstname.lastname in lower case letters, separated by a period (for example, `john.smith`). Each name must have a corresponding user record in *`hi.servicenow.com`*.

Field	Description
	• Enter multiple names and separate them by commas if multiple users have permission to access the form or data. • Enter an asterisk (*) as the name to enable all users to access the form or data.
Description	Overview of what the access control rule restricts or enables.
Type	Type of object the access controls, including the following: • Client-callable script includes • Processor • Record • UI page • UX route For more information on object types, see ACL matching requirements for objects.
Operation	Type of action the system can take on the specified object, such as delete or execute. Some objects, such as records, support multiple operations, while other objects, such as a REST_Endpoint, only support one operation. For more information on action types, see ACL rule types.
Active	Active state of the rule: **true** The rule is active and available for use. **false** The rule is inactive and unavailable for use.
Condition	Any conditions that apply to the rule.
Roles	Any roles the rule applies to.
Admin overrides	Option to force the rule's evaluation for admin overrides at the access level. For more information on admin overrides, see Evaluate the admin override at the access level.
Advanced	Option to associate a script with the rule.

Client Scripts

The Client Scripts rules section enables you to create scripts that control how form fields appear based on defined criteria.

For a complete list of values for client script fields, see Client script form

The following table shows field descriptions for the Client Scripts rules section.

Field	Description
Name	Name for the script.
Description	Overview the script's functionality and purpose.
Table	Table or form that the script is available for.
Active	Active state of the script: **true** The script is active and available for use. **false** The rule is inactive and unavailable for use.
UI type	Type of application the script is available for, such as desktop or mobile.
Type	When the script runs on the table or form, including the following: • onCellEdit • onChange • onLoad • onSubmit
Field name	Field the script is run on.
View	Views on which the client script runs (not applicable to global scripts).
Inherited	Indicates whether the client script applies to extended tables.

Business Rules

The Business Rules section enables you to create business rules to accomplish tasks like automatically changing values in form fields when certain conditions are met.

For a complete list of values for business rules, see Create a business rule.

The following table shows field descriptions for the Business Rules rules section.

Field	Description
Name	Name for the business rule.
Table	Table or form that the business rule runs on.
Active	Active state of the business rule:

Field	Description
	true The business rule is active and available for use. **false** The business rule is inactive and unavailable for use.
When	When the business rule executes: **display**, **before**, **async**, or **after** the database operation is complete.
Filter conditions	Conditions created using the condition builder to determine when the business rule should run based on the field values in the selected table.
Role conditions	Roles that users who are modifying records in the table or form must have for the business rule to run.
Actions	Actions taken by the business rule on the specified fields, such as **insert**, **update**, and **delete**.
Set field values	Table or form fields that the action executes on.
Add message	Whether a message appears when this business rule is run: **true** A message appears when the business rule is run. **false** No message appears when the business rule is run.
Abort action	Whether the business rule aborts the current database transaction: **true** The business rule aborts the current database transaction when run. **false** The business rule doesn't abort the current database transaction when run. For example, on a before insert business rule, if the conditions are met, do not insert the record into the database.
Order	Indicates the sequence in which this business rule should run. If there are multiple rules on a particular activity, the rules run in the specified order specified, from lowest to highest.

Workspace view rules

The Workspace view section enables you to define rules to control how users view workspaces based on criteria.

The following table shows field descriptions for the Workspace view rules section.

Field	Description
Name	Name for the workspace view rule.
Table	Table or form that the workspace view rule is available for.
View	View that is used to render the form. The default view is used if this field is left empty or contains an invalid value.
Roles	Any roles the rule applies to.
Conditions	Any conditions that apply to the rule.
Hide section navigation	Option to enable or disable section navigation.
Disable section collapsing	Option to enable or disable section collapsing.
Default tab order	Order in which form tabs appear by default.

UI Builder

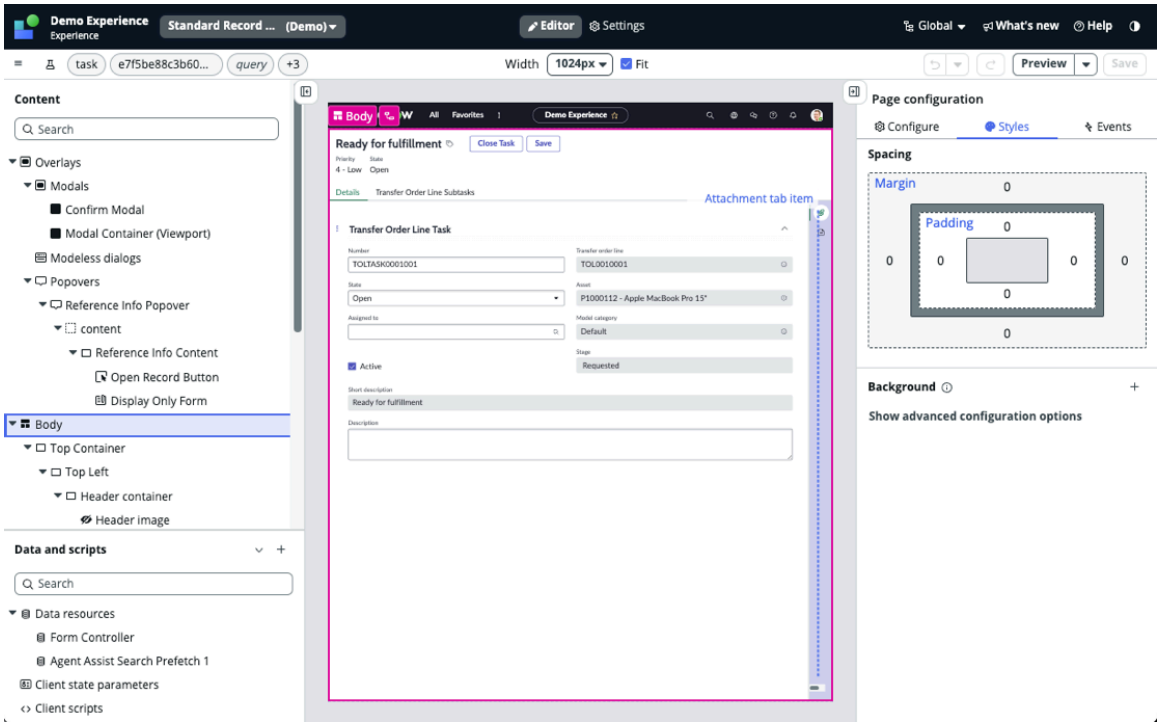
UI Builder is a web user interface builder. Use UI Builder to build pages for App Engine Studio generated workspaces or custom web experiences using Next Experience Components and custom web components.

UI Builder overview

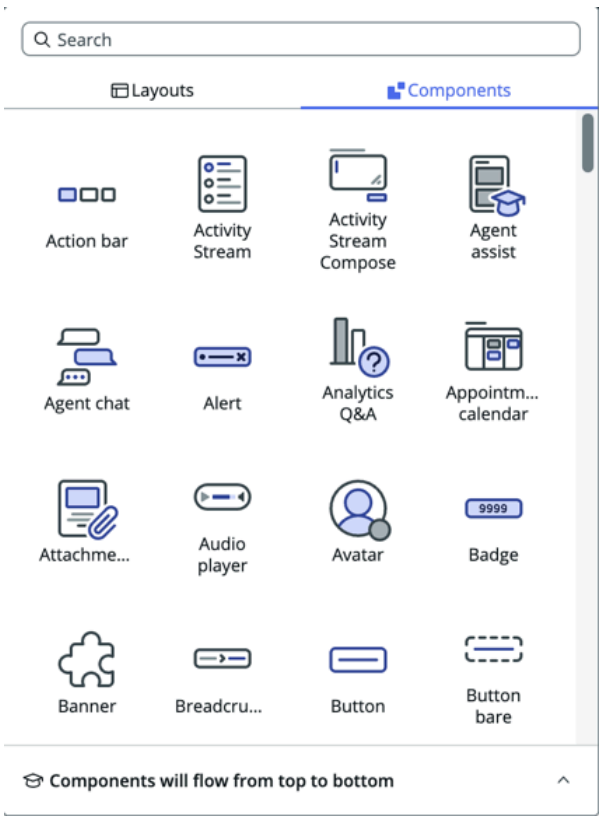
Create or customize pages for workspace experiences. A page is a collection of components that make up a workspace user interface.

Create variants of pages to target experiences for different audiences. For example, you can create a home page for agents, and a variant for managers at the same URL.

Note:
The ui_builder_admin role is required to complete tasks in UI Builder.



Use the UI Builder library of components to build your pages. Configure them any way that you need and then connect your organization's data to the components.



Get started with UI Builder

Explore	Learn
 Explore UI Builder concepts and features.	 Learn the basics of using UI Builder.
Work	**Advanced**
 Dive deeper into configuring UI Builder experiences and pages.	 Learn how to add data and make your pages dynamic.

Note:
UI Builder isn't yet capable of building or configuring ServiceNow base system service portals, such as the Employee Center. For service portals, continue to use the Service Portal Designer.

Troubleshoot and get help with UI Builder

- Contact your company's Customer Admin to unlock or add user accounts, perform restores or zBoots, and more.

  Contact your company's Customer Admin

- Ask or answer questions in the UI Builder community
- Search the Known Error Portal for known error articles
- Learn more about how to create your own apps on the developer site.
- Contact Customer Service and Support

Exploring UI Builder

Explore facets of UI Builder to set you up for creating pages quickly.

Check out the UI Builder quick start topic to understand the basics of UI Builder. If you want a deeper understanding of UI Builder, go through the tutorial to learn how to create your first page.

Find information relating to UI Builder audiences, security and roles settings like application scope and domain separation, as well as experience settings.

See how you can use UI Builder with CSM Workspace and portal experiences.

UI Builder quick start

This quick start guides you through the process of creating your first page in UI Builder. Creating your first page is the first step in understanding how to build user interface pages for your workspace or custom portal experiences.

Before you begin

Role required: ui_builder_admin

In this UI Builder quick start, you perform the following tasks to build your first page in UI Builder:

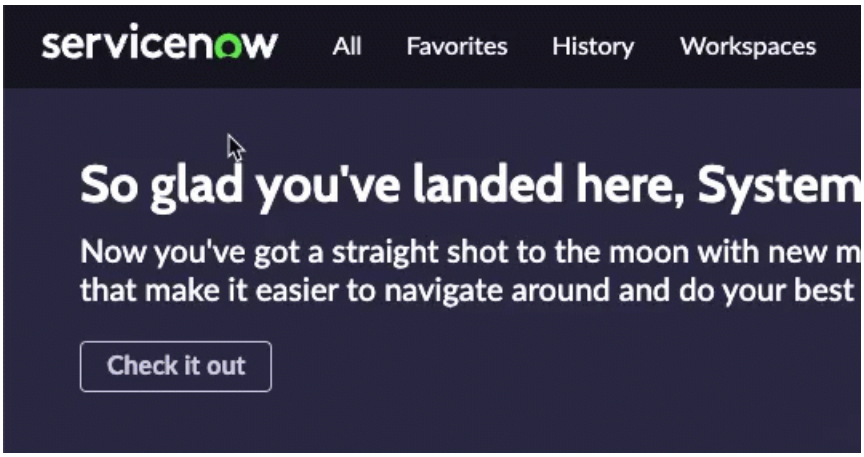
- Start UI Builder.
- Create a page for your workspace or custom portal experience. For more information about creating pages, see Create a page in UI Builder.
- Build your page by adding components. For more information about components, see Customize UI Builder pages using components.

- Save your page.
- Preview your page to see how it looks in a browser.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.

Start UI Builder

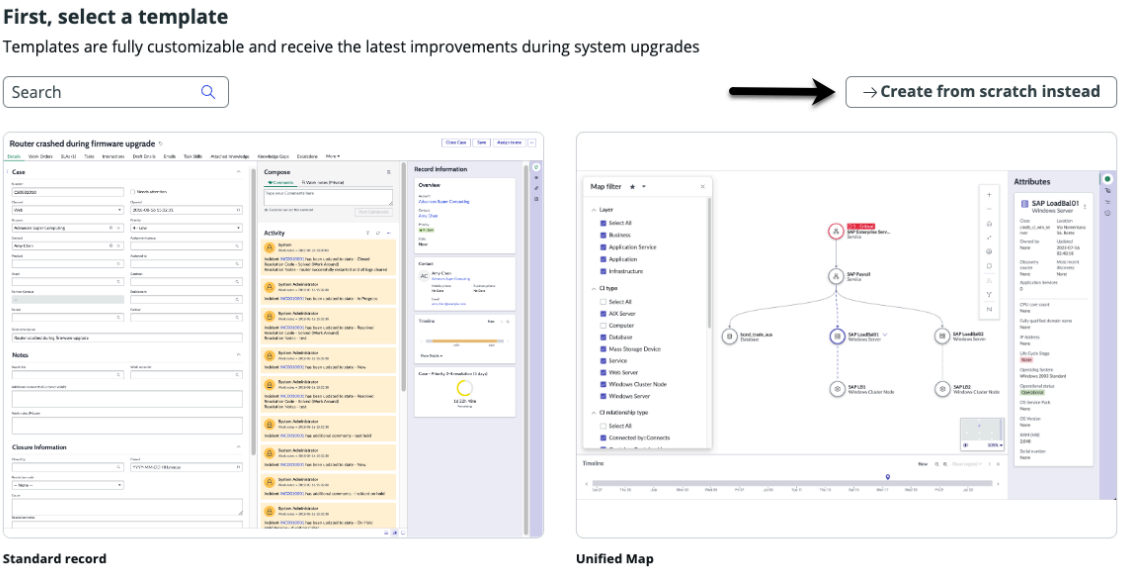


2. Select an experience that you want to work in from the UI Builder home page.
   If you don't see any experiences listed in which to work, contact your administrator to get access to an experience, or create an experience. For more information, see Configure how users interact with your applications in UI Builder.
3. Create a page.

   a. Select the **+** icon in the **Pages and variants** section.

   b. Select **Create a new page**.

   c. Select → **Create from scratch instead**.

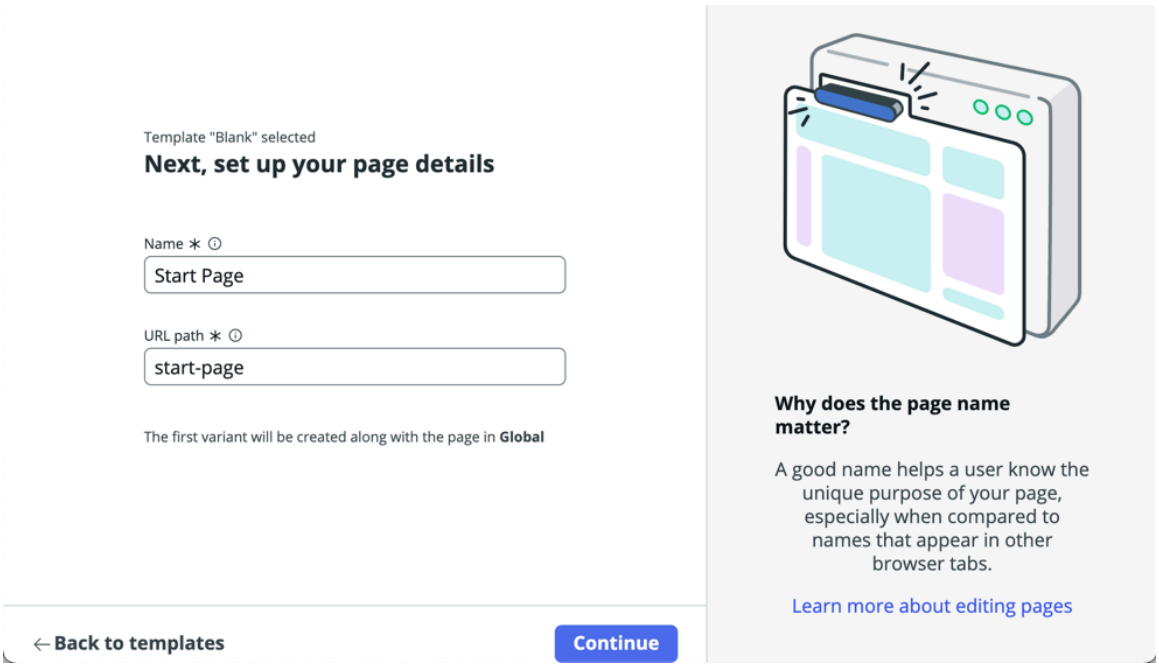


You can also create pages using page templates, see Create a page from a template for more information.

d. Enter `Start Page` as the unique name for the page in the **Name** field.

e. Specify a path for your page in the **URL Path** field. UI Builder generates a default path based on the name that you gave in the last step.

A default path is added based on your page name. You can also create your own path. The path is required and must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a few special characters (`" - "`, `" . "`, `" _ "`, `" ~ "`), with the words separated by a forward slash or hyphen. The **URL preview** shows the path of your page.



Note:
The application scope defaults to the scope that the user is currently in within the ServiceNow AI Platform®. For more information about the application scope, see Learn about security and roles.

f. Select **Continue**.

g. **Optional:** Add parameters to your page URL by selecting **+ Add**.
For more information, see Manage UI Builder pages and page variants.

h. Select **Looks good**.

i. Enter `Manager Start Page` as the name for the page variant.

j. **Optional:** Add one or more audiences for this page.
If an audience you need isn't listed, you can choose the **Open audiences in the platform** link to create one.

k. **Optional:** Add conditions for when to display the page or tab.

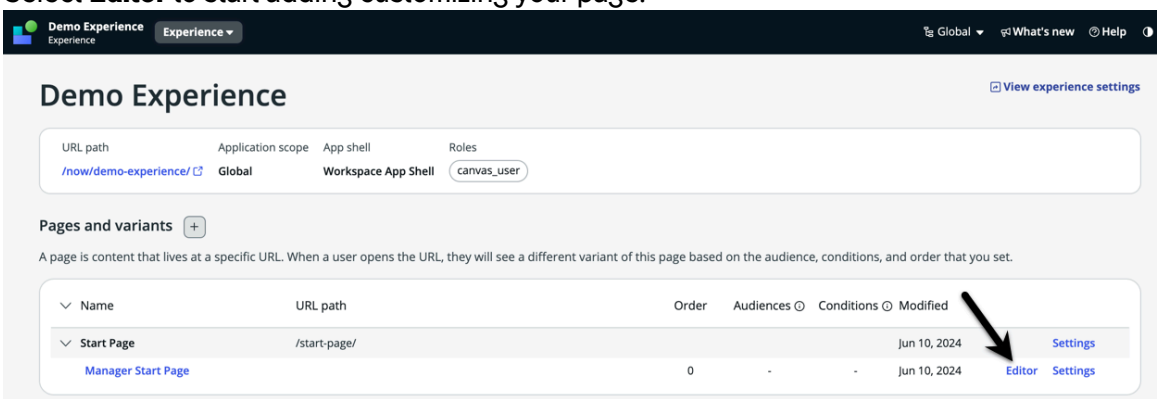
l. Select **Continue**.

m. On the next screen, select **Build responsive**.

n. Select **Create** to create your blank page.

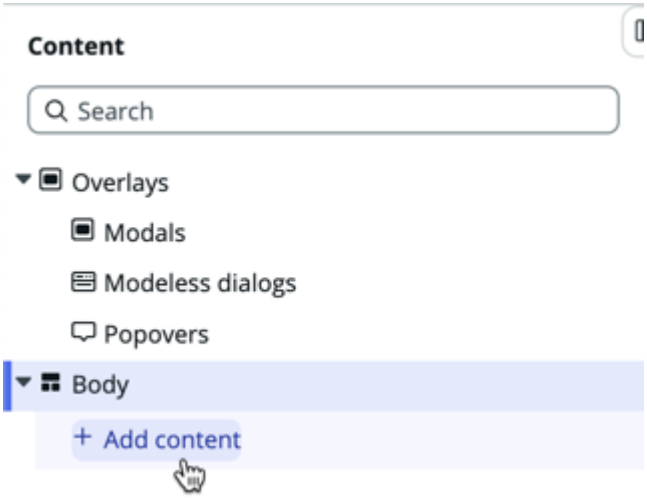
Congratulations! You've created your first page! The page is empty of content. You add components to the page to build functionality to it. Components are the building blocks of a page. UI Builder comes with many components ready for you to add to your page. Components can be as simple as a **Heading**, or as complex as a **List**.

4. Select **Editor** to start adding customizing your page.



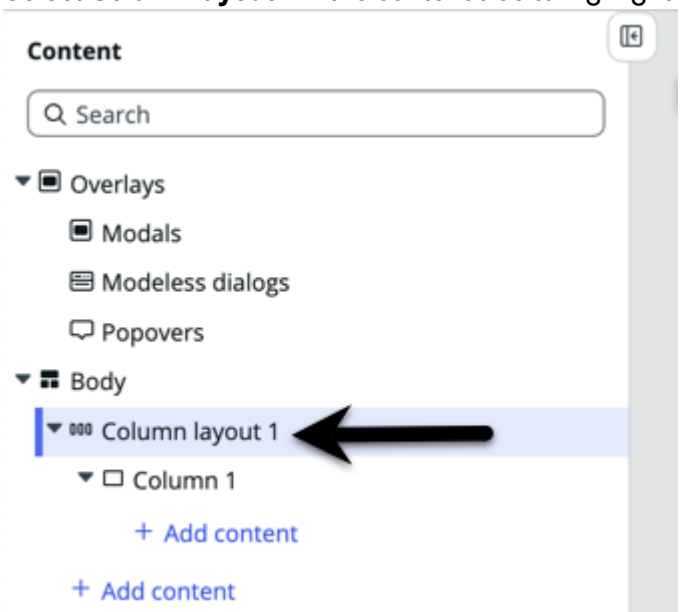
5. Add a container component to your page.
A container is what holds your components. Think of a container as an area of the page where you add information, images, or functionality (your components). You can have as many containers on a page as you want, with as many containers within containers, with as many components in the containers.

a. Select **+ Add content** in the content tree.

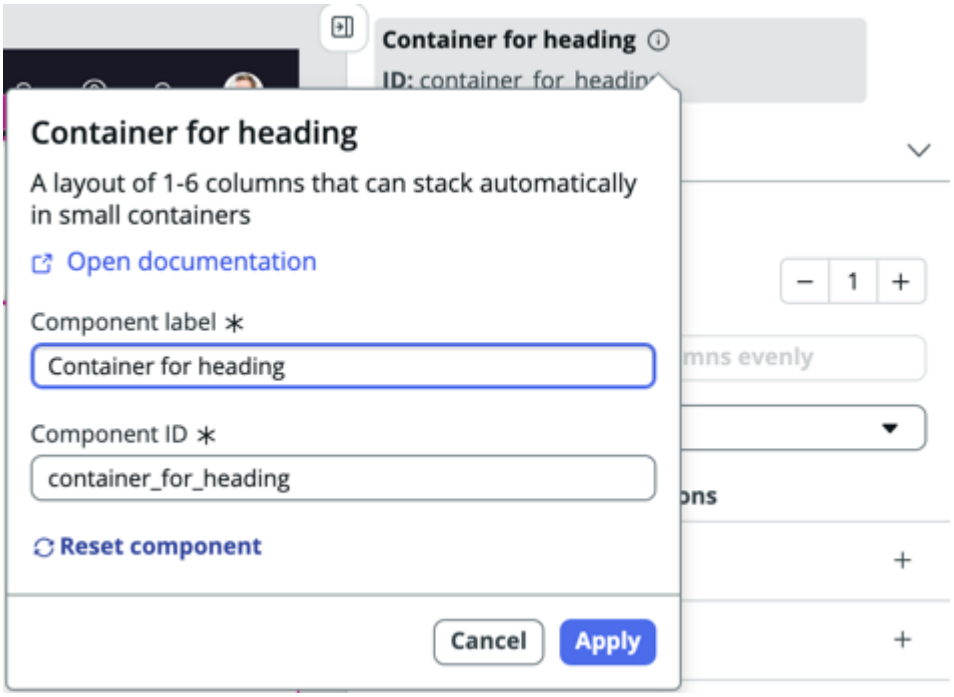


b. Select the **Single column** layout in the toolbox.

c. Select **Column layout 1** in the content tree to highlight the container.



d. Select the component name in the configuration panel.

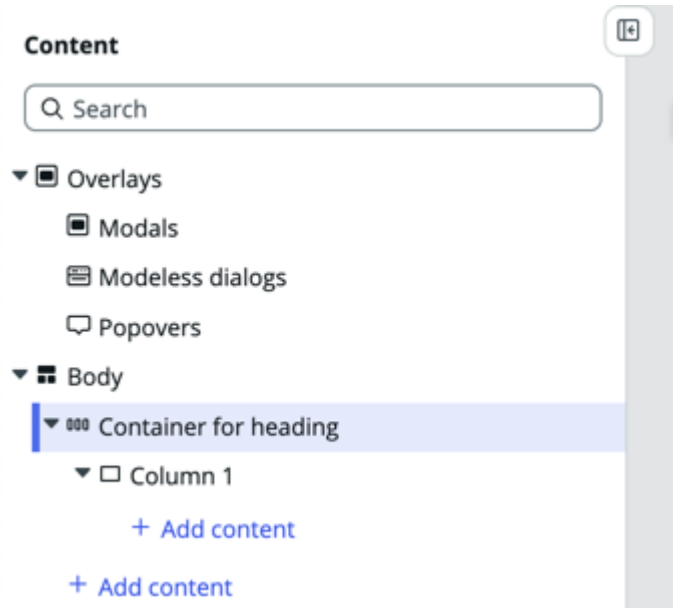


e. In the **Component label** field, type `Container for heading`.

f. In the Component ID field, type `container_for_heading`.

g. Select **Apply**.

See that the column layout name changes to **Container for heading** in the content tree. The content tree is an important concept. The content tree is an easy way to see the structured layout of your page. The content tree is especially important when you have multiple components on your page. You select the component in your content tree to highlight the component on the page, making it easier to build your page. You can do a text search for a component.



For more information on component IDs, see Component ID.

You've successfully added your first column layout to your page.

6. Add a **Heading** component to your column layout.
   You can add components to the page in different ways. For more information on the ways you can add components to your page, see Add and configure components.

   a. Select **+ Add content** in the content tree below the column layout created in step 5.

   b. Type `heading` into the search and select the **Heading** component.

   c. Select your new **Heading** component in the content tree to highlight it.

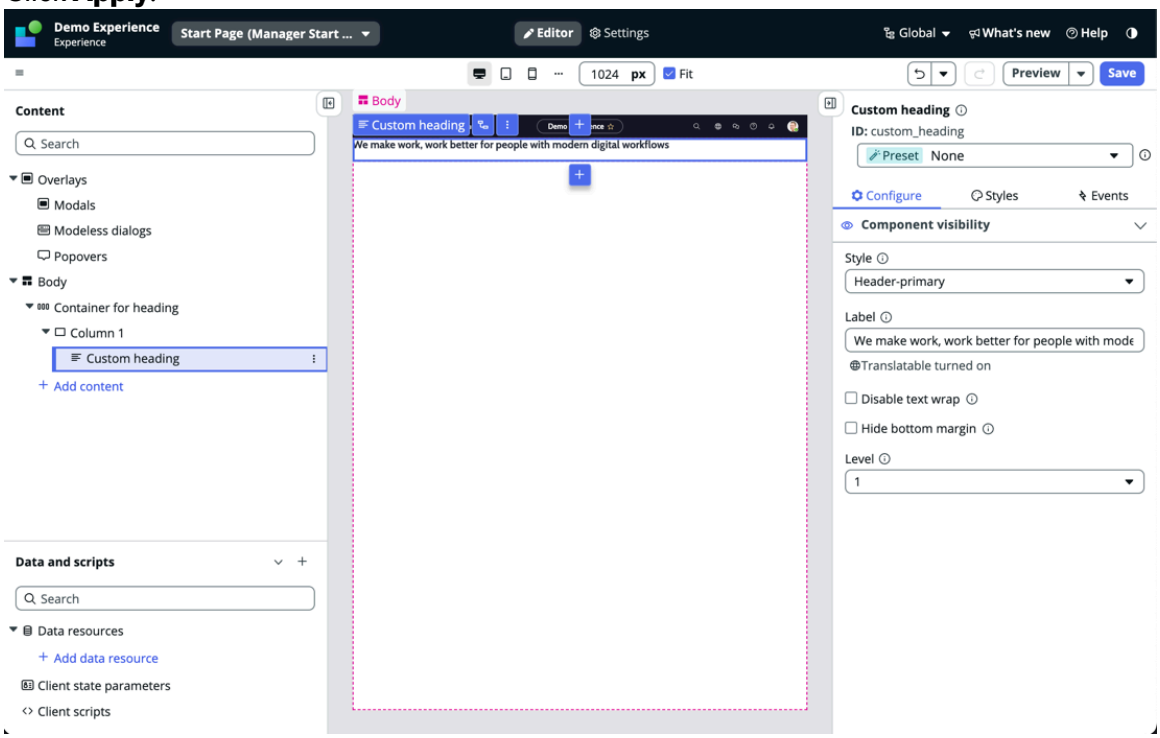
   d. Select **None** in the configuration panel.

   e. Select the component name in the configuration panel.

   f. In the **Component label** field, enter `Custom heading` as the unique label for the heading component.

   g. In the **Component ID** field, enter `custom_heading` as the unique ID for the heading component.

h. Click **Apply**.



7. Customize the heading component.

a. Select the heading component in the content tree.

b. Select the **Configure** tab in the configuration panel.

c. In the **Label** field, enter the text of your heading, such as `My new heading`.

d. The Style changes the size of the heading text.
For example, if you select **Header-secondary**, the text is smaller. Different headings sizes are useful if you have two headings and want the second heading smaller that the primary heading. For more information on configuring components, see Configure components in UI Builder.

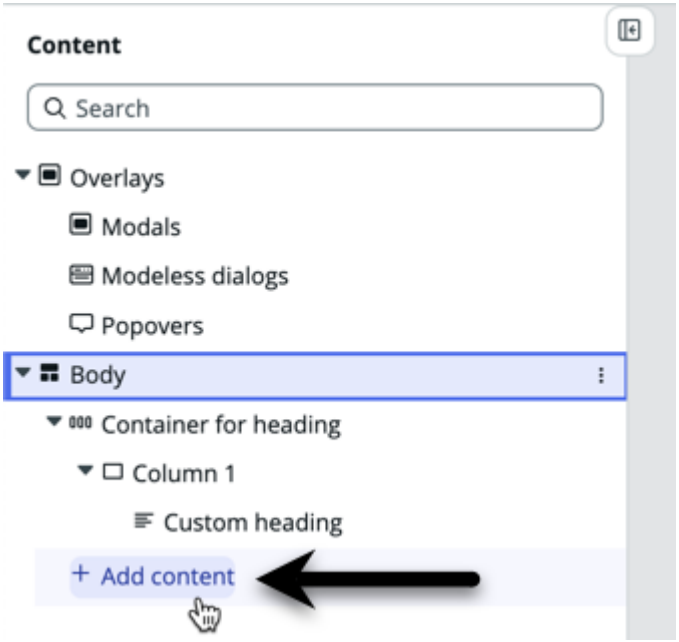
e. Leave the **Level** as **1**.

f. Select **Save**.

You've added and customized a heading component to your page.

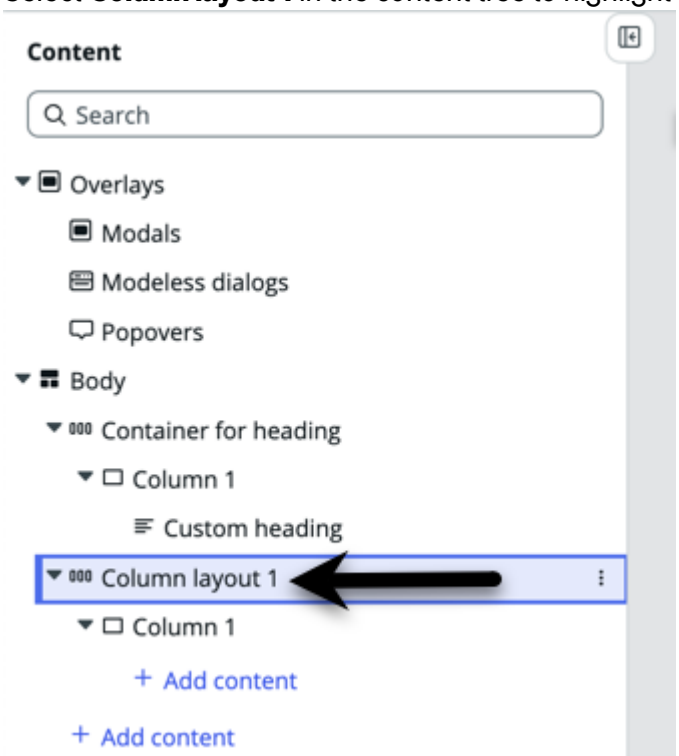
8. Add a second column layout to your page.

a. Similar to before, select **+ Add content** in the content tree.



b. Select the **Single column** layout in the toolbox.

c. Select **Column layout 1** in the content tree to highlight the container.

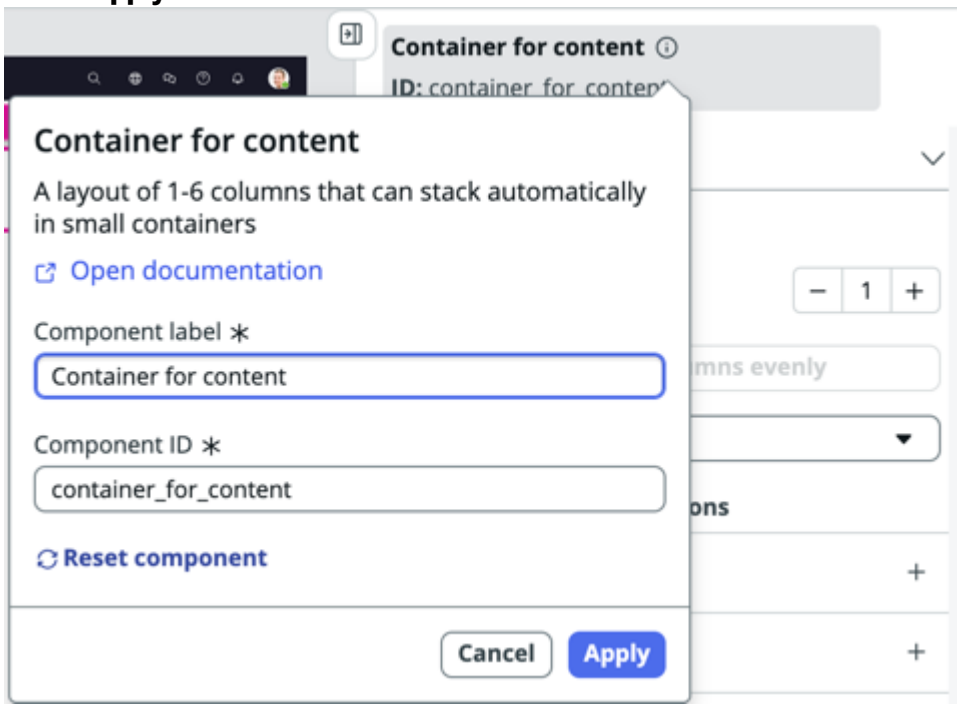


d. Select the component name in the configuration panel.

e. In the **Component label** field, type `Container for content`.

f. In the **Component ID** field, type `container_for_content`.

g. Select **Apply**.



h. Select **Save**.

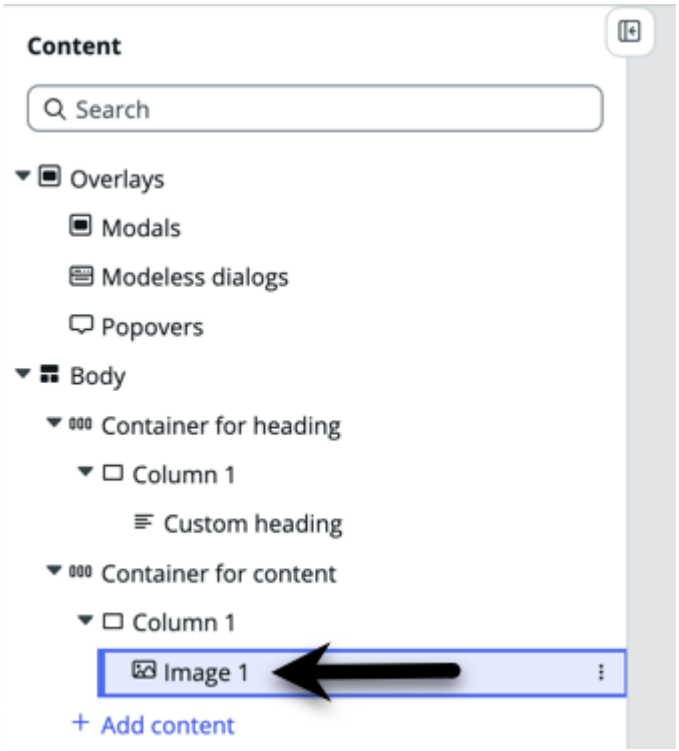
You've successfully added your second container component to your page.

9. Add an image component to your page.
An image is a nice way to add a visual for your page. In this quick start, you add a stock photo that comes with UI Builder. But you can add any image that is available to you.

a. Select **+ Add content** in the content tree below the container created in step 8.

b. Type `image` into the search and select the **Image** component.
A default image is loaded in the image component. You can add your own image by adding a URL to the image. You can use images hosted on the internet or images in the ServiceNow AI Platform®. If you use an image hosted on an external site, you must use the `https` protocol for security.

c. Select the **Image 1** component in the **Content** tree to highlight the image.



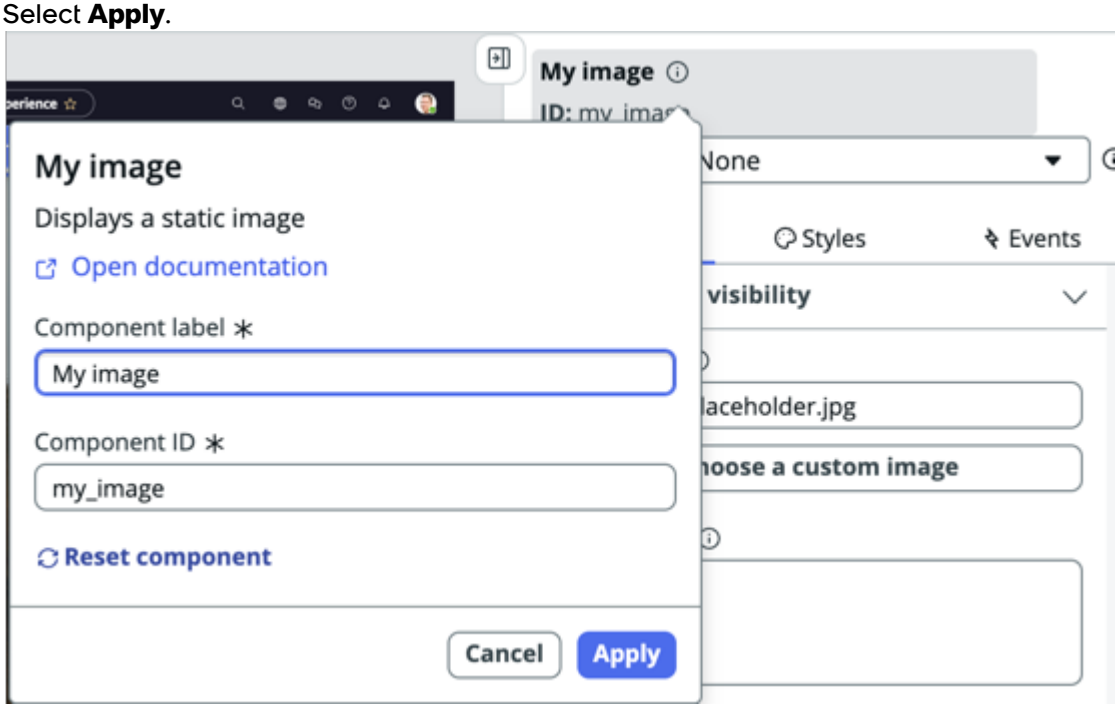
d. Select **None** in the configuration panel.

e. Select the component name in the configuration panel.

f. In the **Component label** field, type `My image`.

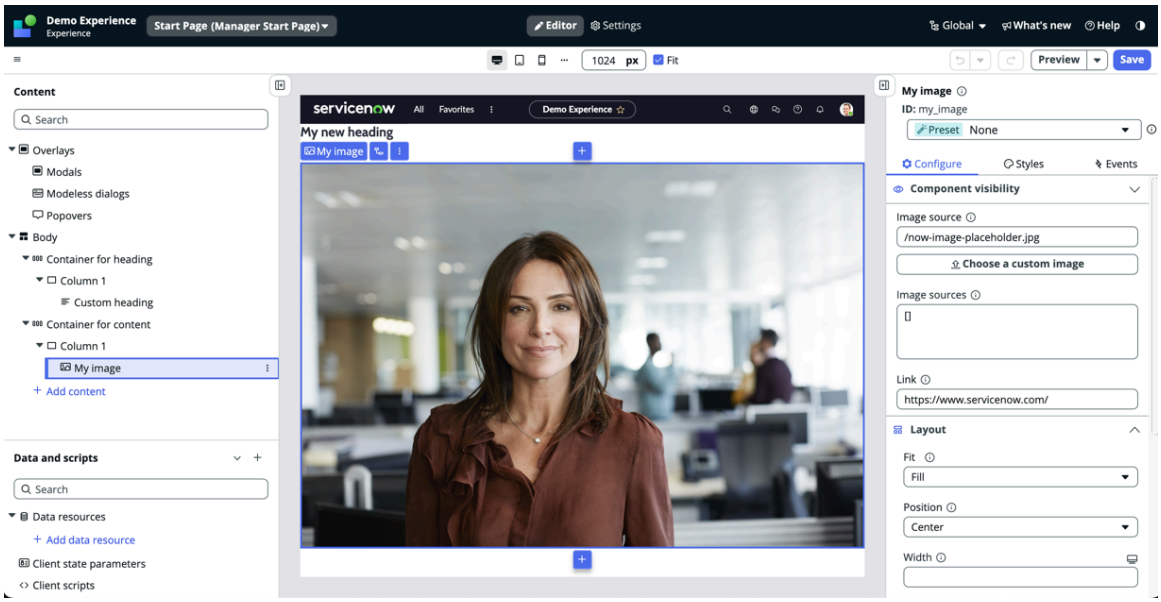
g. In the **Component ID** field, type `my_image`.

h. Select **Apply**.

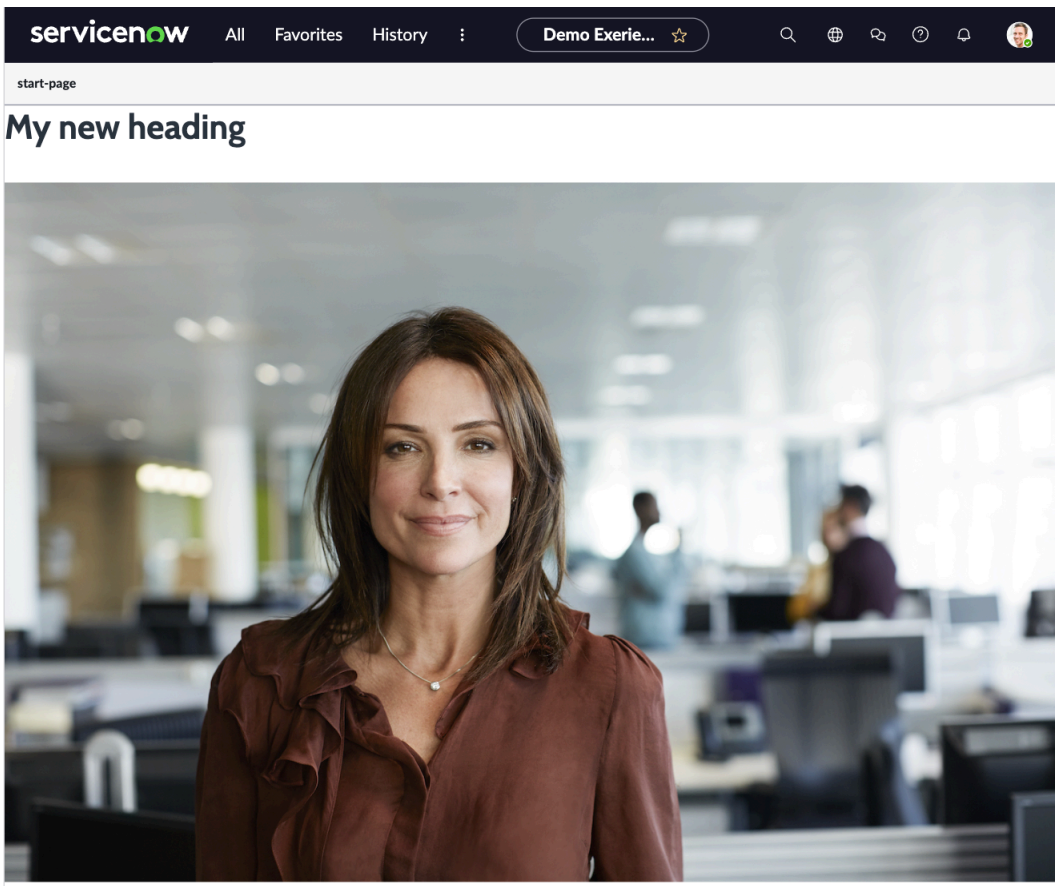


i. Select **Save**.

You added an image component to your page.



10. Select **Preview** in the UI Builder header to preview your page.
Congratulations! You completed the UI Builder quick start. Your page generates a preview of how it looks in your Workspace or portal experience.



Result

1. Created your first page in UI Builder.
2. Added your first container component to the page. You changed the label for the container.
3. Added a **Heading** component as a title to the container. You changed the text of the heading. You also changed the label.
4. Added a second container component to your page. You changed the label for the container.
5. Added an **Image** component. You changed the label of the image component.
6. Saved your new page.
7. Previewed your page in the browser.

You successfully completed the UI Builder quick start!

UI Builder tutorial

Learn how to use the basics of UI Builder to create a page called My Tutorial.

Before you begin

Role required: ui_builder_admin

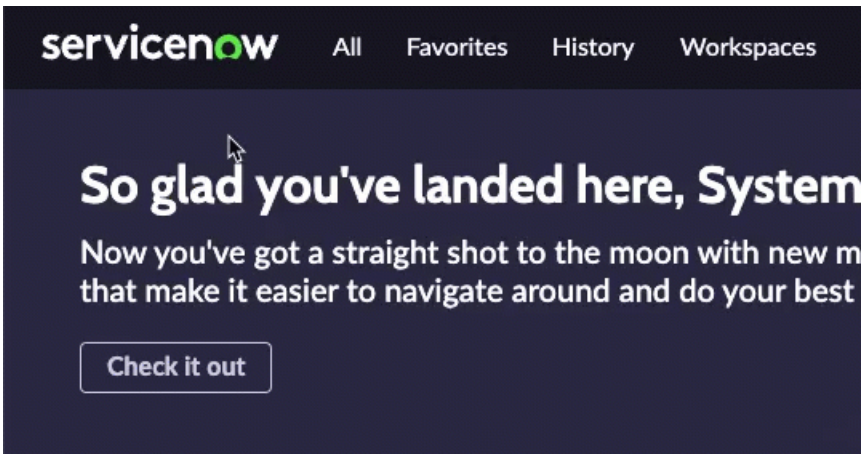
In this UI Builder tutorial, you perform the following tasks to build a page in UI Builder:

- Start UI Builder.
- Create a page for your workspace or custom portal experience. For more information about creating pages, see Create a page in UI Builder.
- Change the layout of the page to have two columns. For more information, see Organize components in UI Builder pages.
- Build your page by adding two container components.
- Rename your container components in the content tree.
- Add a **Heading** component and a **Button** component to the first container. Add a **data visualization component** to the second container. For more information about components, see Customize UI Builder pages using components.
- Configure your components as follows:
  - Link the button to the ServiceNow® website.
  - Connect the **Data visualization** component to a data source to display task data. For more information about data resources, see Dynamically expose data in UI Builder pages (advanced feature).
- Save your page often.
- Preview your page to see how it looks in a browser.

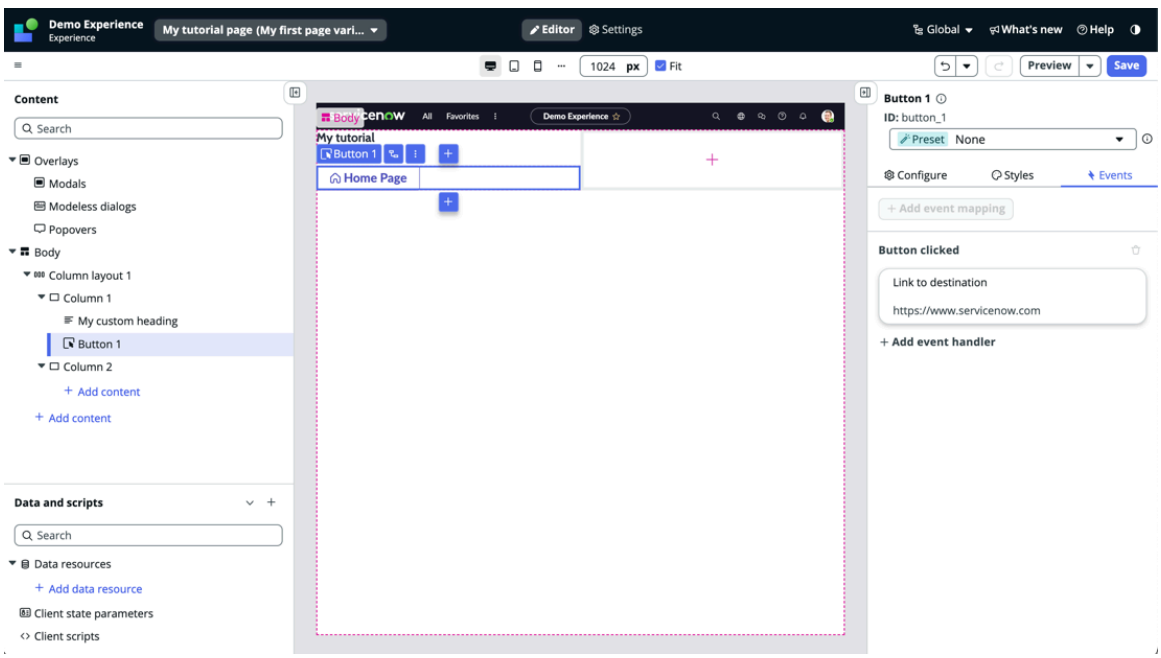
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
   You can also type `UI Builder` directly in the **Filter navigator**.

Start UI Builder



2. From the UI Builder home page, choose an experience you want to work in.
   If you don't see any experiences listed in which to work, contact your administrator to get access to an experience or create an experience. For more information, see Configure how users interact with your applications in UI Builder.
3. Create a page.
   Congratulations! You created your tutorial page! The page is empty of content. You add components to the page to build functionality to it. Components are the building blocks of a page. UI Builder comes with many components ready for you to add to your page. Components can be as simple as a **Heading**, or as complex as a **List**.
4. Change the layout of the page to a two-column layout.
   For more information about layouts, see Organize components in UI Builder pages.
5. Add a **Heading** component, and a **Button** component to the left column.
   You added and configured the **Heading** and **Button** component for your page.



6. Add a **Data visualization** component to the container.

A data visualization component contains data that you display in a visual manner. Configure the data visualization component parameters. Then, add a data resource to it.
You've added a **Data visualization** component to the right column and configured it. You also added a data resource to bring in customer account data.

7. Save the new page one last time.

8. Now preview your page to see what it looks like in a browser.
Congratulations! You completed the UI Builder tutorial.

Result

1. Created a page in UI Builder.
2. Changed the layout of your page to have two columns.
3. Added a **Heading** component as a title to your left column.
   - Changed the text of the heading.
   - Changed the label of the heading.
4. Added a button component below your heading component.
   - Configured your button.
   - Added an event handler for your button.
   - Added an event handler to set up a link to a web page. When you click the button, it opens the web page.
5. Changed the label for the right column.
6. Added a **Data visualization** component.
   - Configured the data visualization component.
   - Added a data resource to bring in task data.
7. Saved your new page.
8. Previewed your page.

UI Builder and configurable workspaces

Use UI Builder to create pages for your configurable workspace experiences.

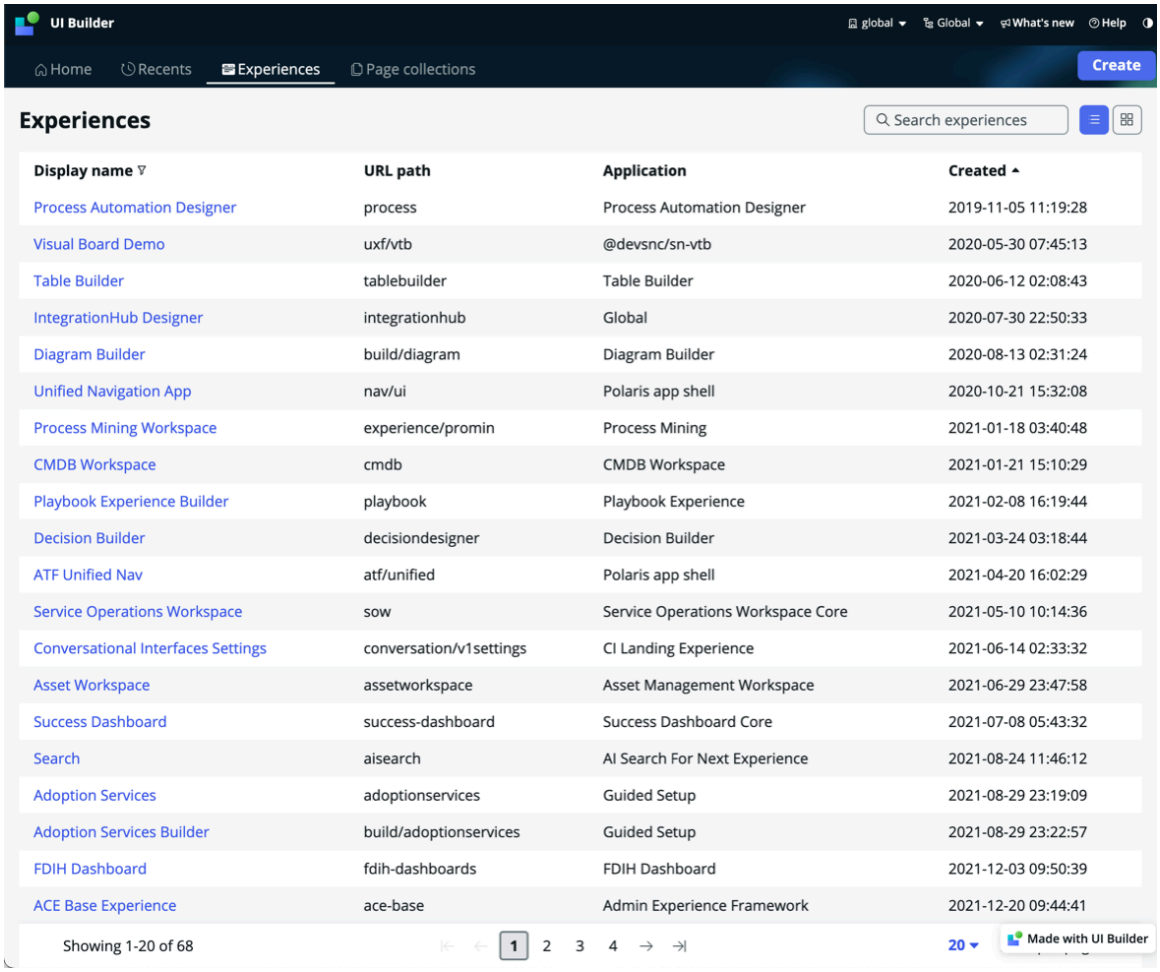
A workspace is a collection of tasks and workflows in a single focused working area that enables a user to efficiently complete an entire job. It includes tools that a user can employ to quickly and easily assist customers and resolve questions and issues. A workspace also includes features that enable a user to be more efficient, including a multi-tab interface for managing multiple cases and a contextual display that provides quick orientation to the current task.

You can use UI Builder to create pages for your workspace experience. UI Builder provides base system components that you can use to build workspace pages.

To create a page in UI Builder for a Workspace experience, you navigate to **All** > **Now experience framework** > **UI Builder** to open UI Builder.

The UI Builder home displays your available experiences under the **Experiences** tab. If you are working in a Workspace experience, you should see the experience listed here.

UI Builder home



Experience settings for UI Builder

Learn about the UI Builder experience settings to build your own workspace and custom portal experiences.

By changing the settings of the workspace or portal experience that you're working in, you can affect how your users interact with the experience, how the experience looks, and how users navigate to and from the experience.

Before you can edit the experience settings, you must be in the correct application scope. If you're in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (

), and then select the application scope that you want. For more information about the application scope, see Learn about security and roles.

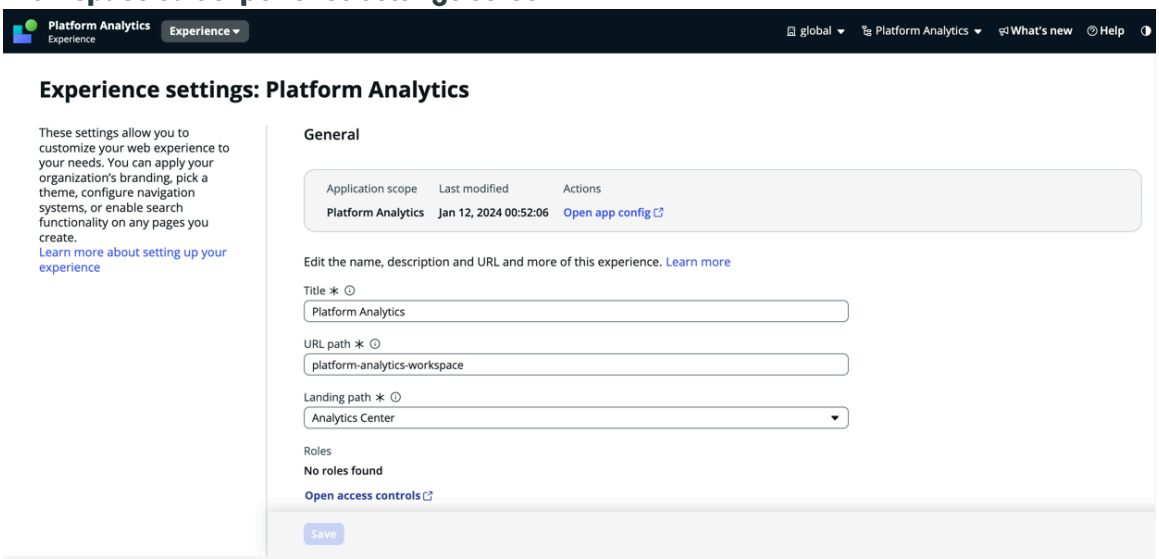
Workspace experience settings

You can change these settings for your workspace experience:

- Modify or add some general settings for your experience. For example, you can change the title, description, and the path of the workspace or portal.
- Apply your organization's branding to all pages in your experience or to a page within your experience.
- Configure your side navigation settings to add pages to the side navigation in your experience.

- Turn on or turn off the notifications for your experience.
- You can change the global search settings for your experience. For example, you can choose to show or hide the search bar in your experience or change the search source that determines where the search results come from.

Workspace edit experience settings screen



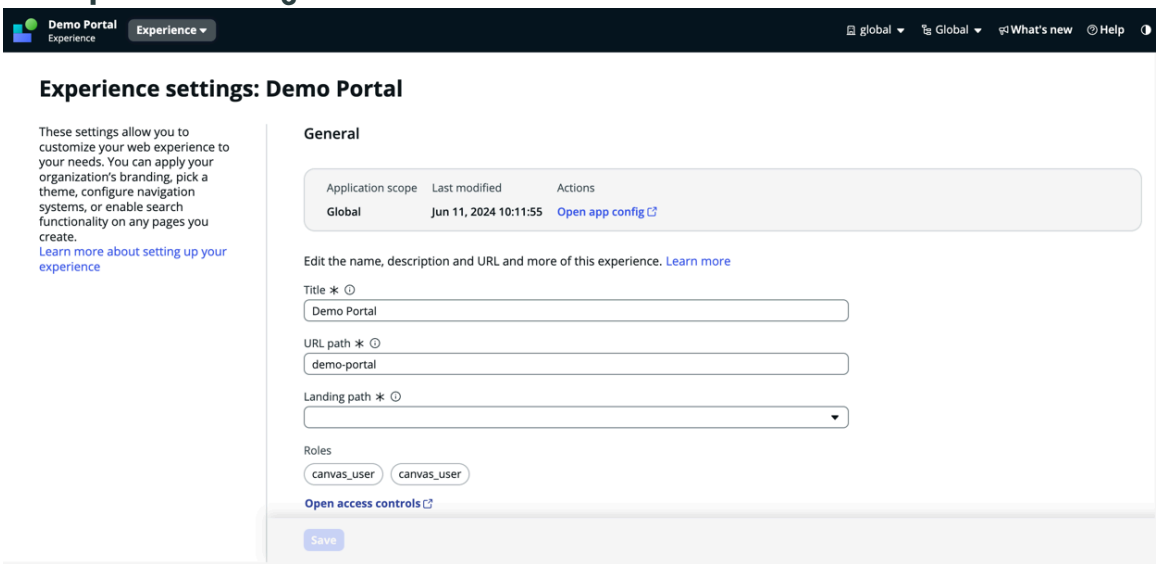
To learn more about the workspace experience settings, see Configure UI Builder workspace experiences.

Portal experience settings

You can change these settings for your portal experience:

- Modify or add general settings for your experience. For example, you can change the title, the description, and the path of the workspace or portal.
- Apply your organization's branding to all of the pages in your experience or to a page within your experience.
- Set up the navigation and menu settings in the app shell of your portal experience. The app shell, which is the wrapper of the portal contents, is similar to a Google Chrome web page.
- Control whether the global search functionality is visible to the users of your portal experience. For example, you can enable or disable the global search for either your public or private pages.

Edit experience settings screen



To learn more about the portal experience settings, see Configure UI Builder portal experiences.

UI Builder glossary

Learn about the terms and concepts used in UI Builder (UIB).

action

Actions in UI Builder are specifically activity on a page or within a page component. Events and event handlers are used to add actions. For example, add a button component to a page and then add an event handler to apply an action for the button, such as opening a web page.

app shell

App shells are the static elements of a web experience (for example, the header, footer, and menu navigation) that stays with the end user as they navigate throughout the experience. App shells are primarily used and supported in Workspace and Portal experiences.

binding

See data binding.

client script

Client-side JavaScript that interact with components and client state parameters on a page. Client scripts are mapped to events as event handlers in UI Builder.

client state parameter

Page variables that are defined for a page to store a piece of data (a client state) only for that page. For example, create three client state parameters to store the input needed to create a record and specify when to refresh the list. Page variables can be updated using client scripts and events to make a page dynamic.

component (UI Builder)

Use the UI Builder library of components to build pages. Components have an interface that an end user can view and interact with. Components can talk to each other through events and properties. Commonly used components include Heading, Image, List, Form, and Button.

component id

Used to reference a component when adding a script or binding data to the component. A component ID is automatically created (based on the component label) when you add a component to a page, but the component ID can be edited.

component preset

Use to apply predefined configuration values and event mappings to components. Presets apply prebuilt configurations to component properties and events handlers. Presets are only available for certain components.

component properties

Available in the Configuration panel and used to configure a component. Each component has unique properties. Component properties are specified within each tab on the Configuration panel: Config, Style, and Event. Some components have presets available. Use the component presets to set component properties automatically.

controller

A type of data resource that includes data and event logic and enables component presets. Controllers are added automatically when using a page template. There are two types of controllers:

- Data controllers contain data resources and can be manually added to a page
- UI controllers are added to pages when using page templates and can't be added manually. Creating controllers isn't supported currently.

data binding

The process of associating data with a UI element that displays the information.

data resource

A dynamic, reusable way of defining what data to fetch for a page's components.

entity view action mapper

Also known as EVAM. Standardizes the format for displaying data in cards and lists.

event (UI Builder)

Action a user takes (such as selecting a button) or an occurrence that happens on a page. Most UI Builder components, pages, and data resources have default-associated events. Use event handlers with the events to add additional actions to pages.

event handler

An action performed when an event occurs.

event mapping

The process of identifying an event handler to run when an event occurs.

macroponent

Core data structure that drives UI Builder pages. Fields contain JSON that builds the page.

modal

User experience window that overlays another content window and takes control of the user experience.

now code editor

A rich-text editor that supports CSS, HTML, JavaScript, XML, and JSON. Use Now Code Editor to change UI configuration, data resource configuration, styles, events, client-side scripts, and server-side scripts in Next Experience UI Builder components.

page

Collection of column layouts, columns, and components. Create or customize multiple UI Builder pages for workspace and portal experiences.

page collection

Group of pages that can be reused in experiences within tabs or modals.

popover

A page overlay that enables users to continue using the rest of the page. Popovers can be configured just like UI Builder pages with text, components, images, fields, and menu items.

repeater

In UI Builder, a repeater is a component that acts as a basic loop that repeats the data you provide in multiple components. Repeaters use an array or an array of objects. Repeaters bind values to a data array property. For example, [{"task": "A"},{"task": "B"}], repeats the content inside it two times.

UI Builder (UIB)

A WYSIWYG web user interface builder. UI Builder enables developers to build new pages or customize existing pages for Agent Workspace and portals using Now Experience UI Framework components.

variant

Version of a UI Builder page with access controlled by role or condition. Create variants of pages to target experiences for different audiences. For example, create a home page for agents and a variant for managers at the same URL. Alternatively, create a page variant that users see under different conditions.

Learning UI Builder

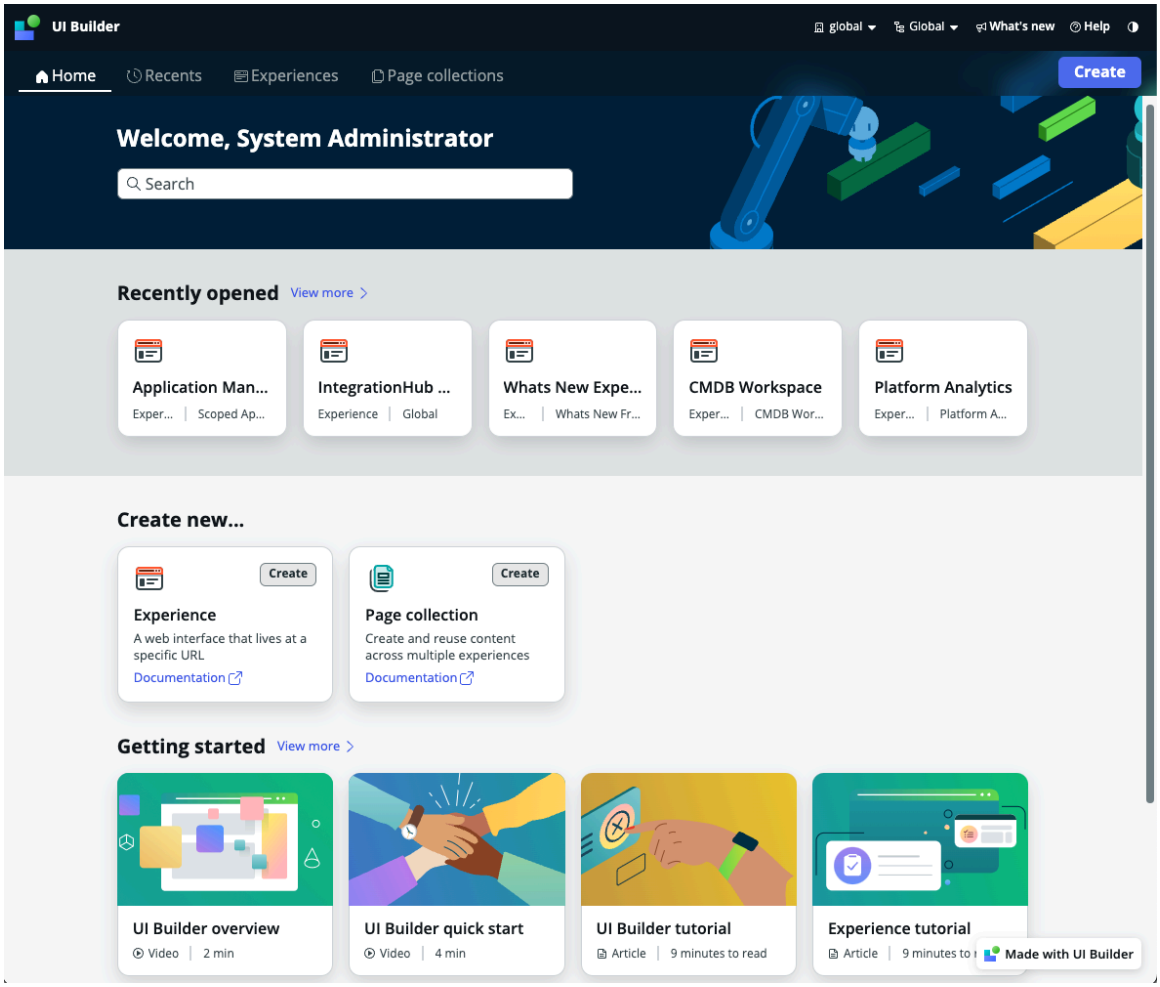
Learn how to navigate the UI Builder and explore some common use cases to learn by example.

Navigate the UI Builder application

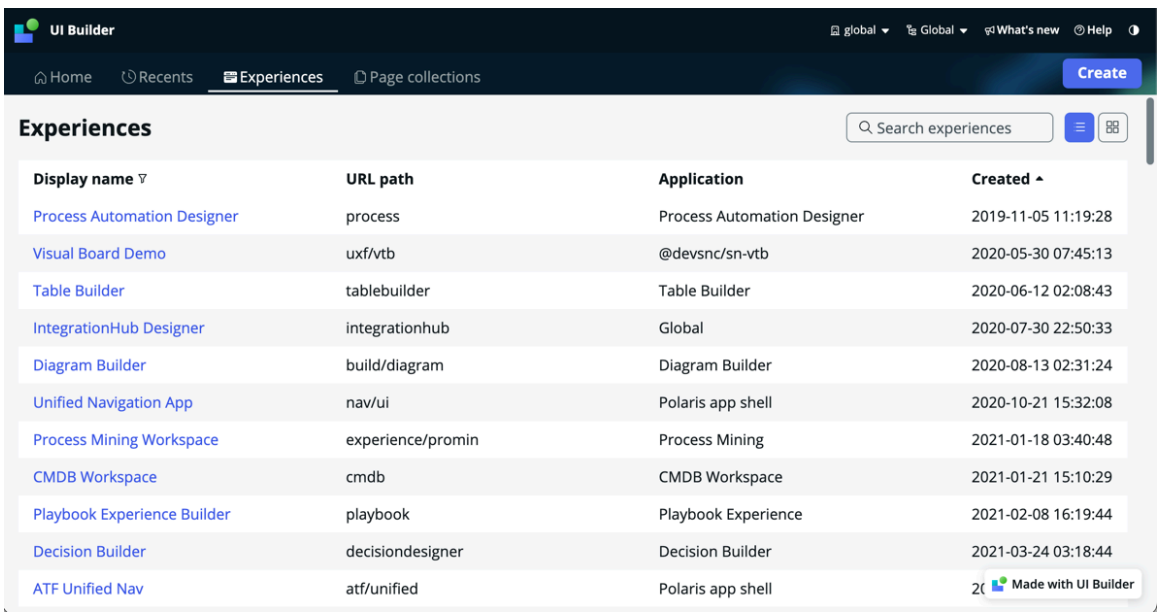
Learn how to navigate through UI Builder.

UI Builder home

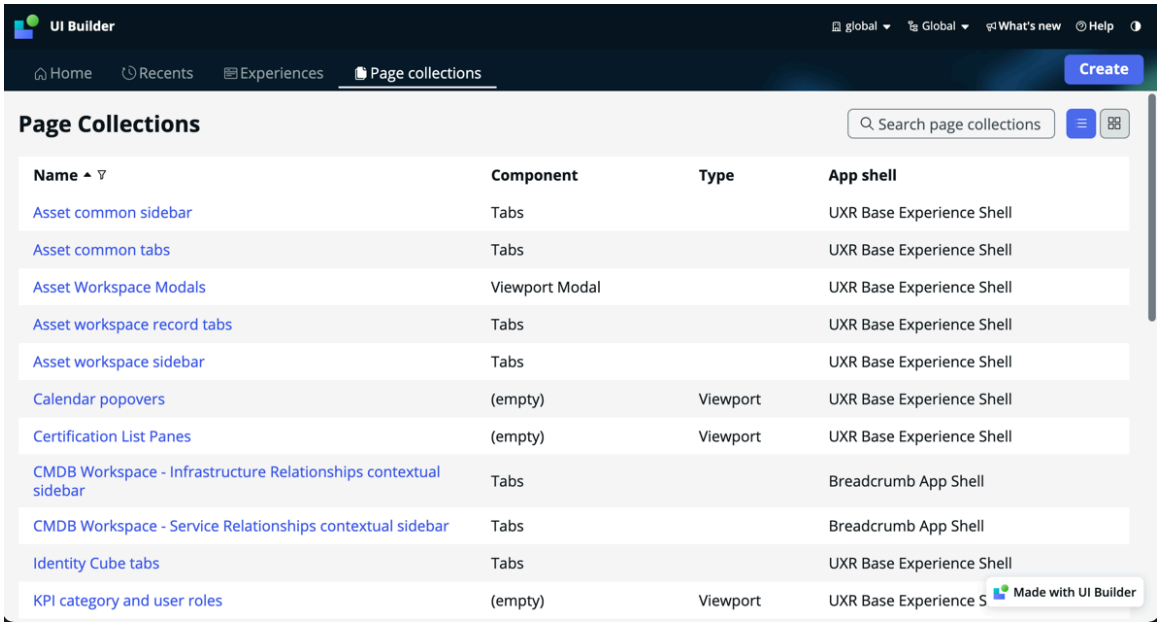
The UI Builder home page provides easy access to recently opened experiences, options for creating experiences or page collections, and help for getting started using UI Builder. You can also use the search bar to quickly find your experiences by name.



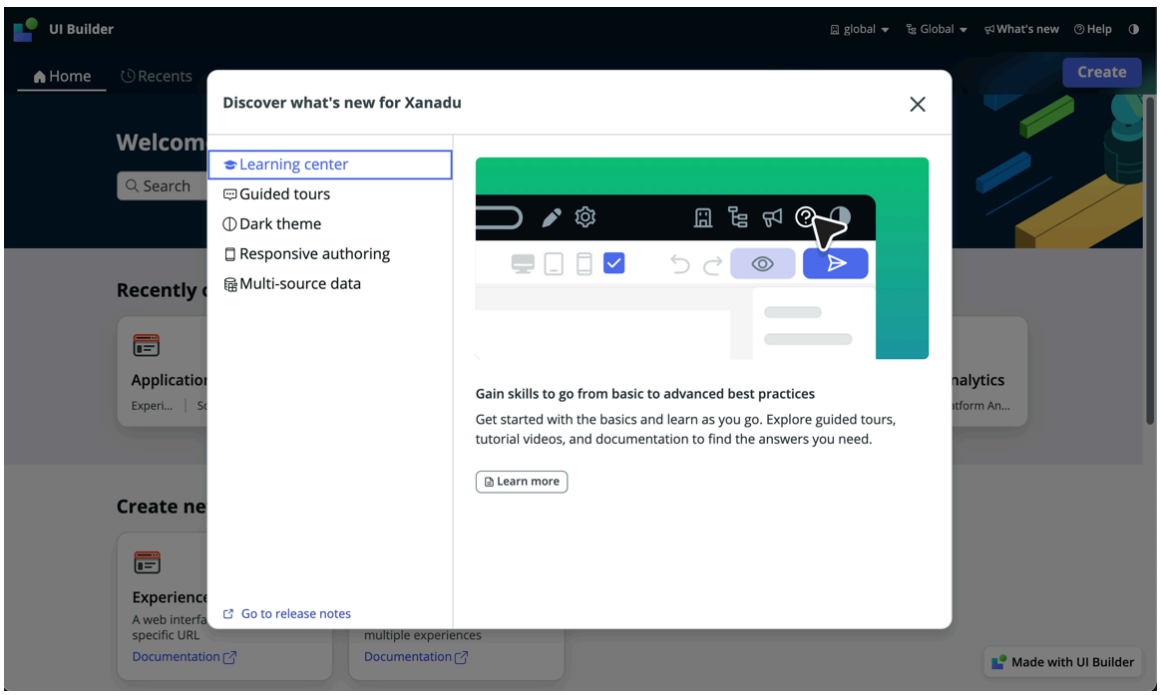
You can access the list of experiences in the top by selecting the **Experiences** tab in the top bar.



You can access the list of page collections in the top by selecting the **Page collections** tab in the top bar.



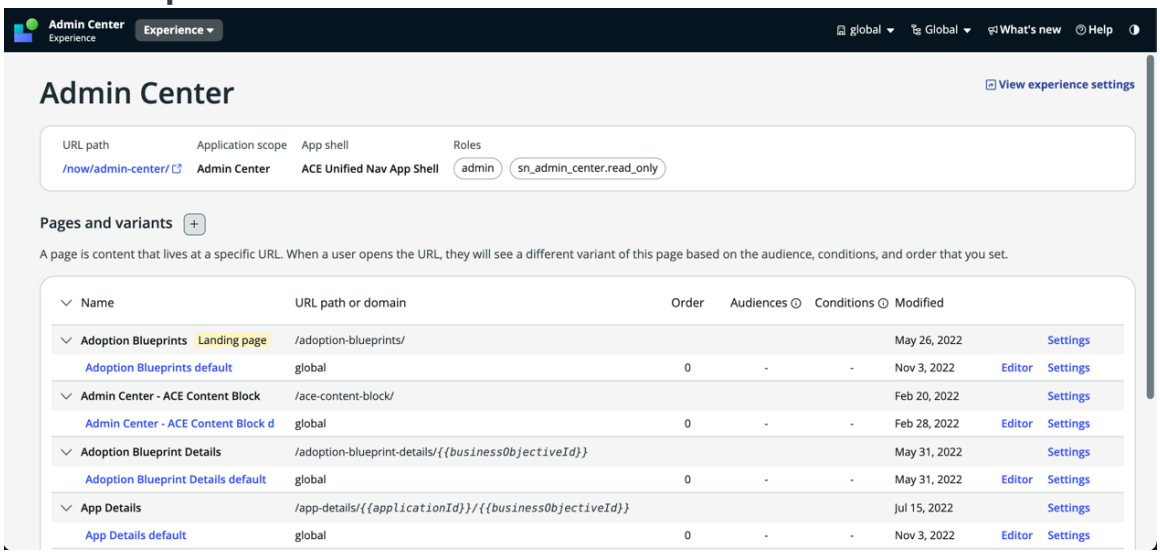
Select the **What's new** link in the header to view the latest changes to UI Builder.



UI Builder experience view

The UI Builder experience view is a central place to view and understand the structure and details of an experience. Use the **Page and Variants** list to select a page to edit.

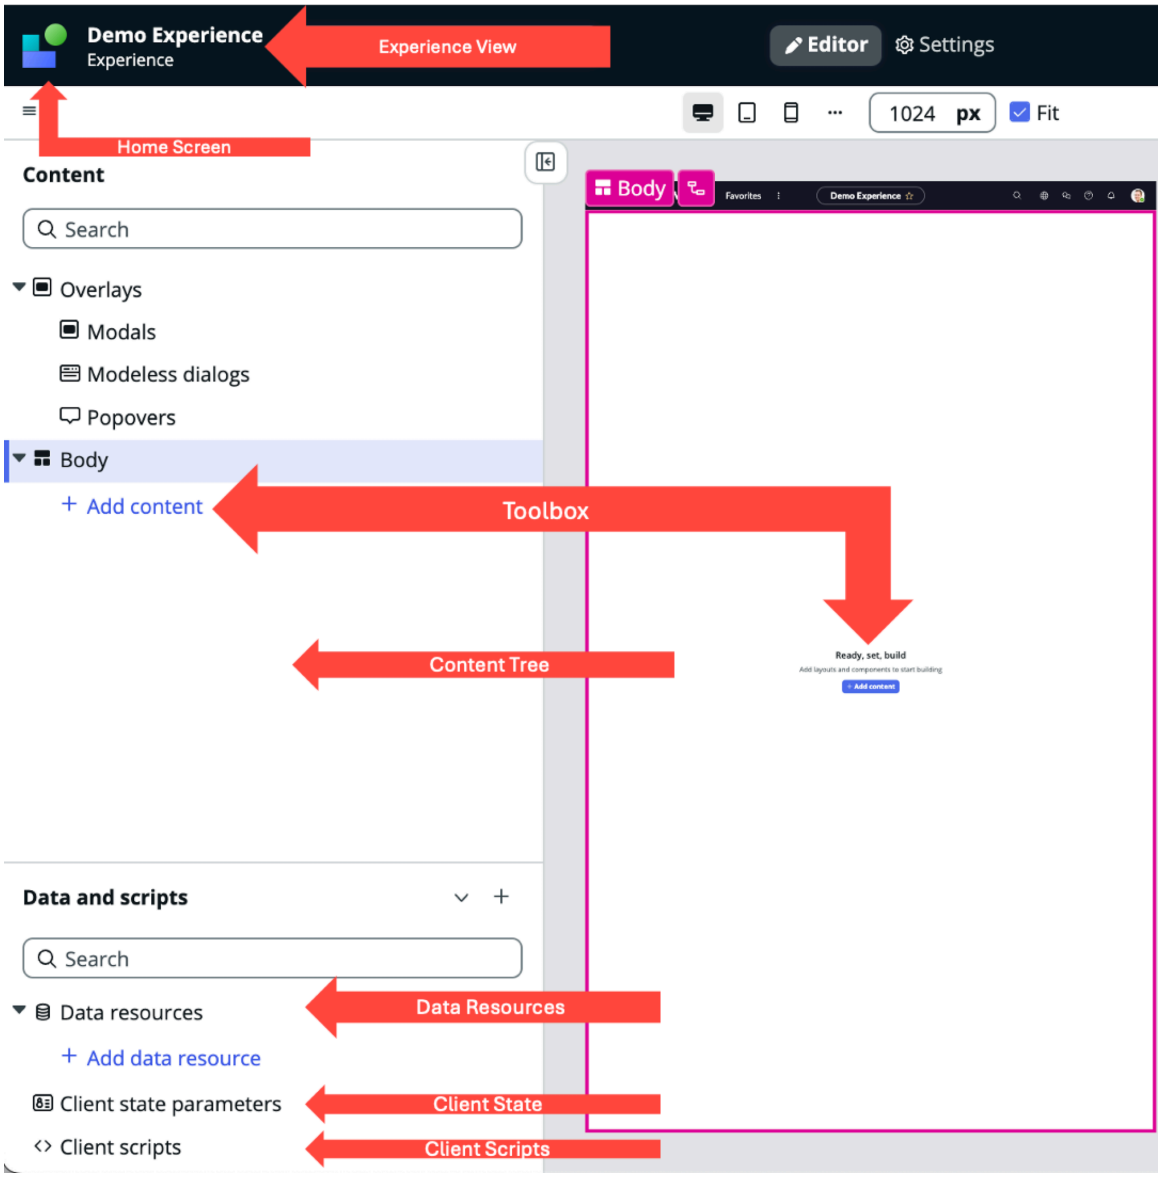
UI Builder experience view



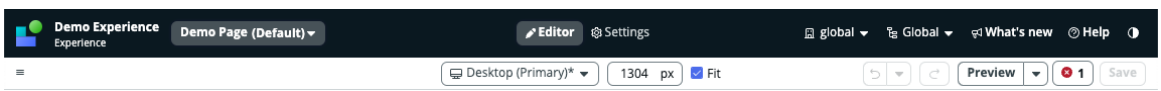
Structure of UI Builder

UI Builder is separated into the following areas.

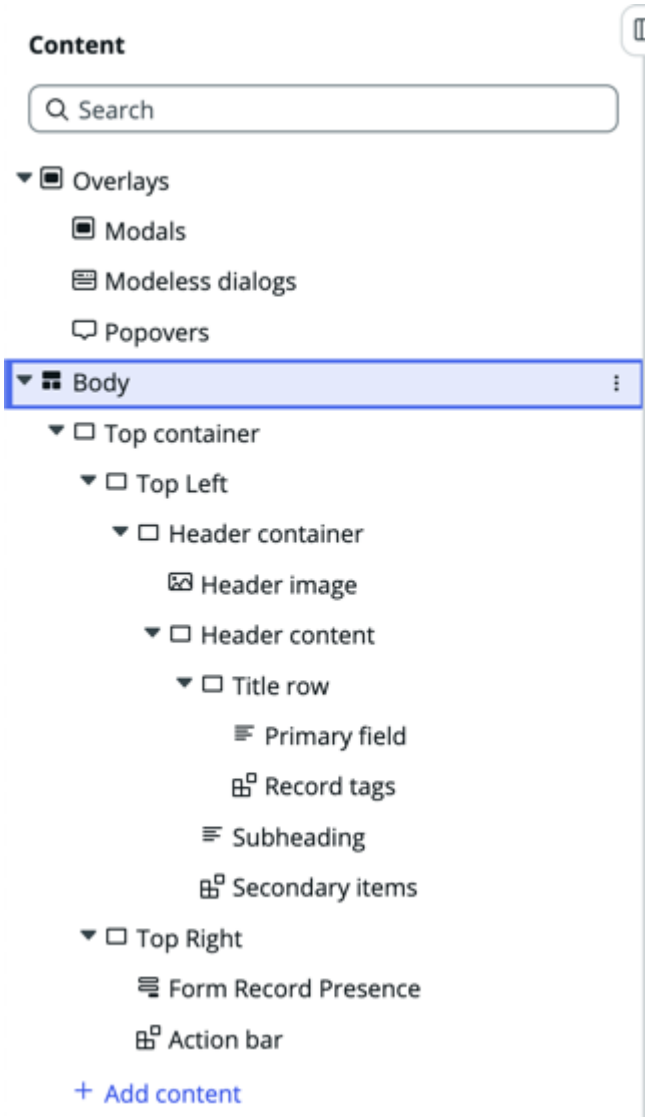
- Use the left vertical bar for access to the following in UI Builder:



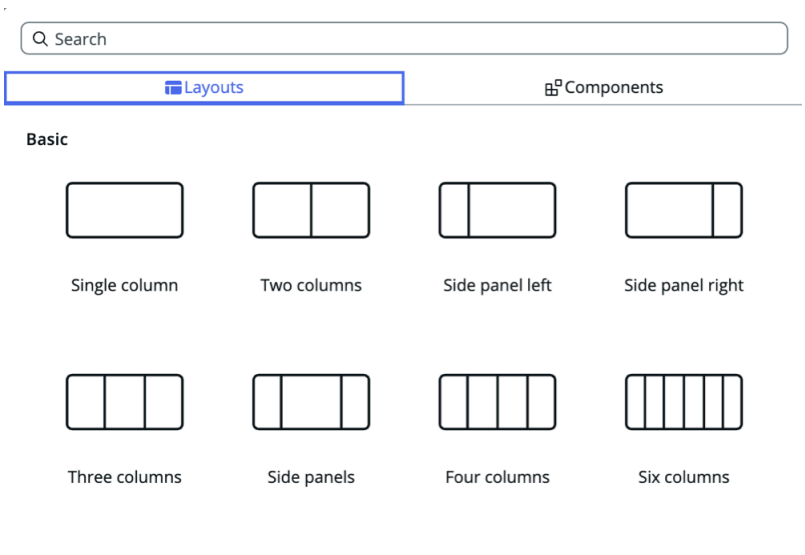
- Use the top bar to access pages in the experience and view Help. Change page settings, such as availability, order, and audience. Preview and open the URL path for the page you're editing to see what the page looks like for users. You can also select a domain and set application scope. View page errors and warnings by selecting the icon next to the save button. And finally, click the **Save** button often to save your page.

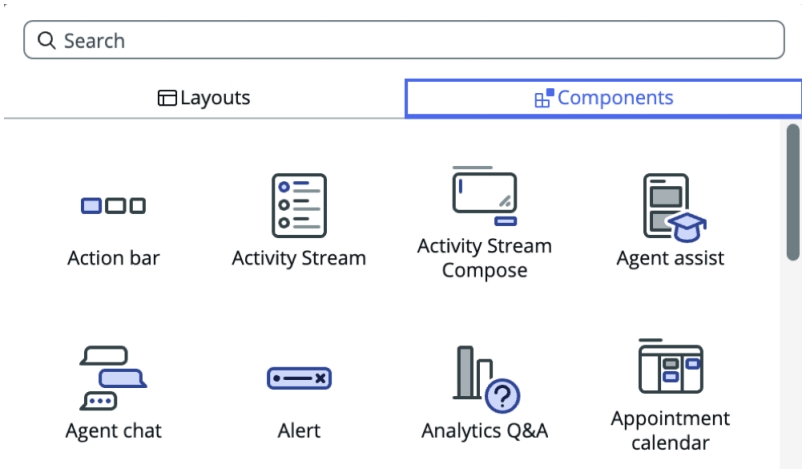


- Use the content tree to view and edit column layouts, columns, and components on your pages.

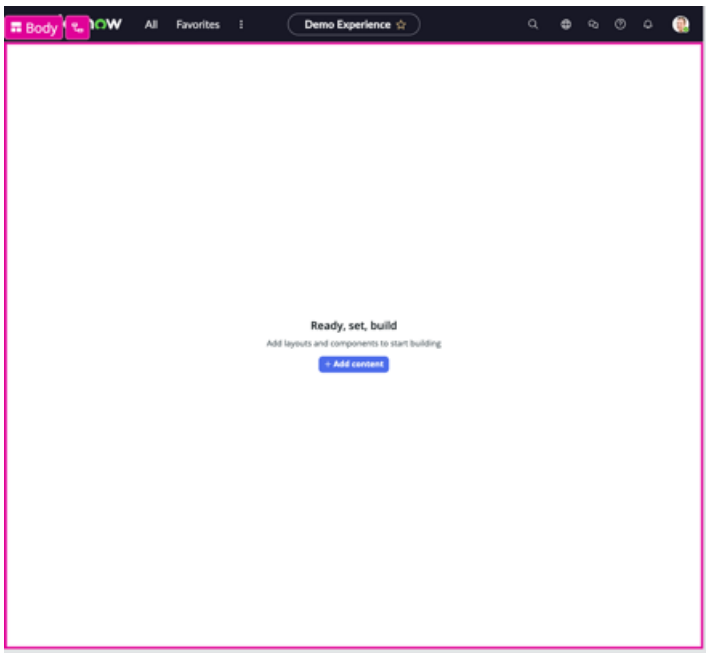


- Add column layouts and components to your page using the UI Builder toolbox.

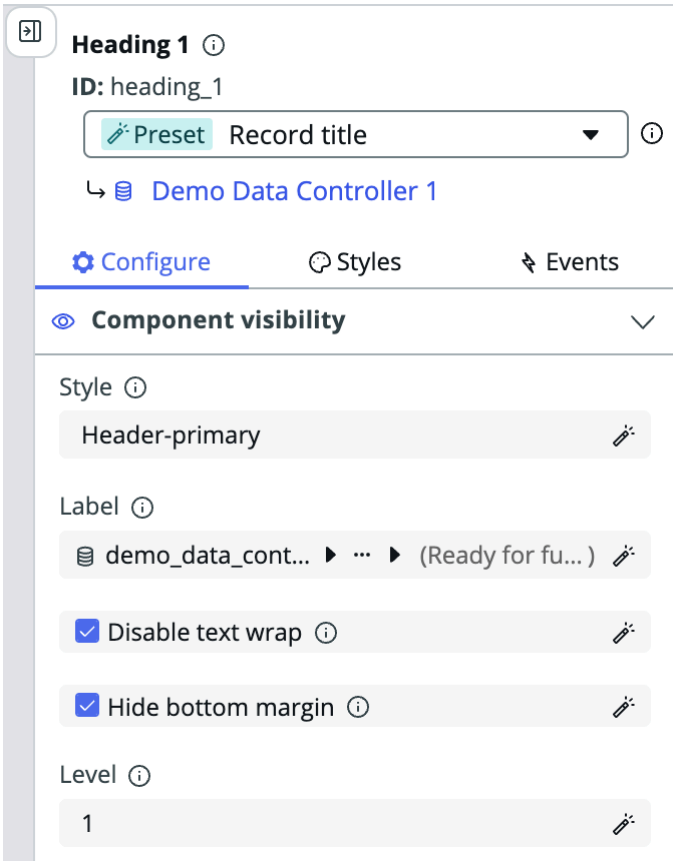




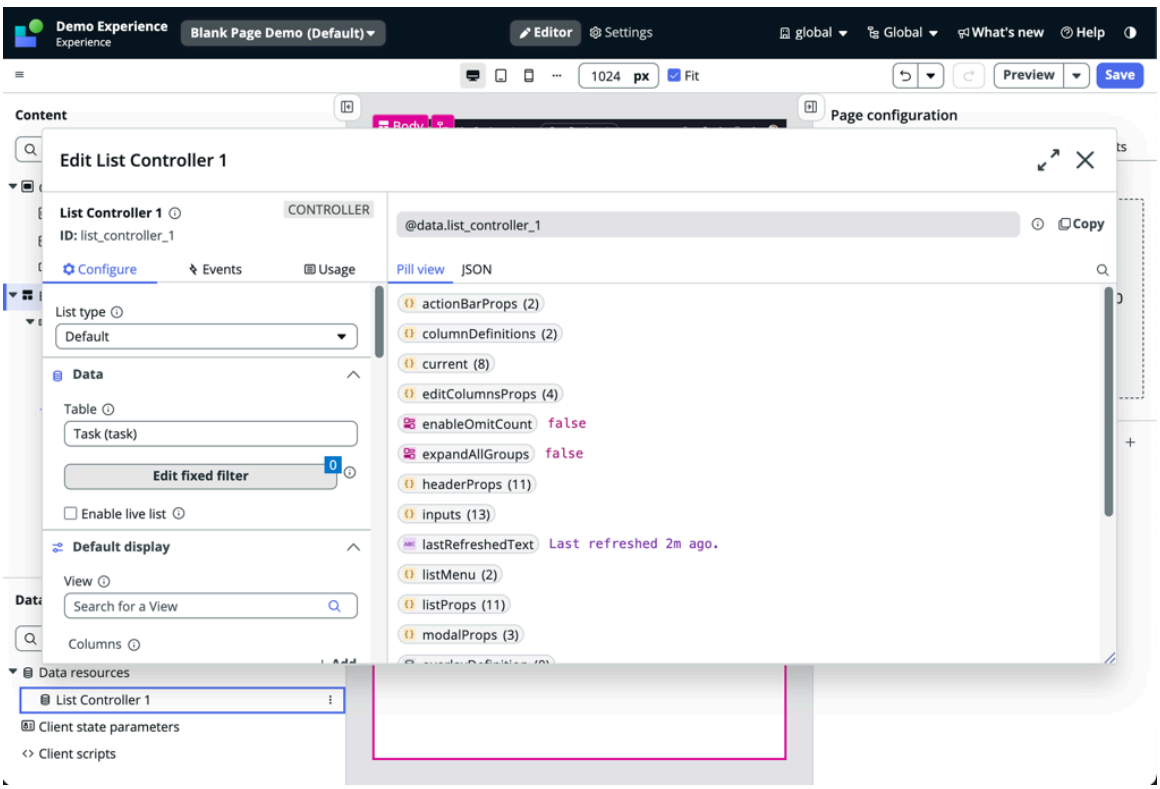
- Work in the UI Builder staging area to build and modify your pages.



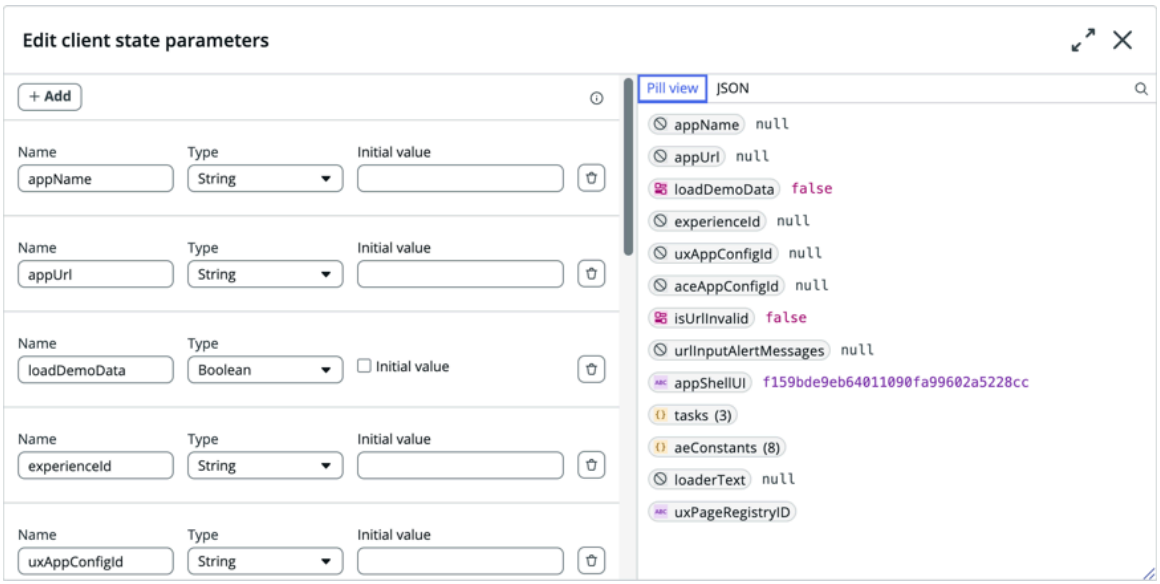
- Go to configuration panel to modify column layouts, columns, components, styling, and events.



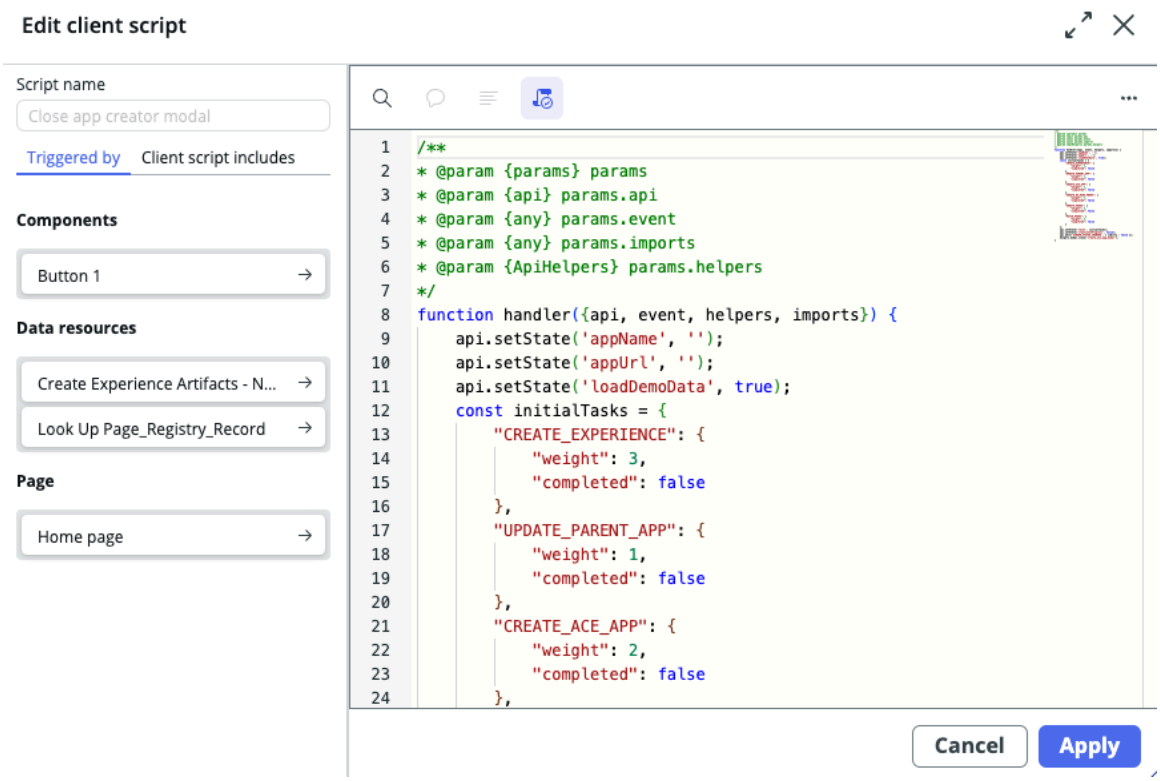
- Data resources: Bind data to your components using data resources to dynamically expose your data from tables, records, or other elements on your page. Data resources enable you to reuse your components. See Connect data to your components for more information.



- Client state: Set the parameters for the client state for your page. The client state parameters consist of a name, a type, and an initial value. You can see the preview of the client state parameters.



- Client scripts: Scripting automates aspects of the page, like event handling.

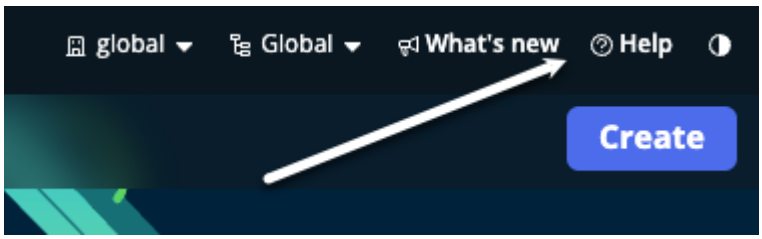


UI Builder Learning Center

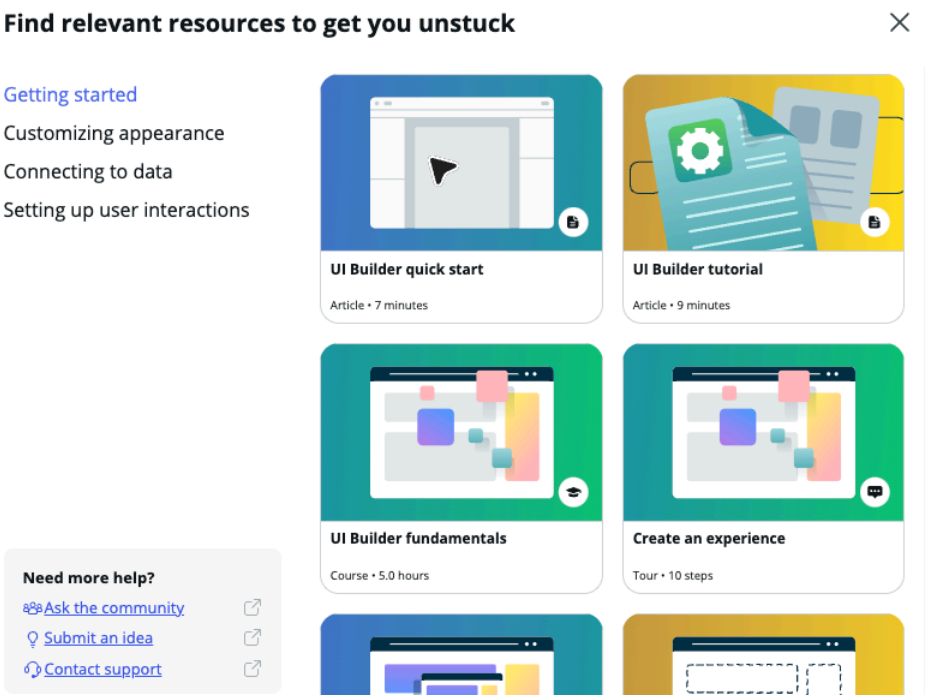
Explore the UI Builder Learning Center for articles, videos, courses, and guided tours to help you get started and build knowledge. The Learning Center is a one-stop shop for learning fundamental features and basic guidelines in UI Builder.

Open the Learning Center

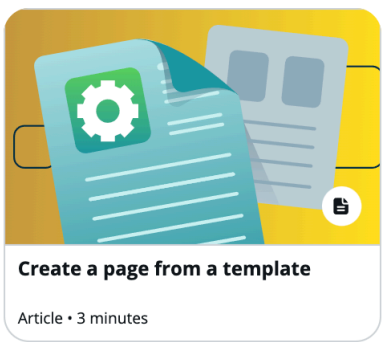
Navigate to Now Experience Framework > UI Builder and select **Help**.



The Learning Center opens in an overlay.



Available information is listed on tiles. Each tile contains a title, the information type, and the time to complete. For example, a tile linking to a product documentation article that takes three minutes to read.



Select a tile to open a resource. Resources are in the following locations:

- Articles: https://servicenow.com/docs
- Videos: created by ServiceNow and available on public, online video platforms

- Courses: https://learning.servicenow.com
- Tours: embedded in your ServiceNow instance

Guided tours in UI Builder

Learn about UI Builder guided tours, including how to use them to build your knowledge and practice using UI Builder.

What guided tours are

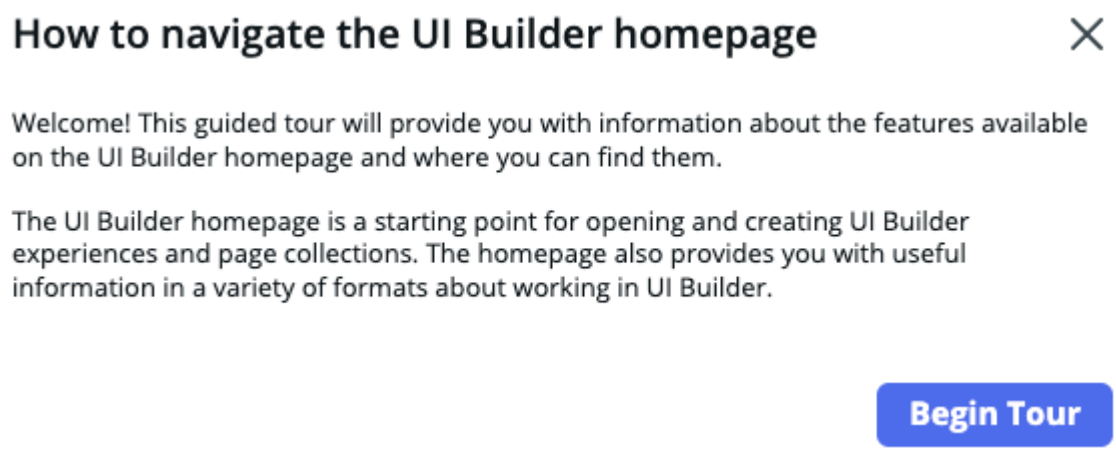
Guided tours are part of the default ServiceNow platform. There are guided tours available to take and you can use the Guided Tours application to create custom tours yourself in your own instances.

Tours contain interactive steps to help train and teach users. Some tours show various features in the user interface, such as an overview of a homepage. Other tours help complete a task, such as creating an experience or previewing an experience page. For more information about what guided tours are and how to create them, see Exploring Guided Tours.

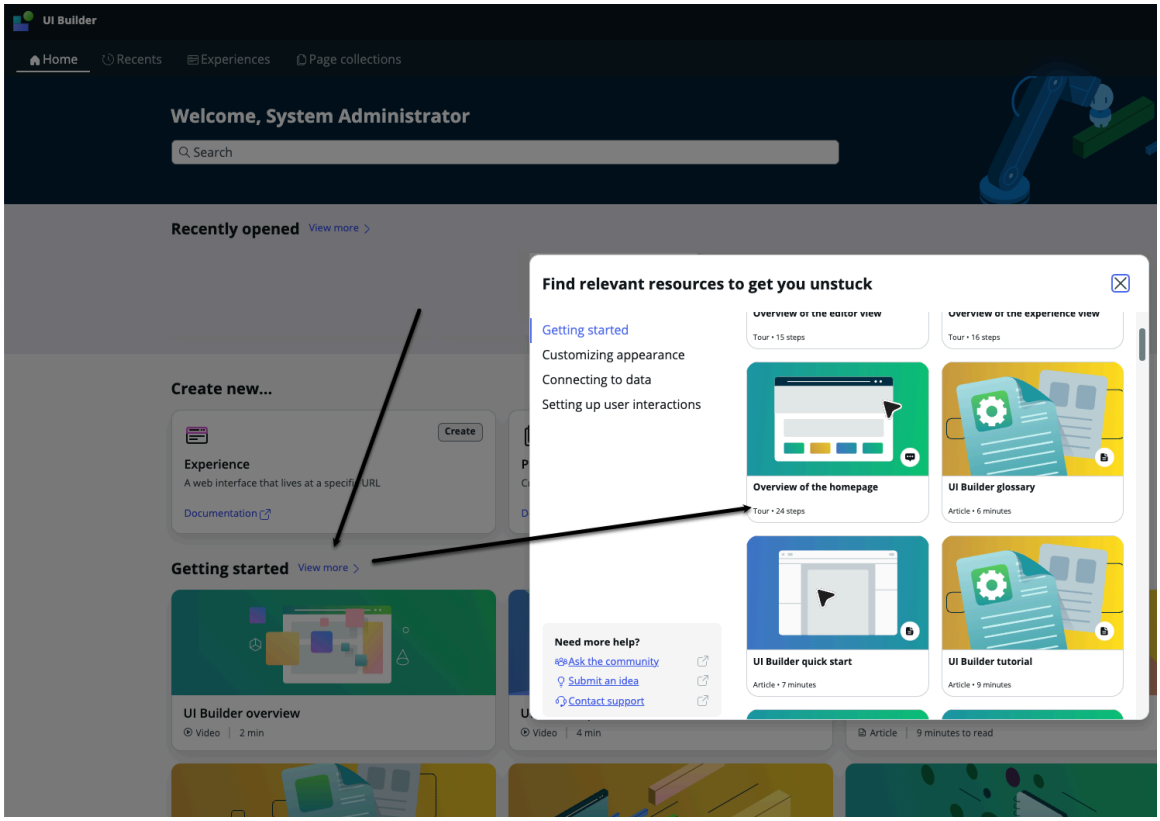
How to access and use UI Builder guided tours

Guided tours about UI Builder may launch automatically. You can also start them manually from the **Getting started** section of the UI Builder homepage or the UI Builder Help panel.

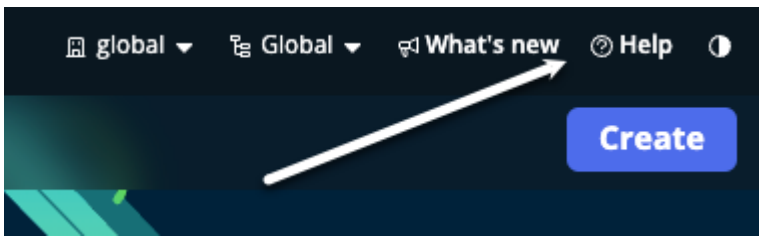
When a guided tour starts automatically, an introduction is displayed. Select **Begin Tour**.



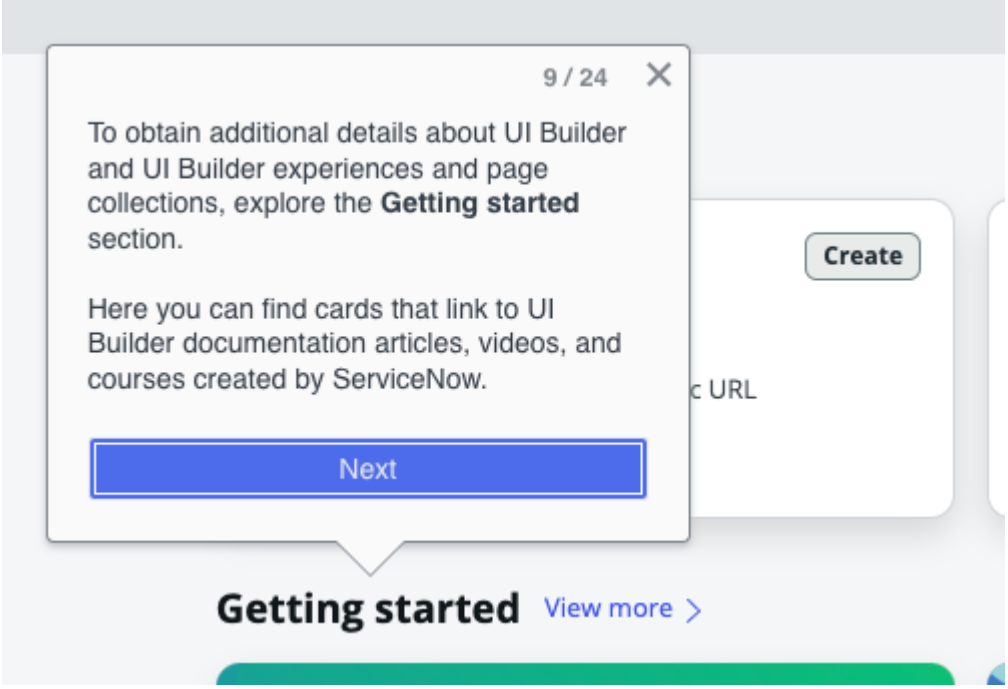
To begin a tour manually from the homepage, navigate to Now Experience Framework > UI Builder and select a tour in the **Getting started** section. If no guided tours appear by default in the section, select **View more** and then select a tour on the **Find relevant resources to get you unstuck** pop-up.



Alternatively, select **Help** and then select a tour on the **Find relevant resources to get you unstuck** pop-up.

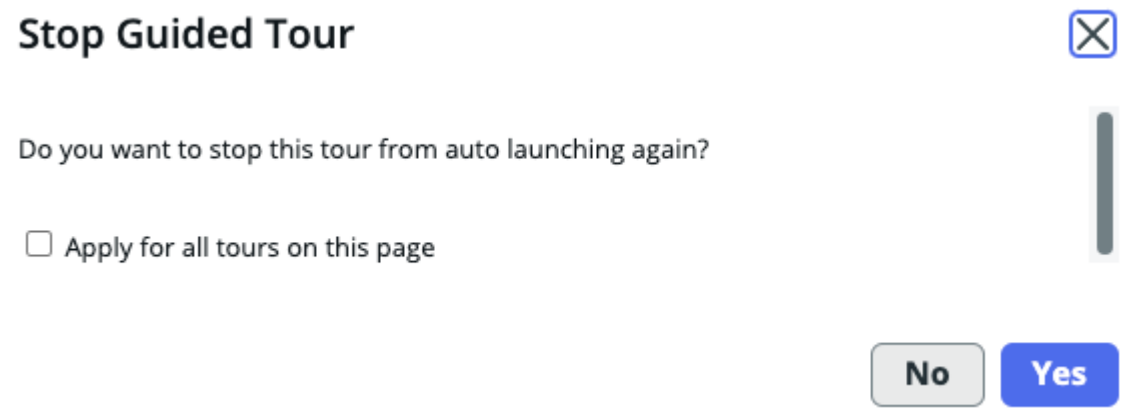


After a tour starts automatically or manually, you're led through a series of steps. Read the text for each step and perform the required actions or select **Next** to continue the tour.



To stop a tour at any time, select the **X**.

Select **Yes** or **No** to stop the tour from auto-launching again. You can also apply your decision to all tours that start on the same page.

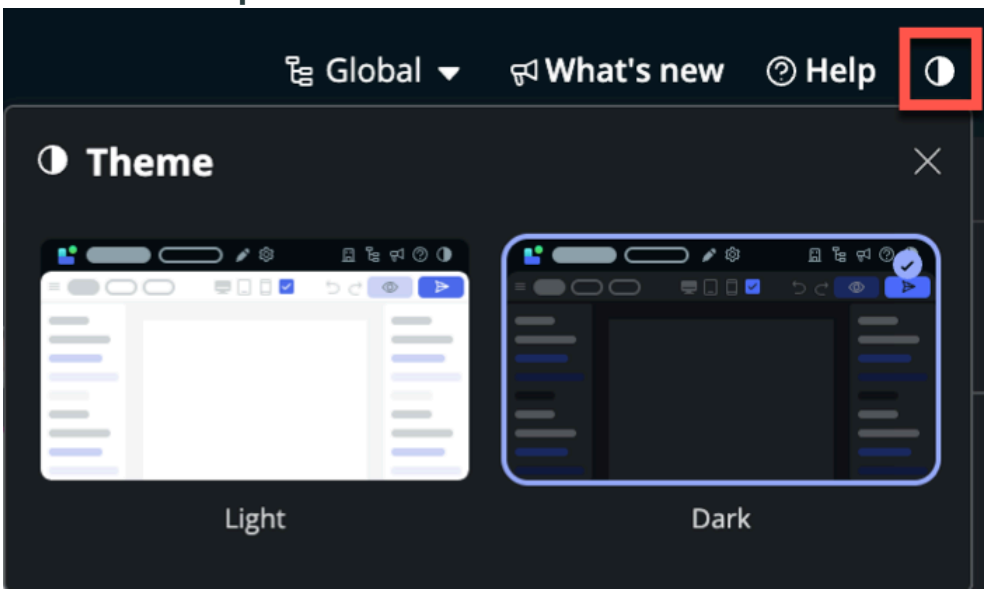


Dark theme in UI Builder

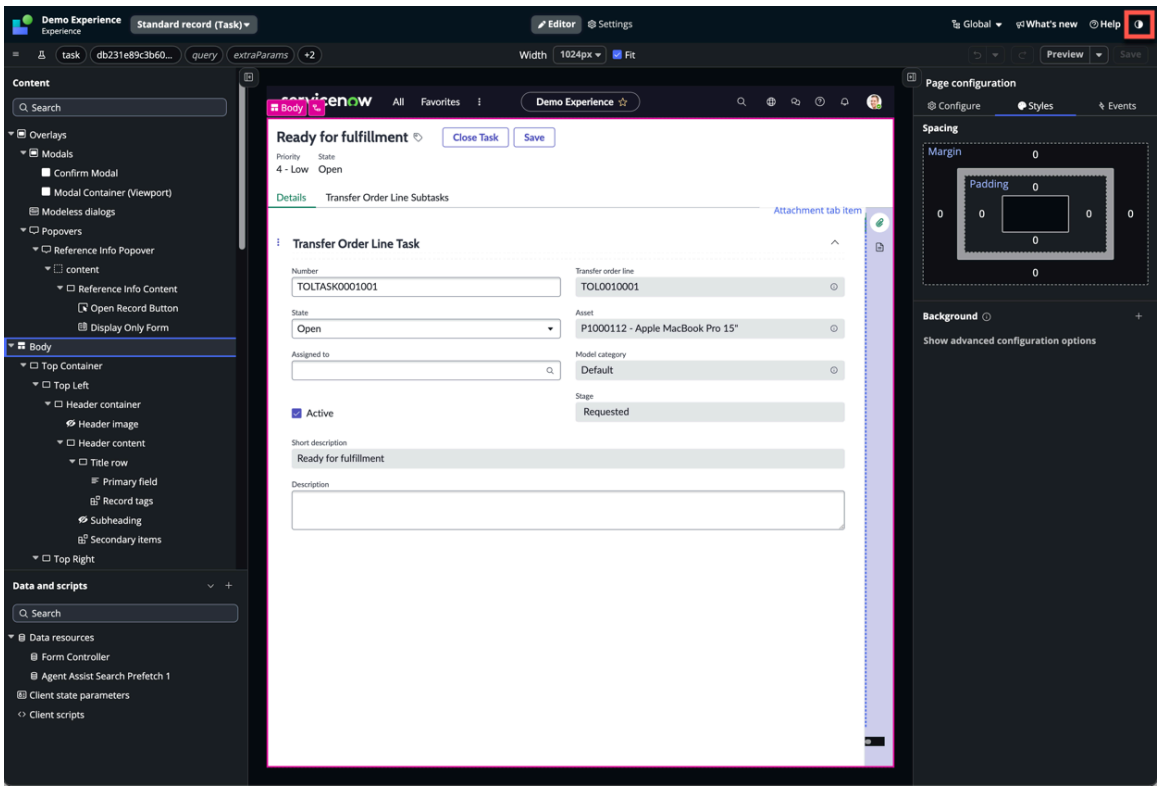
Learn how to switch to the dark theme in UI Builder.

UI Builder includes a dark theme option, offering an eye-friendly alternative to the default light theme. You can enable dark theme by selecting the Choose theme icon ( ) in the banner.

UI Builder theme options



The Dark theme is instantly applied to the UI Builder interface.



Note:
The UI Builder stage uses the theme set in your Platform theme settings. For example, the stage might remain white even when the rest of the interface is dark. To enable UI16 pages to render with the dark theme on the stage, select the **Dark** option in the theme menu of your user preferences. For more information on navigating to the theme menu, see Open the theme menu.

Learn UI Builder by example

Exploring common use cases can be a great way to learn how to use UI Builder. Consider performing each of the tasks in this section in the order presented.

The following use cases are described here.

Create a demo experience to explore UI Builder

An experience in UI Builder is a collection of web pages for users to interact with an application. The experience includes routes, page variants, and the audience and conditions required for each variant, as well as experience settings.

Before you begin

Role required: ui_builder_admin

About this task

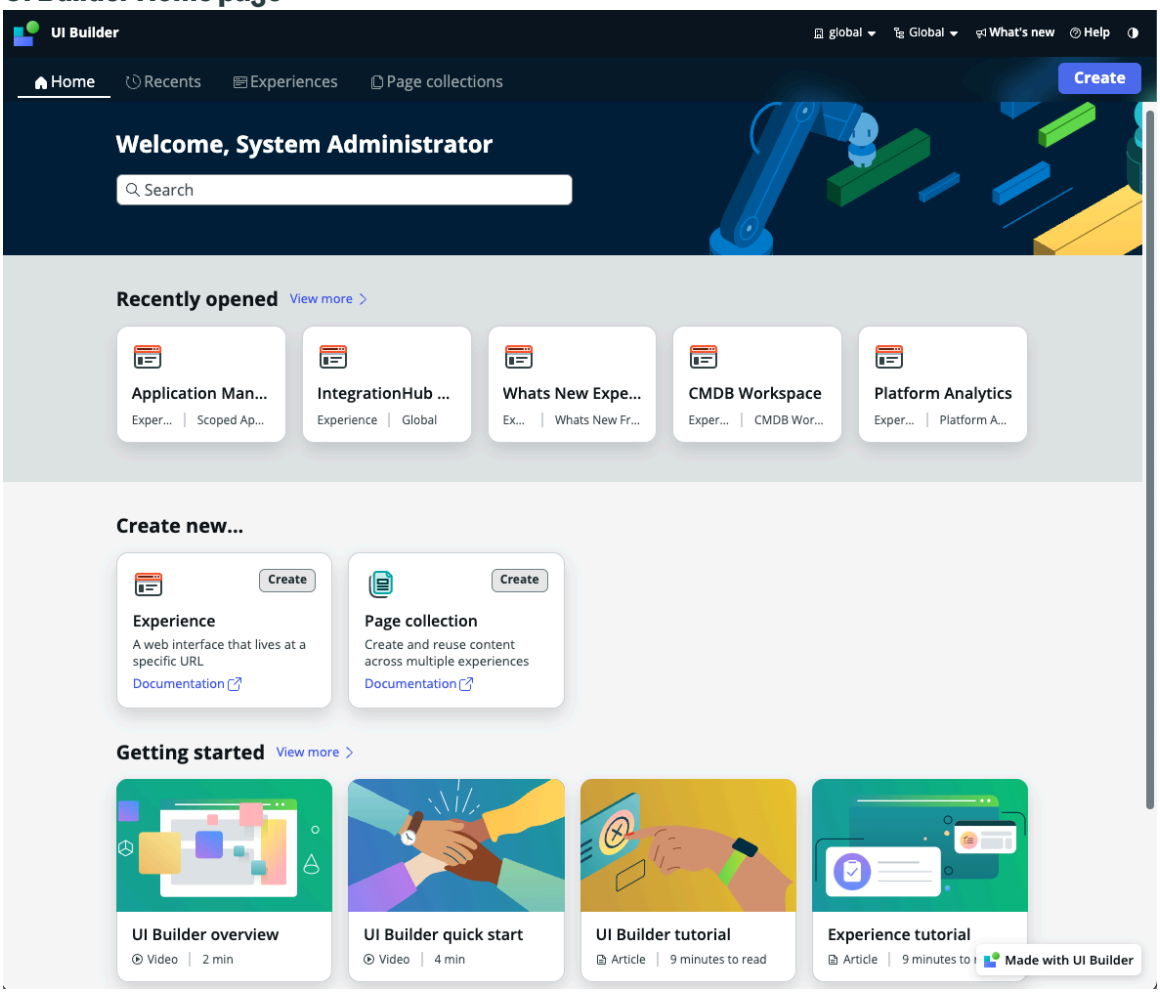
The UI Builder experience view is a central place to view and understand the structure and details of an experience. Use the experience view to see the structure and hierarchy of your experience. You can access UI Builder experience view by selecting an existing experience from the UI Builder home screen or by creating a demo experience, as described here.

Note:
UI Builder is not yet capable of building or configuring ServiceNow base system service portals, such as the Employee Center. For service portals, continue to use the Service Portal Designer.

Procedure

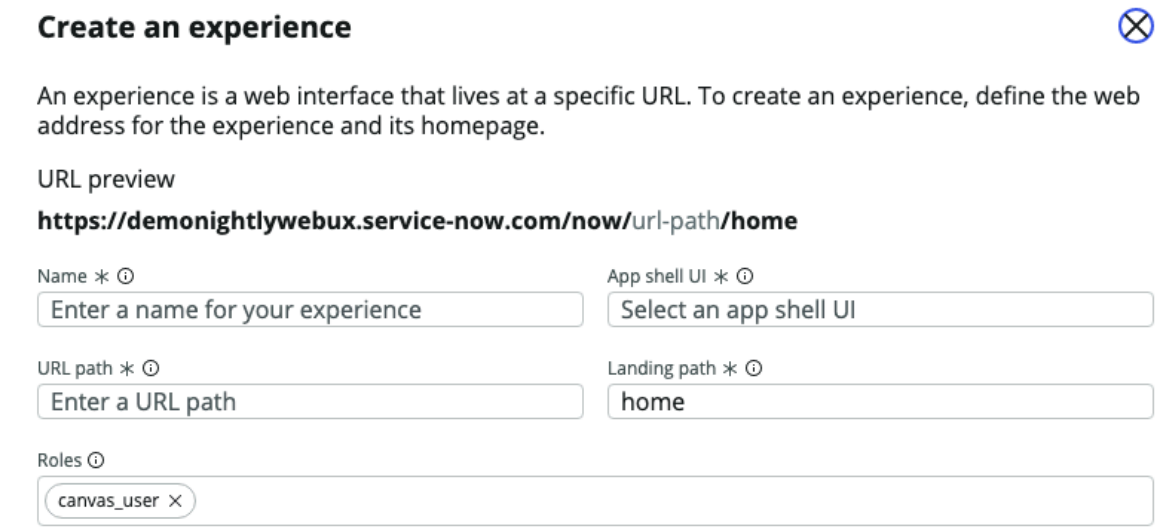
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.

UI Builder Home page



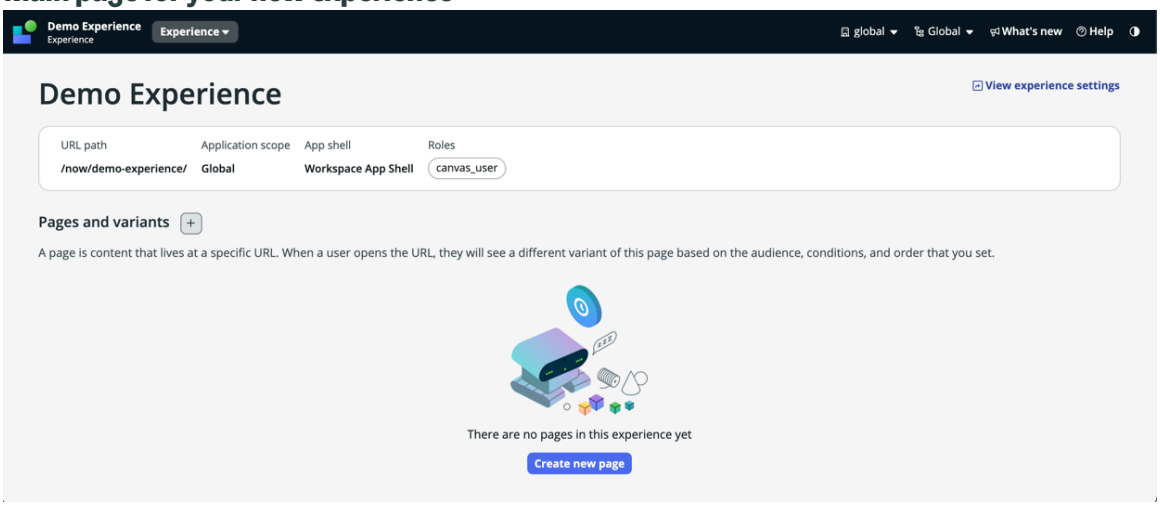
2. From the UI Builder Home page, select **Create**.
3. Select **Experience**

Create an experience dialog box



4. Enter a **Name**; for example, **Demo Experience**.
5. Select an **App shell UI**; for example, **Workspace App Shell**.
6. Select **Create**.
7. Select **Open experience** to view the main page for your experience.

Main page for your new experience



Note:
In addition to the name of your new experience, the screen includes the URL, application scope, admin panel, and the roles of users who can view the experience. Any pages or variants you create for the experience appear in the **Pages and variants** section.

What to do next

Select the **Next topic** link to learn how to create a blank page for this experience.

Create a blank page

After creating a demo experience, you can create a blank page that you can then build on to define what the experience provides to your users.

This video shows you how to perform the following procedure. This video shows you how to create a blank page in a UI Builder experience.

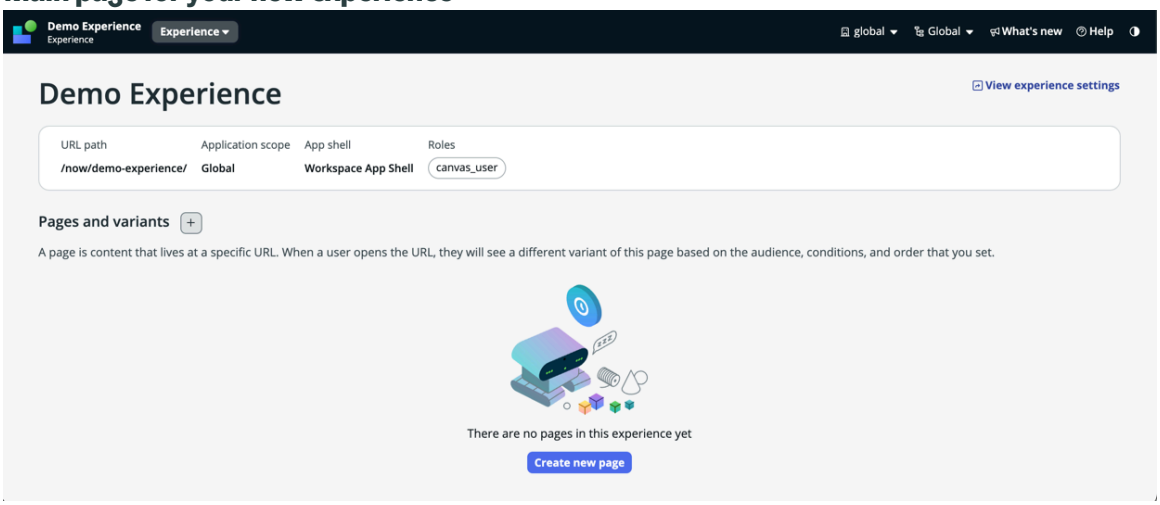
Before you begin

Role required: ui_builder_admin

Procedure

1. If you aren't already viewing the experience you created in the previous procedure, navigate to **All** > **Now Experience Framework** > **UI Builder**, and select the experience you created.

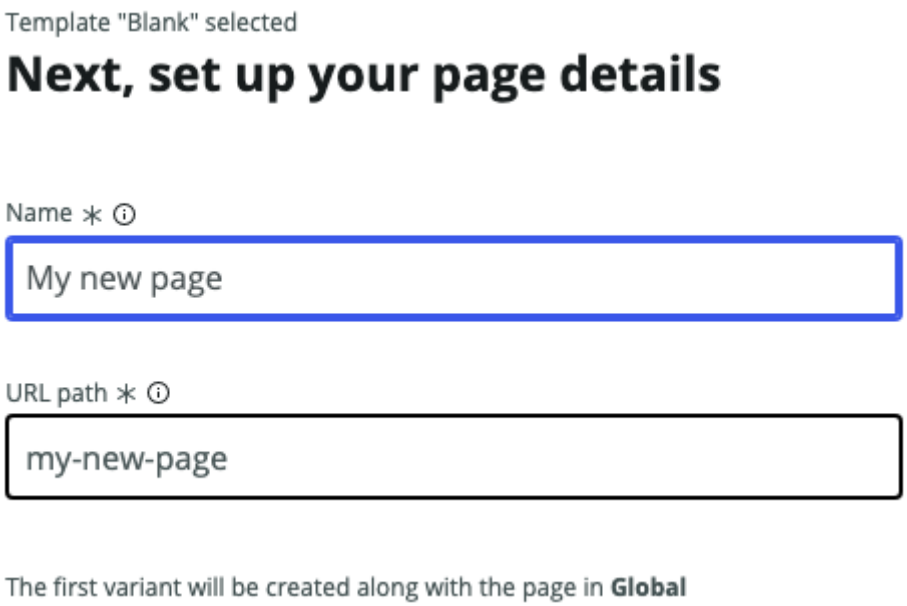
Main page for your new experience



2. From the main page for your experience, either select **Create new page** or select the plus (**+**) sign next to **Pages and variants**.
3. On the **First, select a template** screen, select **Create from scratch instead**.

   There are templates you can use, but we are going to create a page from scratch.

Page details

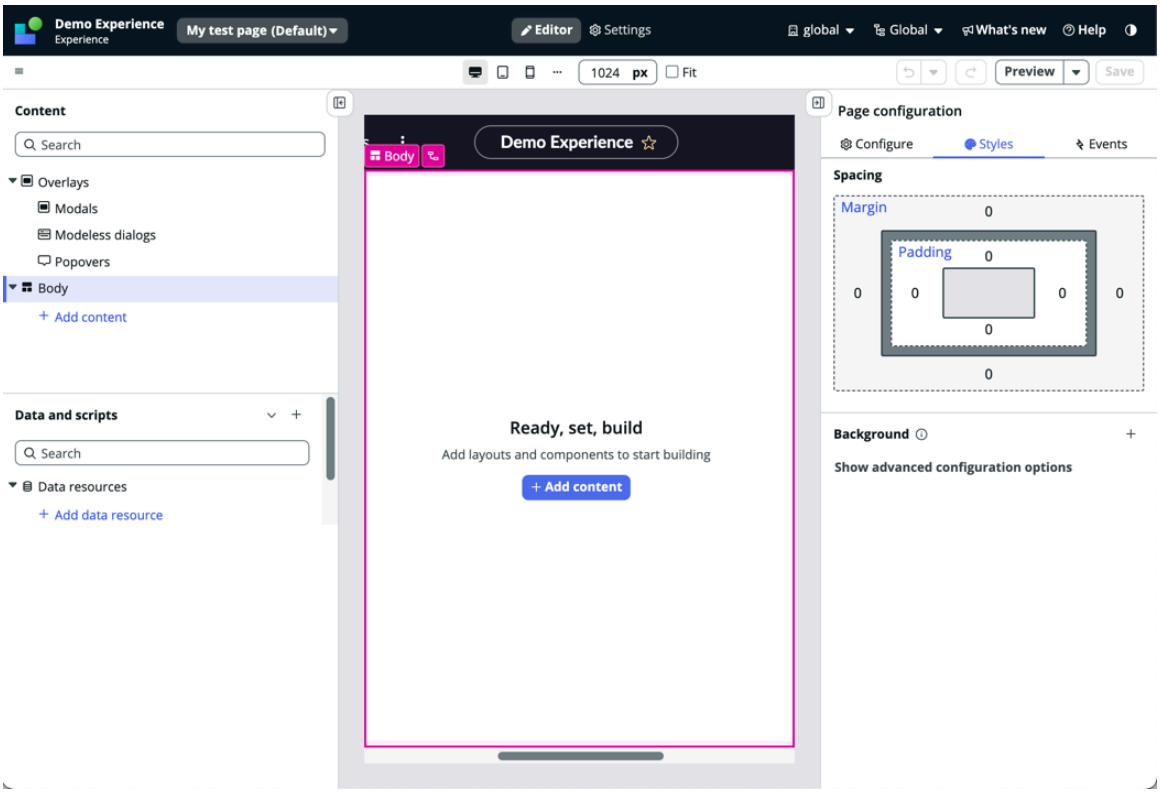


4. In the **Name** field, type **My test page**, and select **Continue**.

Note:
The **URL path** shows the URL that users can navigate to access the page.

5. Select **Looks good** on the next screen.
6. On the **Tell us about your variant** screen, do not make any changes.
7. Select **Continue**.
8. Select the **Build responsive** option (default) for greater control of how the page appears at different screen widths.
9. Select **Create**.
   The visual editor opens. Here, you can begin editing your new page.

UI Builder visual editor



What to do next

Select the **Next topic** link to learn how to create a button that opens a modal.

Create a record page using a template

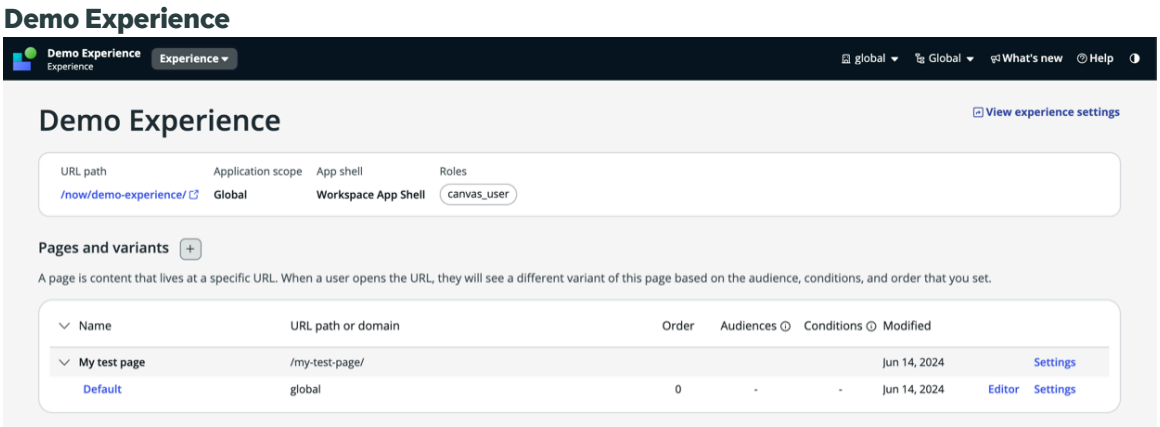
After you've created your demo experience, you can create a record page from a template. A record page shows data from a table.

Before you begin

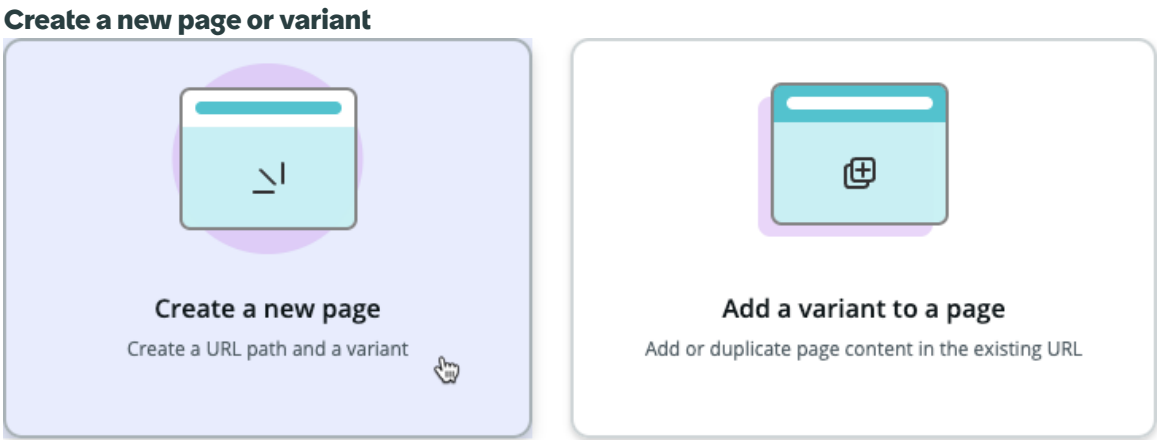
Role required: ui_builder_admin

Procedure

1. Open the main page for your demo experience.

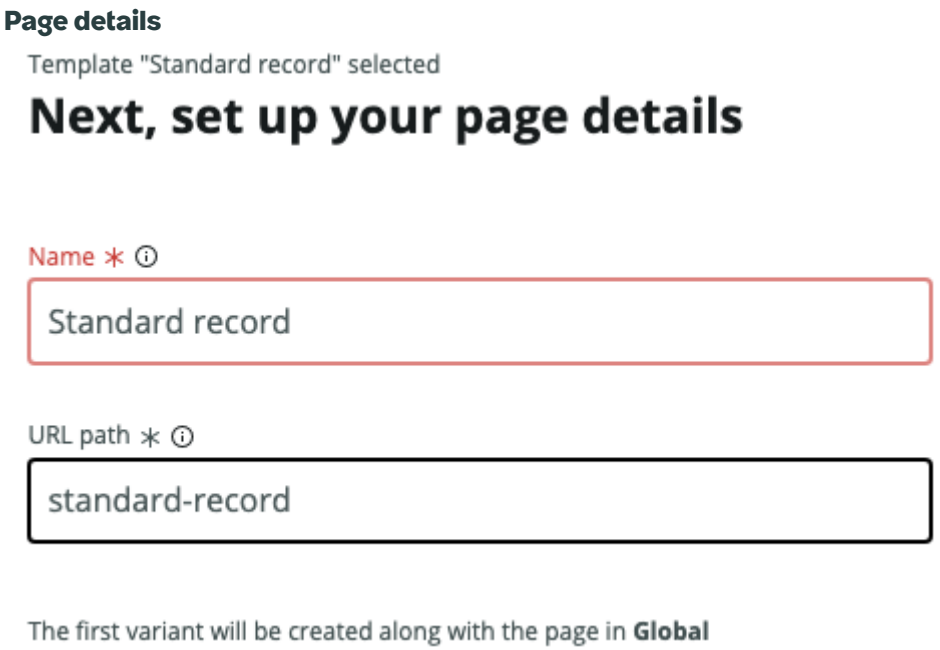


2. From the main page for your experience, select the plus (**+**) sign next to **Pages and variants**.



3. Select **Create a new page** to create a page that resides at a different URL.
4. On the **First, select a template** screen, locate the **Standard record** template and select **Use template**.

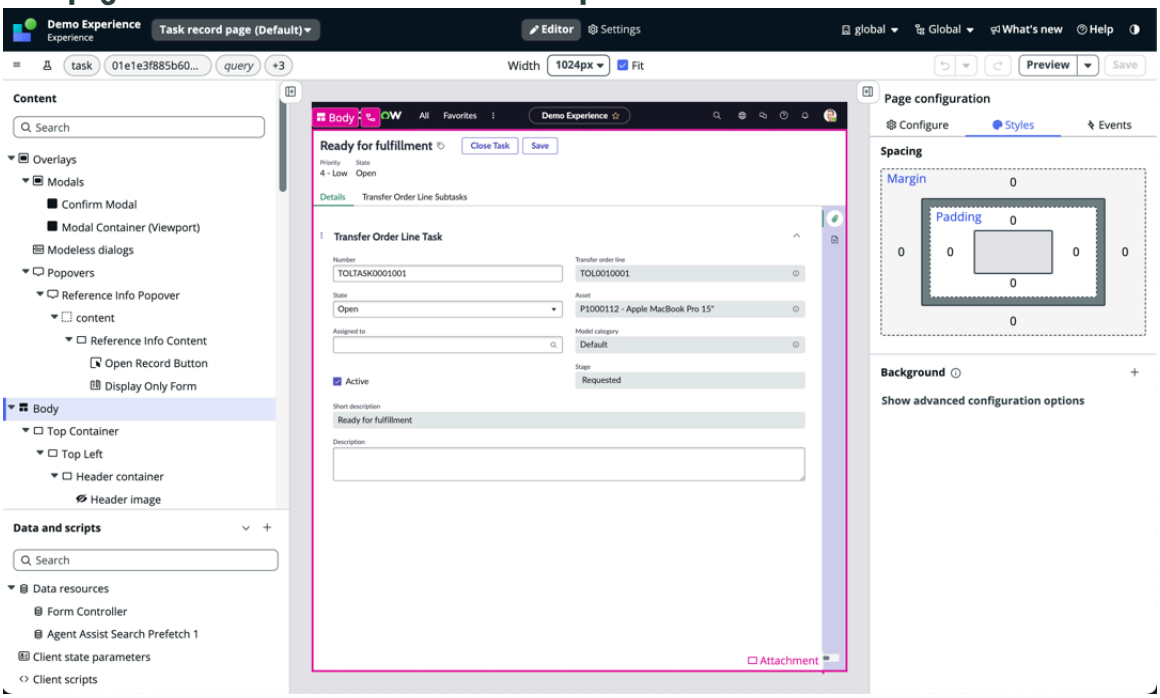
> **Note:**
> Optionally, you could select **Learn more** to read about the template before selecting it.



5. In the **Name** field of the Page details screen, type `Task record page`, and select **Continue**.
6. Select **Looks good** on the next screen.
7. On the **Tell us about your variant** screen, enter a condition to determine when the page is visible.
   a. In the **Parameter** field, select **table**.
   b. In the **Operator** field, select **is**.
   c. In the **Value** field, enter `task`.

   This page is visible to users accessing a record from the Task table.
8. Select **Create**.
   The visual editor opens. Here, you can begin editing your new page.

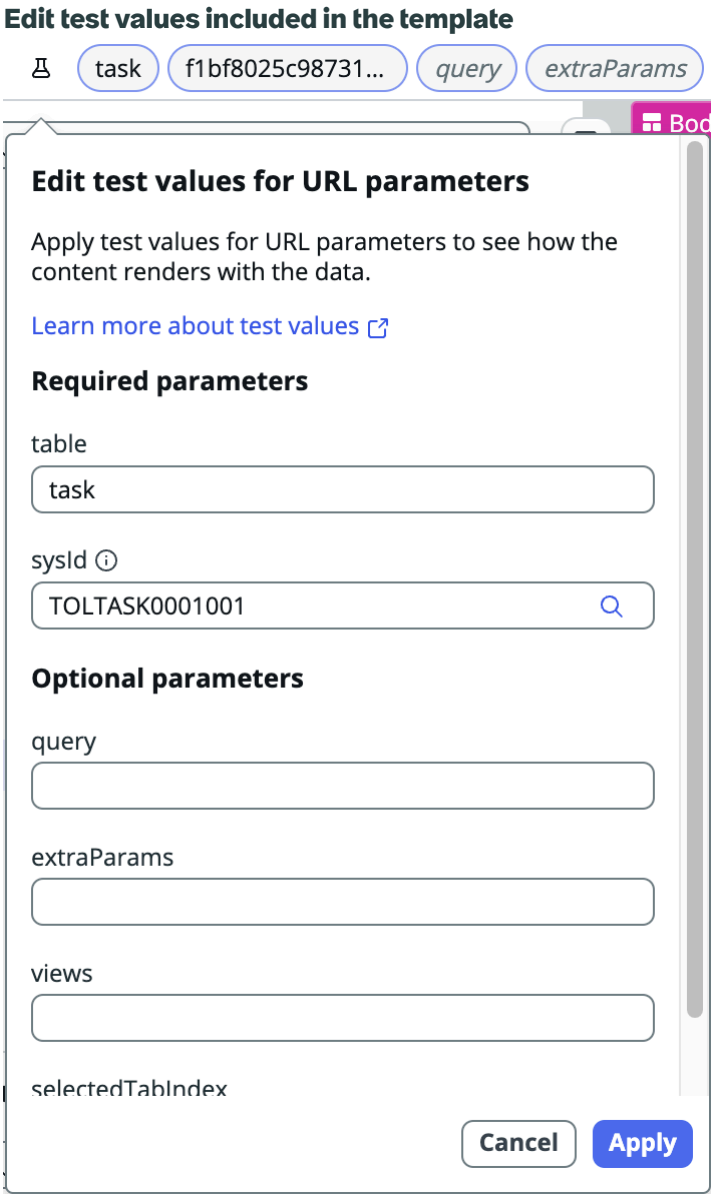
New page created from Standard Record template



Note:

The new page includes LOTS of layout, preconfigured components, data, and modals. Additionally, it includes test values you can modify for your own particular use cases. Using templates can be a significant time-saver when creating new pages.

9. You can select the area above the Page content pane to view information about test values included in the template.



What to do next

Select the **Next topic** link to learn how to define audiences who can view your pages in UI Builder.

Create a button that opens a modal

After you've created your demo experience and added a blank page, you can edit the page variant as needed. For the sake of this demo, you can create a button and a modal, and configure the button to open the modal.

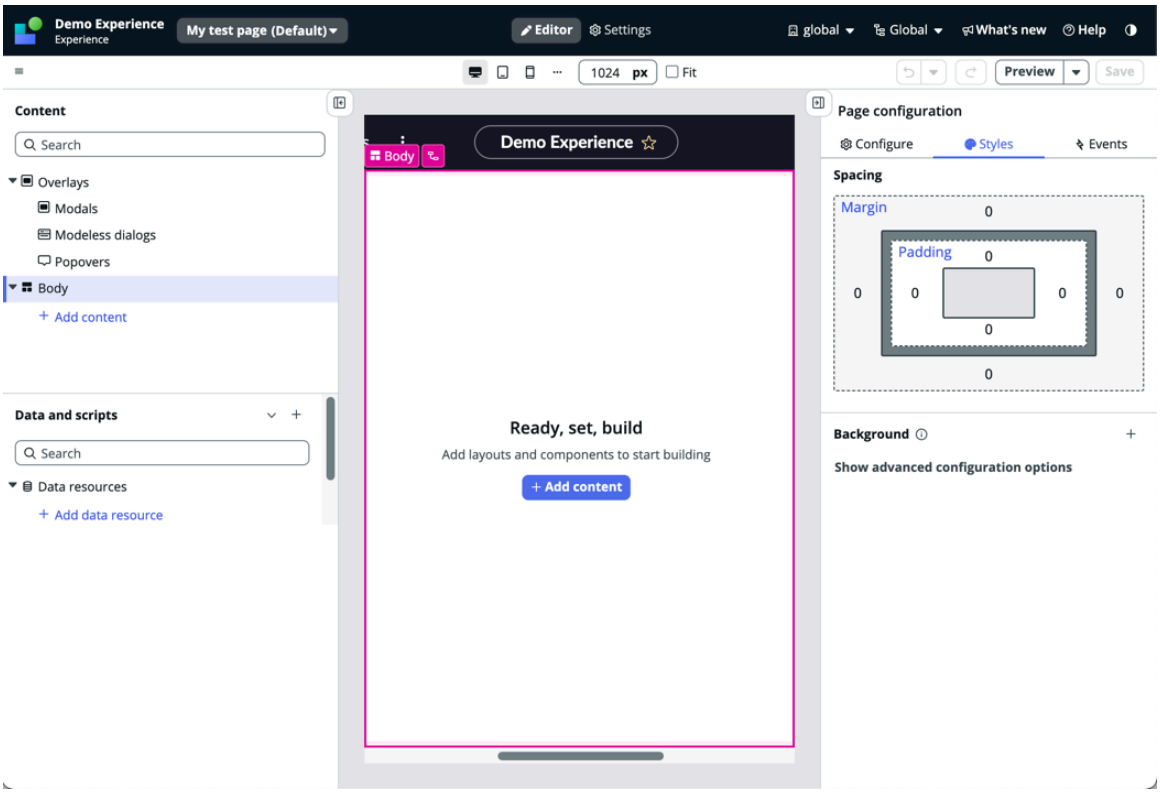
Before you begin

Role required: ui_builder_admin

Procedure

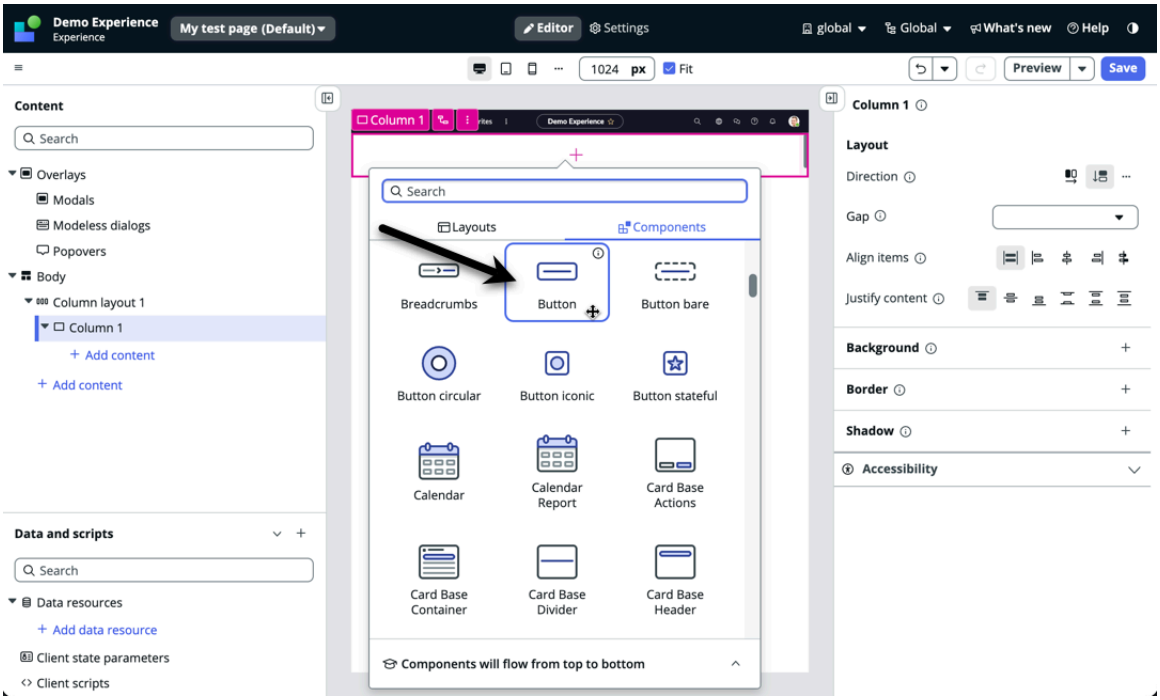
1. Open the UI Builder page for your demo experience.

UI Builder visual editor



2. Click the **+ Add content** button on the stage to open the toolbox.
3. Select a **Single column** layout.
4. Next, click the **+** icon in the column to open the toolbox.
5. Select the **Button** component to add it to the stage.

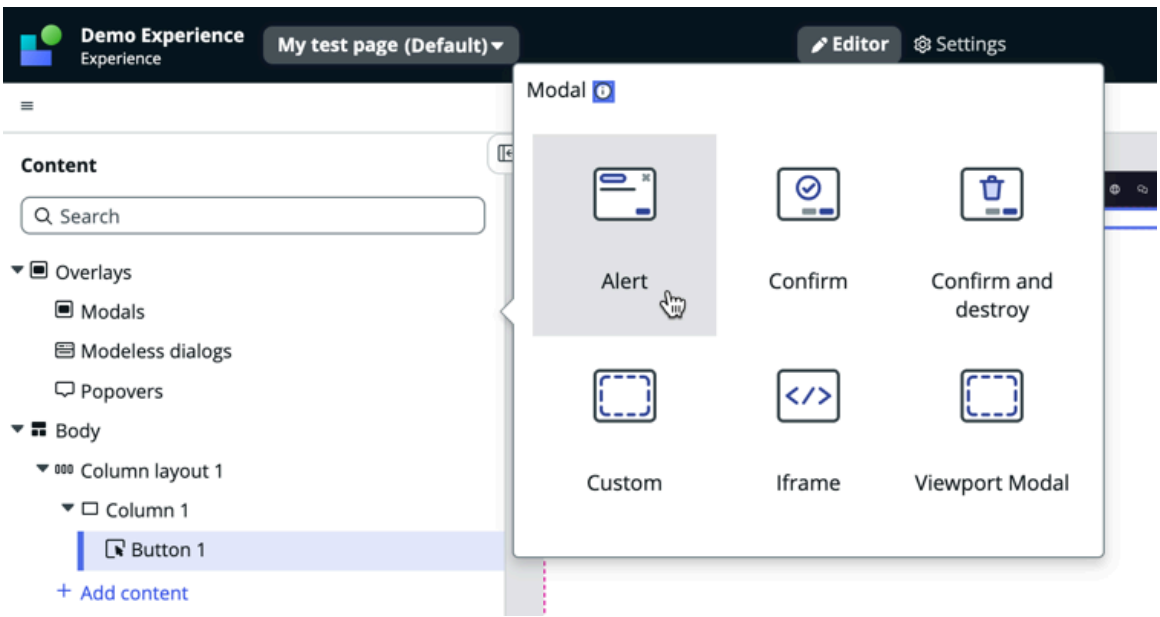
Add a button



Note:
When you have selected the component, the Page configuration pane includes some presets you can use to automatically configure components on compatible pages. For the sake of this exercise, however, you will be configuring the component manually. For more information on presets, see Customize UI Builder pages using components.

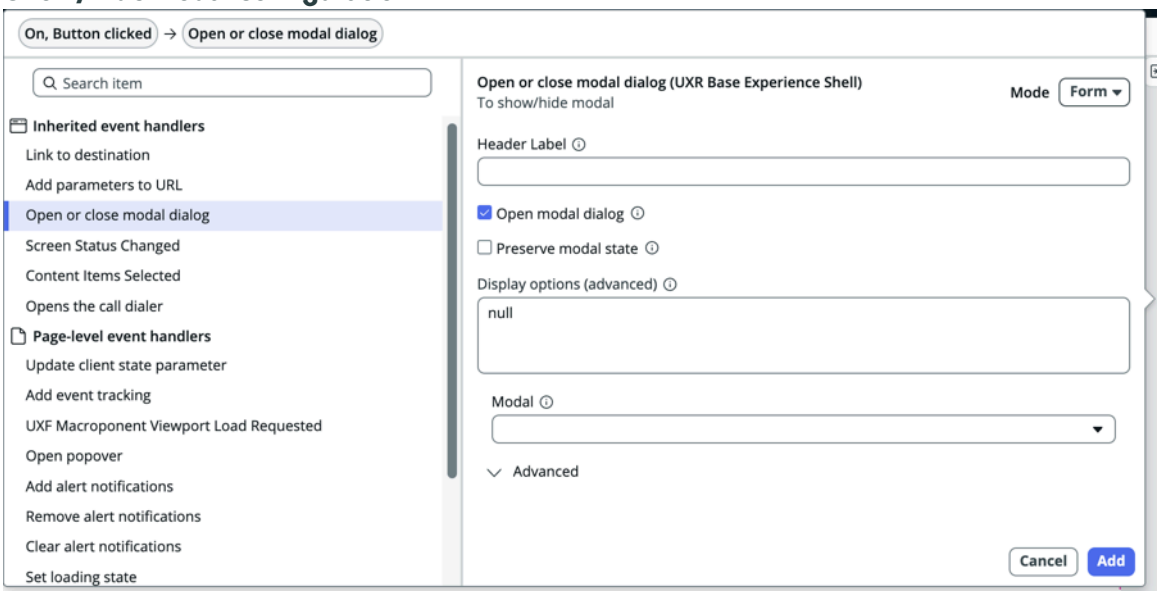
6. In the Page configuration pane, select **Configure the component manually**.
7. In the Page content pane, select **Button 1** and, in the Configuration pane, change the button label to **Open modal**.
8. Select **Save**.
9. In the Page content pane, click the plus icon next to **Modals** and select an **Alert** modal.

Add an Alert modal



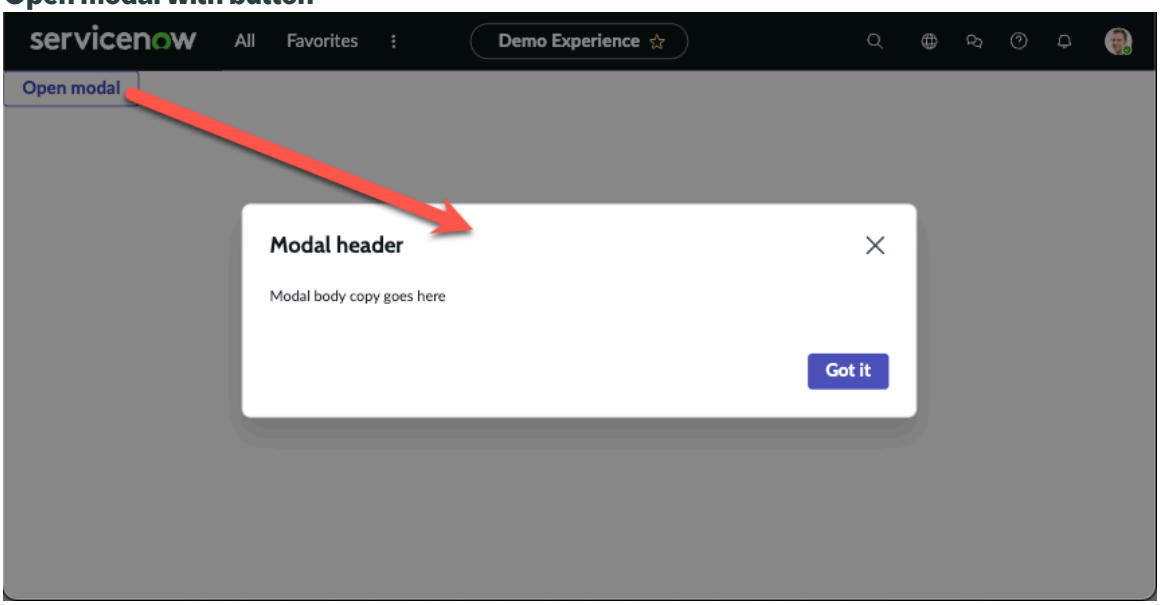
10. Select **Save**.
11. In the Page contents pane, select **Button 1** and, in the Configuration pane, select the **Events** tab.
12. Select **+ Add event handler** and, under **Inherited event handlers**, select **Open or close modal dialog**.

Show/hide modal configuration



13. Activate the **Open modal dialog** and, select **Alert 1** in the **Modal** field, and select **Add**.
14. Select **Save**.
15. Select **Preview**.
16. When the preview opens, select **Open modal**.
    The modal you defined opens.

Open modal with button



17. Select **Got it** in the modal, and then select the browser back button to return to the experience main screen.

What to do next
Select the **Next topic** link to learn how to create a page using a template.

Define an audience for your variant

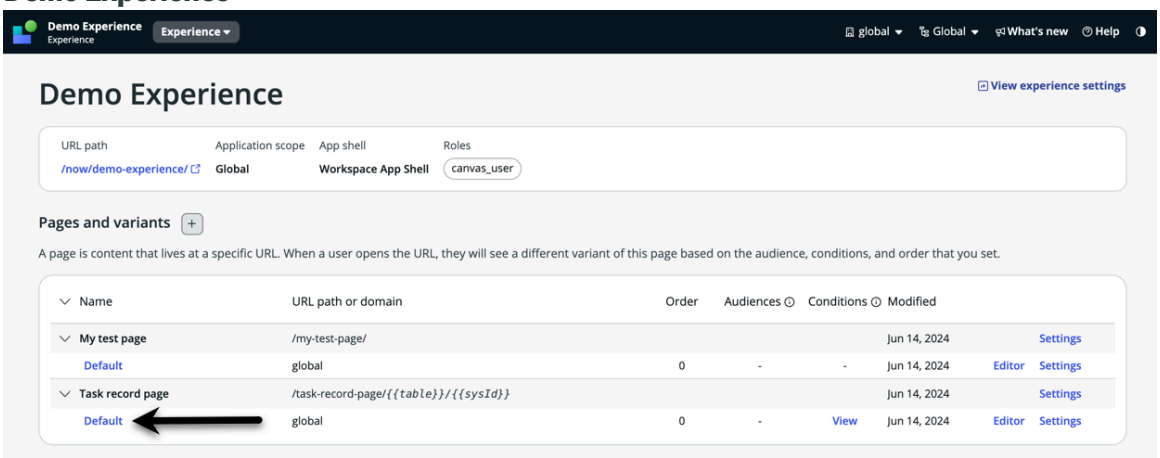
An audience represents a group of users in your organization. You can define who can access this page variant by adding one or more predefined audiences.

Before you begin
Role required: ui_builder_admin

About this task
In the previous procedure, you created a page variant that can be viewed by anyone accessing a record from the Task table. For this procedure, you will duplicate the variant and configure it so that it is accessible only to audiences with the Admin role.

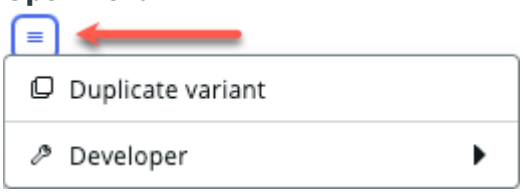
Procedure
1. Open the main page for your demo experience.
2. Select the experience you created, and select **Default**.

Demo Experience



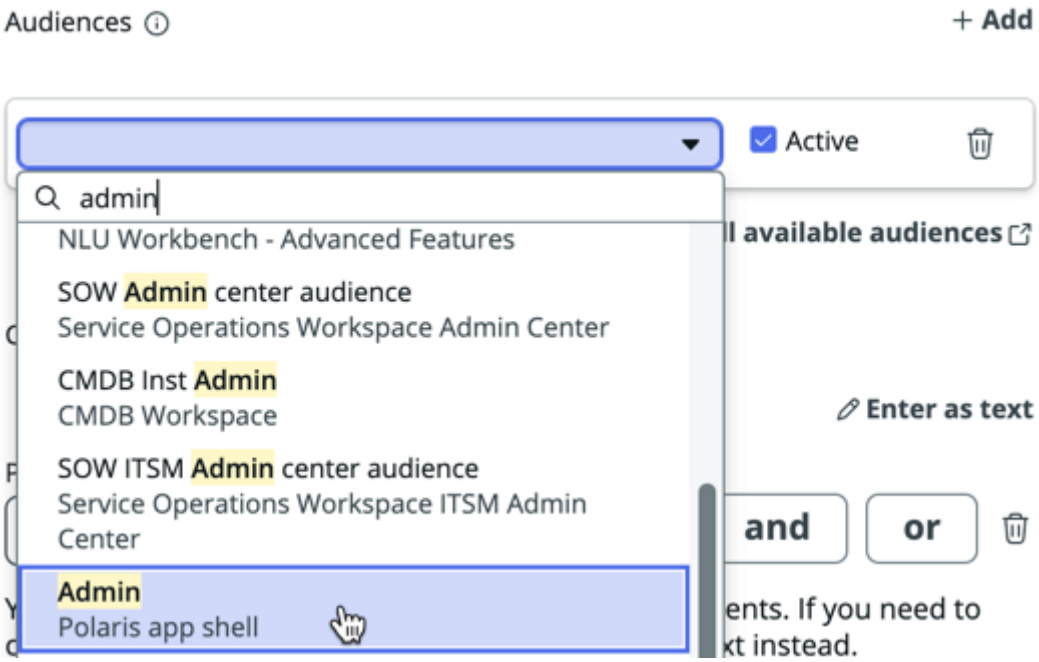
3. Select the **Open menu** icon.

Open menu



4. Select **Duplicate variant**.
5. On the **Tell us about your variant** screen, enter **Admin only** in the **Name** field.
6. Select **+ Add** next to **Audiences**, and select the **Admin** audience.

Select the Admin audience



7. Select **Create**.
   The variant is duplicated and only users with the Admin role can view this page.

What to do next

Select the **Next topic** link to learn how to apply conditions to the variant so that the variant is visible only when the defined conditions are met.

Define conditions for your variant

You can define conditions to determine when a page variant is shown. The conditions are based on setting an order, and declaring the criteria that must be met for the page variant to display.

This video shows you how to perform the following procedure. This video shows you how to define conditions for your page variant in a UI Builder experience.

Before you begin

Role required: ui_builder_admin

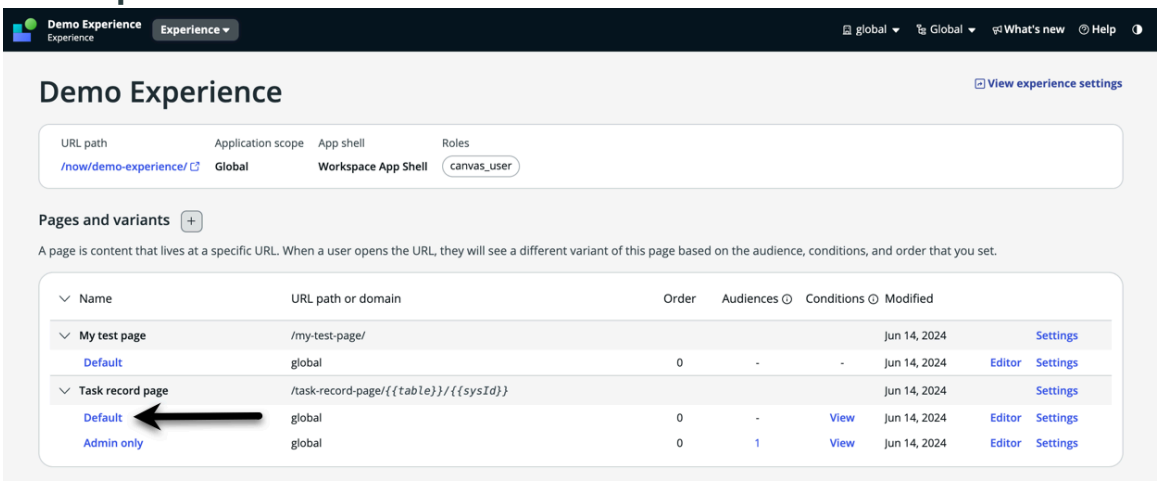
About this task

If you have multiple page variants that all have the same conditions, the variants go by the order setting.

Procedure

1. Open the main page for your demo experience.
2. Select the experience you created, and select **Default**.

Demo Experience



3. On the Default variant under the **All users record page**, select the **Menu** icon (⋮), and select **Duplicate variant**.
4. On the **Tell us about your variant** screen, enter **Incident record page** in the **Name** field.
5. Since the intent of this task is to restrict this page to users who are opening a record in the Incident table, enter the following under Conditions:

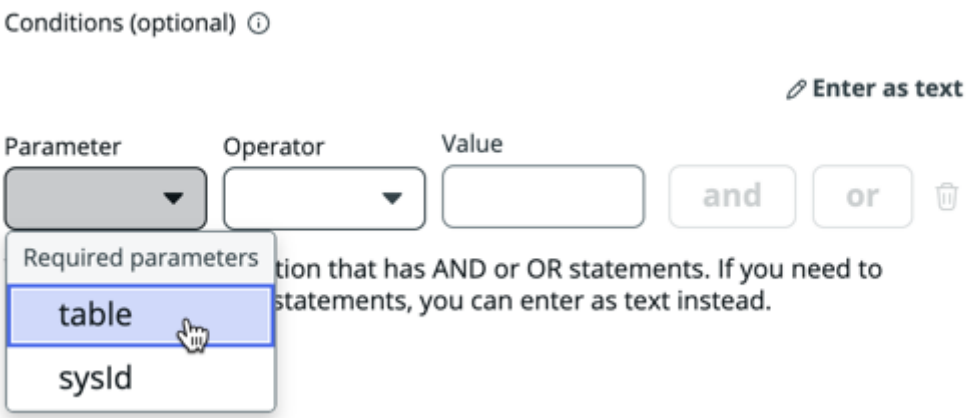
   a. In the **Parameter** field, select **table**.

   b. In the **Operator** field, select **is**.

   c. In the **Value** field, replace the text with `incident`.

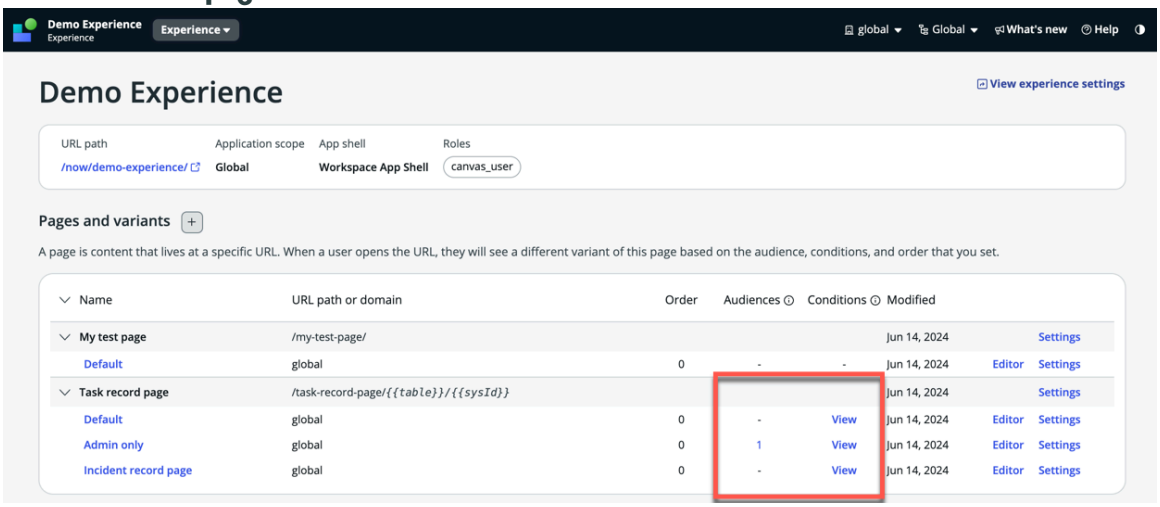
   When you created this page earlier in the series, you set this condition to the Task table. Now, you are configuring the page to display only to users accessing a record from the Incident table.

Condition fields



6. Select **Create**.

Incident record page



Note:
You can view the structure of your pages and variants in this experience. The **Conditions** column shows a **View** link for each page. You can select **View** to see the condition for that variant (that is, table=incident). The **Audiences** column for the Admin only variant shows a 1. You can select the **1** to view the role required to view that variant.

Customize forms within a form component

Customize your form components by accessing Form Builder in UI Builder.

Before you begin

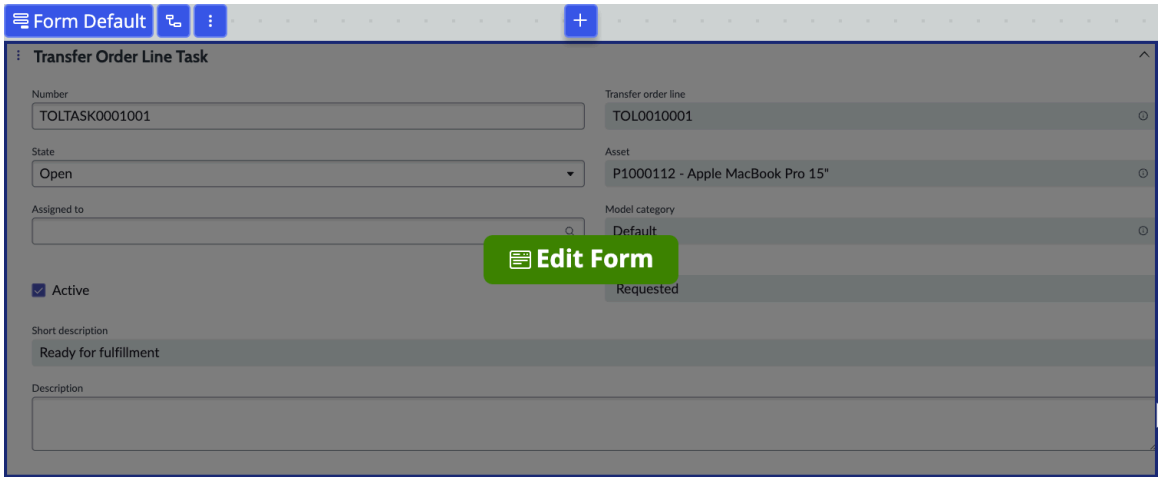
Role required: admin

About this task

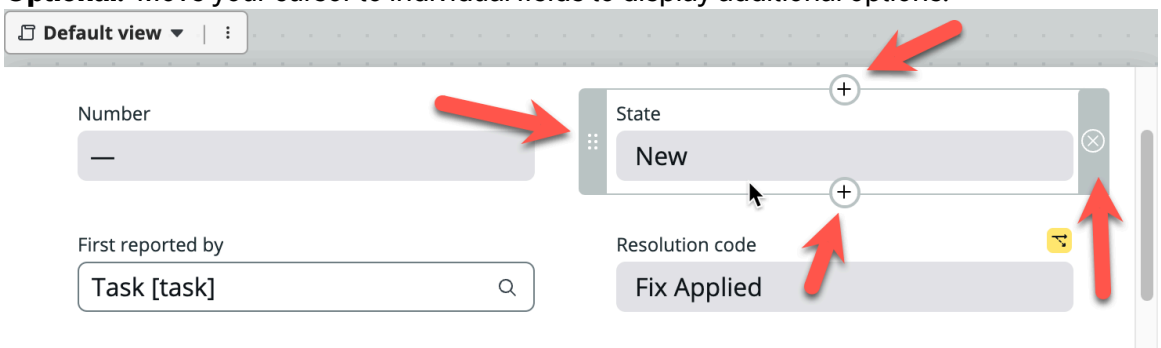
You can edit form components without leaving UI Builder. Access Form Builder from within a form component on the UI Builder stage. After you save the form, your edits remain, and anyone who views the form sees the modified version. Changes made in Form Builder are reflected on the stage.

Procedure

1. Add a form component to your page.
   a. In the content tree, select **+ Add content**.
   b. Select **Form**.
2. On the stage, move your cursor to the form component to display the **Edit Form** button.



3. Select the **Edit Form** button.
   Form Builder opens in a full-screen modal.
4. **Optional:** Move your cursor to individual fields to display additional options.



5. **Optional:** Insert fields by moving your cursor to the **+** button, which displays the **+ Add** button, then selecting **+ Add**.
   You can also drag additional fields onto the form from the **Fields** column.

   Example
   For example, you can add the **Due date** field below the **Configuration item** field, then select **Save** and **Preview** to save and preview the form.
6. **Optional:** Move a field by dragging the edge of a field to another place in the form and then selecting **Save**.

   Example
   For example, select the **State** field and place it below the **Duplicate of** field, then select **Save**.
7. **Optional:** Delete a field by selecting the **X** button on the field.
8. Select **Save**.
9. Close Form Builder to see your edits appear on the stage.

What to do next

You can enhance the functionality of a custom form by configuring additional features. For more information, see Forms in Table Builder.

Learn about audiences

Learn how to apply the correct audiences to your UI Builder pages.

Audiences

Understanding your audiences in UI Builder is an important part of creating pages. The audience defines who can see your pages. You create pages for targeted experiences tailored to audiences and roles such as agents and managers. For example, you may want to create a page for agents to solve issues for your employees. You want to ensure that only people who have the agent role can see the page.

Audiences are generally made of allow/deny lists based on role and domain. They can also target the following:

- Role
- Group
- User

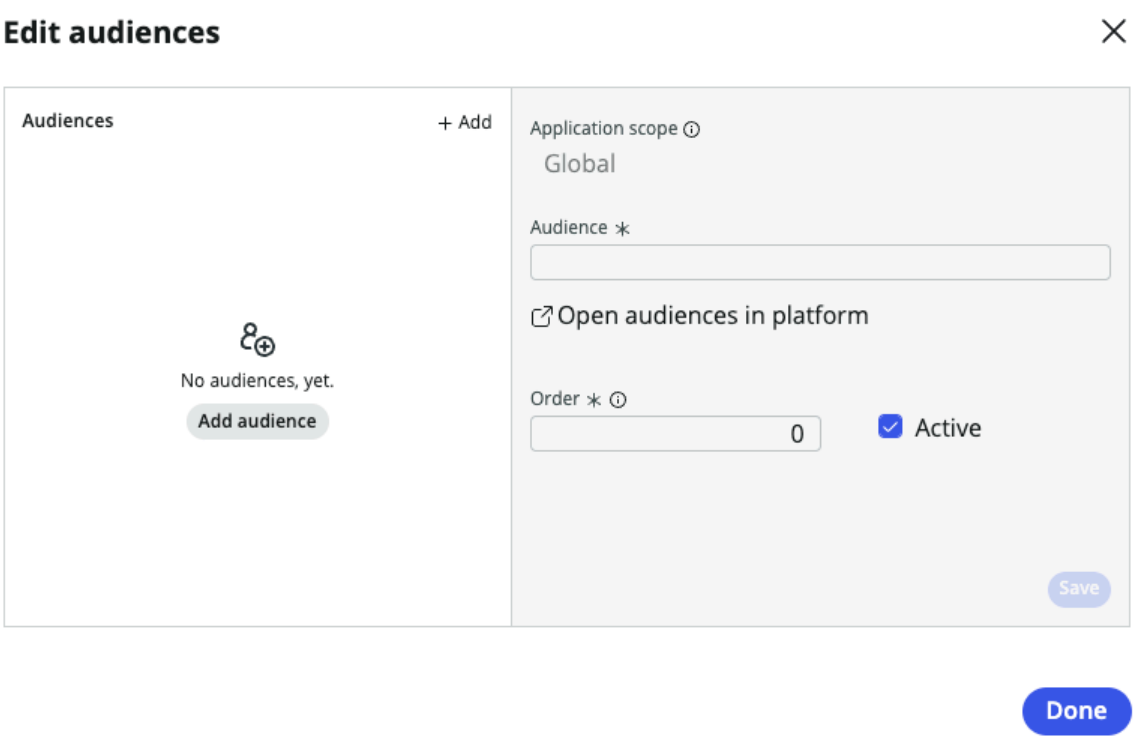
- Company
- Department
- Location
- Script

You can set audiences to fit a specific role based on one or more criteria. For example, you could create an audience for an ITSM user in Europe who is not a manager.

The *glide.ux.user_criteria_enabled* property needs to be set to **true** to configure access for users based on role, department, group, location, or company. See Enable the user criteria property, for more information.

Set an audience in UI Builder when you create your page or page variant. You can also set the priority of the audience record. The lower the number the higher the priority. Ensure the **Active** check box is selected to make this page active.

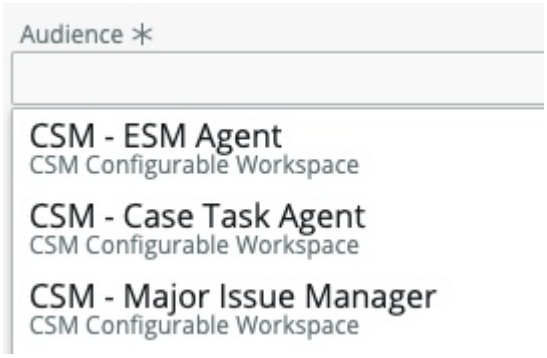
Add audiences modal



If you do not see an audience that you need, you can click **Open audiences in platform** to define an audience in the ServiceNow AI Platform®.

- Choosing an audience from the list in the **Audience** field.

Audience list



- Selecting **Open audiences in platform** to edit or create an audience record in the ServiceNow AI Platform®.
- If you have multiple audiences, define the **Order** for each audience record. The order defines the importance of each audience record. For example, a CSM Manager could have a higher priority than a CSM Consumer Agent. To give higher priority to an audience, enter a lower number.
- Ensuring the **Active** check box is selected to make this page active.

Learn about security and roles

Set up the security and roles for your UI Builder instance.

Security and roles in UI Builder are controlled through your application scope, domain separation, and protection policy settings.

Roles

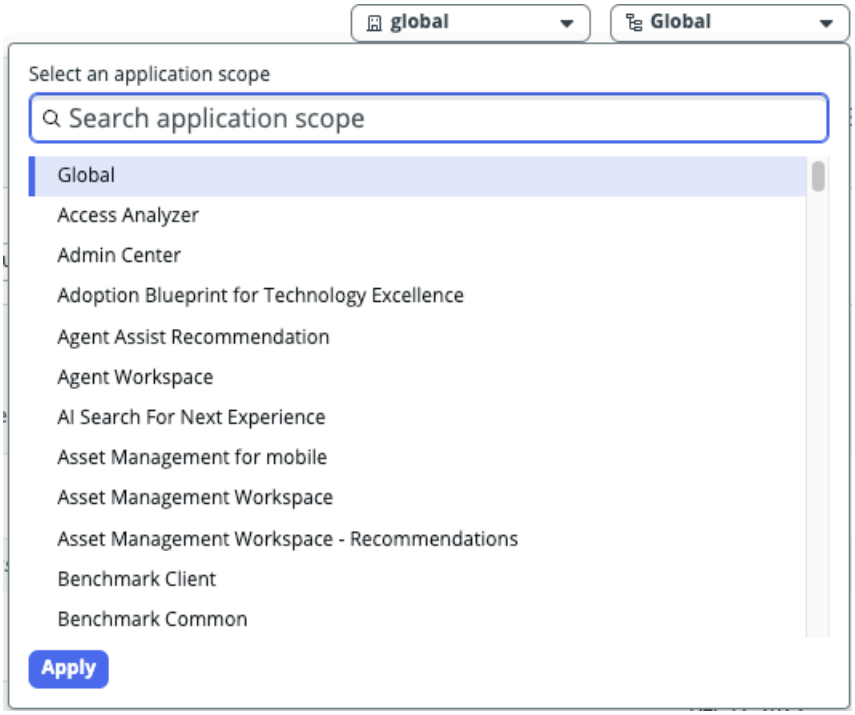
Roles control access to features and capabilities in UI Builder. The admin role provides access to all features and capabilities. After access has been granted to a role, all the groups or users assigned to the role are granted the access. Roles can contain other roles, and any access granted to a role is granted to any role that contains it. For more information, see Managing roles.

Application scope

Application scoping protects applications by identifying and restricting access to application files and data. Administrators can specify what parts of an application are accessible to other applications, which helps to protect data and application files. In UI Builder, System administrators and developers set application scope when creating a page. Note, you cannot change the application scope after creating the page, so choose your scope carefully.

Changing the scope in UI Builder also changes the scope in the ServiceNow AI Platform®, and vice versa.

When creating a page, it's important for admins and developers to be aware of the scope they are in for the workspace or portal experience. Choose the correct application scope for your experience. The scope picker is to the right of the URL field. The scope defaults to the scope that the user is currently in within the ServiceNow AI Platform®.



If you change to a different scope while in a page, you're notified that you are in a different application scope from the one the page was created in. For more information, see Application scope.

Delegated developers for UI Builder

If you have the application-specific admin role or the system-level admin role, you can delegate application development in ServiceNow® Studio to designated developers at the UI Builder application level.

Protection policy

A protection policy prevents anyone from modifying and/or copying an application file or its related record. A protection policy is typically used when the author of an application is different than the company that uses the application. UI Builder notifies you if you try to modify a protected record. For more information, see Application file protection policy.

Learn about domain separation

Domain separation is supported for UI Builder . Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Standard

- Includes all aspects of **Basic** level support.
- Application properties are domain-aware as needed.
- Business logic: The service provider (SP) creates or modifies processes per customer. The use cases reflect proper use of the application by multiple SP customers in a single instance.
- The instance owner must configure the minimum viable product (MVP) business logic and data parameters per tenant as expected for the specific application.

Sample use case: An admin must be able to make comments required when a record closes for one tenant, but not for another.

For more information on support levels, see Application support for domain separation.

Overview

UI Builder is a web user interface builder. UI Builder enables developers to build new pages or customize existing pages for web-based workspace experiences using Next Experience Components and custom web components. In addition, UI Builder supports Domain Separation, which is the ServiceNow® instance-wide multi-tenant architecture.

Enable developers or dashboard builders in domain-separated environments to safely create UI application screens or dashboards while in the same browser window. Domain Separation in UI Builder works similarly to application scope to help administrators safely create or edit in a multi-tenant environment.

It's important to understand a key principle to maintaining a stable, healthy, and scalable ServiceNow® instance, where Domain Separation is installed.The primary principle is standardization. Standardization means a common configuration that most the instance operates by. When an instance has hundreds or thousands of domains, managing them successfully requires rigorous governance. Domain-specific configurations should be used only if they are deemed necessary by the instance owners. Generally, most instances should follow the common instance configuration. Doing so provides a more uniform experience across the instance. It also lets instance owners minimize code sprawl that slows the adoption of new ServiceNow® features included as part of release upgrades.

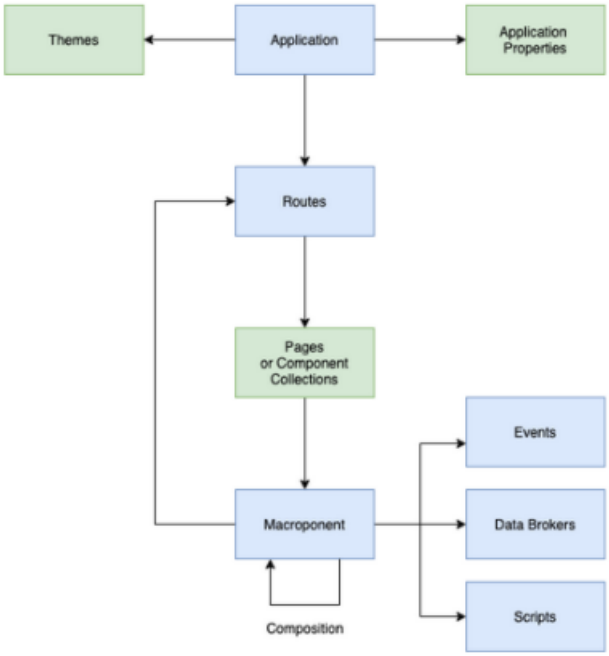
How domain separation works in UI Builder

Domain separation in UI Builder works similarly to application scope to help administrators safely create or edit in a multi-tenant environment.

UI Builder is compromised of a framework of interlocked components that you use to create web-based workspaces, dashboards, or portals. While the application supports domain separation, it does not mean every component or table is domain separated, which is important for instance owners to understand.

If the current domain does not match the domain of the variant or dashboard, the record is read-only. If a user has access to the domain, they can choose to switch their domain to the domain of the record. Alternatively, users can edit the record. Editing the record temporarily forces the user session into that record's domain. They can then make edits without fear of accidentally creating an override.

The following diagram shows what is (in green) and is not (in blue) domain separated in UI Builder.



Not shown in the diagram are viewports, declarative actions, and screen applicabilities, which are domain supported as process.

Data and Process/UI separation are important when considering domain separation architecture. UI Builder fully supports data and process/UI separation, and any data (records) displayed in the web-based workspace, dashboard, or portal experiences.

For example, a change request that belongs to the domain of Acme only shows for users who have access to the domain of Acme in an experience built using UI Builder. Conversely, if an application does not support data separation, its records won't be domain separated by the workspace or portal experience.

Process/UI separation tables that form the underpinning framework in UI Builder are process separated, and a sys_override column exists on those tables. For example, if a page is created in Global, any changes to the logic created and saved in a sub domain results in an override.

For items that are not domain separated, any change to the logic globally affects any page or dashboard that references its content. Understanding domain separation is critical when interacting with these elements.

Domain Selection menu, messaging, and managing overrides

When designing a workspace, dashboard, or portal experience using the UI Builder (including Dashboard Builder), a system administrator or ui_builder_admin has access to a **Domain Selection** menu in UI Builder. A system administrator or ui_builder_admin should switch to the proper domain prior to creating, editing, or overriding a variant or dashboard page.

By default, the ui_builder_admin role does not have access to the **Domain Selection** menu. The **Domain Selection** menu must be coupled with a role that grants access, such as ITIL, or it can be added via system property. For more information, see Enable domain selection menus in Core UI.

In addition, the **Domain Selection** menu also shows **Expand/Collapse Domain Scope**, that is displayed while the system administrator or ui_builder_admin is in Global. Select **Expand** to show any variant or dashboard that has been overridden, or exists as a standalone in a sub domain. Select **Collapse** to only show variants or dashboards created in Global.

Lastly, domain hierarchy is available from the **Domain Selection** menu. For deep-domain hierarchies, the user may have to collapse the branches of the domain hierarchy to physically select the domain. In these environments, perform a search to find the domain.

UI Builder has governance controls for editing and overriding variants or dashboards, similar to the way application scope is handled. Both application scope and domain scope are handled concurrently in UI Builder.

For example, if a variant was created in Global, but the current domain of the system administrator is set to Acme, then that variant is read-only. As long as that screen is not in a private scope that prevents editing, the system administrator or ui_builder_admin have two options. They can temporarily transact into the global domain if they have access to Global. Or, they can create an override.

You can edit the domain separation to make quick changes to the variant or dashboard and its content. When you edit the domain, you temporarily transact into the same domain scope as the variant or dashboard. Going into the same scope prevents accidental overrides when modifying certain settings such as Name, Order, Event Mappings, Page Definition configurations) tied to the variant. While in edit mode, not all settings are available in page management. For full capabilities, switch into the correct domain prior to editing the record.

Create Override allows a system administrator or ui_builder_admin to create an override of an existing variant or dashboard. Create an override of a variant or dashboard to perform an extensive copy of the page definition content, minus screen conditions and audiences in the user's currently selected domain. The sys_override column is then updated appropriately.

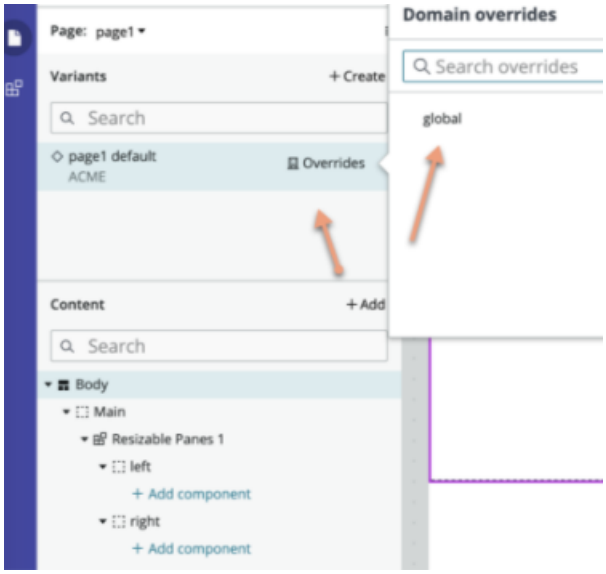
Viewports, which are variants in and of themselves, are domain separated, and are typically nested inside page definition content. Some viewports may not copy over. For example, a viewport (displayed as a tab set) that was created as an override in a domain of a Global viewport would not be carried in the page definition content during the override creation process.

As screen conditions and audiences may be specific to a domain, this content is not carried over during the override creation process. A screen prompts the system administrator or ui_builder_admin to create screen conditions and audiences.

A user cannot create an override of a variant or dashboard in Global if the item exists in a sub domain, or if an override exists for that variant or dashboard in the same sub domain.

After the override and the conditions and audiences are set, the content and configurations can be configured as needed. As standard to domain separation, the override is no longer affected by any changes done to the original variant or dashboard. The workspace, dashboard, or portal experience displays these overridden configurations if the user's current domain session is within the affected domain or sub domains where this override was created. Audiences further determine what a user may or may not see.

In addition, a user can access the domain hierarchy to view existing overrides from higher domains. For example, Global <- Top <- Acme <- Current domain. If no overrides exist, the default variant or dashboard are displayed. The exception is if the default variant or dashboard is in a child domain or a peer domain.



If you select **Expand Domain Scope** while in Global, all variants and overrides in sub domains are shown as previously mentioned.

System administrators and ui_builder_admin can see what has been created in the ServiceNow® platform.

Viewports and domain separation

Viewports are variants that can be nested in page definition content. They can be created as a common configuration in Global, or can be overridden per sub domain.

Declarative actions and domain separation

Declarative Actions can be overridden per domain as well. A system administrator or ui_builder_admin should select the appropriate domain prior to creating a domain specific declarative action override.

Domain separation for service providers

Working in UI Builder

Get a full understanding of everything that you can do when creating a page for your workspace or custom portal experience in UI Builder.

Using UI Builder resources

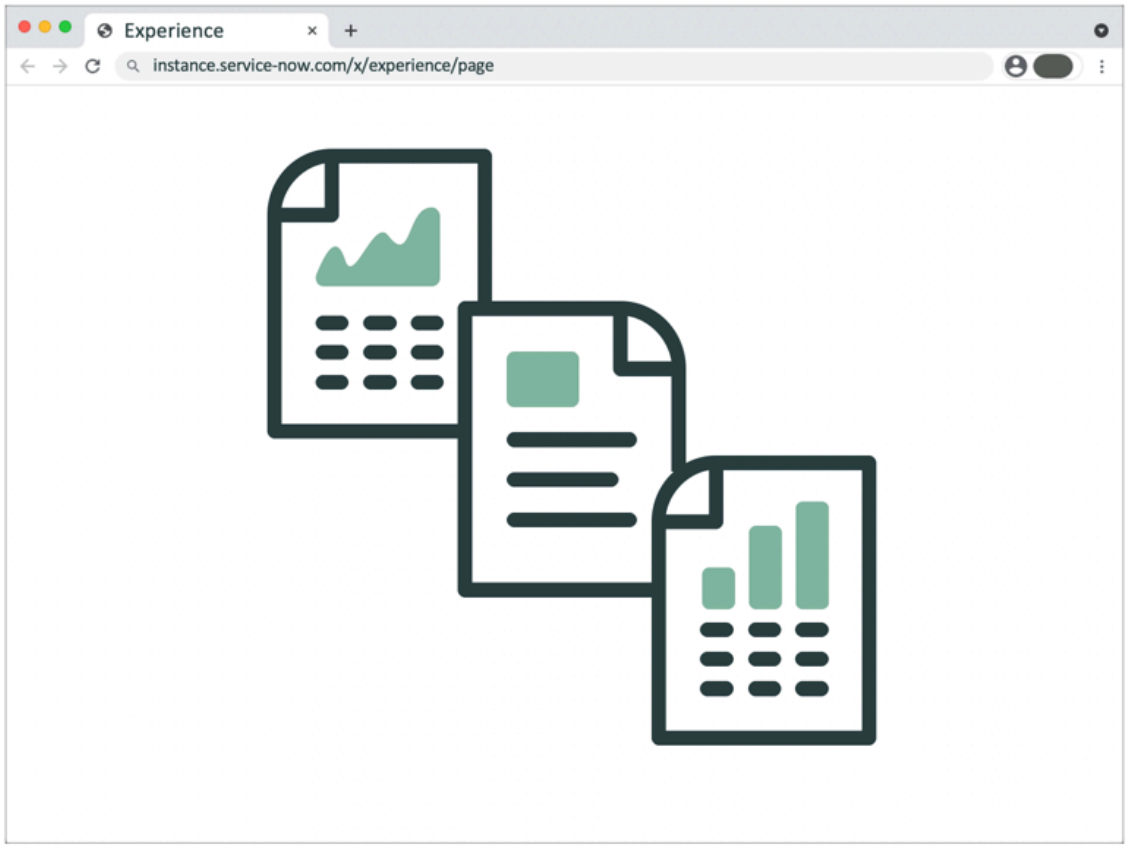
The following information helps you along your UI Builder journey:

Configure how users interact with your applications in UI Builder

Learn what an experience is in UI Builder. Understand what an experience contains.

What is a UI Builder experience

An experience in UI Builder is a collection of web pages for users to interact with an application.



Many websites use the same basic structure on every page. For example, every page contains the same header, the same footer, and the same menus. These common page elements are called a shell. Experiences can have a shell, or wrapper, for each page in the experience. A shell gives an experience a consistent look and feel as users navigate from page to page. Shells are recommended but not required. For more information, see Define UI experiences using app shells.

Ways to create an experience

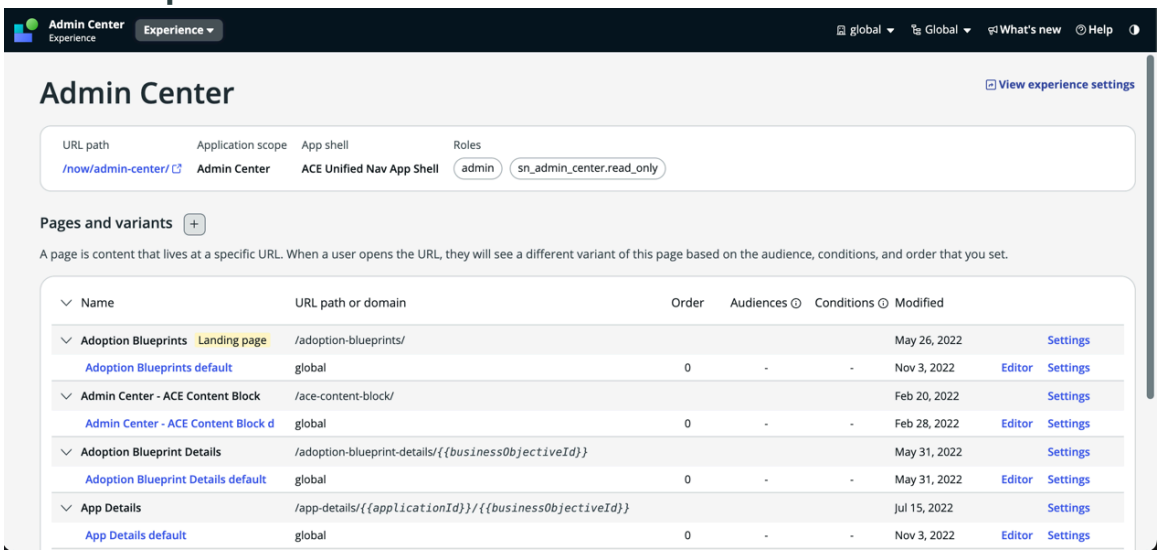
You can Create an experience for UI Builder from scratch or use UI generation to assist you in building an experience.

Experience view in UI Builder

The UI Builder experience view is a central place to view and understand the structure and details of an experience. This includes routes, page variants, and the audience and conditions required for each variant, and experience settings. Use the experience view to see the structure and hierarchy of your experience.

- View the experience URL, application scope, app shell, and roles for the experience.
- Edit experience settings.
- Quickly view and compare variants.
- Create pages and page variants.
- View a list of page collections.
- Edit page and page variant settings.
- Duplicate page variants.

UI Builder experience view



Create an experience for UI Builder

Learn how to create a workspace or portal experience for UI Builder in the ServiceNow platform.

Before you begin

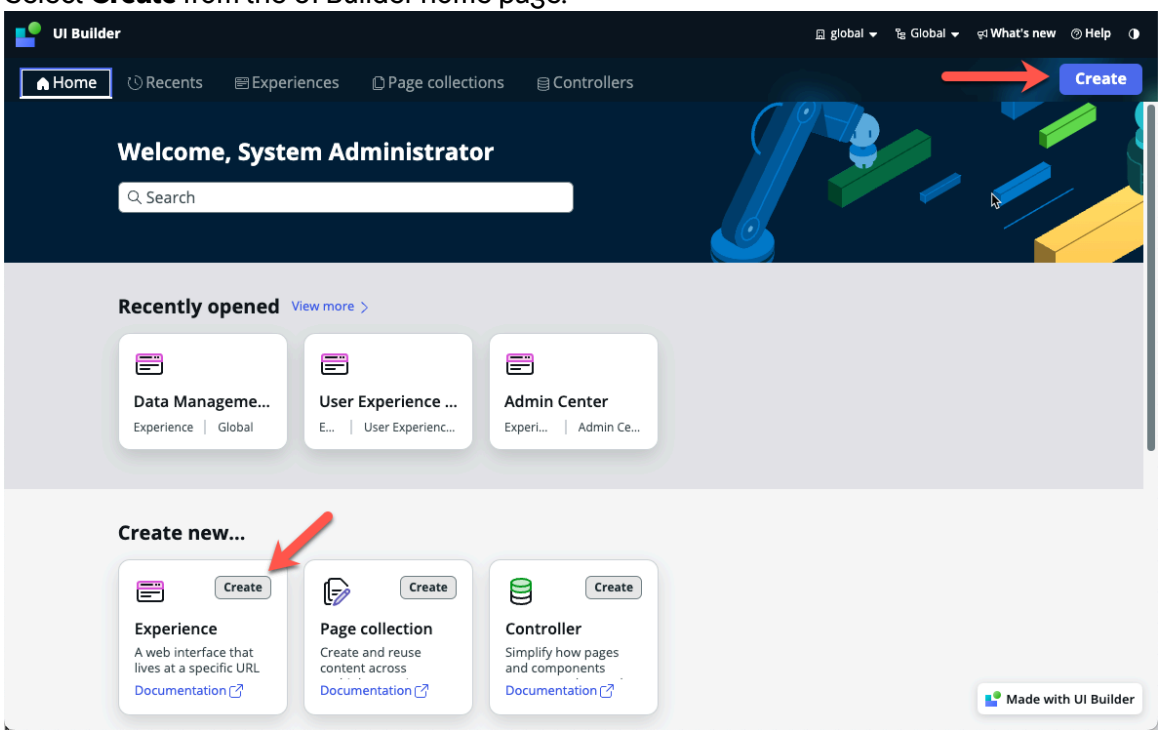
Role required: ui_builder_admin

About this task

This task shows you a basic example of how to create a workspace or portal experience for UI Builder. This example creates an experience called My App to demonstrate the process.

Procedure

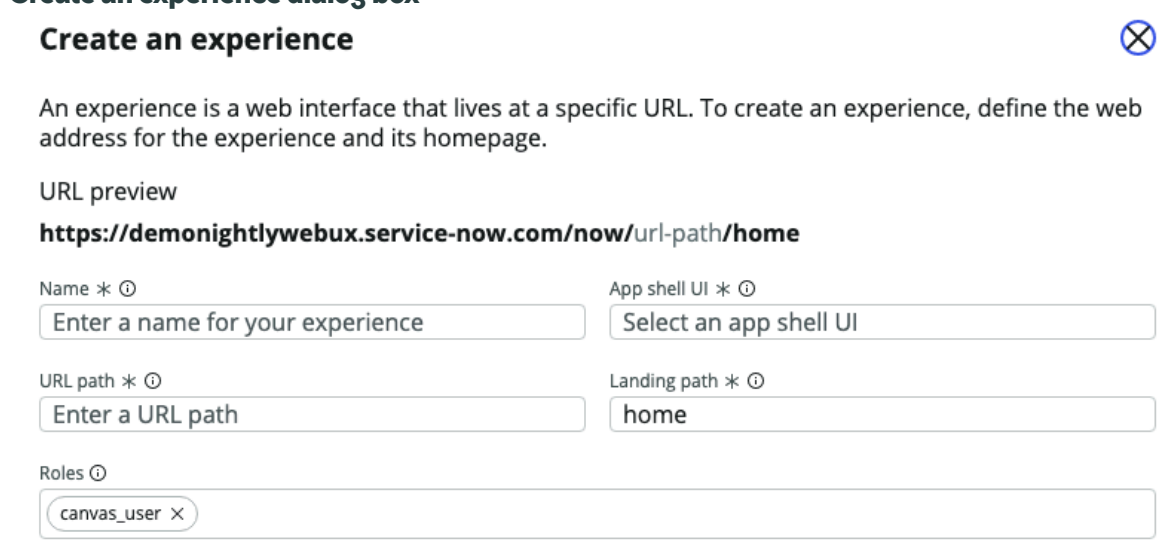
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Select **Create** from the UI Builder home page.



3. Select **Experience**.

4. In the form, fill in the fields.

Create an experience dialog box

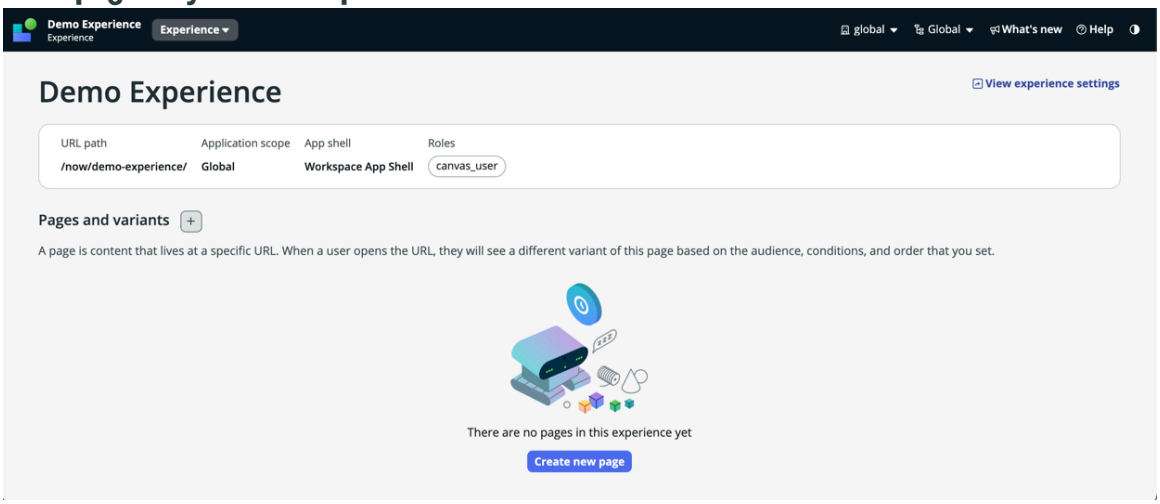


Create an experience form

Field	Description
Name	Add a name to track your experience internally. The experience name is visible to users from the browser tab. For this example, it is `MyApp`.
App Shell UI	You must choose an app shell for the experience to work. For example, you could choose a workspace or portal app shell. The app shell is the wrapper of the page contents, which is similar to the functionality of a web page. The app shell can show things like the logo of your company, user preferences, the search icon. For more information, see Define UI experiences using app shells.
URL path	Add a path for your experience. The path appends to the end of the URL parameter of your experience. For example, if you used `MyApp` as the title for your experience, you could type `my/app` for the path.
Landing path	The landing path is the prefix that people use to reach your experience homepage. To designate a page as the homepage, you must create a page that has a matching path.
Roles	Only users with these assigned roles can access the experience. If you leave this field empty, the experience is open to all logged-in users by default.

5. Select **Create** to create your experience.
6. Select **Open experience** to view the main page for your experience.

Main page for your new experience



Note:
In addition to the name of your new experience, the screen includes the URL, application scope, admin panel, and the roles of users who can view the experience. Any pages or variants you create for the experience appear in the **Pages and variants** section.

What to do next

Now that you have created an experience you can add and customize pages. For more information, see Manage UI Builder pages and page variants.

Configure UI Builder workspace experiences

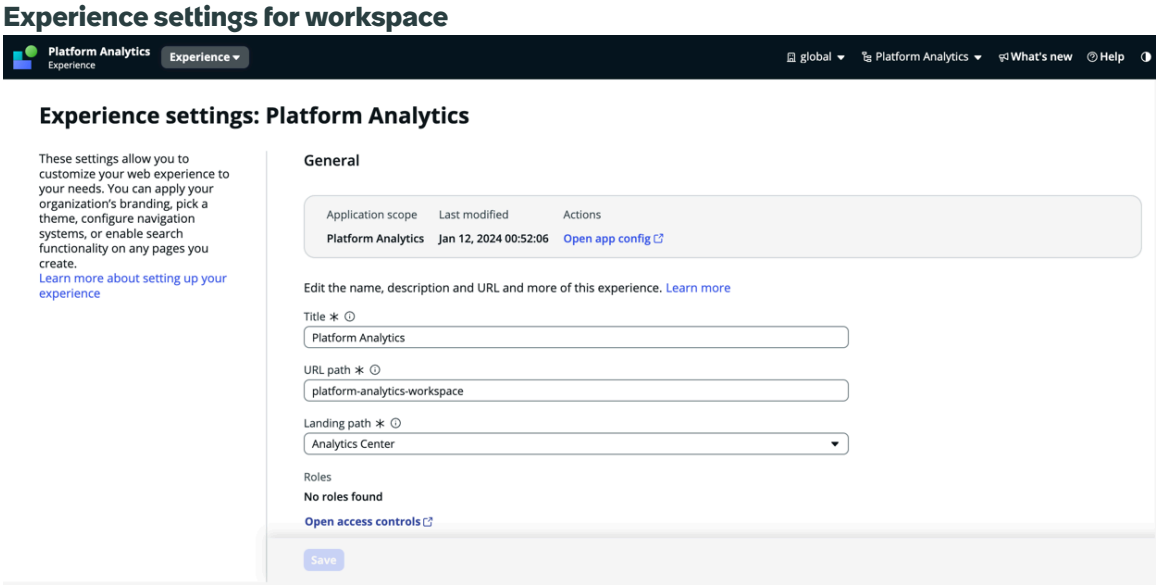
You can change the UI Builder workspace experience settings to fit your company goals.

By changing the experience settings, you can affect how your users interact with your workspace experience, how your workspace looks, and how users navigate to and around your workspace.

Before you can edit the experience settings, you must be in the correct application scope. If you're in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (Global), and then select the application scope that you want. For more information about the application scope, see Learn about security and roles.

Learn how you can change these workspace experience settings:

- Change or add the workspace general settings for your workspace experience. For example, you can change the title, the description, and the path of the workspace.
- View the brand and theme setting in your workspace experience to see the theme currently assigned to your experience. The theme sets the look and feel of the experience.
- Change the workspace side navigation settings to add pages to the side navigation in your workspace experience.
- Modify the workspace utility settings to turn on or turn off notifications for your workspace experience. Also, you can change the global search settings for your workspace experience. For example, you can choose to show or hide the search bar in your workspace experience or change the search source that determines where the search results come from.



Change the general settings in your workspace experience

Change the general settings for your workspace experience in UI Builder to fit the needs of your organization. For example, you can modify the title, description, and path for your workspace experience.

This video show you how to perform the following procedure. This video shows you how to change the general setting in a UI Builder workspace experience.

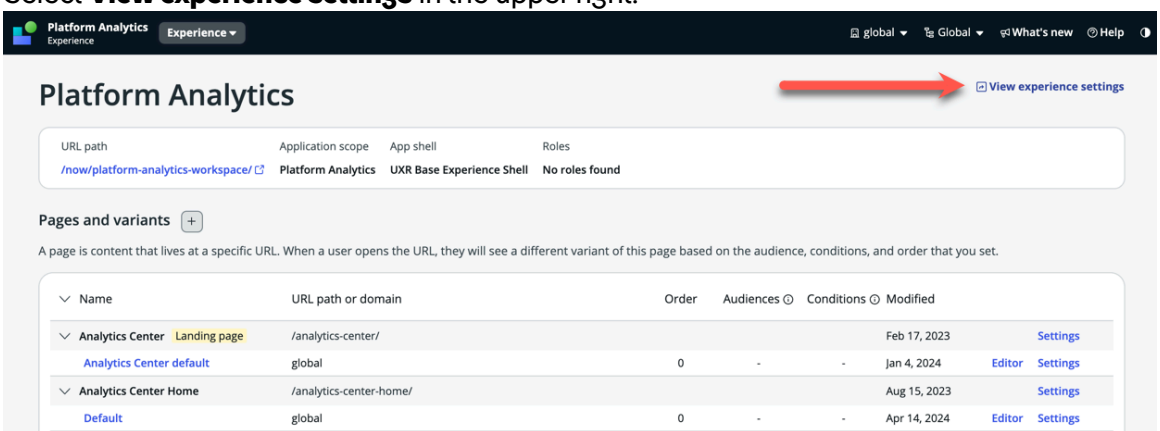
Before you begin

You must be in the correct application scope to edit the experience settings. If you're in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (Global), and then select the application scope that you want. For more information about the application scope, see Application scope.

Role required: ui_builder_admin

Procedure

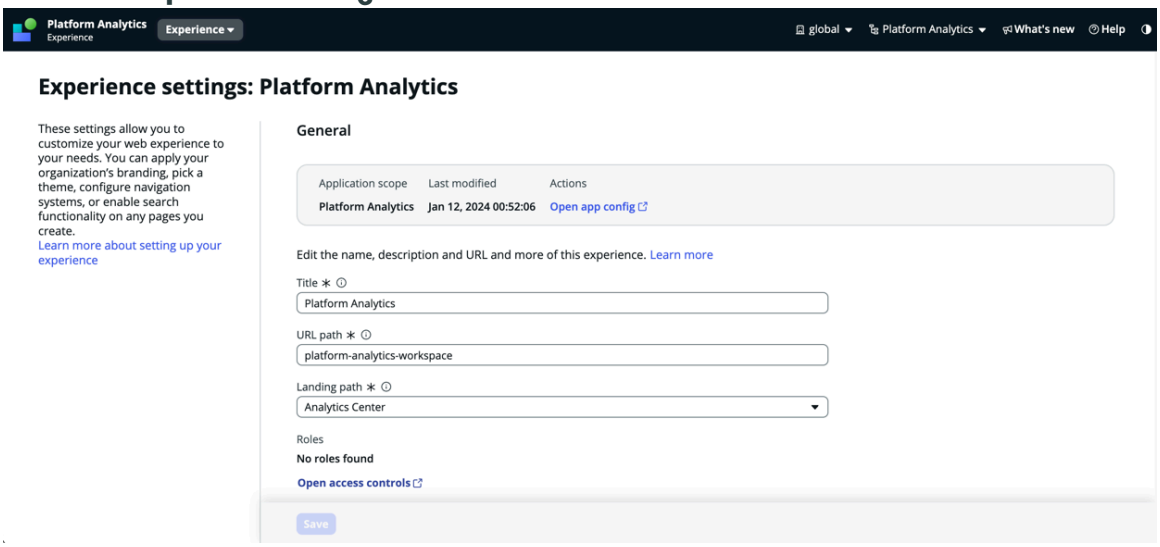
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. For more information, see Configure how users interact with your applications in UI Builder.
3. Select **View experience settings** in the upper right.



4. Change the title, description, and path of your workspace experience.

- The title lets everyone know what the workspace is called. Take care when choosing a name for your workspace.
- The description lets your users know the details of the workspace.
- The path must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a few special characters (`" - "`, `" . "`, `" _ "`, or `" ~ "`) with the words separated by a forward slash or hyphen.

UI Builder experience settings



5. **Optional:** Select **Advanced settings** to edit the workspace record on the ServiceNow AI Platform.

   a. Update the record in the platform when you're finished.
   When you go back to your workspace experience settings in UI Builder, you see the changes that you made to the general settings.

6. Click **Save**.

View the brand and theme setting in your workspace experience

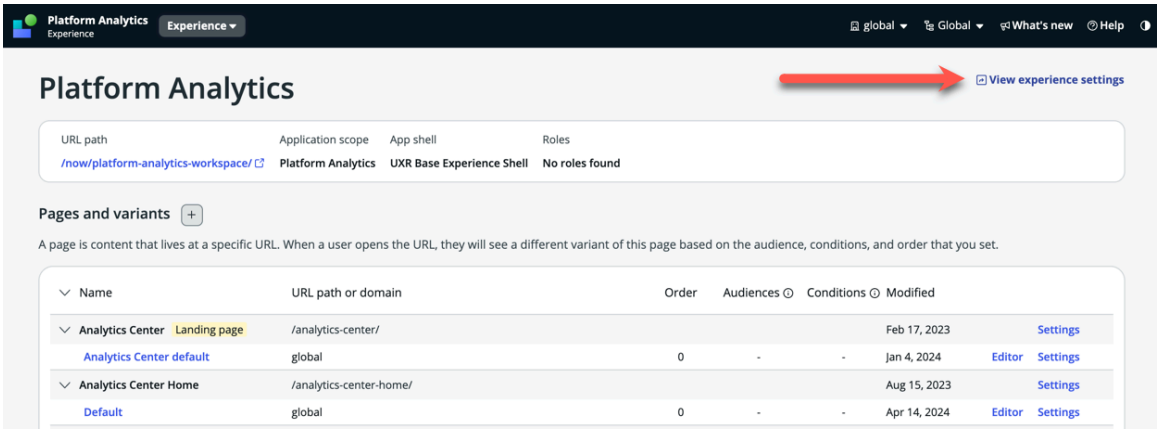
View the theme setting for your workspace experience in UI Builder. The theme sets the visual style of the experience and provides a consistent look and feel across all pages.

Before you begin

Role required: ui_builder_admin

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Select **View experience settings** in the upper-right.



4. Scroll to the **Branding and theming** section and note what is listed in **Themes**.
   By default, the Polaris theme is applied to UI Builder experiences.

What to do next

If you want to customize the theme, there are two options:

- **Theme Builder** enables you to create, edit, manage, and apply Next Experience themes using a friendly visual interface. For more information, see Configuring Next Experience with Theme Builder.
- If you are an admin user comfortable working in style records and JSON code, you can create a custom theme to override the default Polaris style. This option gives you the most control over typefaces, colors, and images (including the banner and logo) in a theme. For more information, see Configuring Next Experience themes and preferences.

Change the navigation and menu settings in your UI Builder workspace experience

Select pages for side navigation in your UI Builder workspace experience. From any page in the workspace experience, users can navigate to the pages you selected.

Before you begin

This task has the following prerequisites:

- You have an existing workspace experience on UI Builder. For more information, see Configure how users interact with your applications in UI Builder.
- This workspace experience was created with the Workspace App Shell.
- This workspace experience includes at least two pages.
- You want users to be able to navigate from a page to other pages that you specify.

Role required: ui_builder_admin

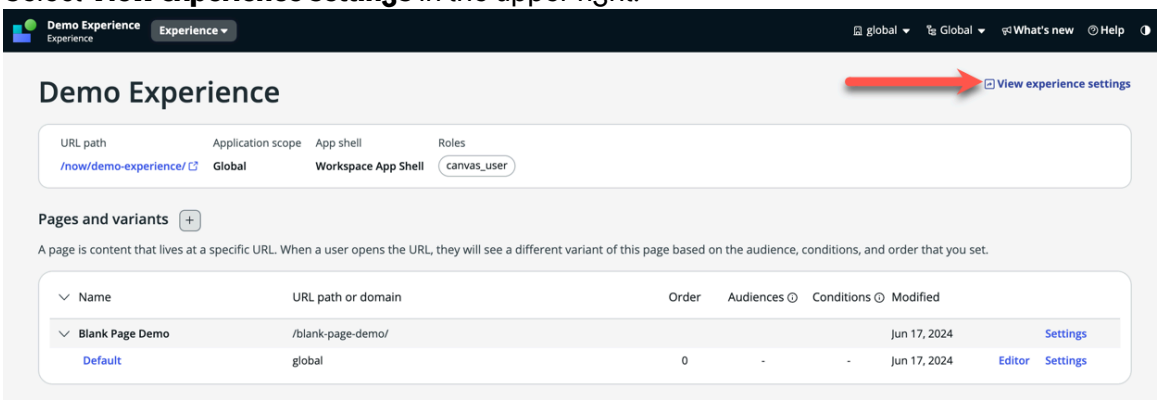
About this task

You can add up to seven pages to your side navigation.

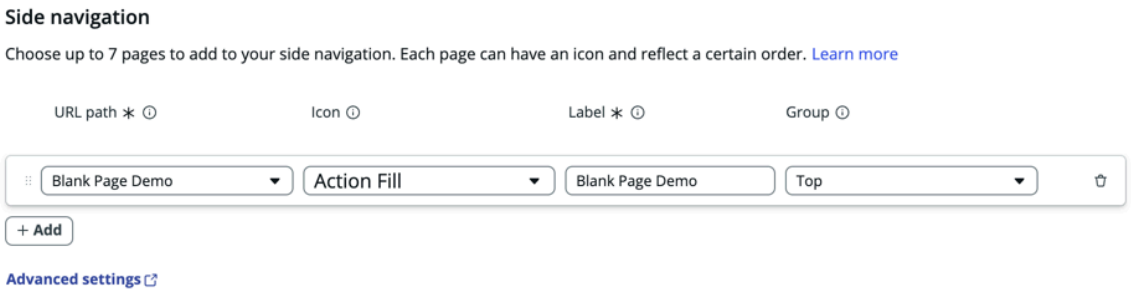
You must be in the correct application scope to edit the experience settings. If you are in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (Global), and then select the application scope that you want. For more information about the application scope, see Learn about security and roles.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open your workspace experience in the UI Builder.
3. Select **View experience settings** in the upper-right.



4. Scroll down to **Side navigation**.
5. Select **+ Add**.



6. Fill in the following fields:

Field	Description
URL path (required)	Select the page that you want to navigate to. **Tip:** The landing page is usually the first page that you want a link to.
Icon	Select an icon for the link. Default: No icon
Label (required)	Enter a name for the page, which appears in a tooltip for the link.
Group	Place the link in the top or the bottom group of the side navigation panel. Default: Top

7. Add more pages as needed.
8. Select **Save**.

9. Select the experience name (for example, Demo Experience) in the UI Builder header.
10. Select the **URL path** link to open the experience in a new tab and check that the side navigation is displayed on the left side.

> **Tip:**
> If the side navigation doesn't work as expected, consider reviewing the UX Page Property [sys_ux_page_property] record underlying the side navigation. Reopen the Side Navigation experience settings, as described in Steps 3-4. Select **Advanced side navigation settings** to open the record. Verify that the fields have the correct values, such as Type=`json`.

Set up notifications in workspace utility settings

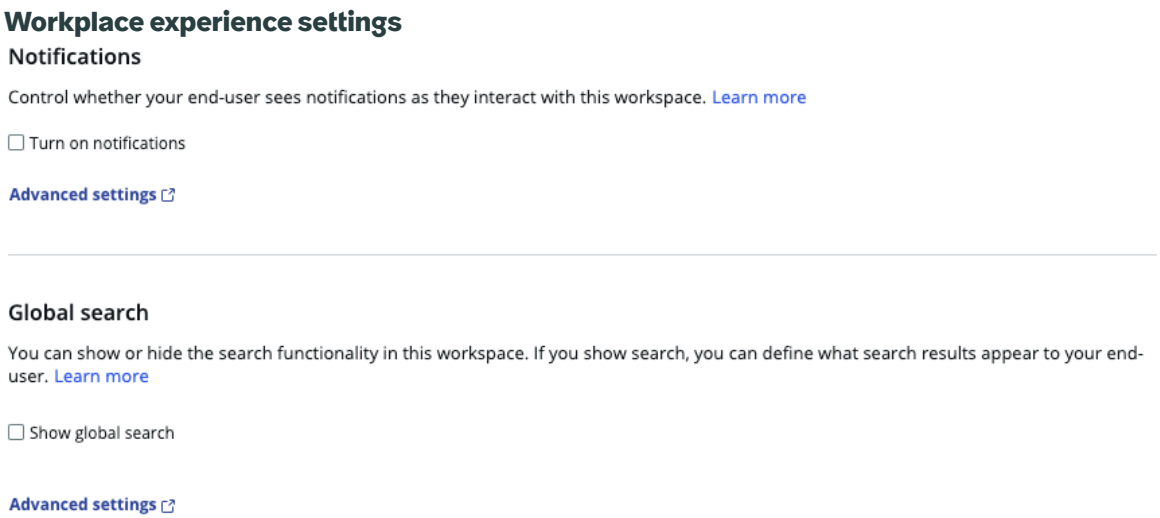
Set up the advanced notification and search settings in your workspace experience so that you can control how your users see notifications and search options.

Before you begin

Role required: ui_builder_admin

About this task

Set up the advanced notification and search settings in your workspace experience. You can turn notifications on or off to control how people see notifications in your workspace experience.



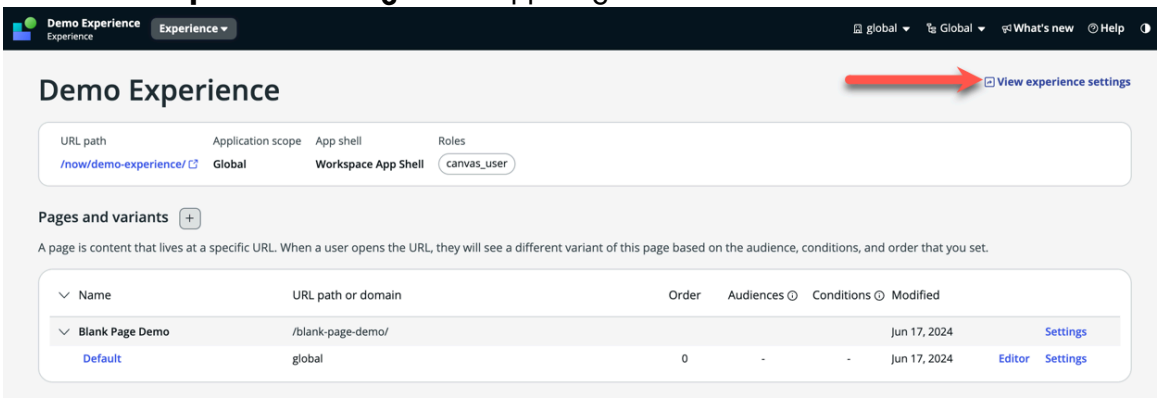
You can also control whether the search functionality is visible to the users of your workspace experience. If you choose to display a search option, you can define what search results are returned by choosing a source for the search.

Before you can edit the experience settings, you must be in the correct application scope. If you're in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (
), and then select the application scope that you want. For more information about the application scope, see Learn about security and roles.

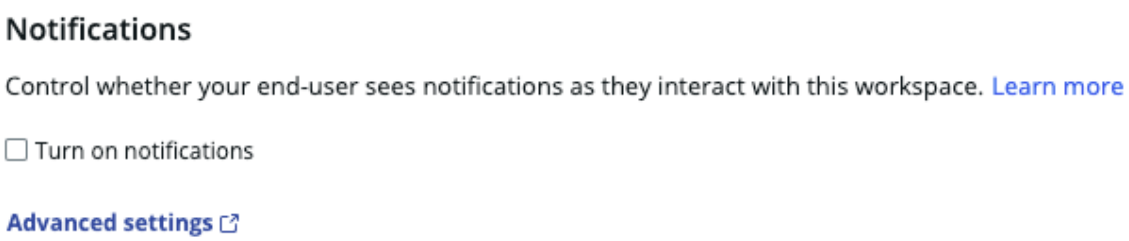
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. For more information, see Configure how users interact with your applications in UI Builder.
3. Open or create a page in your workspace experience.

4. Select **View experience settings** in the upper-right.



5. Scroll down to **Notifications**.



6. Select the **Turn on notifications** option.
7. Click **Save**.
8. **Optional:** Click **Advanced settings** to go to the ServiceNow AI Platform® and edit the JSON values of the record.

> **Note:**
> If you have the Record component on a page, you can have a record open in the workspace experience when a notification is selected. Follow the instructions in Record UIB Setup on the ServiceNow developer site and define a featureRoutes page property.

Display global search in a workspace experience

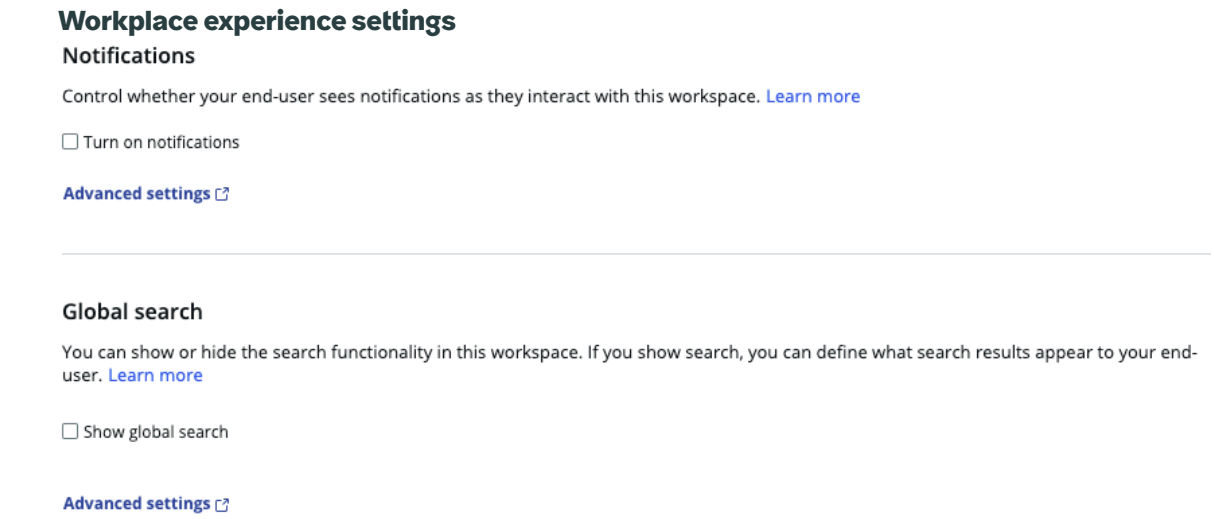
Show or hide the search functionality in your workspace.

Before you begin

Role required: ui_builder_admin

About this task

You can control whether the search functionality is visible to the users of your workspace experience. If you choose to display a search option, you can define what search results are returned by choosing a source for the search.

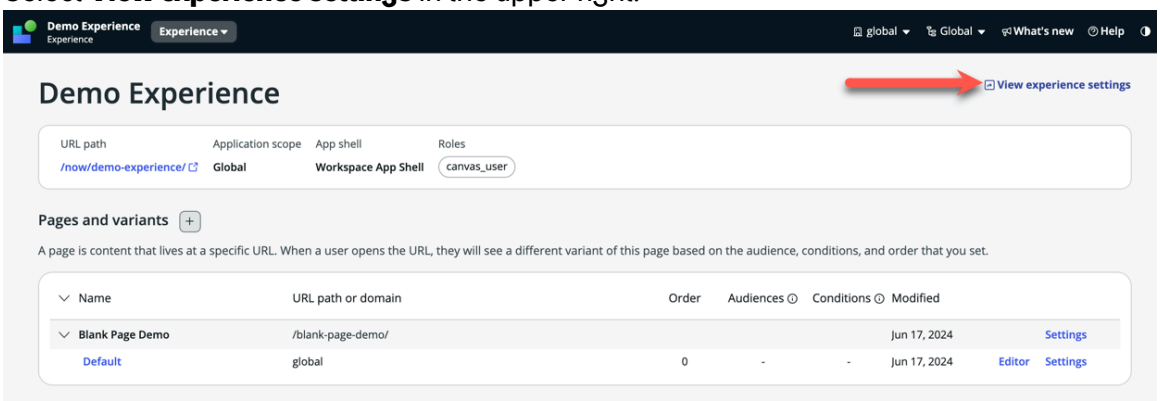


Before you can edit the experience settings, you must be in the correct application scope. If you're in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (

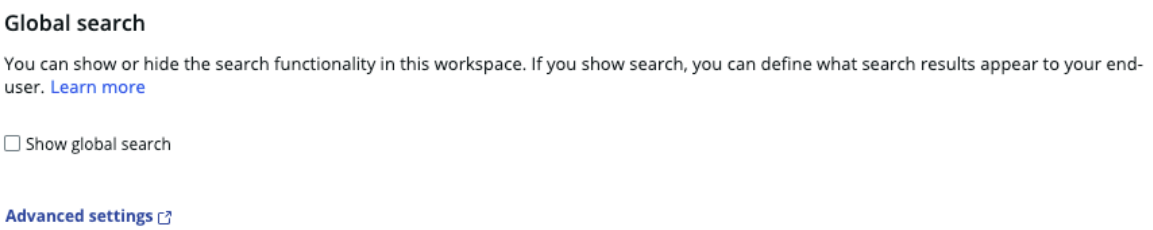
), and then select the application scope that you want. For more information about the application scope, see Learn about security and roles.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. For more information, see Configure how users interact with your applications in UI Builder.
3. Open or create a page in your workspace experience.
4. Select **View experience settings** in the upper-right.



5. Scroll down to **Global search**.



6. Select the **Show global search** option.

7. Click **Save**.
8. **Optional:** Click **Advanced settings** to go to the ServiceNow AI Platform® and edit the JSON values of the record.

Configure UI Builder portal experiences

You can change your UI Builder custom portal experience settings to affect how your users interact with your portal experience.

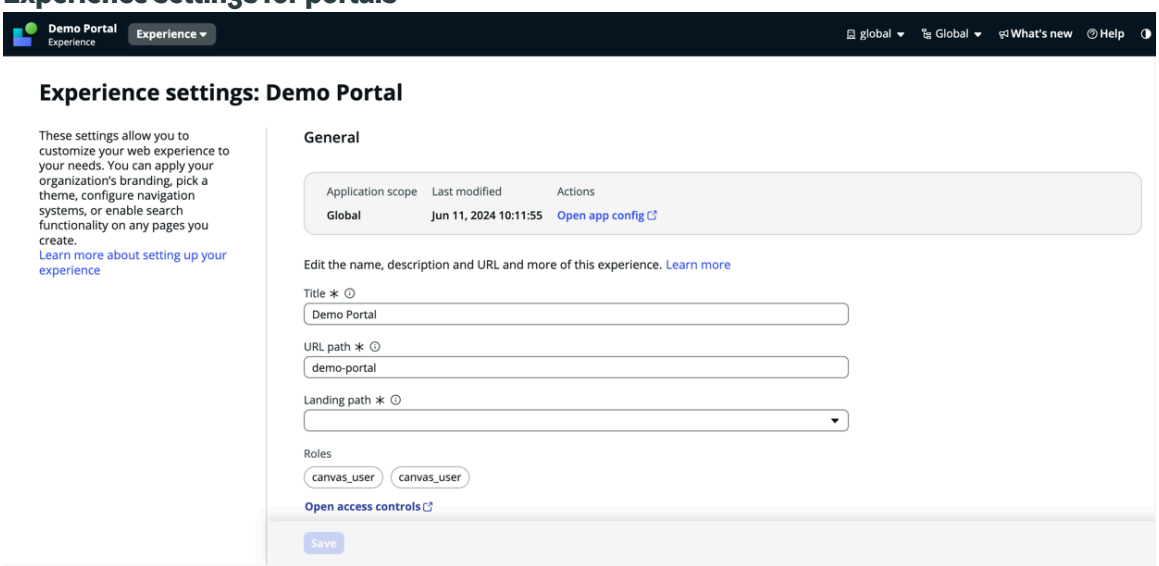
Use experience settings to change the settings for the custom portal experience that you are working in. These settings affect how your users interact with your portal experience, how your portal looks, and how users navigate to and around your portal.

You must be in the correct application scope to edit experience settings. If you are in a different scope, the experience settings are read-only. To change your application scope, in the main header, select the application picker (Global), and then select the application scope that you want. For more information about the application scope, see Learn about security and roles.

Learn how to change the following portal experience settings.

- Modify or add portal general settings for your portal experience. Change the title of your portal, the description, and the path of the portal.
- View the brand and theme setting in your portal experience to see the theme currently assigned to your experience. The theme sets the look and feel of the experience.
- Use portal navigation and menu settings to set up the navigation and menu settings in the app shell of your portal experience. The app shell is the wrapper of the portal contents. For example, the app shell can show things like the logo of your company, user preferences, the search icon, the configuration icon, and the user menu. For more information about app shells, see Define UI experiences using app shells.
- Modify the portal search settings to show or hide the global search functionality on public or private pages in your portal experience.

Experience settings for portals



Change the general settings in your portal experience

Change the general settings for your custom portal experience in UI Builder. For example, you can modify the title, description, and path for your portal experience.

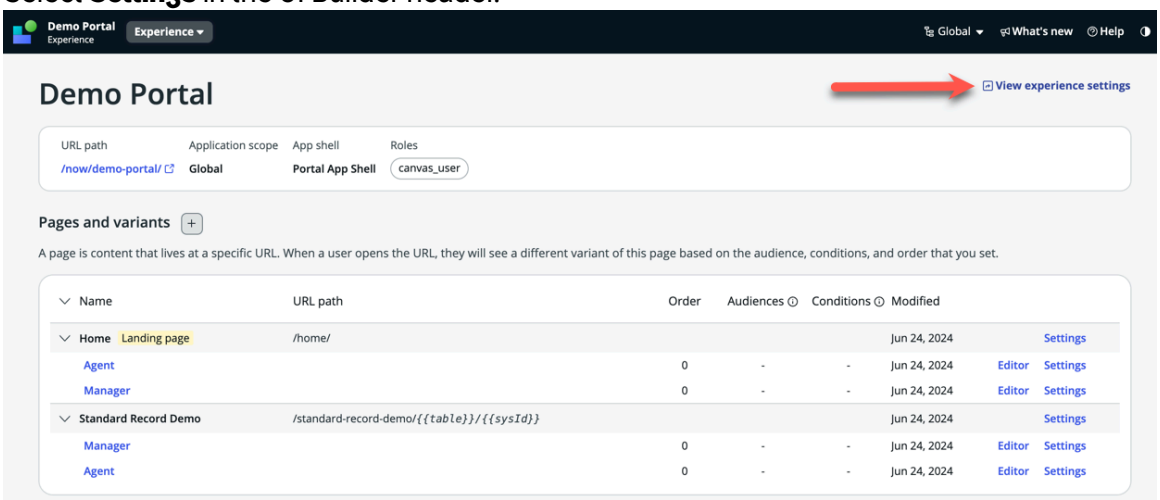
Before you begin

You must be in the correct application scope to edit the experience settings. If you're in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (Global), and then select the application scope that you want. For more information about the application scope, see Learn about security and roles.

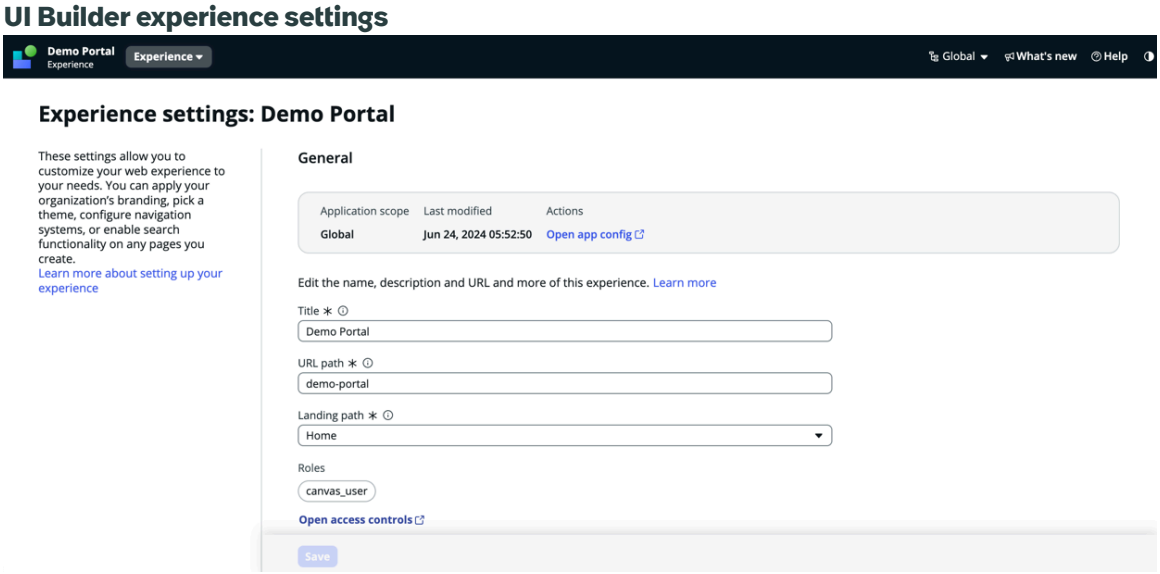
Role required: ui_builder_admin

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open a portal experience to work in or create an experience by selecting **Create** > **Experience**. For more information, see Configure how users interact with your applications in UI Builder.
3. Select **Settings** in the UI Builder header.



4. Change the title, description, and path of your portal experience.
   - The title lets everyone know what the workspace is called. Take care when choosing a name for your workspace.
   - The description lets your users know the details of the workspace.
   - The path must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a few special characters (`" - "`, `" . "`, `" _ "`, or `" ~ "`) with the words separated by a forward slash or hyphen.



5. **Optional:** Select **Advanced settings** to edit the workspace record on the ServiceNow AI Platform.

   a. Update the record in the platform when you are finished.
   When you go back to your workspace experience settings in UI Builder, you see the changes that you made to the general settings.

6. Click **Save**.

Result

When you go back to your portal experience settings in UI Builder, you see the changes that you made to the general settings.

View the brand and theme setting in your portal experience

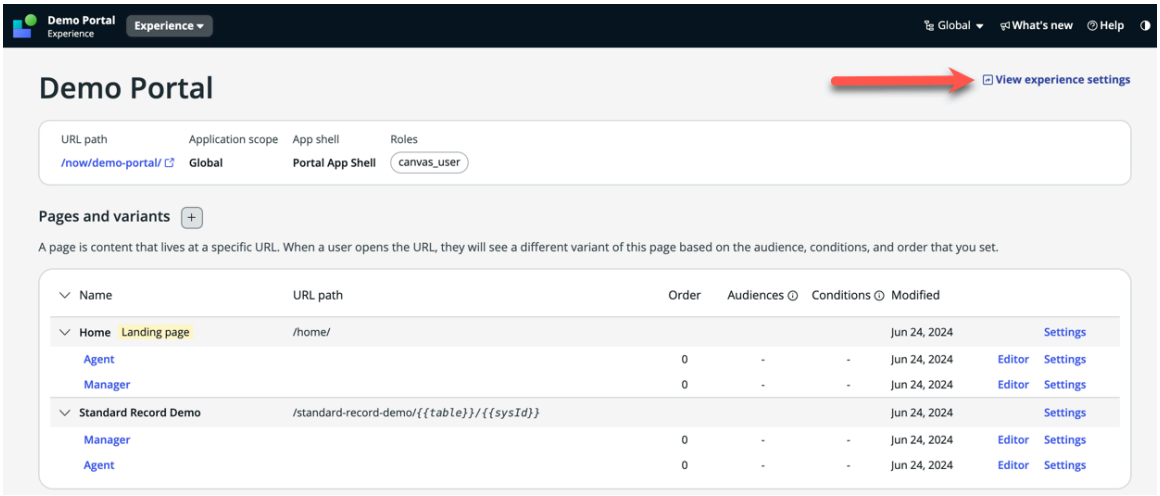
View the theme setting for your portal experience in UI Builder. The theme sets the visual style of the experience and provides a consistent look and feel across all pages.

Before you begin

Role required: ui_builder_admin

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open a portal experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Select **Settings** in the UI Builder header.



4. Scroll to the **Branding and theming** section and note what is listed in **Themes**.
   By default, the Polaris theme is applied to UI Builder experiences.

What to do next

- **Theme Builder** enables you to create, edit, manage, and apply Next Experience themes using a friendly visual interface. For more information, see Configuring Next Experience with Theme Builder.
- If you are an admin user comfortable working in style records and JSON code, you can create a custom theme to override the default Polaris style. This option gives you the most control over typefaces, colors, and images (including the banner and logo) in a theme. For more information, see Configuring Next Experience themes and preferences.

Change the navigation and menu settings in your portal experience

Change the header, footer, and menu settings for your custom portal experience in UI Builder to fit the needs of your organization.

Before you begin

This task has the following prerequisites:

- You have an existing portal experience on UI Builder. For more information, see Configure how users interact with your applications in UI Builder.
- This workspace experience contains at least two pages.
- You want users to be able to navigate from a page to other pages that you specify.

Role required: ui_builder_admin

About this task

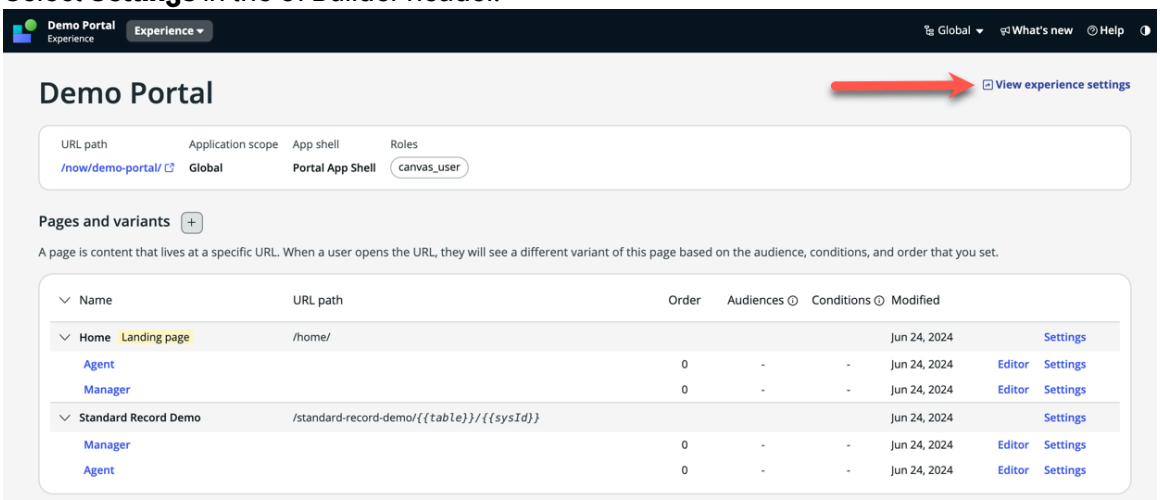
Set up the navigation and menu settings in the app shell of your portal experience. The app shell is the wrapper of the portal contents. For example, the app shell can show things like the logo of your company, user preferences, the search icon, the configuration icon, and the user menu. You can configure this app shell in the ServiceNow AI Platform. For more information about app shells, see Define UI experiences using app shells.

You must be in the correct application scope to edit experience settings. If you are in a different scope, the experience settings are read-only. To change your application scope, in the main header, select the application picker (
), and then select the application scope. For more information about the application scope, see Learn about security and roles.

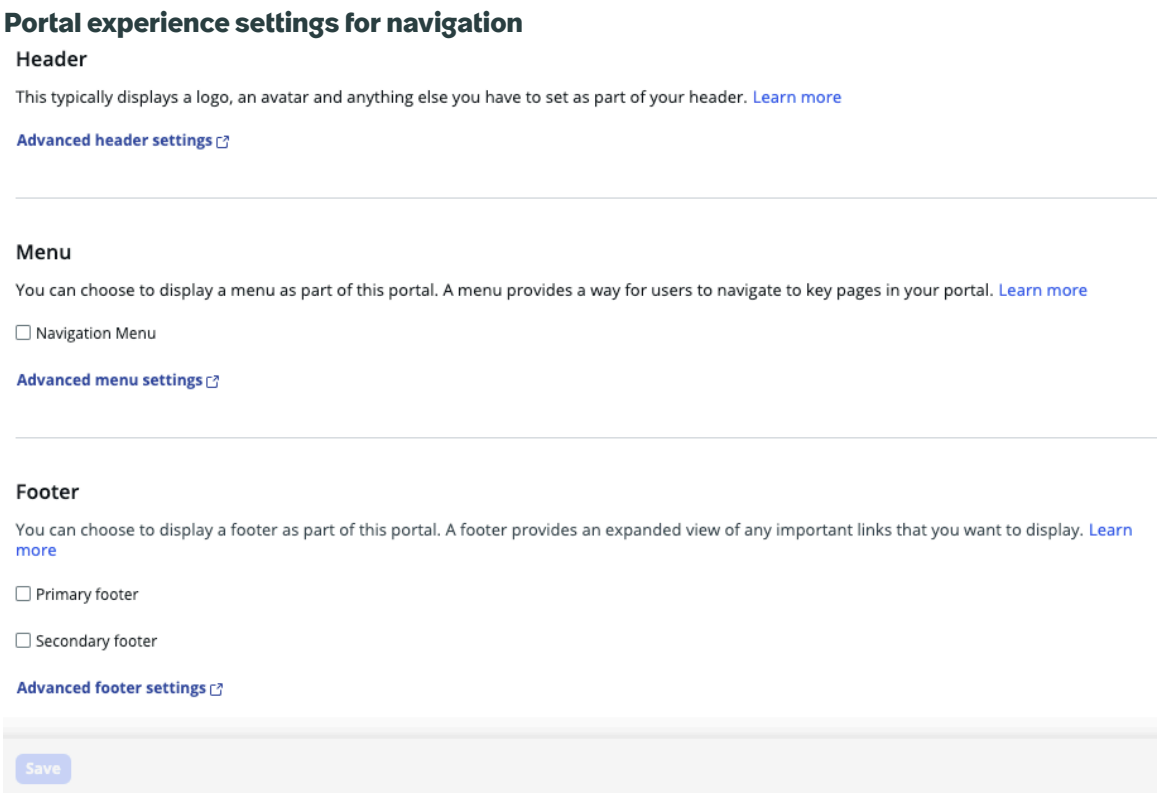
Note:
For advanced information about UX page properties, including JSON examples, see https://www.servicenow.com/community/next-experience-articles/workspace-app-shell-ux-page-properties/ta-p/2331956.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open a portal experience to work in or create an experience by selecting **Create** > **Experience**. For more information, see Configure how users interact with your applications in UI Builder.
3. Select **Settings** in the UI Builder header.



4. To change the settings for the header, footer, and navigation menu for the app shell of the portal experience you're working in, select the advanced settings links.



Action	Procedure
Change the header	To go to the ServiceNow AI Platform®, click **Advanced header settings**. Here, you can change what information shows in the header of your portal experience. You can change things like a company logo, user preferences, the search icon, the configuration icon, and so on.
Show the menu	**a.** To add a menu to your portal experience, select **Navigation Menu**. **b.** To remove the navigation menu, deselect **Navigation Menu**. **c.** To go to the ServiceNow AI Platform, select **Advanced navigation menu settings**. Here, you can change what menu and menu items are displayed in the navigation menu. For more information, see Define UI experiences using app shells.
Display a footer	**a.** To add a primary footer to your portal experience, select **Primary footer**. The footer can show a footer logo, content, and other important links for your portal. **b.** To go to the ServiceNow AI Platform, click **Advanced navigation menu settings**. **c.** To add a second footer to your portal experience, select **Secondary footer**. A secondary footer includes additional text links, social media elements, and copyright information.

5. Click **Save**.

Show or hide the search settings for your portal experience

Show or hide the global search functionality on the public or private pages for your custom portal experience in UI Builder so that your users can search on the portal.

Before you begin

Role required: ui_builder_admin

You can control whether the global search functionality is visible to users of your portal experience. You can enable or disable the global search for either public or private pages.

You must be in the correct application scope to edit the experience settings. If you are in a different scope, the experience settings are read-only. To change your application scope, in the main header, select the application picker (

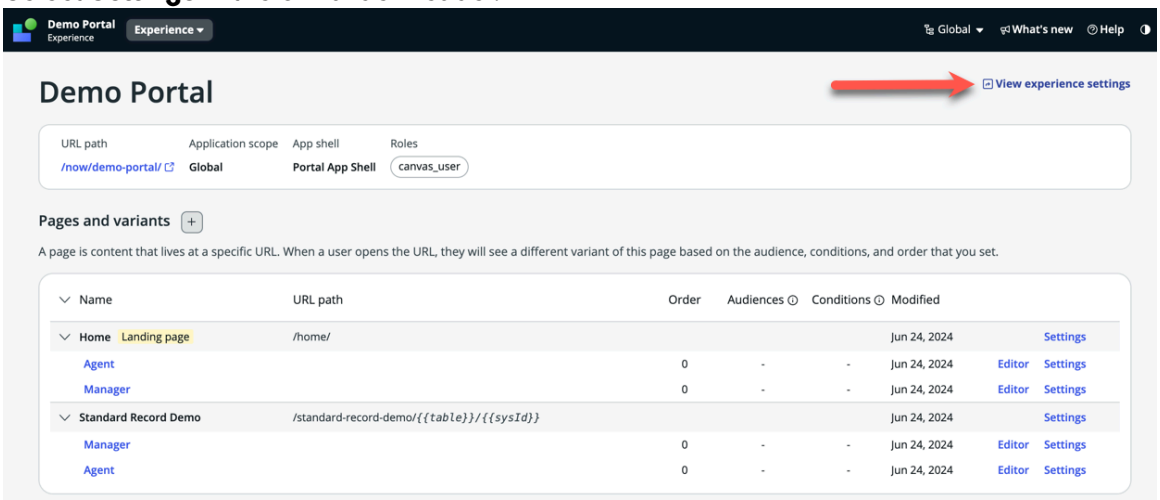
), and then select the application scope. For more information about the application scope, see Learn about security and roles.

Procedure

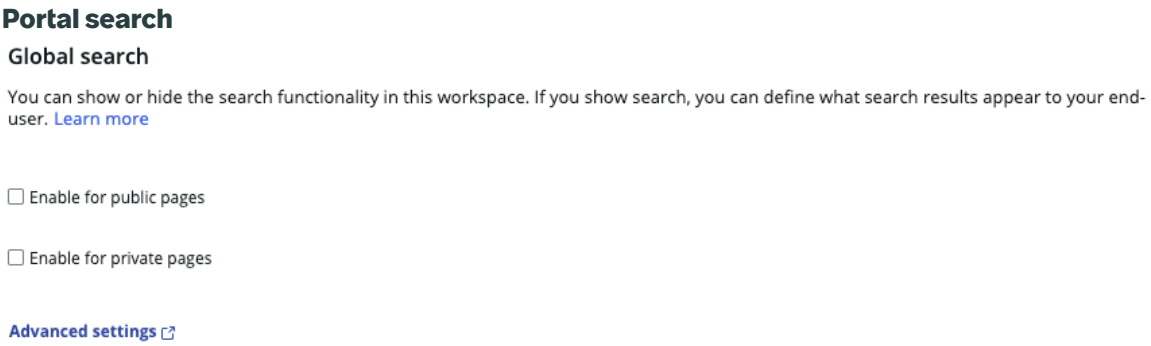
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open a portal experience to work in or create an experience by selecting **Create** > **Experience**.

For more information, see Configure how users interact with your applications in UI Builder.

3. Select **Settings** in the UI Builder header.



4. Scroll down to **Global search**.
5. Select the **Enable for public pages** or **Enable for private pages** to show or hide the global search in public or private pages.



6. **Optional:** Click **Advanced settings** to go to the ServiceNow AI Platform to make changes to the application record on the ServiceNow AI Platform®.
   To enable or disable the search for a page, you must create a separate UX Page property. The UX Page property overrides the global search setting.
7. Click **Save**.

Define UI experiences using app shells

Understand what app shells are, what app shells are available for UI Builder, and why you would pick one over another.

App shells

An app shell is the wrapper of the contents of an experience page. An app shell includes functionality similar to a web page. For example, an app shell can show things in a header or footer of your experience, such as a logo for your company, user preferences, a search icon, configuration icon, user menu, and so on.

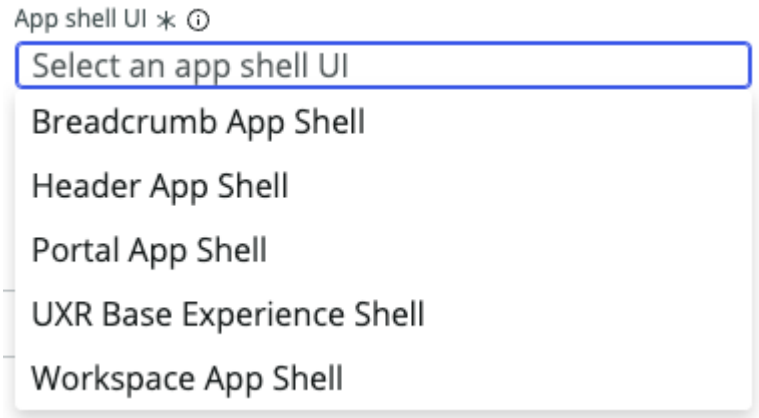
An app shell is required for UI Builder.

The app shell defines whether your experience has a workspace or portal design. A workspace is a graphical user interface that puts multiple tools on one page for handling requests from users.

A portal is a page where users can add requests, such as order items, track their tickets, and so on.

You choose which app shell to apply to your experience when you create an experience in the ServiceNow® platform. For more information on how to create an experience, see Configure how users interact with your applications in UI Builder.

You can choose from various app shells when creating an experience.



App shell descriptions

App shell	Description	Example
Breadcrumb app shell	The breadcrumb app shell includes a header, breadcrumb style navigation, and a primary navigation bar for a workspace experience. Use the breadcrumb app shell for focused workflows and wizard flows that don't require multi-tasking.	Header app shell	The header app shell includes a header and user menu for a workspace experience. Use the header app shell for experiences that require minimal navigation and few actionable items in the header.	Portal app shell	The portal app shell includes the header and footer for a portal experience. The portal app shell record is a reference implementation of how the menu, utilities, logo, and login are configured for a portal experience.	UXR Base Experience app shell	The UXR Base Experience shell creates an experience with the Next Experience banner. The UXR Base Experience shell provides base functionality support for experiences that are configured within a parent app, including experience configuration, context binding, routing, screen loading, and	
App shell descriptions (continued)

App shell	Description	Example
	caching. The UXR Base Experience shell has no visual or experience-specific components. The UXR Base Experience shell can also be used for experiences that have no shell customization. For example, Identity Center directly uses UXR Base Experience Shell as its app shell.	
Workspace app shell	The workspace app shell includes the headers and footers for a workspace experience. Use the workspace app shell to provide tools that users need to find, research, and resolve issues. To manage the visual style of experiences created with this app shell, see Configuring Next Experience with Theme Builder.	
Manage UI Builder pages and page variants

Learn what a page is in UI Builder. Understand the building blocks of a UI Builder page, such as column layouts and components.

UI Builder quick start

Create pages in UI Builder as part of a workspace or custom portal experience. UI Builder pages consist of layouts and components. You build a page using column layouts and components to guide a user through an experience. For example, you could build a page to manage travel requests for your employees. The page could have column layouts with components that contain lists of all travel requests submitted and approved. You can add buttons that let users add and submit travel requests. The way you build your page is limitless.

Note:
One developer should work on any one variant at a time.

Column layouts and components in UI Builder

Column layouts and components are the building blocks of your UI Builder page. Add column layouts and components to your page to build or customize your workspace or portal experience. For example, add a column layout and within a column place a button component that lets users submit requests.

You can add column layouts, columns, and components, as well as navigate between them, from the stage or the Content tree.

A column layout can contain one or more columns. Columns can contain components. Change the visual styling of column layouts, columns, and components to make it your own experience.

Types of page layout elements

Type	Description
Column layout	A flexible container with one to six columns. Add column layouts to provide structure and a framework for a page.
Column	Fill columns with components.
Component	Base elements of a page, such as buttons, lists, and forms.
Modal	Use a modal to create a page type in UI Builder that renders on top of the page and requires action.
Popover	A popover is a type of container that appears above a UI Builder page when triggered by an event. Use the popover component to display additional information or actions related to the page.

See Customize UI Builder pages using components for more information.

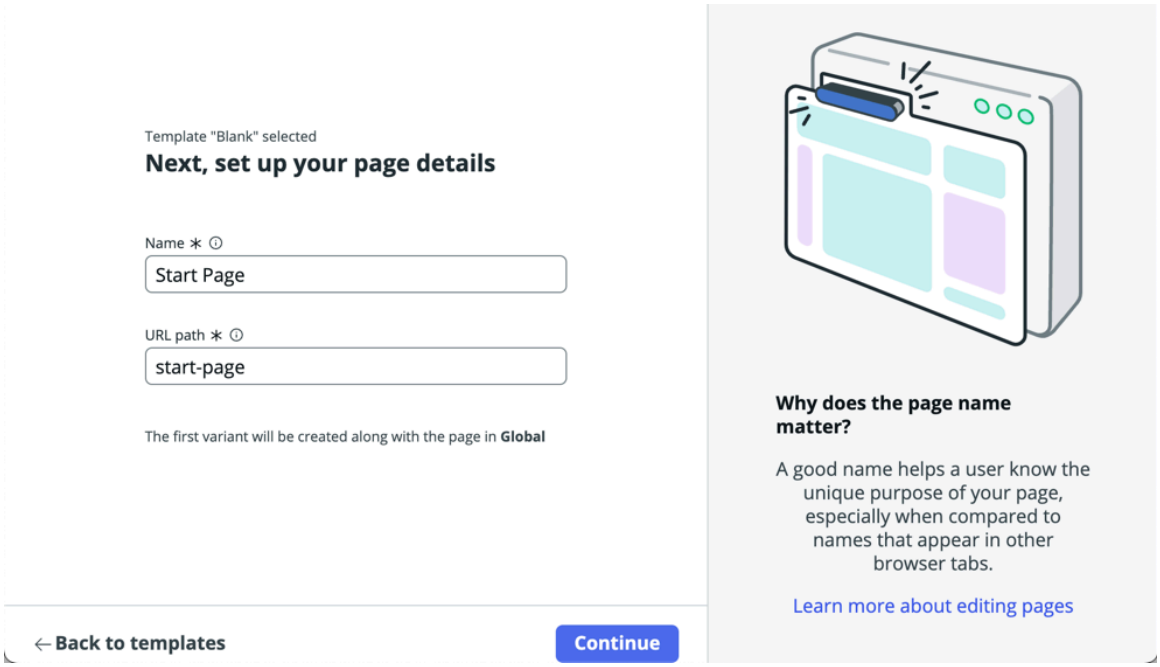
Create a UI Builder page

Create a UI Builder page to build a page experience from scratch or use a page template. Build a page one component at a time. If you use one of the pre-defined page templates, you start from a base structure and can customize it to meet your needs.

Name your UI Builder page. Set the path (or keep the default path that is automatically added based on your page name). A default path is added based on your page name. You can also create your own path, but the path must be unique. The **URL preview** shows the path of your page.

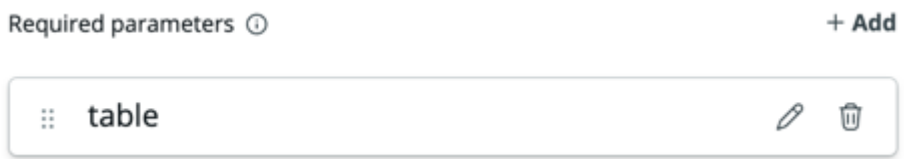
The application scope protects applications by identifying and restricting access to application files and data. The application scope defaults to the scope that the user is currently in within the ServiceNow AI Platform®. For more information about application scope, see Learn about security and roles.

Use a UI Builder page template to create a page based on a pre-defined page template, and then customize the page to your needs. You can reference or copy a page template. For more information, see Create a page from a template.



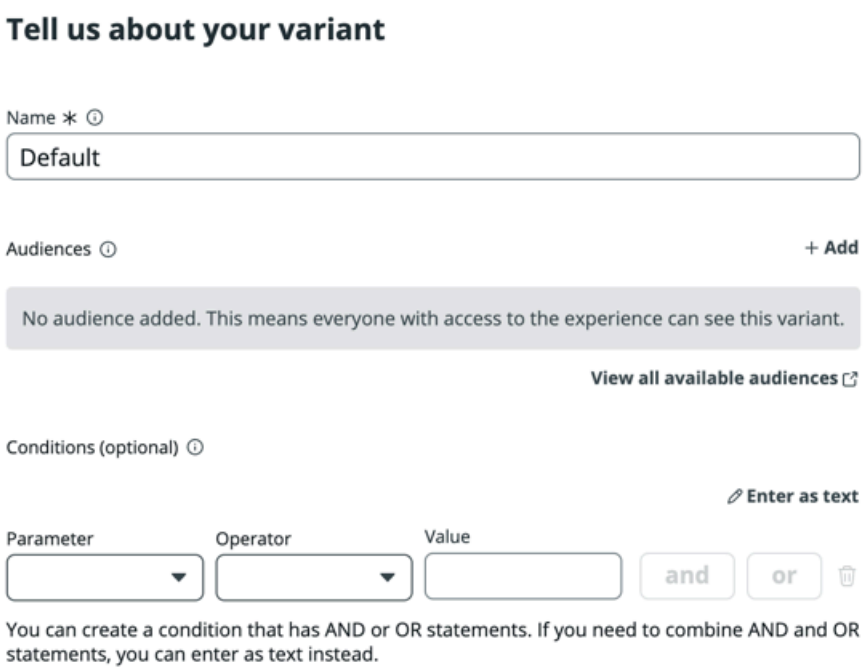
Create a UI Builder page: Advanced settings

Add required parameters to your UI Builder page. A required parameter is a piece of data that your page requires, such as a sys_id, table, or query. Required parameters are useful for components as they can bind to the value of the required parameter. For example, you can add a table parameter to the URL field and then bind data to that table. When the table is referenced, it exposes the table data to any components on the page. Required parameters are visible in the URL when you add them to your page. In the following example, a required parameter called table was added. Notice it was appended to the URL.



Add optional parameters to your UI Builder page. Optional parameters are optional pieces of data that you can add to the URL of your page. Unlike required parameters, optional parameters are always name and value pairs that work no matter what order they're provided.

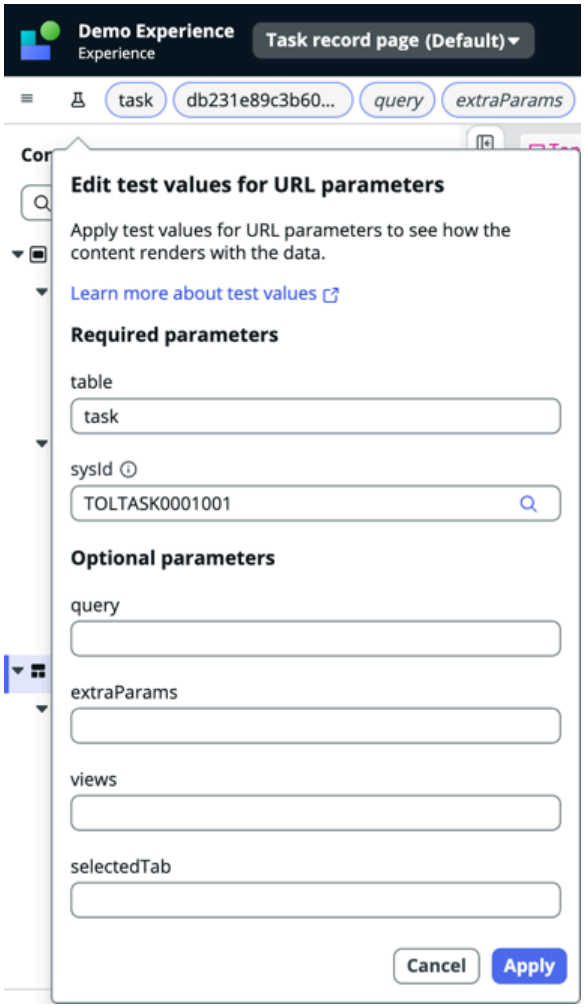
Set the audience and conditions settings for UI Builder page variants. When you create a page, UI Builder also creates a variant of the page for you by default. A page variant is a variation of your page at the same path that lets you target experiences for different audiences using user criteria. For example, a page for managers, and a variant of that page for the manager's direct reports. For more information about creating a variant, see Create a page variant.



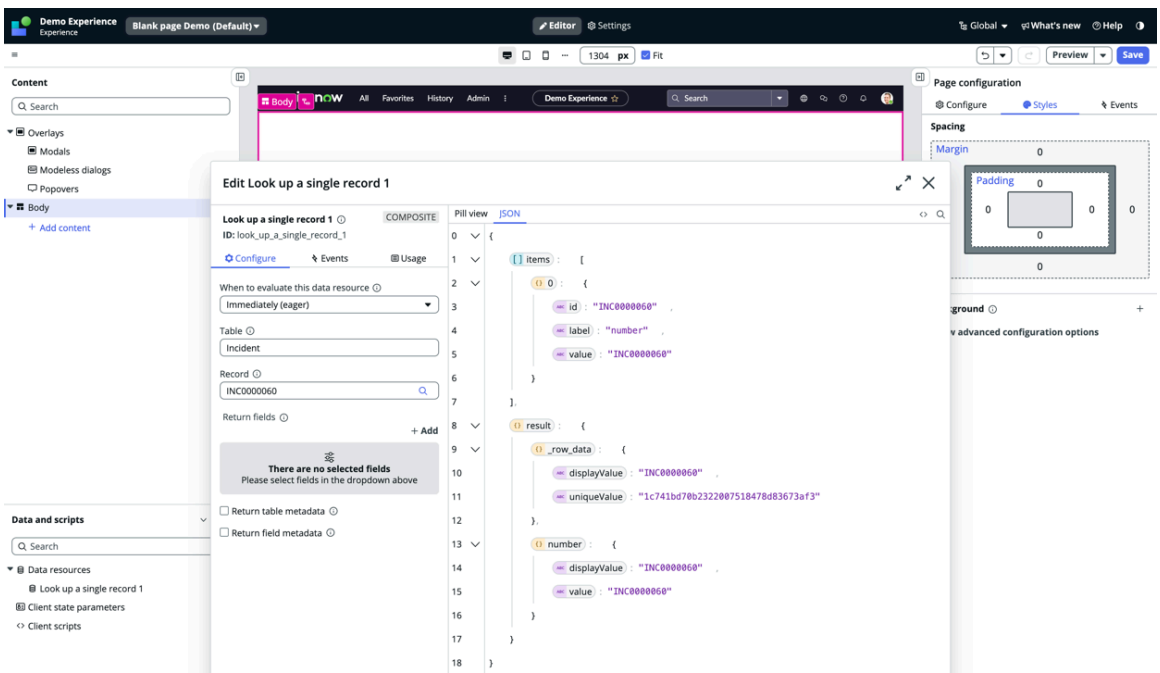
For more information about audiences, see Learn about audiences.

Test values in UI Builder

Add a test value to your UI Builder page as a way to bring test data into the page for testing purposes. For example, if you add a table as a required parameter, you could add a test value of incident and bind a data resource to it to bring in test data on the incident for that table.

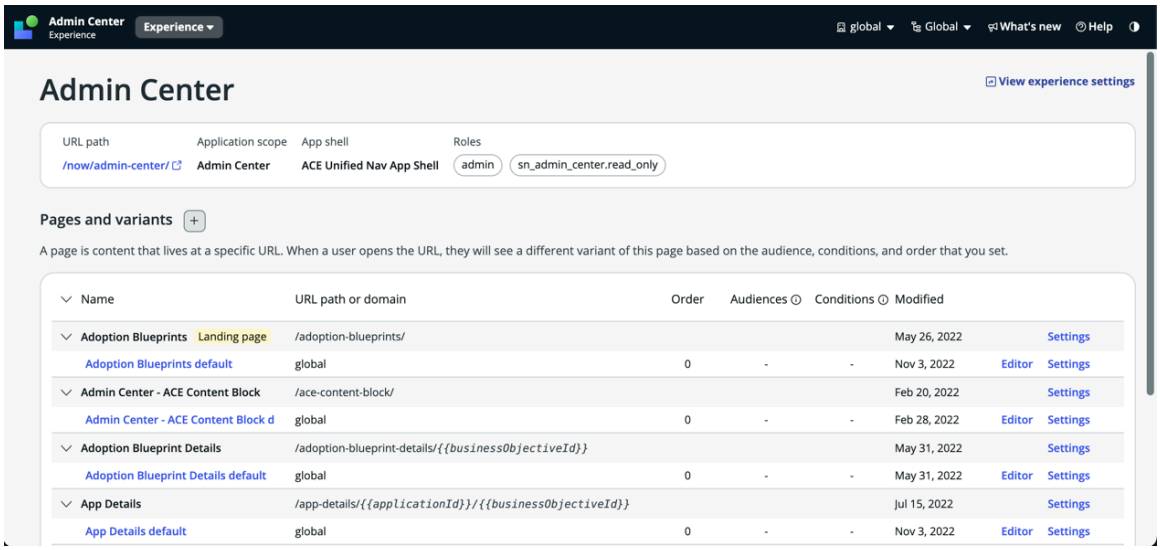


To get test values to show data, add a data resource, then configure the data resource to bind a record to the test value in the URL. For example, you could add `incident` as a test value. Then add a data resource named **Look up a single record**. In the **Table field**, dynamically bind the incident test value to a `context.props.table` table, as shown in the following image.

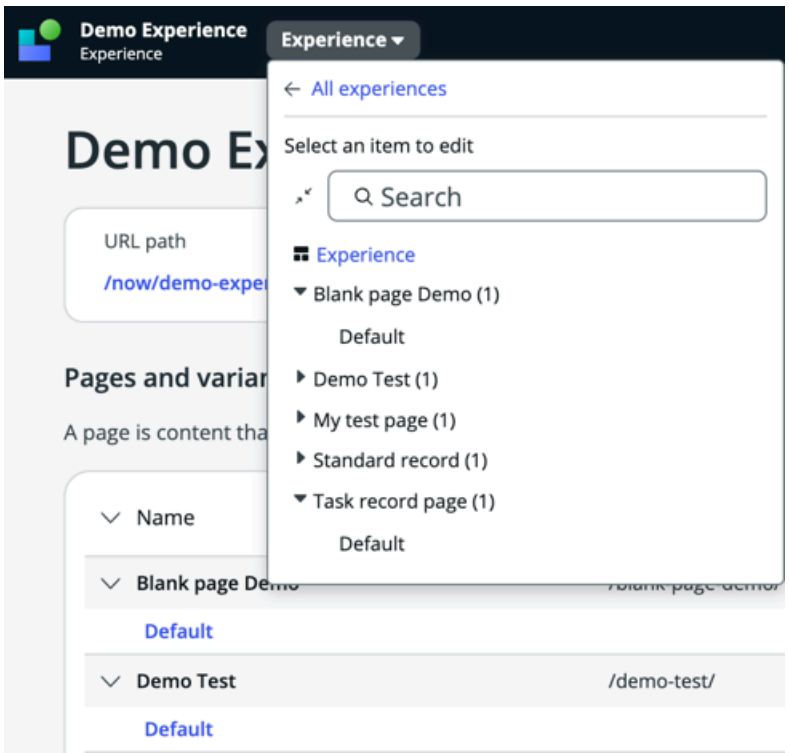


View an existing UI Builder page

You can work in any UI Builder page in your experience based on your role settings. Click on the name of the page you want to work in while in the experience view of your experience.



While in the page editor, open a different page variant by selecting the drop-down in the header.



Create a UI Builder page variant

A variant lets you target different audiences with different content, using user criteria. For example, you can create a homepage for agents, and a variant of the page for managers that exists at the same URL path.

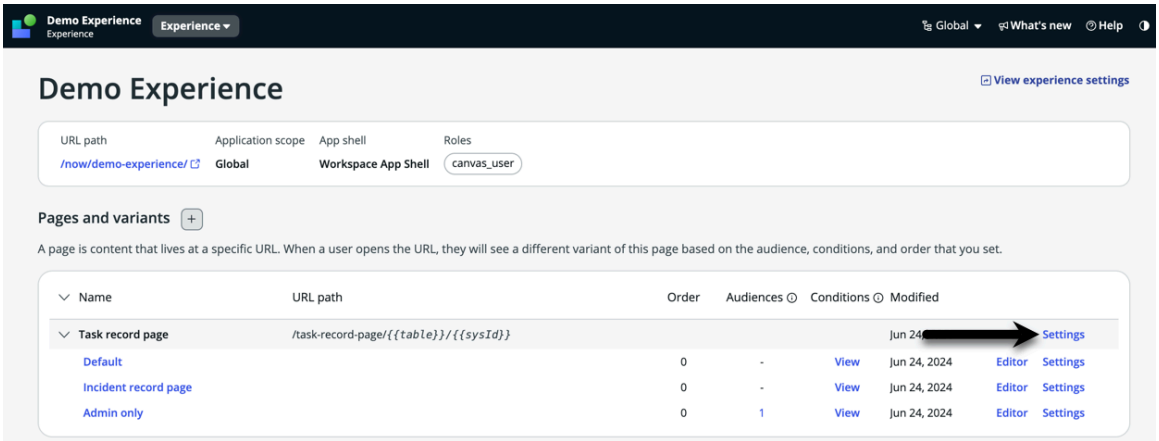
You set the audience for each UI Builder page variant. The audience determines who uses the page variant. For example, if you create a travel request page, create a variant of that page for managers to manage the employee travel requests. You set the audience for the manager page

for anyone in the manager role. Employees cannot view that variant. For more information about audiences, see Learn about audiences.

See Create a page variant for more information.

Edit UI Builder page settings

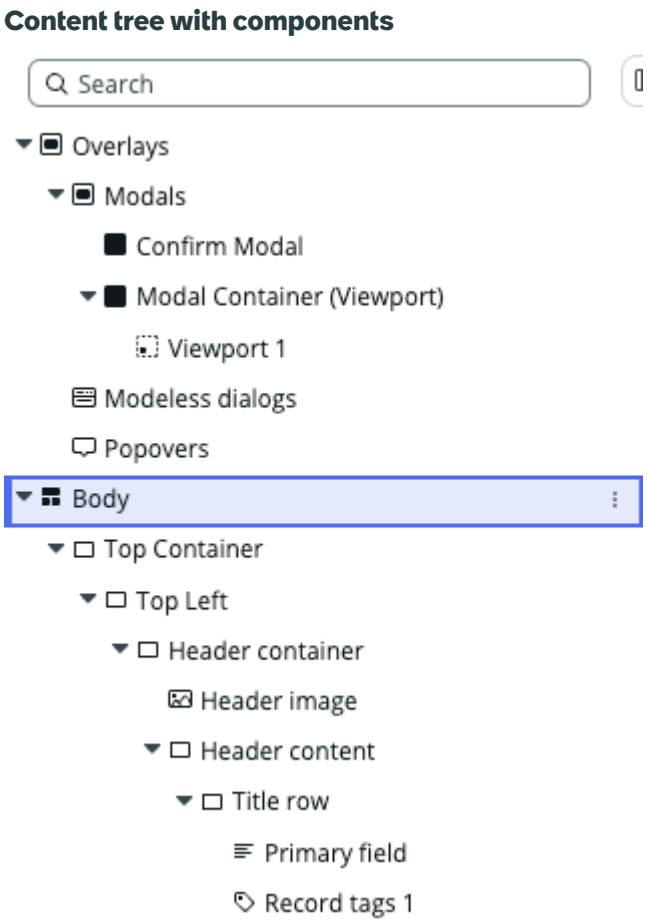
Change the settings of your UI Builder page at any time by selecting **Settings** in the UI Builder experience view. You can change the name, path, and parameters of your page after you create a page.



See Edit a page for more information.

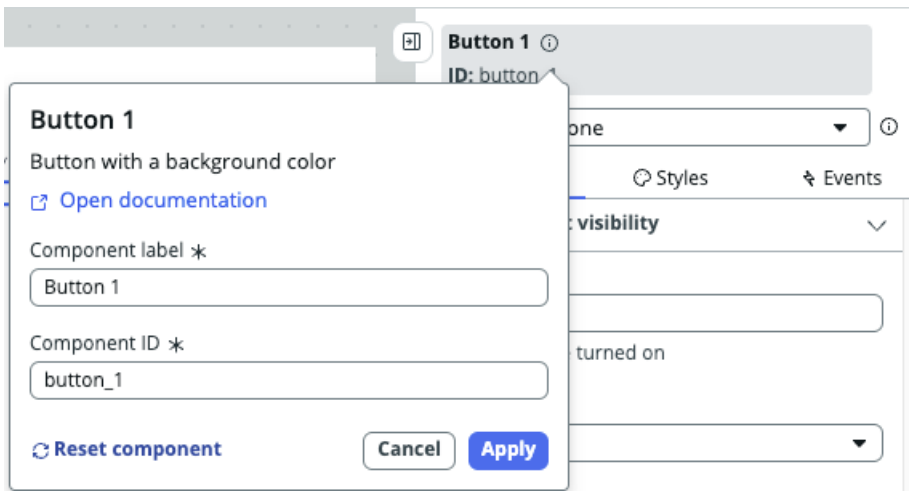
UI Builder Content tree

The content tree in the page management panel is important. It not only shows every column layout, column, and component on your UI Builder page, it lets you easily find your components and work with them. The content tree is especially important when you have multiple components on your page. You select the component in your content tree to highlight the component on the page, making it easier to build your page.



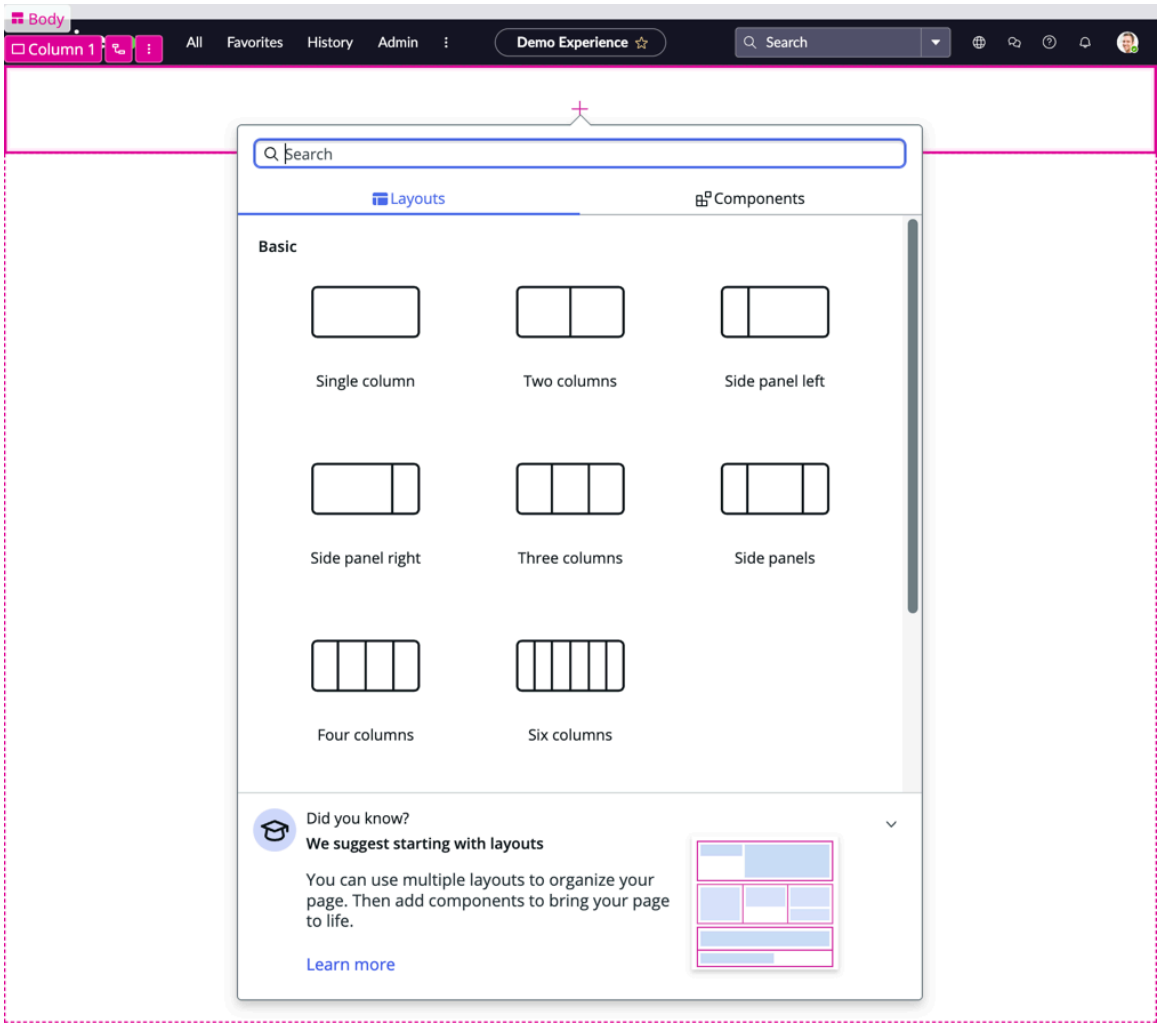
When you click a component in the content tree, it highlights the component on your stage so you can configure, add styling, events, data, and so on. You can drag items in the content tree to reorganize your page.

It's important to add a component label when you add a component to your page. The component label is used in the content tree to apply labels IDs to each component in the content tree. You can identify the components much easier in the content tree when they're labeled appropriately.



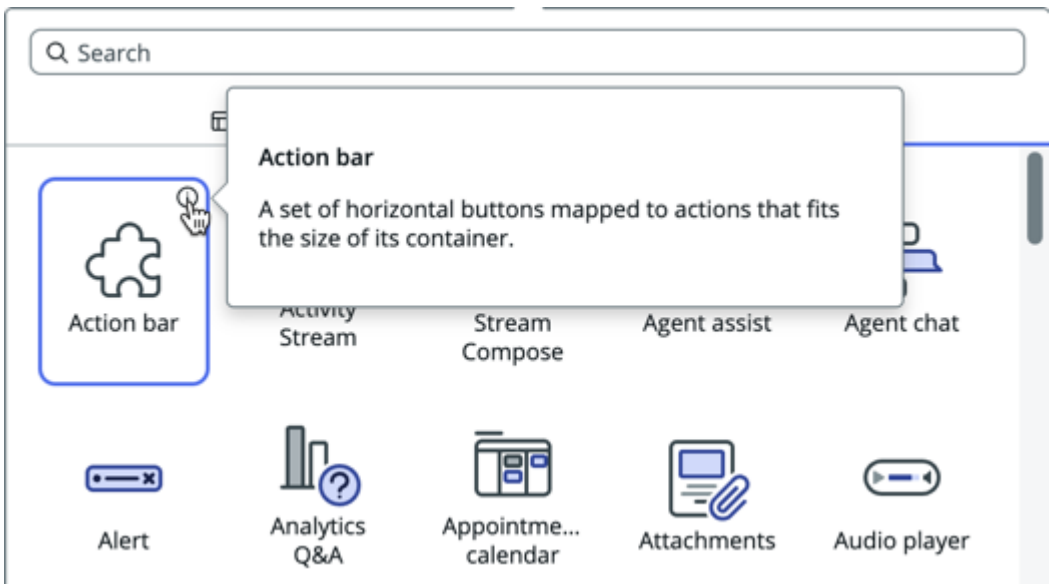
UI Builder Toolbox

Use the UI Builder toolbox to add layouts and components to your page. Access the UI Builder toolbox by selecting **+ Add content** or the **+** icon in the stage.



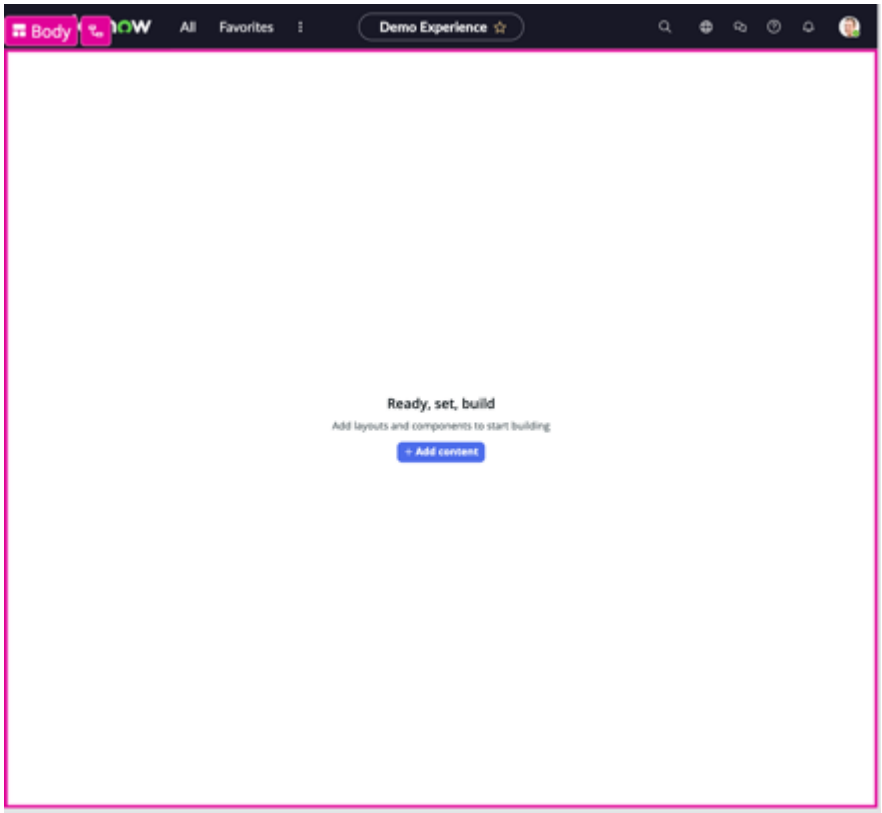
Search the toolbox to find layouts and components that you want to add to a UI Builder page.

View a brief description of a layout or component by selecting the information icon ⓘ to view the tooltip. The components tab displays different colors if a component can use a preset or is bundled with multiple components.

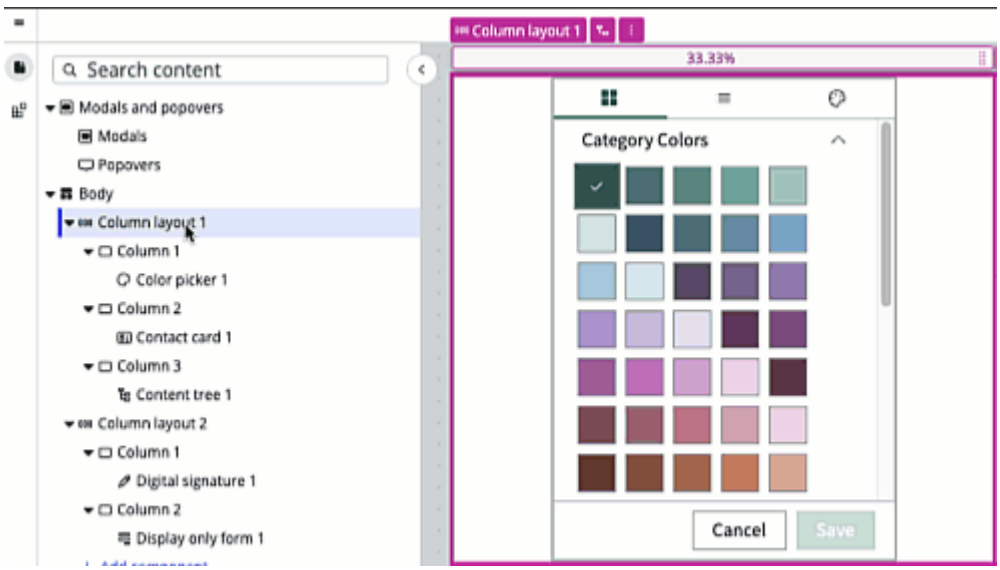


UI Builder Stage

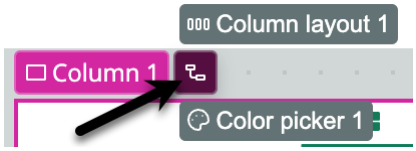
The stage is the largest area in the UI Builder editor and is used for building pages. Add your column layouts and components here by either selecting a + button, or dragging from the Component pane to the page.



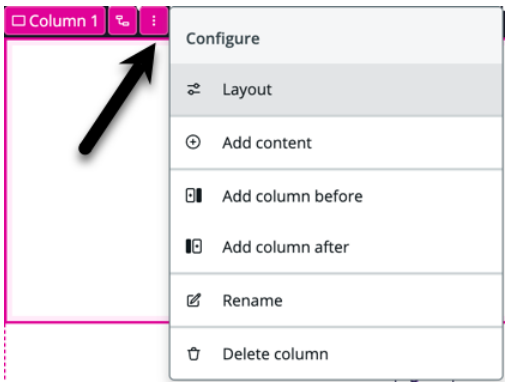
On the stage, the body, column layouts, and columns are outlined in magenta. Components are outlined in blue.



Use the Tree item icon to navigate to a different layer of content. For example, if a column is selected, easily navigate to the parent column layout or a component within the column.



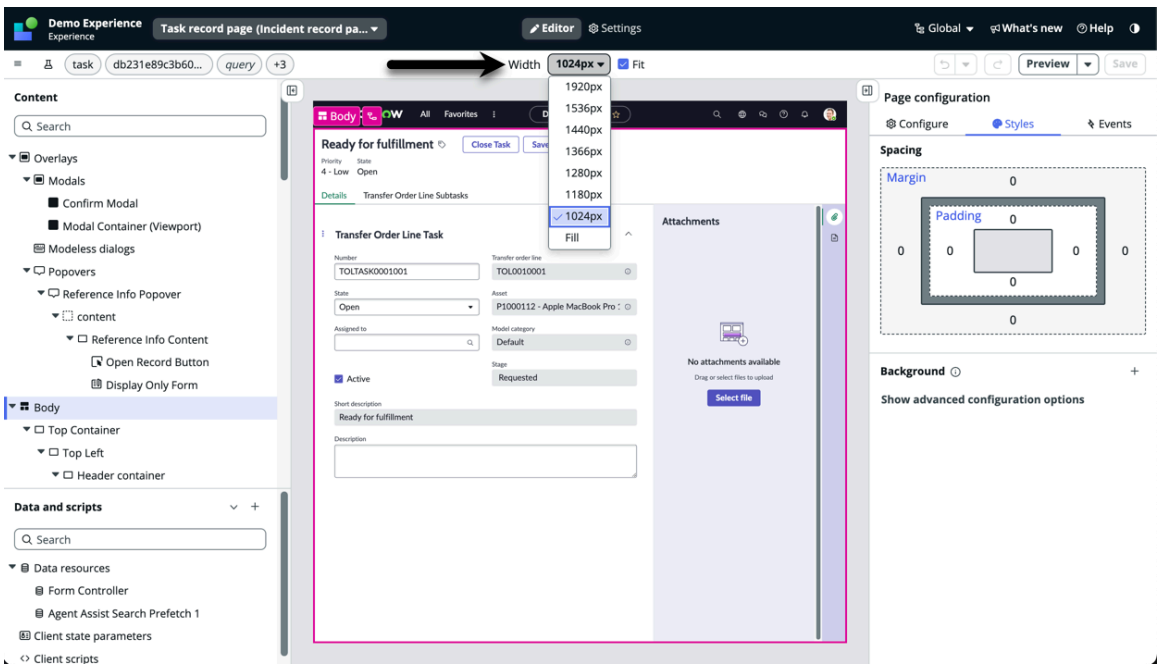
Select the Menu icon on a column layout or component for options such as duplicate and delete.



Changes made on the stage are reflected in the Styles panel at right. Changes made in the Styles panel immediately update the elements on the stage.

Scale the size of the stage in UI Builder

Adjust the size of the stage in the UI Builder editor by selecting the Width drop-down.

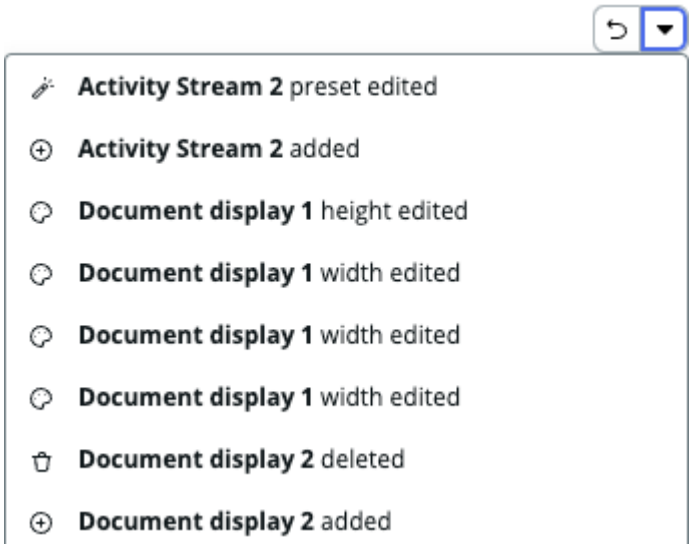


Undo and Redo in UI Builder

Undo and redo changes you've made to your UI Builder page. Reverse any action you make to a page layout, component, style or layout.

The undo and redo function can be found in the header toolbar. You can select the undo ( ) or redo ( ) button to reverse an action. You can also click the undo drop down to go back multiple steps. You cannot undo and redo changes made in the data shelf.

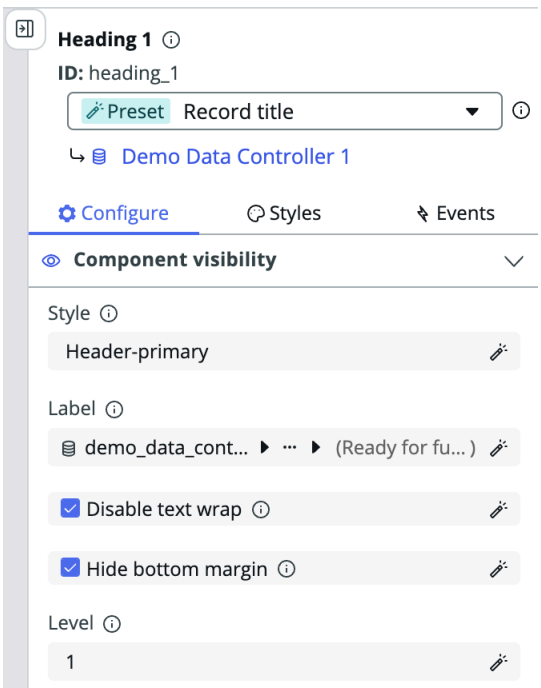
You can undo the previous 20 actions by selecting the undo drop-down.



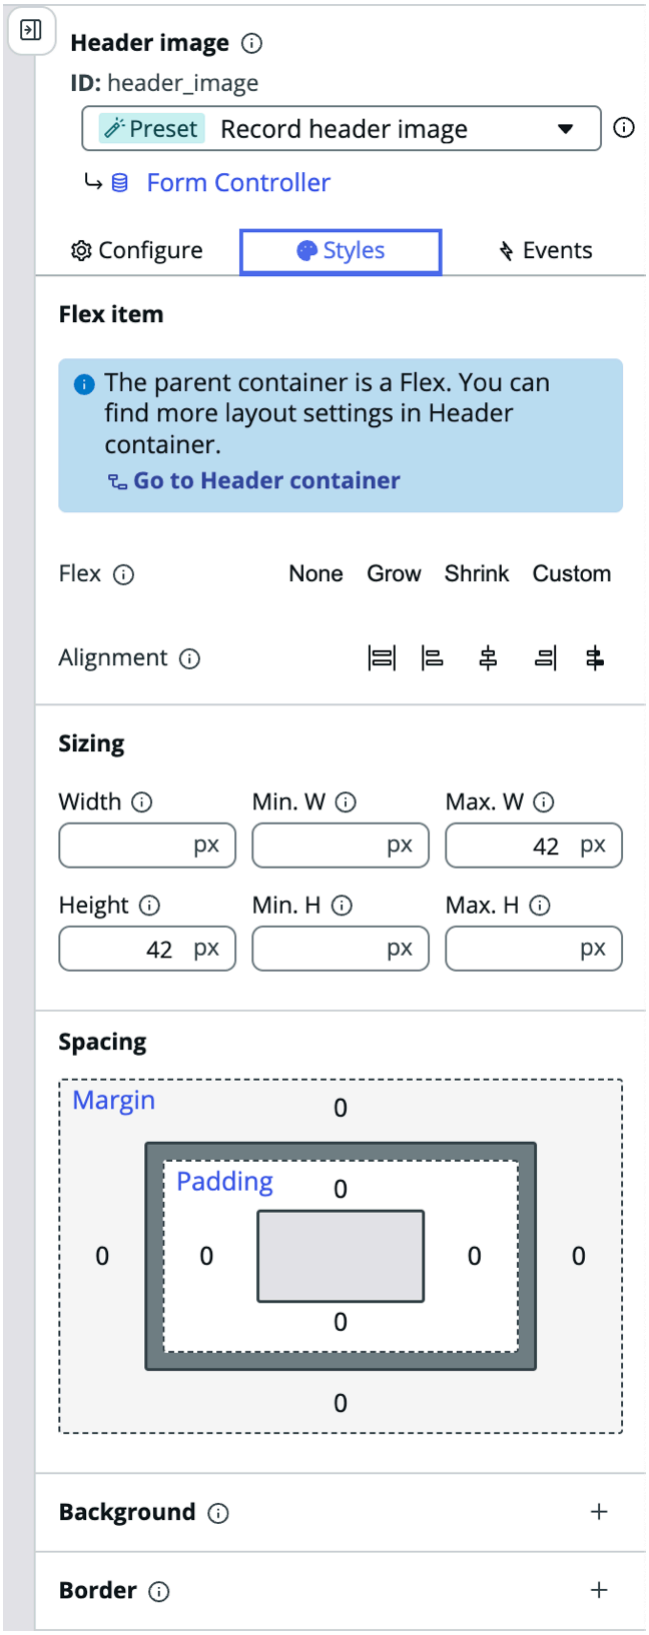
UI Builder Configuration panel

Use the configuration panel to work with components, including arranging, styling, and setting up event handlers.

- Select the **Config** tab to configure components. Each component has different configuration options that let you control the necessary parts of the component. For example, a button component is simple, and you can only configure its appearance, label, and a few properties. A list component is more complicated, and contains dozens of editable list parameters.

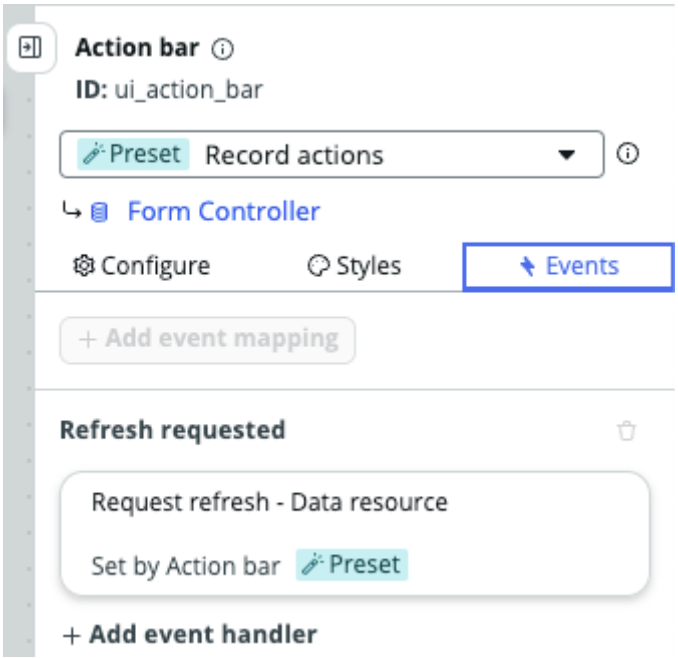


- Select the **Styles** tab in the configuration panel to add styling to a component. You can use standards-based Cascading Style Sheets (CSS) to change the visual style of a component. For example, add or change a background color, a border, or any other CSS style.



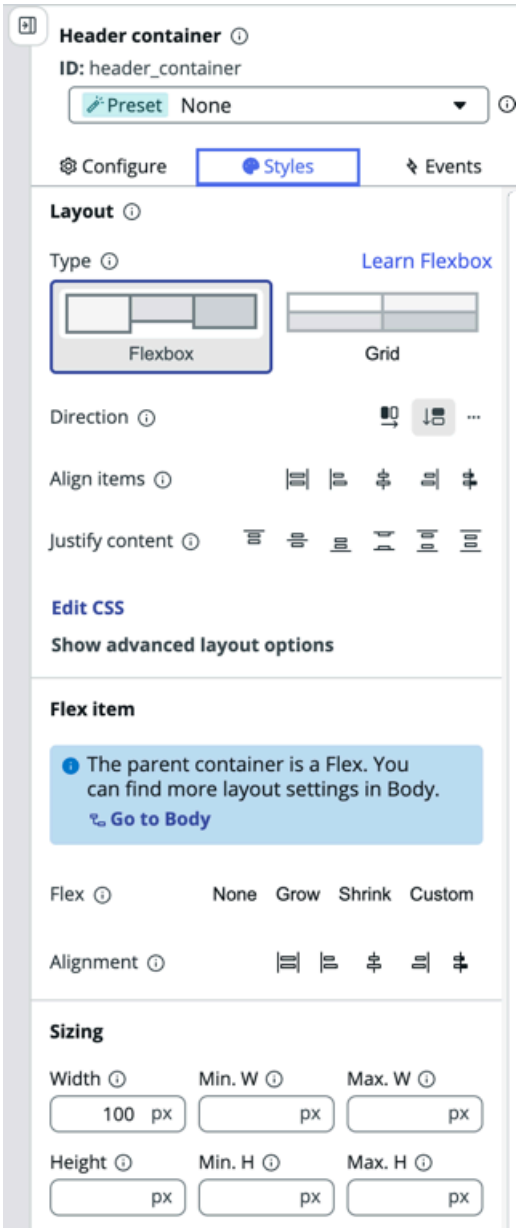
See Change the default appearance of components for more information.

- Select the **Events** tab to configure events that add actions to your components, pages, data resources, and declarative actions. When you add components to your UI Builder page, they are not configured to perform any action. For example, a button component is static and does not do anything until you bind an event action to it, such as deleting a record.



See Manage actions in UI Builder pages for more information.

- Column layouts govern how components are arranged on a page. When you add a column layout to a UI Builder page, you can configure how you want the layout designed. After you add a component to a column in the layout, you can configure the elements in more advanced ways. For example, you can justify the content, align items, and set the height, width, margins, background, borders, and padding of your column layout, columns, and components. CSS grid is the most powerful layout system. CSS Grid is built on top of a two-dimensional grid that gives you power over how you create your pages.



See Organize components in UI Builder pages for more information.

Open a UI Builder page to preview it

Preview a UI Builder page to see what the page looks like as a web page.

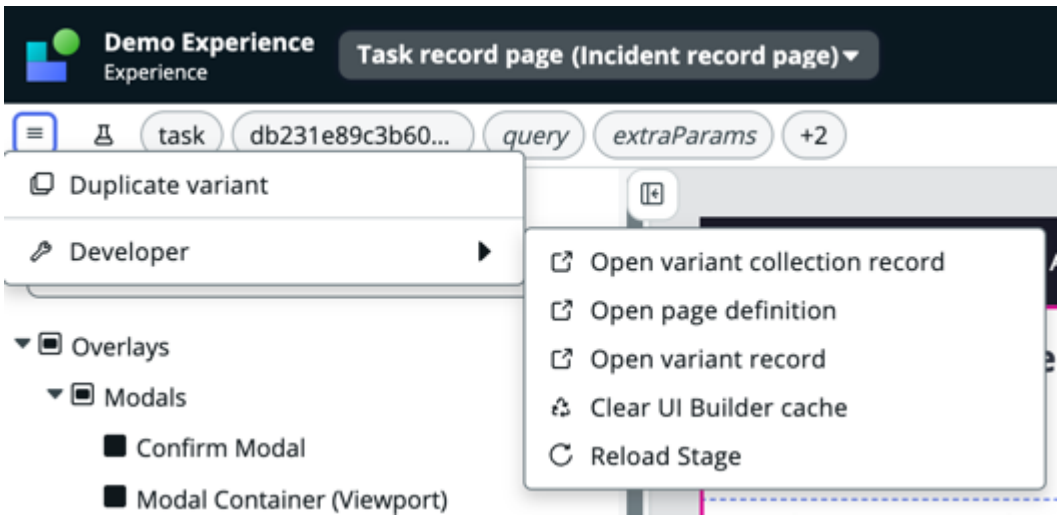
Select the Preview button to test the variant that you're currently working on, including modals, viewports, components, data resources, and dynamic data. Previewing a page variant is useful for seeing how it looks and functions while building an experience.

Another method of previewing a page is to request the URL path from the server. Use this method to test if a user sees the variant when they open the page. Select the drop-down arrow next to **Preview** and select **Open URL path** or select **Preview > Open URL path** Open URL path.

See Learn how to view and test your UI Builder experience for more information.

Developer editing in UI Builder

From the Menu, edit the UI Builder page as a developer on the platform. This option lets you change the platform-level details of your page and takes you out of UI Builder. You must have the proper role as a developer.



Create a page in UI Builder

Create a page in UI Builder for a portal, workspace, or custom application so that you can build a web experience for your users.

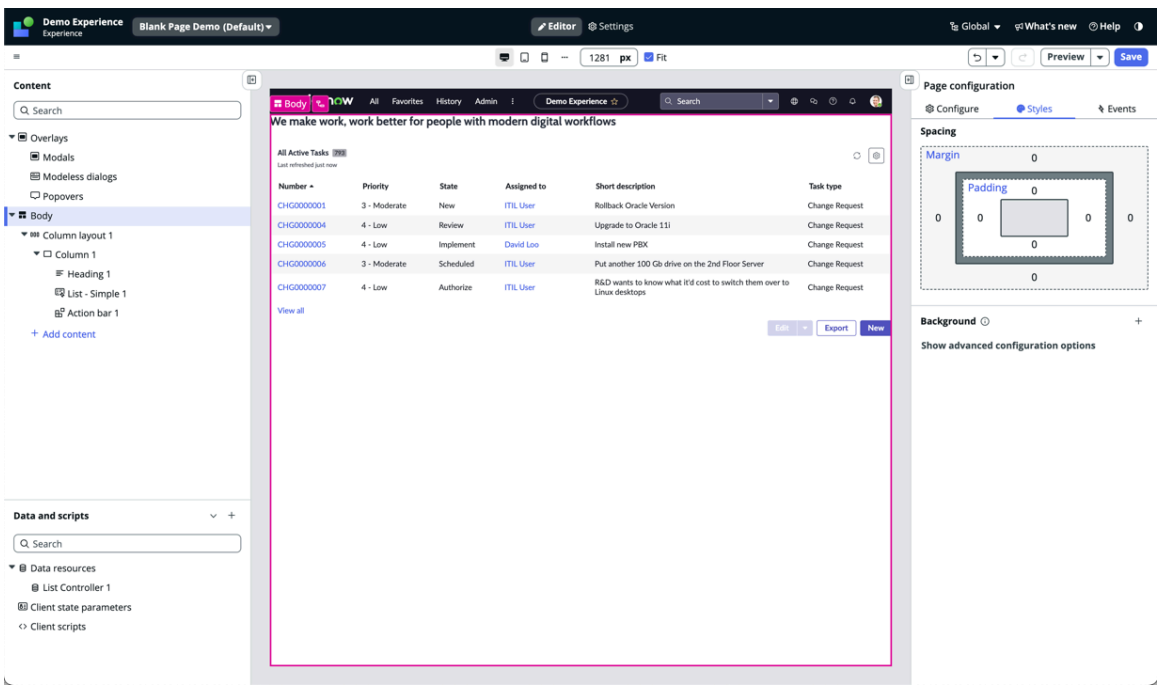
Before you begin

Role required: ui_builder_admin

About this task

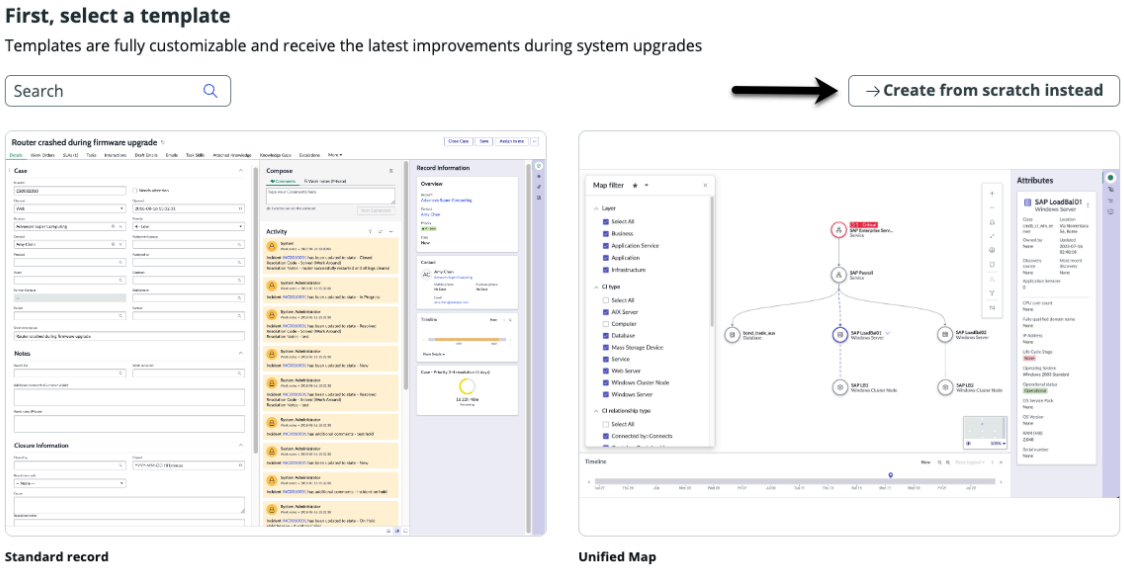
A page has a collection of components that make up a workspace, portal, or custom application user interface (UI).

UI Builder



Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Select the **Create new page** in the center of the screen.
4. Select **Create from scratch instead**.

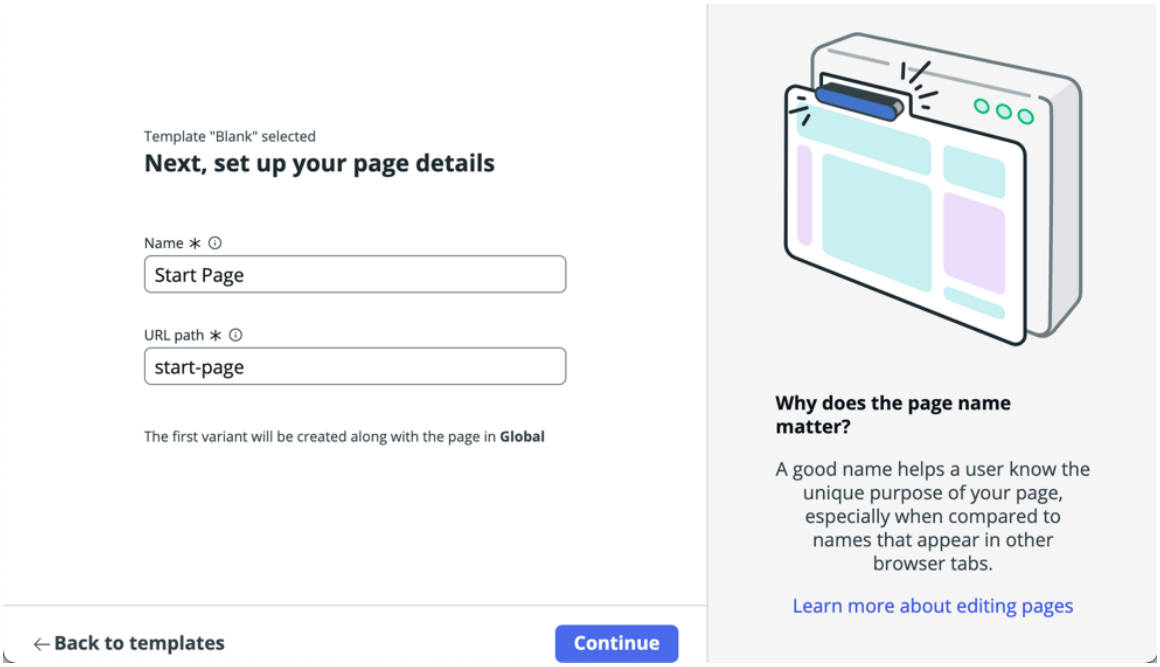


You can also create pages using page templates, see Create a page from a template for more information.

> **Note:**
> As of Xanadu Store Release 1, responsive authoring is available when creating a new UI Builder page from scratch. Responsive authoring is not available for existing pages or pages created with a template, however, these types of pages will continue to use the existing, default reflow model. For more information, see Responsive authoring.

5. Enter a unique name for the page in the **Name** field.
6. Specify a path for your page in the **URL Path** field. UI Builder generates a default path based on the name that you provided in the previous step.

   A default path is added based on your page name. You can also create your own path. The path is required and must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a few special characters (`" - "`, `" . "`, `" _ "`, `" ~ "`), with the words separated by a forward slash or hyphen. The **URL preview** shows the path of your page.



Note:
The application scope defaults to the scope that the user is currently in within the ServiceNow AI Platform®. For more information about the application scope, see Learn about security and roles.

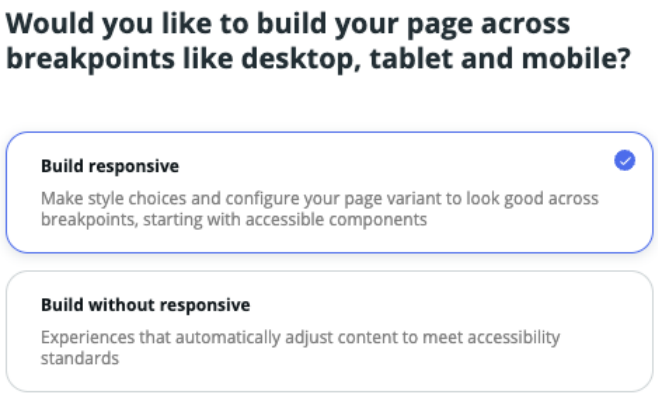
7. Select **Continue**.
8. Add required parameters to your page URL.
   a. Click **+ Add**.
   b. Enter the required parameters for your page.
   A required parameter is a piece of data that your page requires, such as a sys_id, table, or query. Required parameters are useful for components, because they can bind to the value of the required parameter.

   For more information, see Manage UI Builder pages and page variants.
9. **Optional:** Add optional parameters to the URL of your page.
   a. Click **+ Add**.
   b. Enter the optional parameters for your page.
   Unlike required parameters, optional parameters are always name and value pairs that work no matter what order that they are provided in.

For more information, see Manage UI Builder pages and page variants.

10. Select **Looks good**.
11. Enter a name for the page variant.
    The form automatically contains **Default** but you can edit the page variant name.
12. **Optional:** Add one or more audiences for this page.
    If an audience you need is not listed, you can choose the Open audiences in platform link to create one.
13. **Optional:** Declare conditions for when to display the page by either using the provided dropdown menus or writing an encoded query string.

    (Optional) For more information on writing encoded queries, see Encoded query strings.
14. Select **Continue**.
15. Select the **Build responsive** option (default) for greater control of how the page appears at different screen form factors or select **Build without responsive** for automatic adjustment.



For more information, see Responsive authoring.

16. Select **Create** to create your blank page.
    The page opens in Editor view so you can start adding content such as layouts and components. For more information, see Customize UI Builder pages using components.

Create a page from a template

Use a template to create a page based on a pre-defined page template. A page template can help you create pages faster and keep pages consistent within an experience. Page templates may include components, data resources, and a layout.

This video shows you how to perform the following procedure. This video shows you how to create page from a template within a UI Builder experience.

Before you begin

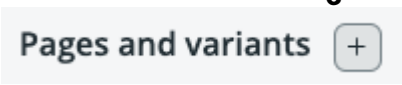
Role required: ui_builder_admin

About this task

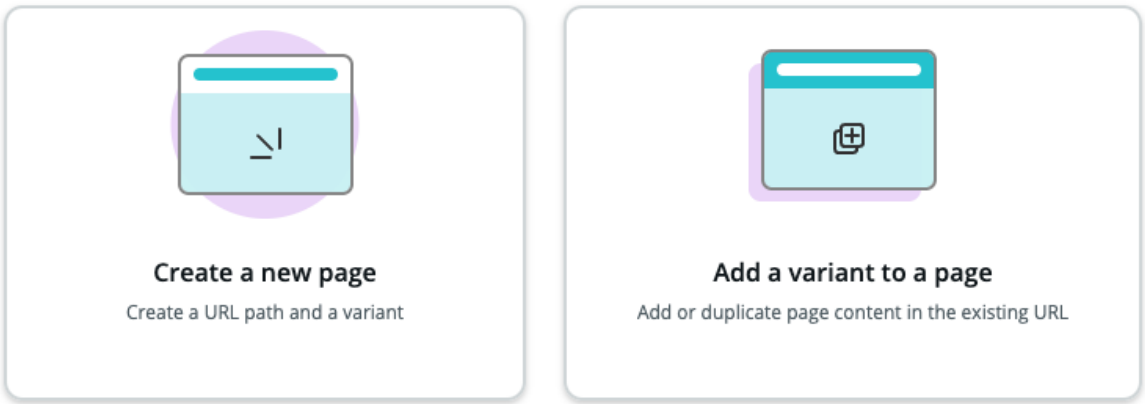
Select a page template when creating a page in your experience. After creating a page from a template, you can customize the page to your needs. Page templates include controllers that can be used with component presets. See Bind data to UI Builder pages using controllers (advanced feature) for more information.

Procedure

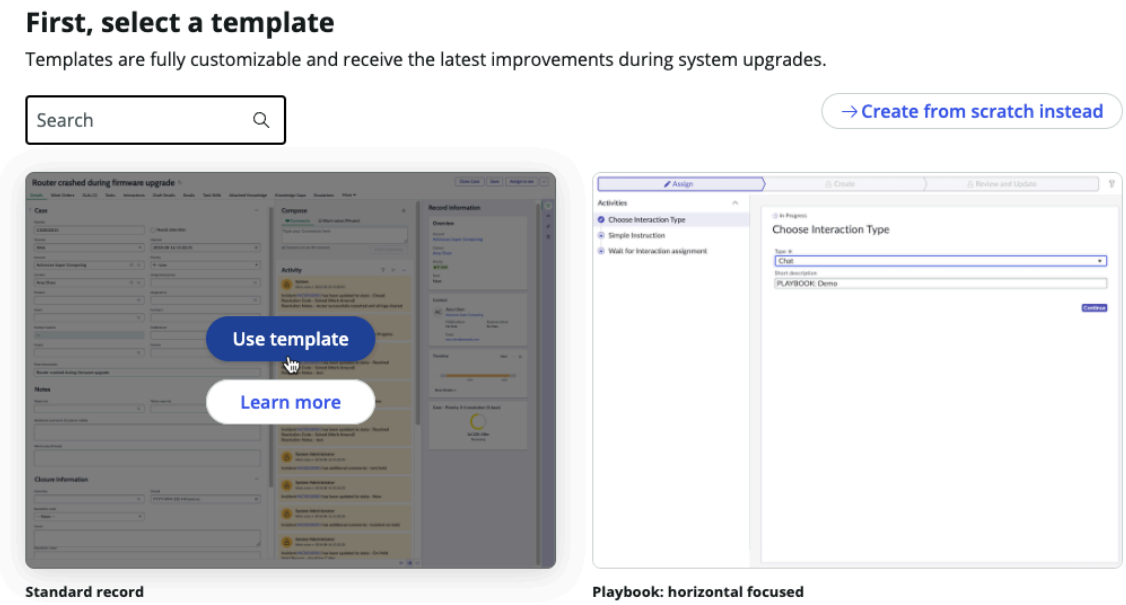
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Select the **+** icon in the **Pages and variants** section.



4. Select **Create a new page**.

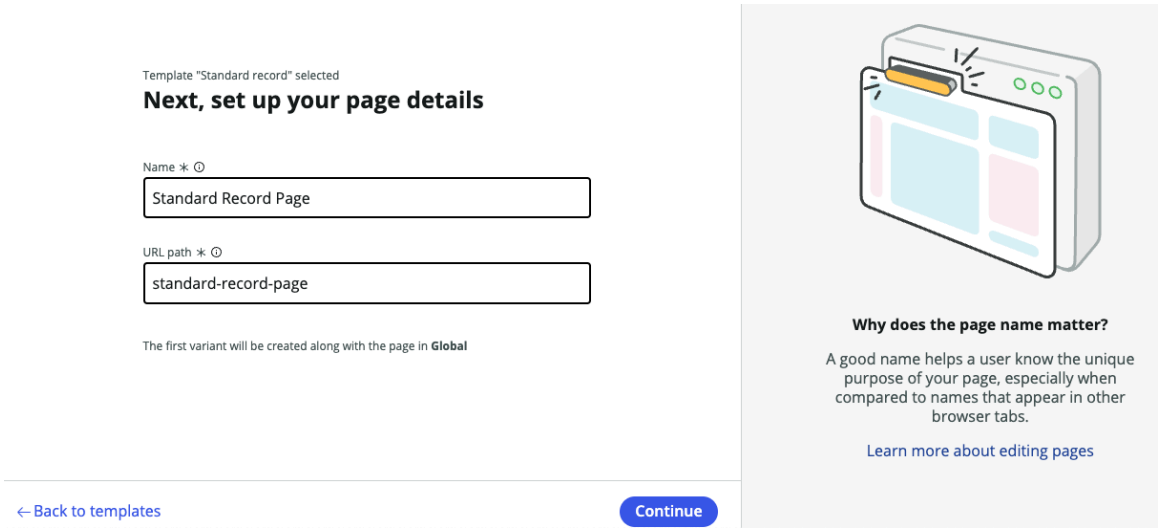


5. Select **Use template** when pointing to the template that you want to use.



6. Enter a unique name for the page in the **Name** field.
7. Specify a path for your page in the **Path** field. UI Builder generates a default path based on the name that you provided in the previous step.

A default path is added based on your page name. You can also create your own path. The path is required and must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a few special characters (`" - "`, `" . "`, `" _ "`, `" ~ "`), with the words separated by a forward slash or hyphen. The **URL preview** shows the path of your page.



Note:
The application scope defaults to the scope that the user is in within the ServiceNow AI Platform®. For more information about the application scope, see Learn about security and roles.

8. Select **Continue**.
9. Review the page parameters included in the template.
   For more information about required and optional page parameters, see Adding Page Parameters in the ServiceNow Developer website.
10. Select **Looks good**.
11. Enter a name for the page variant.
    The first variant you create is named **Default** by default.
12. Add one or more audiences for this page.
    If an audience you need is not listed, you can choose the Open audiences in platform link to create one.
13. **Optional:** Declare conditions for when to display the page (this variant) by either using the provided dropdown menus or writing an encoded query string.

    (Optional) For more information on writing encoded queries, see Encoded query strings.
14. Select **Create** to create your page from template.
    The page you created displays in the **Page and variants** section of your experience. Select **Editor** to start adding components to your page. For more information, see Customize UI Builder pages using components.

Create a page from a legacy template

Use legacy page templates to reuse a page definition, such as record or list page, for pages in your workspace or portal.

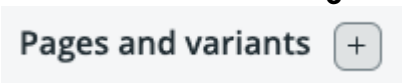
This video shows you how to perform the following procedure. This video shows you how to create a page from a legacy template in a UI Builder experience.

Before you begin

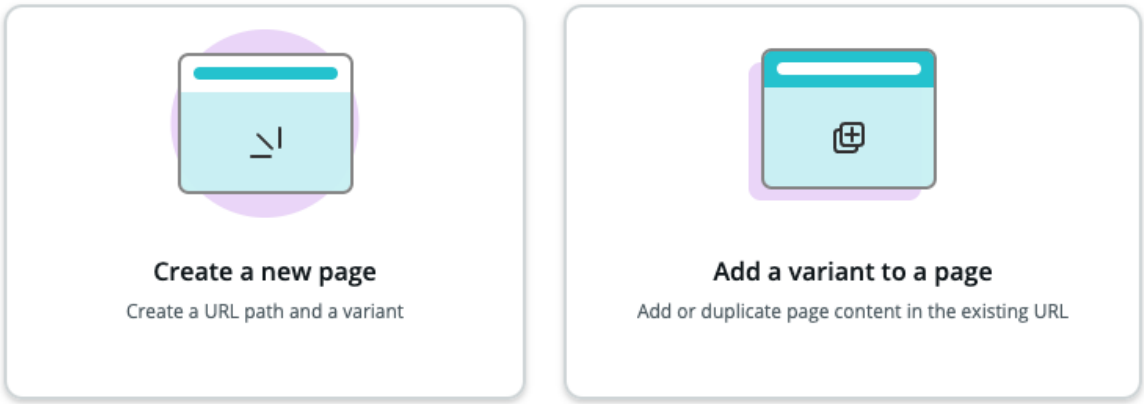
Role required: admin

Procedure

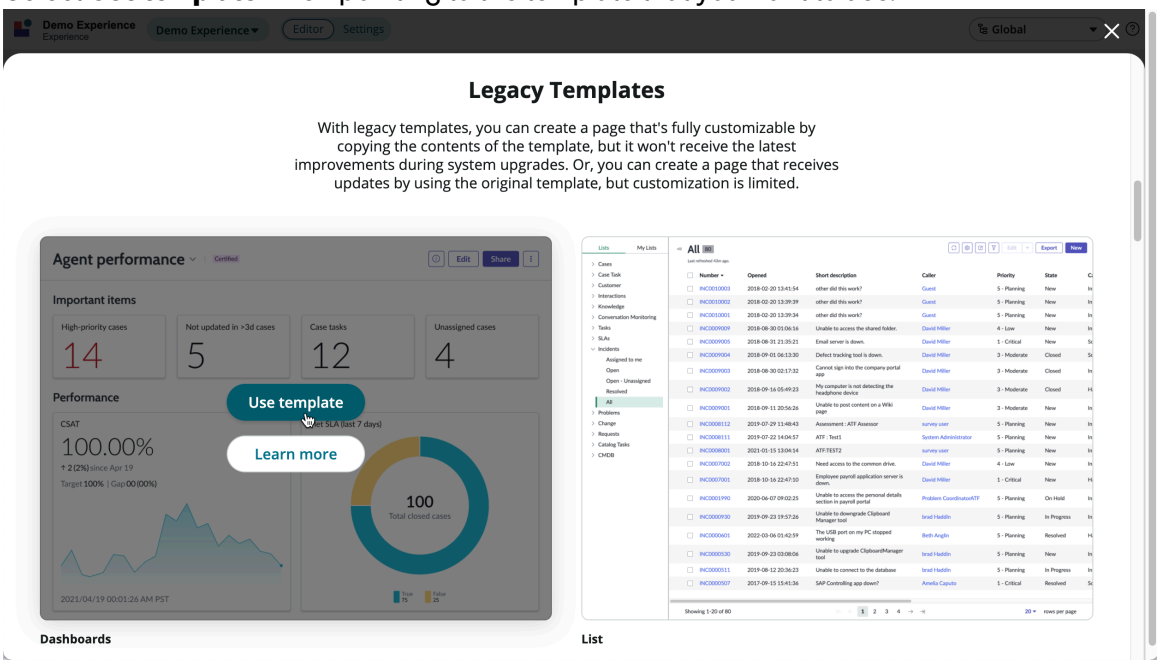
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Select the **+** icon in the **Pages and variants** section.



4. Select **Create a new page**.



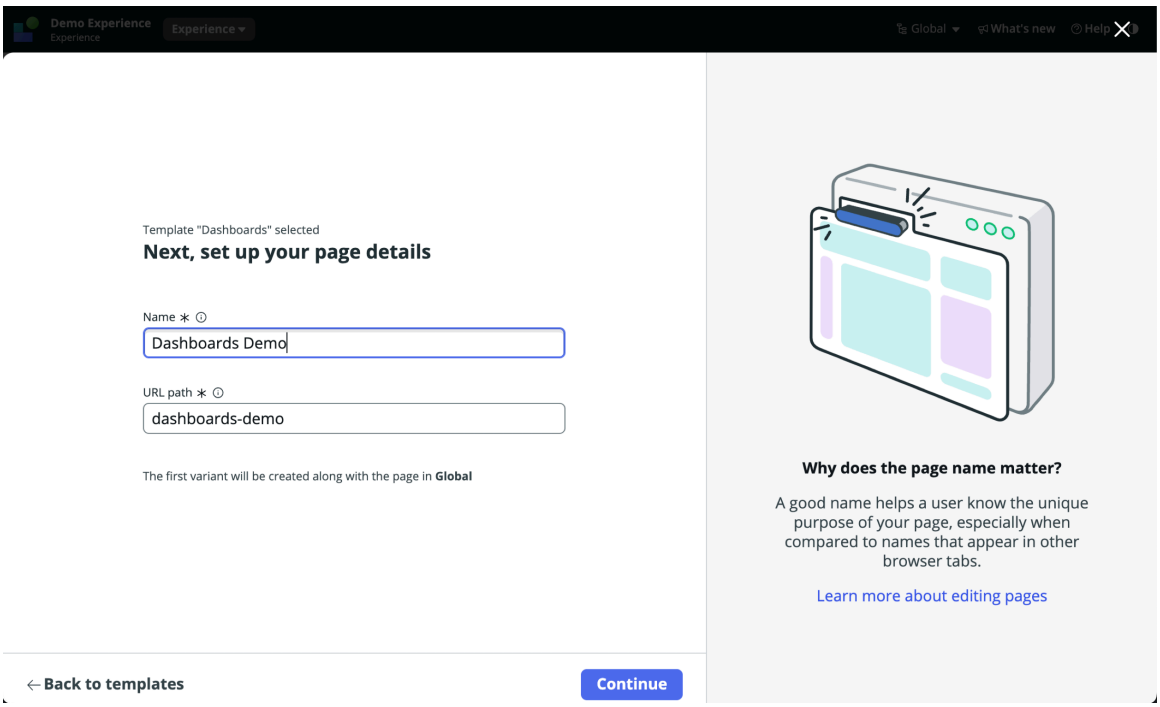
5. Select **Use template** when pointing to the template that you want to use.



6. Enter a unique name for the page in the **Name** field.
7. Specify a path for your page in the **Path** field. UI Builder generates a default path based on the name that you gave in the earlier step.

   A default path is added based on your page name. You can also create your own path. The path is required and must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a

few special characters (`" - "`, `" . "`, `" _ "`, `" ~ "`), with the words separated by a forward slash or hyphen. The **URL preview** shows the path of your page.

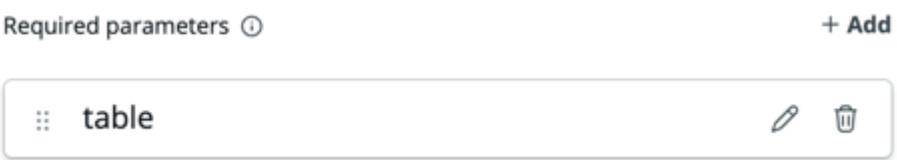


Note:
The application scope defaults to the scope that the user is in within the ServiceNow AI Platform®. For more information about the application scope, see Learn about security and roles.

8. Select how you want to use the base page template.
   Select **Use the original page (customization limited)** if you want to reference the template and its data. Select **Copy contents of the page (fully customized)** to copy the contents of the page template. When you reference a page template, your page automatically updates when you upgrade to a new release. If you copy the page template, your page will not update after upgrade.
9. Select **Continue**.
10. **Optional:** Add required parameters to your page URL.

    a. Click **+ Add**.

    b. Enter the required parameters for your page.
    A required parameter is a piece of data that your page requires, such as a sys_id, table, or query. Required parameters are useful for components, because they can bind to the value of the required parameter.



For more information about required and optional page parameters, see Adding Page Parameters in the ServiceNow Developer website.

11. **Optional:** Add optional pieces of data that you want to add to the URL of your page.

    a. Click **+ Add**.

    b. Enter the optional parameters for your page.
    Unlike required parameters, optional parameters are always name and value pairs that work no matter what order that they are provided in.

    For more information, see Manage UI Builder pages and page variants.

12. Select **Looks good**.
13. Enter a name for the page variant.
    The form automatically adds **Default** to the page name.
14. Add one or more audiences for this page.
    If an audience you need is not listed, you can choose the Open audiences in platform link to create one.
15. **Optional:** Declare conditions for when to display the page by either using the provided dropdown menus or writing an encoded query string.

    (Optional) For more information on writing encoded queries, see Encoded query strings.

16. Select **Create** to create your blank page.
    The page you created displays in the **Page and variants** section of your experience. Select **Editor** to start adding components to your page. For more information, see Customize UI Builder pages using components.

Edit a page

Edit a page to change the page name, path, and parameters.

Before you begin

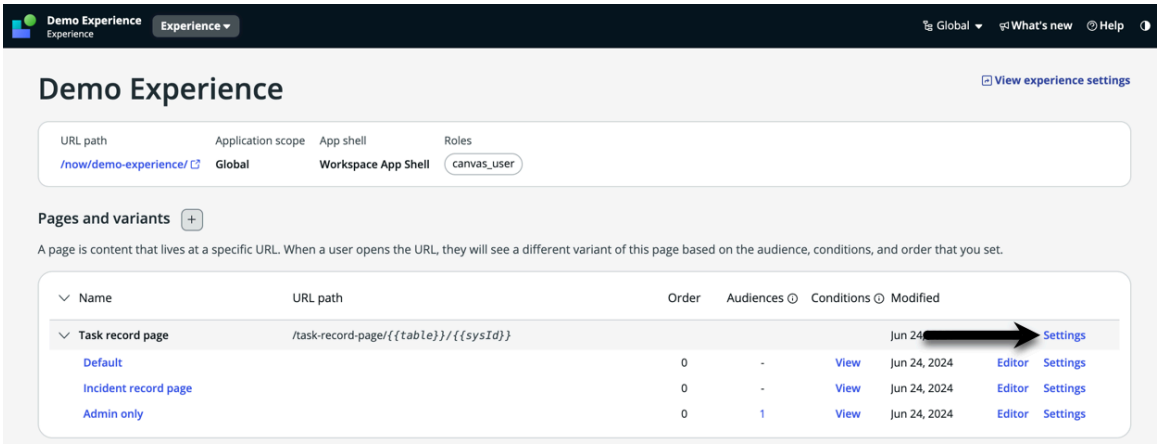
Role required: ui_builder_admin

About this task

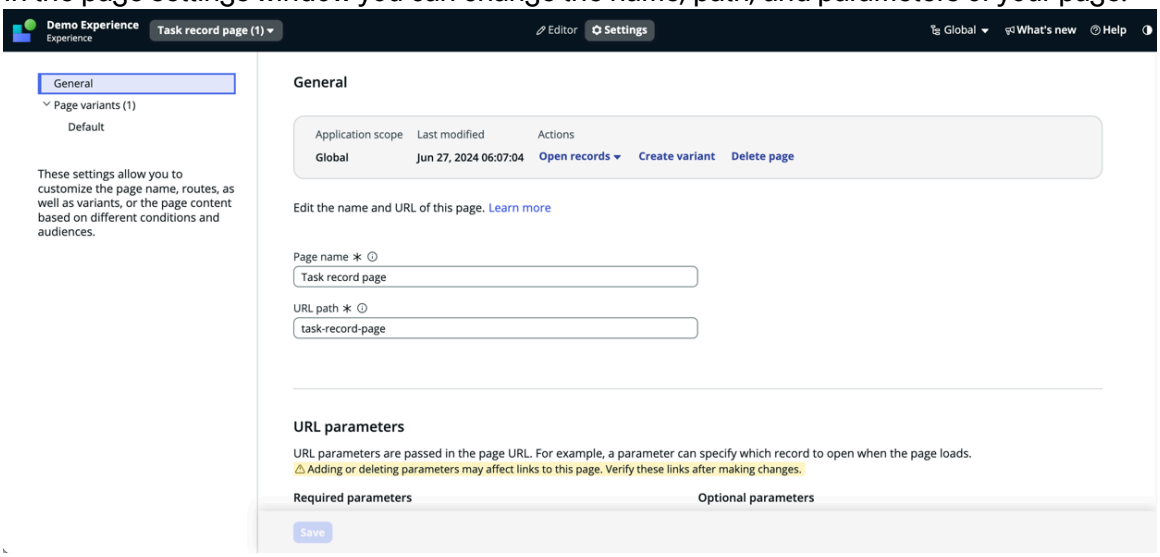
Edit page settings to change the name and path of your page. This is useful if you decide the name or path should be changed after you create the page. If your page is in a different application scope, you can choose to edit it in the original scope.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open the experience with the page that you want to edit.
3. Select **Settings** next to the page that you want to edit.



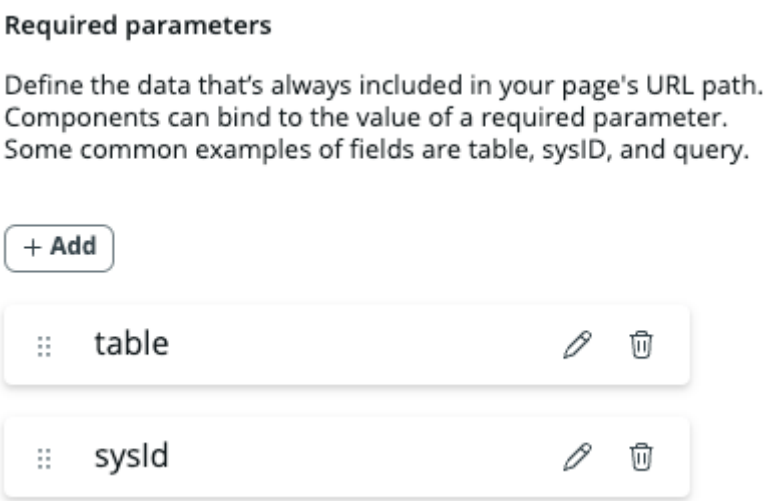
4. In the page settings window you can change the name, path, and parameters of your page.



5. Optional: Add required parameters to your page URL.

a. Click **+ Add**.

b. Enter the required parameters for your page.
A required parameter is a piece of data that your page requires, such as a sys_id, table, or query. Required parameters are useful for components, because they can bind to the value of the required parameter.



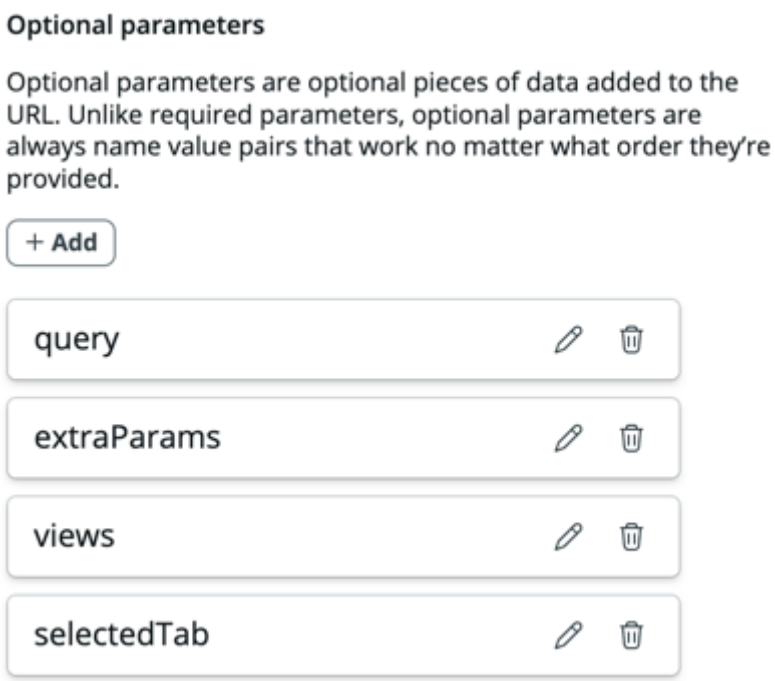
(Optional)

For more information, see Manage UI Builder pages and page variants.

6. **Optional:** Add optional pieces of data that you want to add to the URL of your page.

   a. Click **+ Add**.

   b. Enter the optional parameters for your page.
   Unlike required parameters, optional parameters are always name and value pairs that work no matter what order that they are provided in.



(Optional)

For more information, see Manage UI Builder pages and page variants.

7. Click **Save**.

Add an audience to your UI Builder page

Add one or more audiences to your page or page variant.

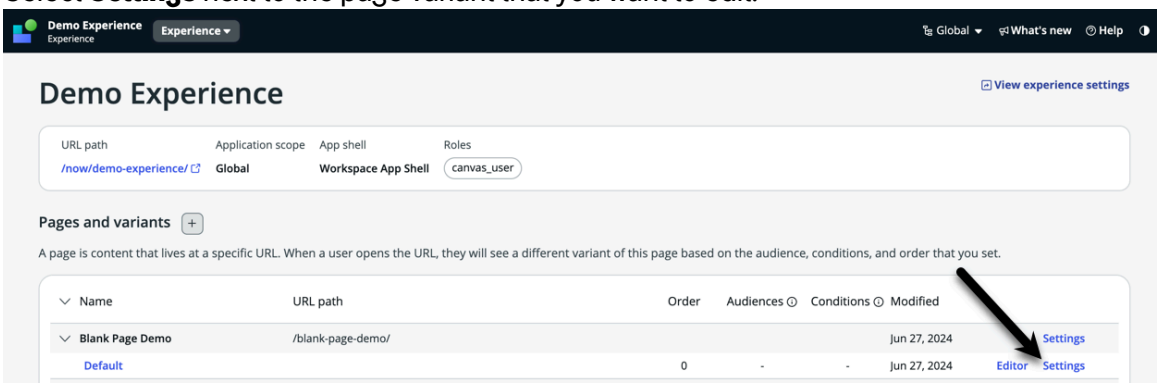
Before you begin

Role required: admin

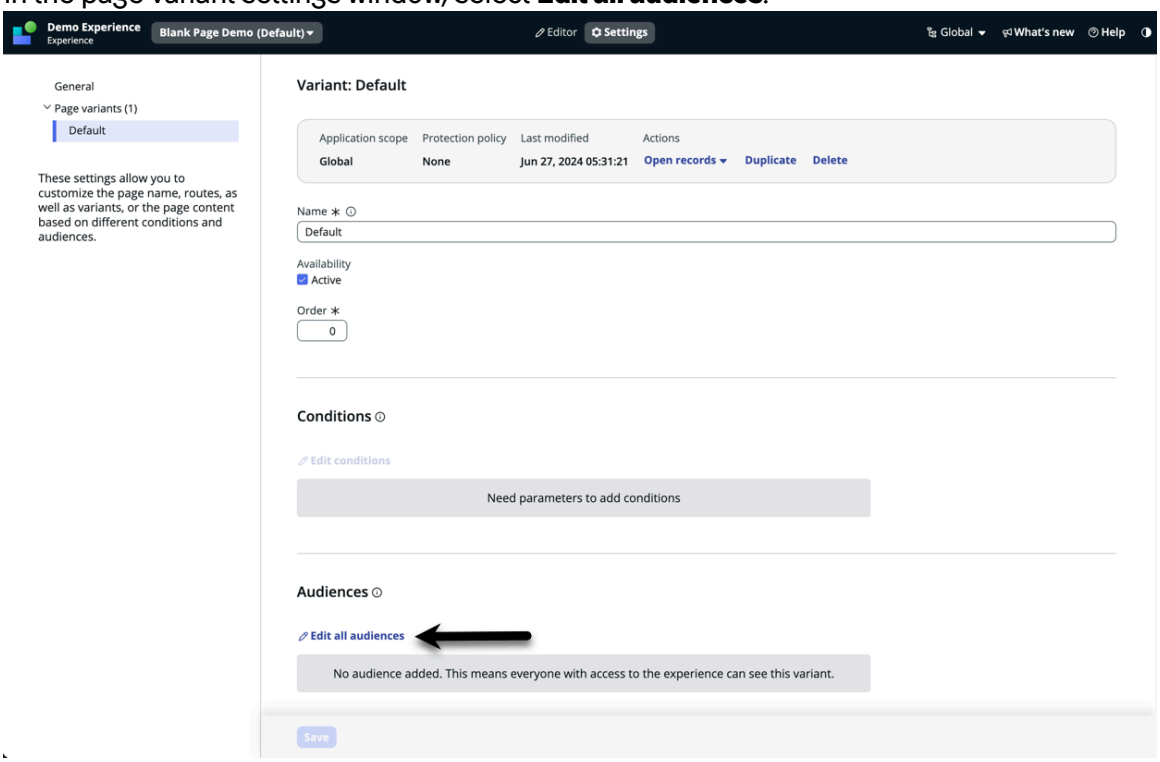
The *glide.ux.user_criteria_enabled* property needs to be set to **true** to configure access for users based on role, department, group, location, or company. See Enable the user criteria property, for more information.

Procedure

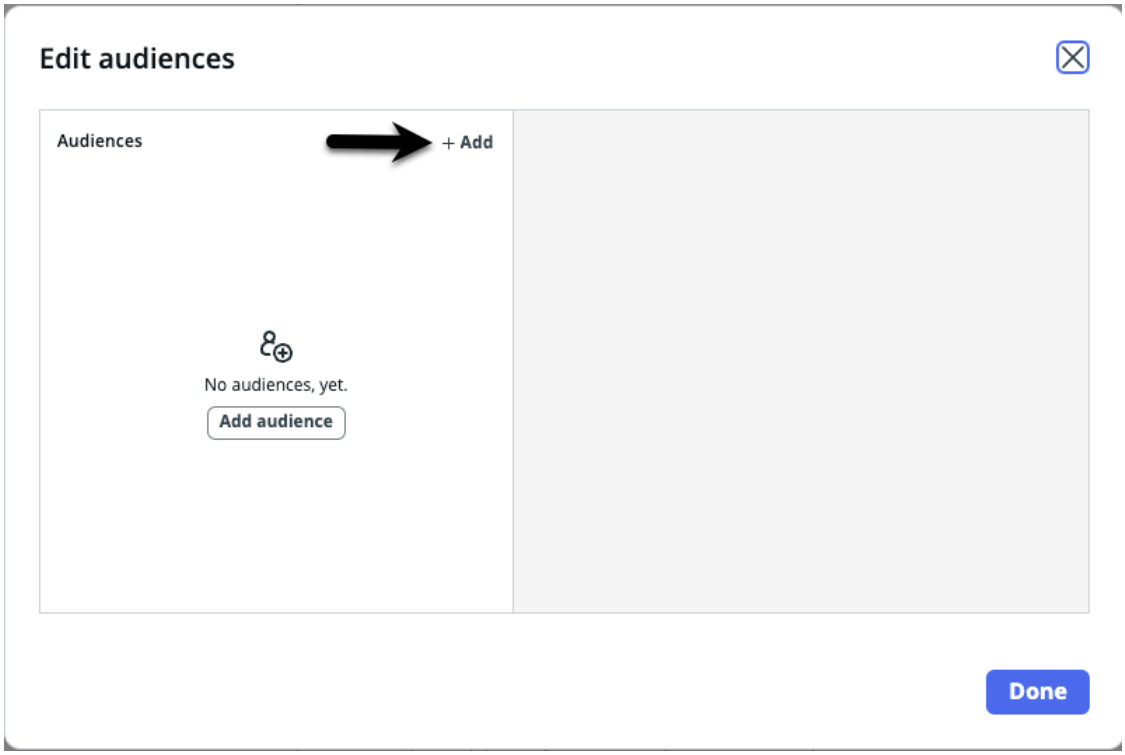
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open the experience with the page that you want to edit.
3. Select **Settings** next to the page variant that you want to edit.



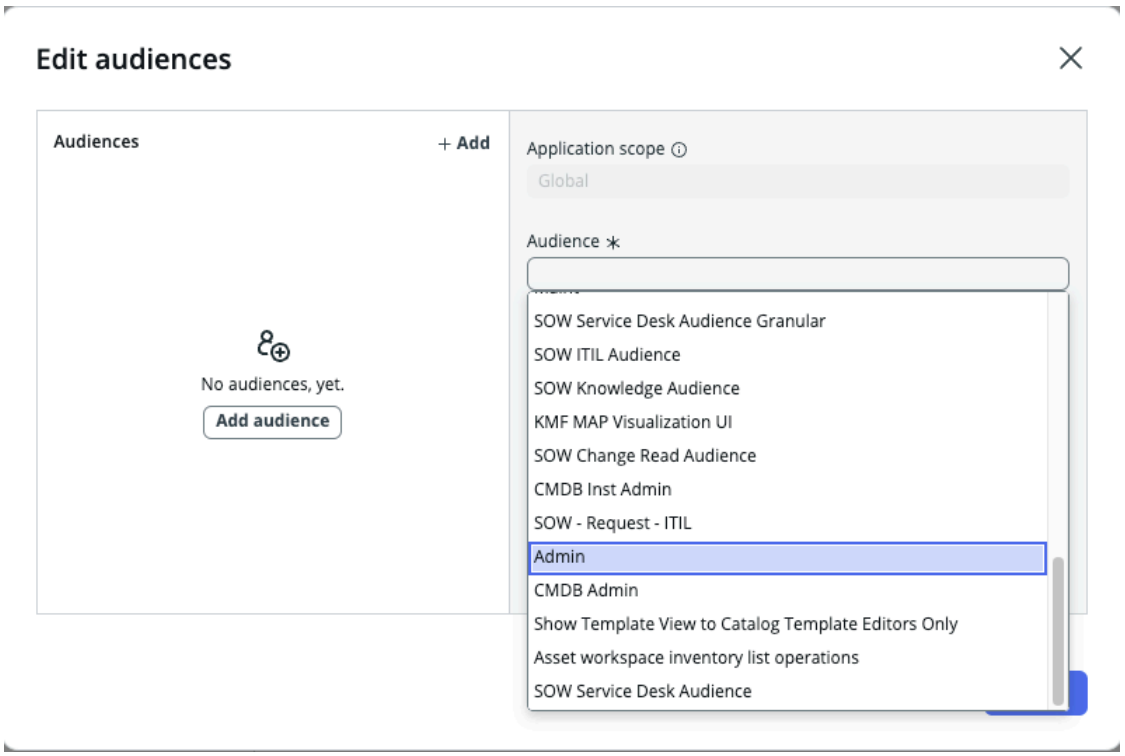
4. In the page variant settings window, select **Edit all audiences**.



5. Click **+ Add**.



6. Select an audience in the audience field.

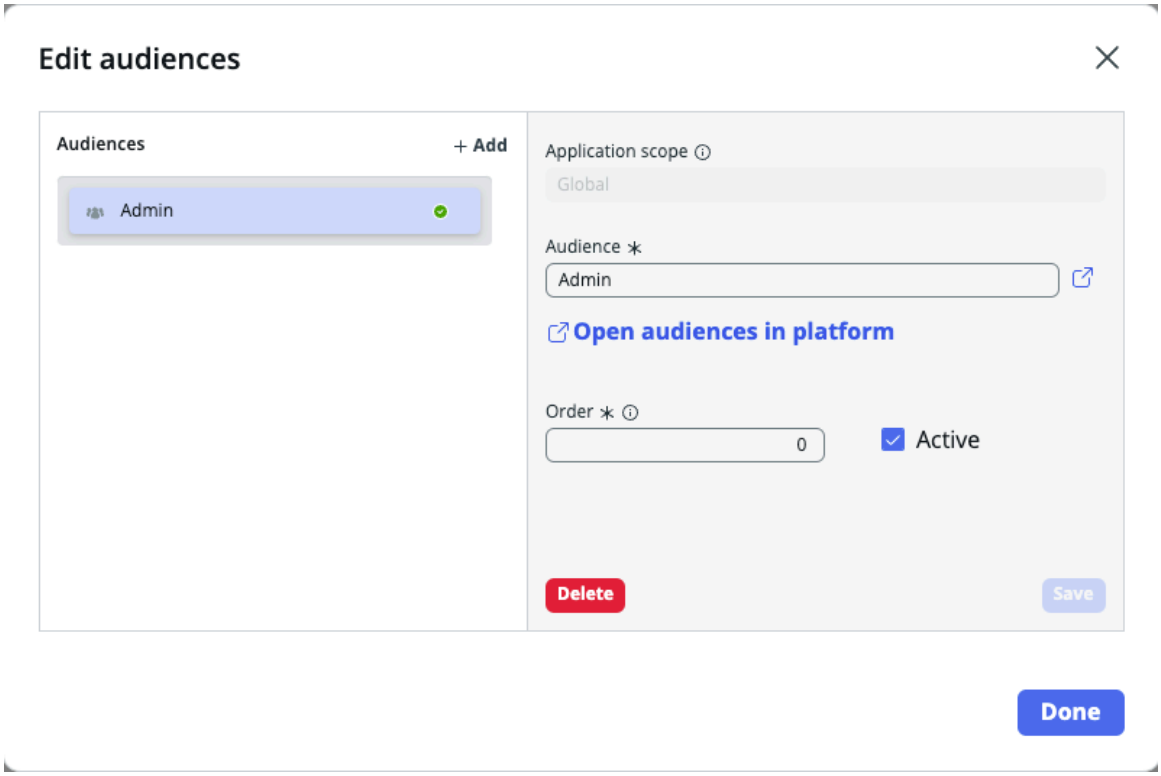


Note:
If an audience you need is not listed, you can choose the **Open audiences in platform** link to create one.

7. Set the order of the audiences.

Note:
To give higher priority to an audience, enter a lower number. If a user is part of multiple audiences, the audience with the highest priority is used.

8. Check **Active** if you want the audience to be able view the page.
9. Select **Save**.
   The audience displays in the **Audiences** list.



10. Select **Done**.

Enable the user criteria property

Enable the user criteria property to configure access for users based on role, department, group, location, or company in UI Builder.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **sys_properties.list**.
2. Select the *glide.ux.user_criteria_enabled* property.
3. In the **Value** field, specify **true**.
4. Click **Update**.

What to do next

Add audiences to your pages in UI Builder. For more information, see Add an audience to your UI Builder page.

Test values in a page

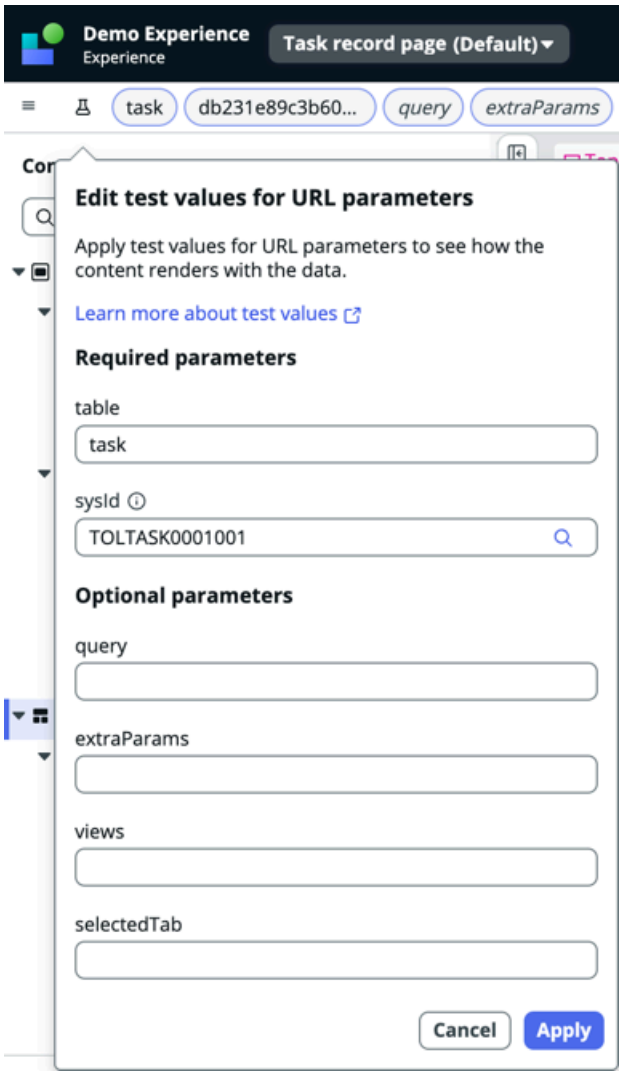
Add test values to your URL as a way to bring test data into a page.

Use test values to give values for required and optional URL parameters as a way to test your page with actual data.

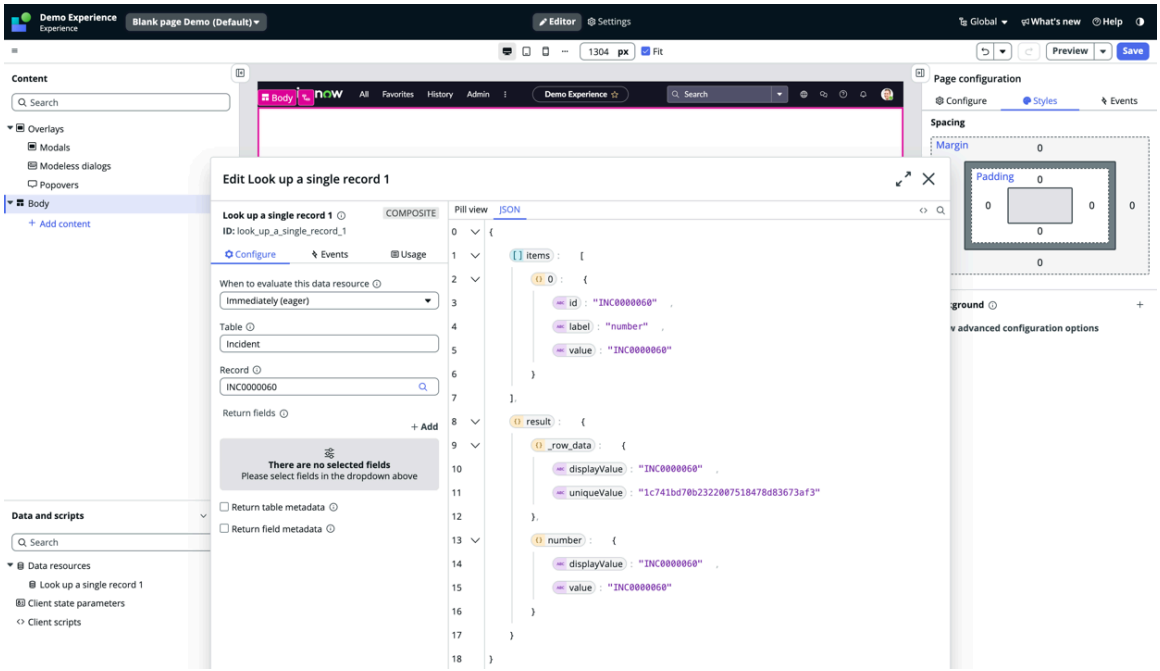
Test values are important because you can use them to simulate how your page behaves when the page gets its required or optional parameters from the URL. A UI Builder URL is not the same as the URL when you preview your page. So, UI Builder needs a way to simulate what happens to the page during different states of the preview URL.

For example, say that you're building a record page that displays a form for a single record. For the record page to load, the page must have a <table> and <sysId> in the URL so that it can get and display the proper record. In UI Builder, you must supply test values for the table and sys_id so that you can see how the page looks when you preview the page.

To get test values to show data, add a data resource, then configure the data resource to bind a record to the test value in the URL. For example, you could add `incident` as a test value.



Then add a data resource named **Look Up Record**. In the **Table field**, dynamically bind the incident test value to a `context.props.table` table, as shown in the following image.



Create a page variant

A page variant in UI Builder is a variation of a page that exists at the same path that targets different audiences using user criteria.

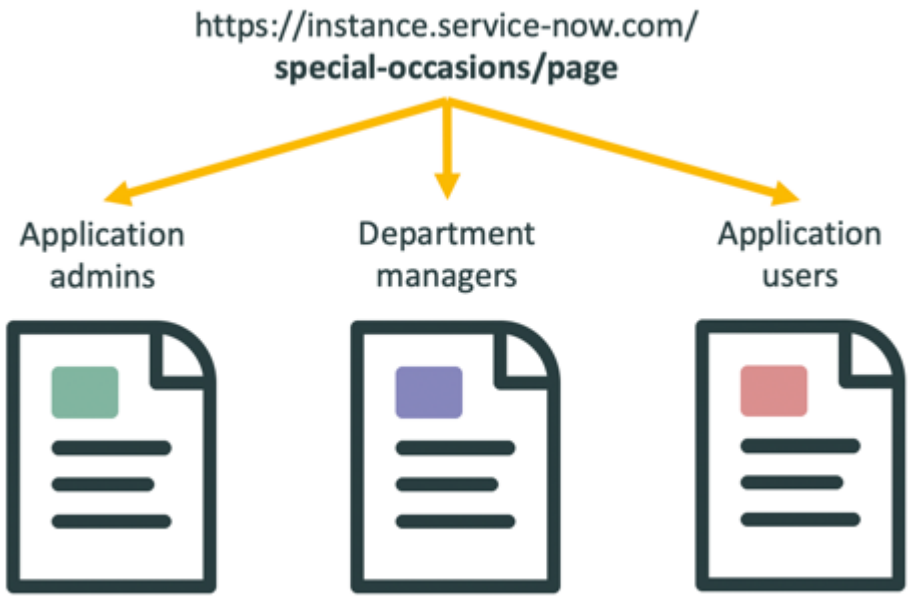
This video show you how to perform the following procedure. This video shows you how to create a page variant.

Before you begin

Role required: ui_builder_admin

About this task

Learn how to create a page variant in UI Builder. A page variant is based on your page with content targeted for a different audience. For example, you can create a homepage for agents, and a variant of that page for managers of those agents. The variant exists at the same URL.



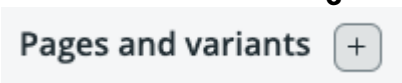
- When someone who is part of the application admins audience accesses the page URL, the user sees a version of the page that has application admin-specific details, such as application metrics and usage details. For the Special Occasions application the page would show how many users have birthdays and work anniversaries and how many do not. The page would also show how many issues have been reported with special occasions.

- When someone who is part of the department managers audience accesses the page URL, the user sees department-related information for the application, such as people in their department with upcoming birthdays and work anniversaries, and whether or not those people are okay with their special occasions being shared.

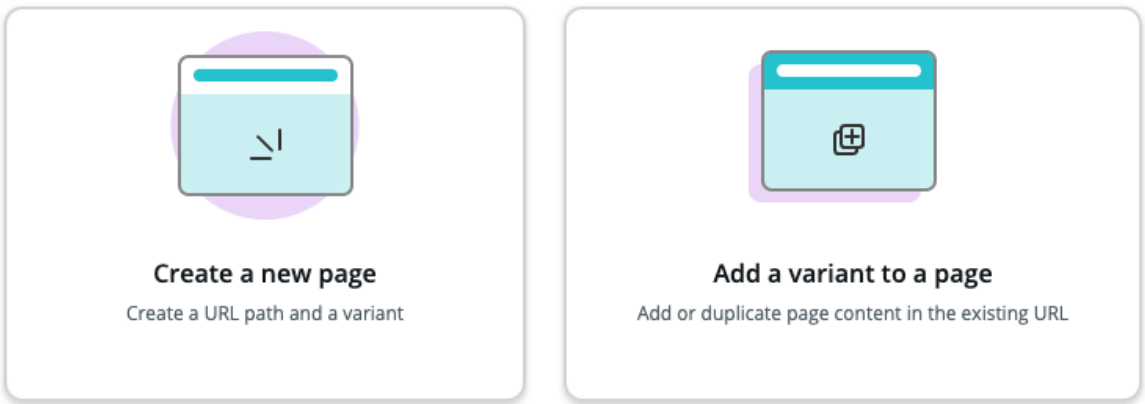
- When someone who is part of the application users audience accesses the page URL, the user sees a user-specific version of the page with their special occasions that allows them to configure whether or not they want others to see their special occasions.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open the experience with the page for which you want to create a variant.
3. Select the **+** icon in the **Pages and variants** section.



4. Select **Add a variant to a page**.



5. Click **+ Add variant**.

6. Click **Build from scratch instead** or select **Use template** when pointing to the template that you want to use.
7. Enter a name for the variant page.

   The name can be similar to your page name, or what ever you want it to be.

Note:
The application scope defaults to the scope that the user is in within the ServiceNow AI Platform®. For more information about application scope, see Learn about security and roles.

8. Specify one or more audiences for your variant page by selecting **Add an audience**. The audience is important because it lets you assign your page variant to a specific role or group. If an audience you need is not listed, create one by selecting **View all available audiences**, and then selecting **New**.
9. Declare conditions for when to display the page by either using the provided dropdown menus or writing an encoded query string.

   To learn more about declaring conditions, see Control the conditions for a page variant. For more information on writing encoded queries, see Encoded query strings.
10. If creating a page from scratch, select **Continue** and then select the **Build responsive** option (default).
11. Click **Create** to create your page variant.

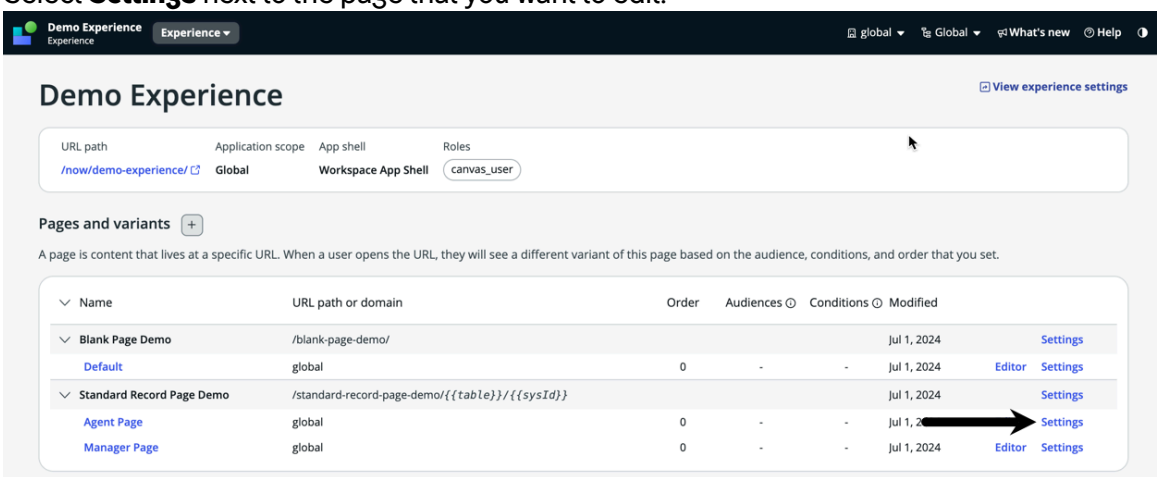
Edit page variant settings

Edit page variant settings to add additional criteria to determine when the page variant displays to users.

Before you begin
Role required: admin

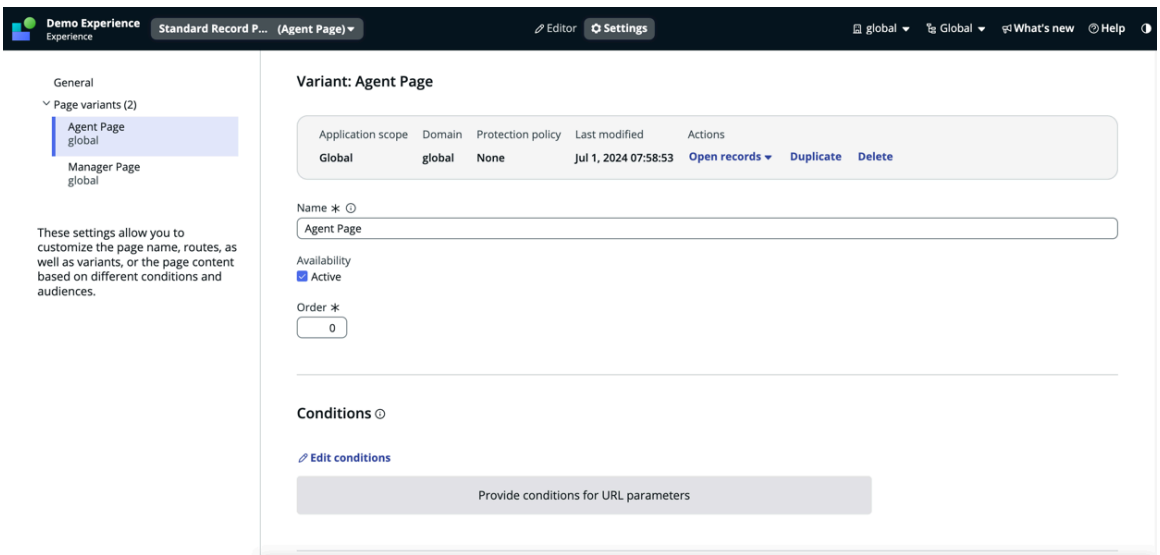
About this task
Customize page variant settings to set who sees the page variant. You can add and remove audiences as well as edit conditions to determine when a page variant is shown. Conditions can only evaluate the listed parameters. Conditions are based on setting an order and adding a query string that sets the criteria that must be met for the page variant to display. If you have multiple page variants that all have the same conditions, then the variants go by the order setting. The following task shows how to set the variant conditions and order.

Procedure
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open the experience with the page variant that you want to edit.
3. Select **Settings** next to the page that you want to edit.



4. On the form, fill in the fields.

Field	Description
Name	Enter a name for the page variant.
Availability	Select **Active** to make the page variant viewable to the selected audience.
Order	Add an order for the condition in the **Order** field. You may want certain conditions to have a higher priority than others. The lower the number, the higher the priority.
Conditions	Set the rules for when your pages are shown. For more information, see Control the conditions for a page variant.
Audiences	Add or remove audiences for the page variant. For more information, see Learn about audiences.



5. Click **Save**.

Control the conditions for a page variant

Set the conditions and manage the criteria that determine when a page variant is displayed. UI Builder page variants enable you to create different versions of a page to tailor content for a specific audience.

Before you begin

Role required: ui_builder_admin

About this task

If you have multiple page variants that all have the same conditions, the variants go by the order setting.

Procedure

1. Create a page variant.
   For more information, see Create a page variant.
2. Set the conditions for a new variant.

In this example, you configure a page variant to display when you open a record from the Task table.

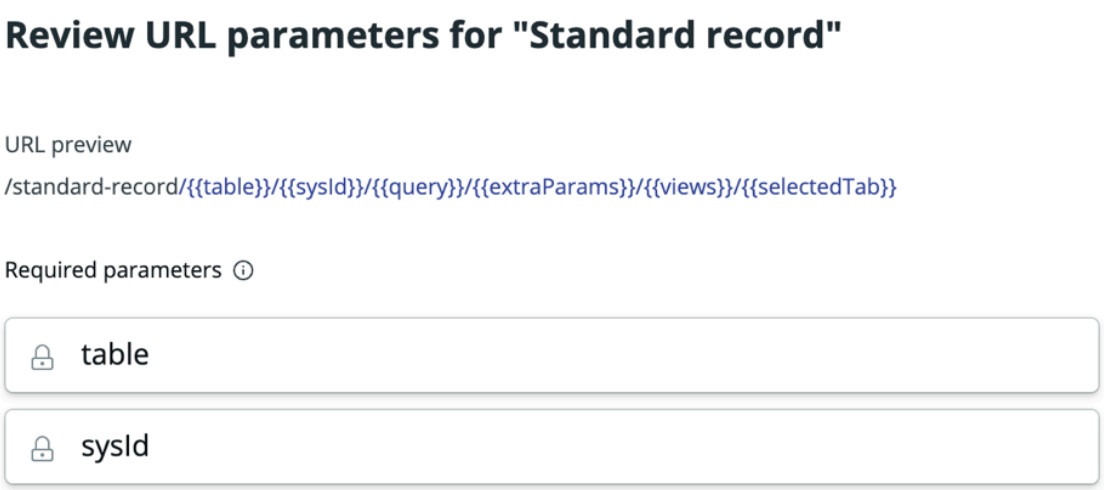
a. On the **First, select a template** screen, locate the **Standard record** template and select **Use template**.

> **Note:**
> Conditions can only evaluate parameters that have been added. In this example, the **Standard record** template includes the *table* and *sys_id* parameters.

b. Enter a name for your page and select **Continue**.

c. Review the URL parameters and select **Looks good**.

Notice that *table* and *sysId* are added as required parameters, which appear in the URL preview.



d. On the **Tell us about your variant** screen, enter a name for your variant.

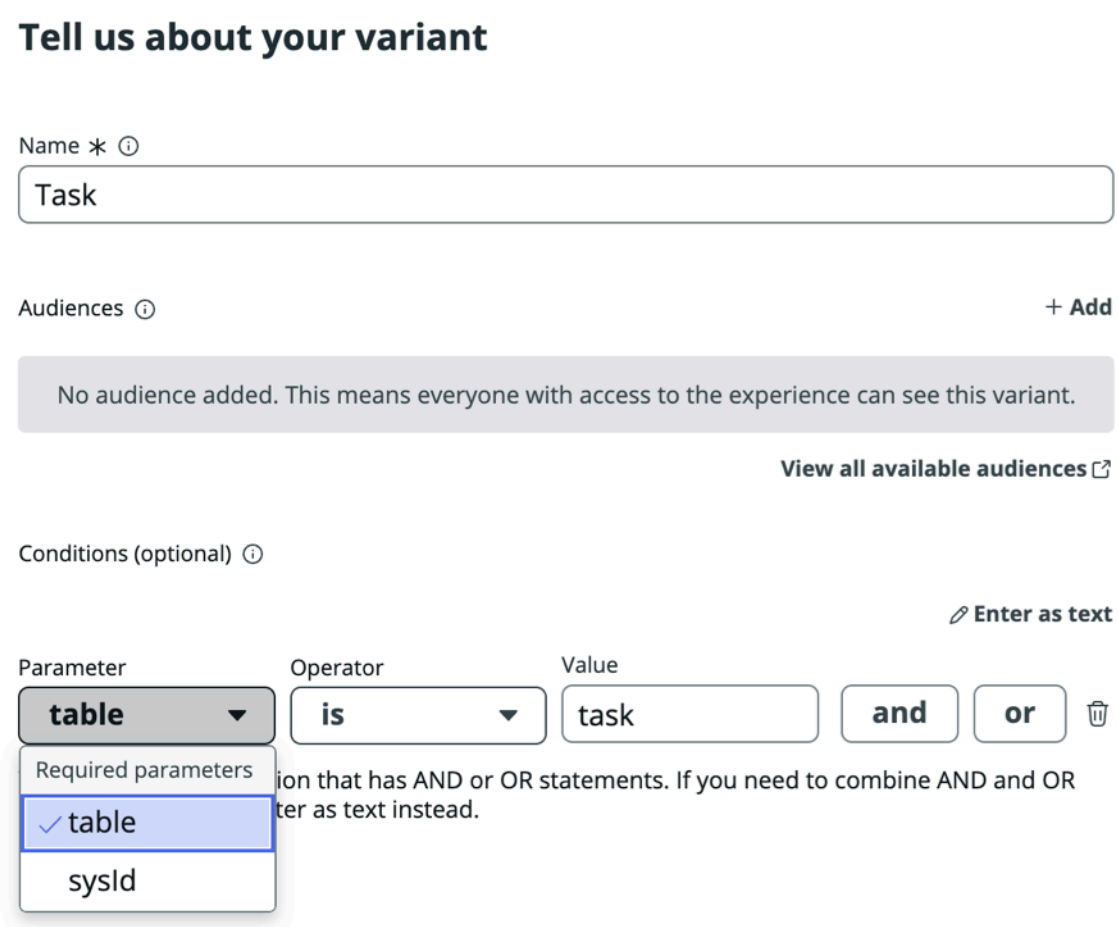
e. In the form section, fill out the fields.

Variant condition form section

Field	Description	Example
Parameter	The aspect or attribute that you want to check.	*table*, *sys_id* **Note:** Conditions can only evaluate the added parameters. However, conditions written for subpages inherit additional outputs from the parent page controllers, providing a wider range of parameters options.

Field	Description	Example
Operator	The rule that compares the parameter to the value. It tells you how the comparison is made.	**is**, **is not**, **starts with**
Value	The number, text, or option input that you want to compare with the parameter.	`"Incident"`, `"12345"`, `"Active"`, `"Change Request"`

Note:
The *`table`* and *`sysId`* parameters are available options for the **Parameter** field because they're required parameters as a part of the **Standard record** template.



f. Select **Create**.

3. Review the conditions created for your variant.

a. In the Experience view, find the variant for which you want to view the conditions.

b. Select the **View** button to display the conditions set for that variant.

4. Edit the existing conditions for your variant.

a. From the Experience view, find the variant for which you want to edit the conditions.

b. Select **Settings**.

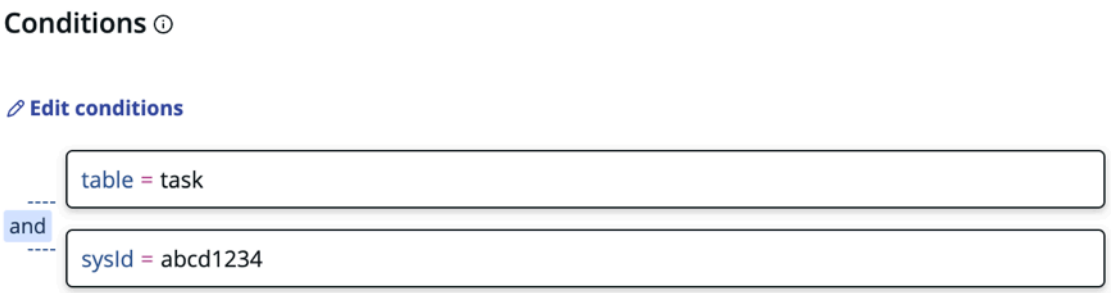
c. Under Conditions, select **Edit conditions**.

The condition you previously set appears. You can update these fields.

d. On the **Edit variant conditions** screen, next to the condition, select the **and**(and) or **or**(or) button to add another condition and specify the criteria.

For example, by adding the following **AND** condition (**[sysId] [is]** `[abcd1234]`), you configure the page variant to display when you access a record from the Task table with a sys_id of abcd1234.

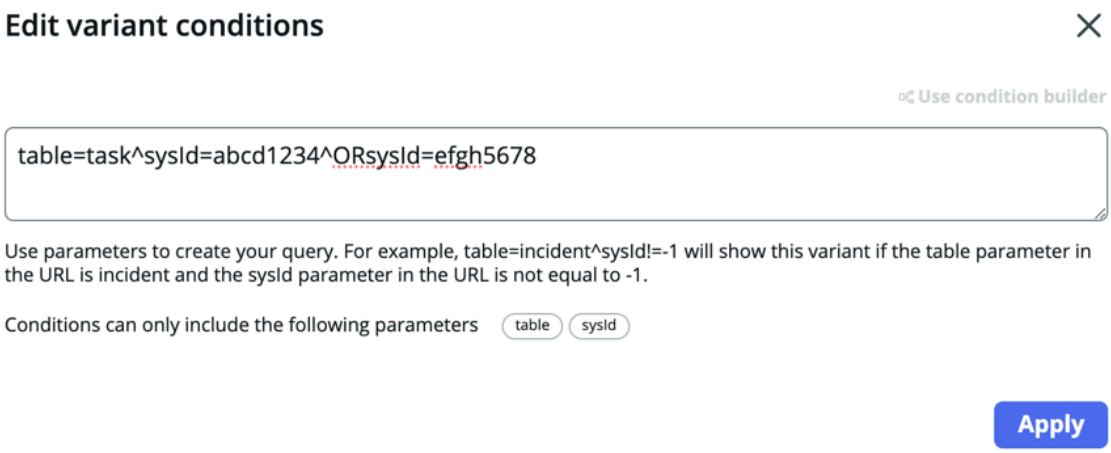
Note:
You can add **AND** or **OR** conditions. To mix both types, you must write an encoded query.



e. Optional: Select **Enter as text** to write an encoded query that specifies the criteria.

(Optional) The **Edit variant conditions** screen displays the encoded query field, where the conditions you previously set are shown in encoded query form: `table=task^sysId=abcd1234`.

For example, by adding the following 'OR' condition (`^ORsysId=efgh5678`), you set the page variant to display when you access a record from the Task table with a sys_id of either abcd1234 or efgh5678. For more information on writing encoded queries, see Encoded query strings.



Responsive authoring

Use responsive authoring to create UI Builder pages that adjust smoothly to different form factors (sizes), such as desktop, tablet, and mobile.

Responsive authoring in UI Builder

Responsive authoring enables you to create pages that look good and function properly at any form factor, making it easier for people to interact with the content. For example, a page containing three columns when viewed on a laptop, can adjust to a single column for smaller screens.

UI Builder currently offers three default form factors:

- Desktop (1281 pixels to infinity)
- Tablet (1280 pixels and smaller)
- Mobile (500 pixels to zero)

In addition to these form factors, you can create up to three additional custom breakpoints (widths). For more information, see Create a breakpoint for responsive authoring.

There are different techniques for editing pages so they're usable at different form factors. Use any of the following options:

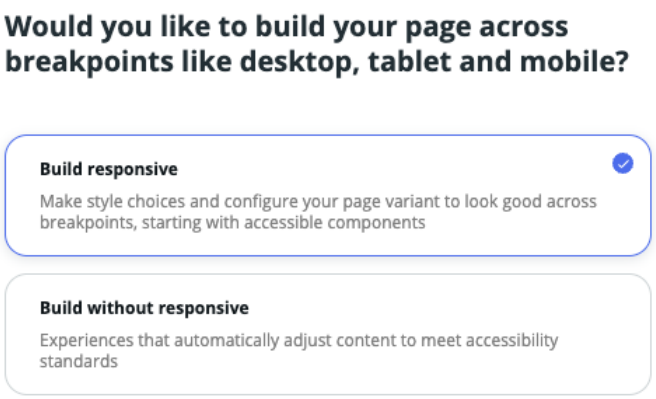
- Show or hide components
- Change component configuration
- Edit styles
- Rearrange the layout

Responsive authoring and reflow

As of Xanadu Store Release 1, responsive authoring is only available when creating UI Builder pages from scratch. Responsive authoring isn't available for existing pages or pages created with a template. These types of pages continue to use the existing, default reflow model to adjust pages for different screen widths.

Reflow transforms page layouts into a vertical, stacked view automatically without loss of content or functionality when users increase browser zoom to 400%. This adjustment helps users with low vision or who have trouble seeing web content in a browser due to monitor size, device type, poor lighting, or other situations.

All existing pages that were created with templates or from scratch use reflow automatically. Now, when creating pages from scratch in UI Builder, an extra step shows you that responsive authoring is selected by default. You can choose to use reflow instead by selecting **Build without responsive**, however, using the responsive authoring option gives you more control over how pages work and look at different form factors. For more information about creating pages in UI Builder, see Create a page in UI Builder.



For more information about reflow, see Reflow for Configurable Workspace.

For a list of UI Builder components that support reflow, see the **Support for reflow** section of the Next Experience Components release notes.

Application and cascading of changes

All changes made to a form factor are applied to all smaller form factors automatically. For example, any changes made to tablet apply to both tablet and mobile. However, if you then make changes to the mobile form factor, it overrides the cascaded settings from the tablet form factor. This cascading functionality enables you to make specific changes for each smaller form factor so the page looks and functions well.

Note:
Changes don't cascade up to larger sizes. For example, changes made to tablet aren't applied to the desktop.

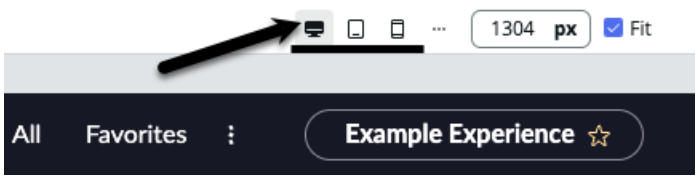
Responsive authoring and controllers

If you add a controller to a page, the controller properties are global and cannot be set per form factor. For more information about controllers, see Bind data to UI Builder pages using controllers (advanced feature).

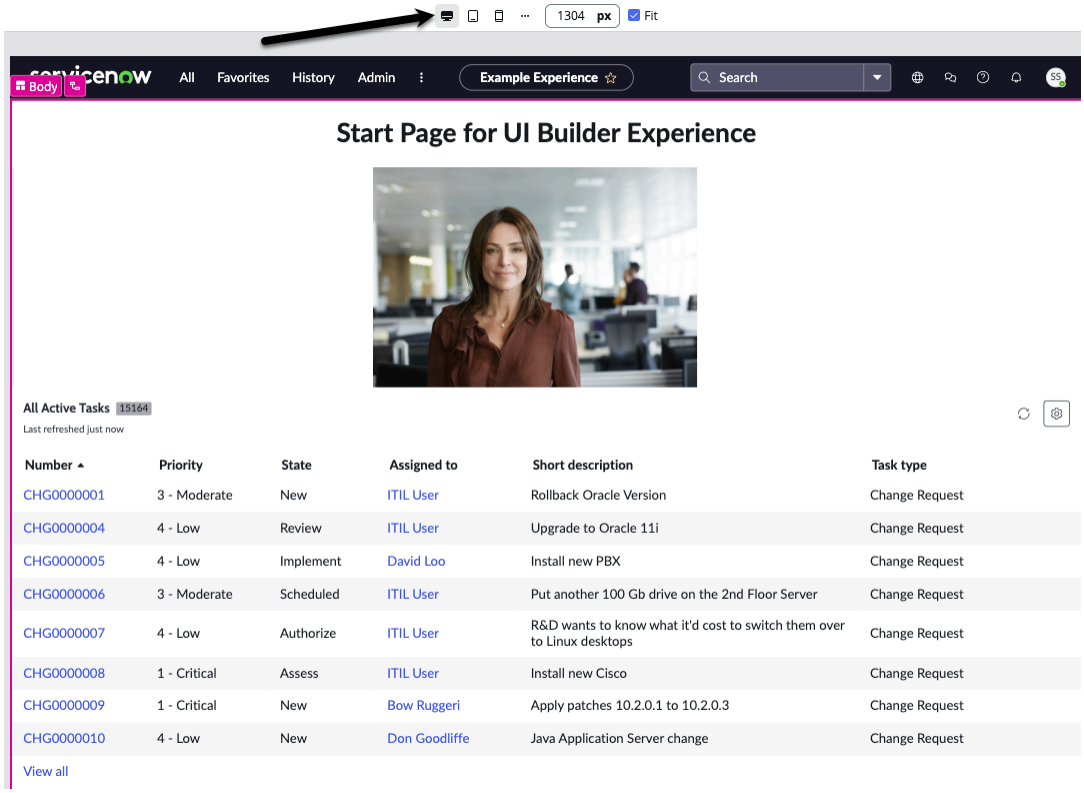
Using responsive authoring as you create pages

As you build pages, create tailored designs to control the look and feel for different form factors.

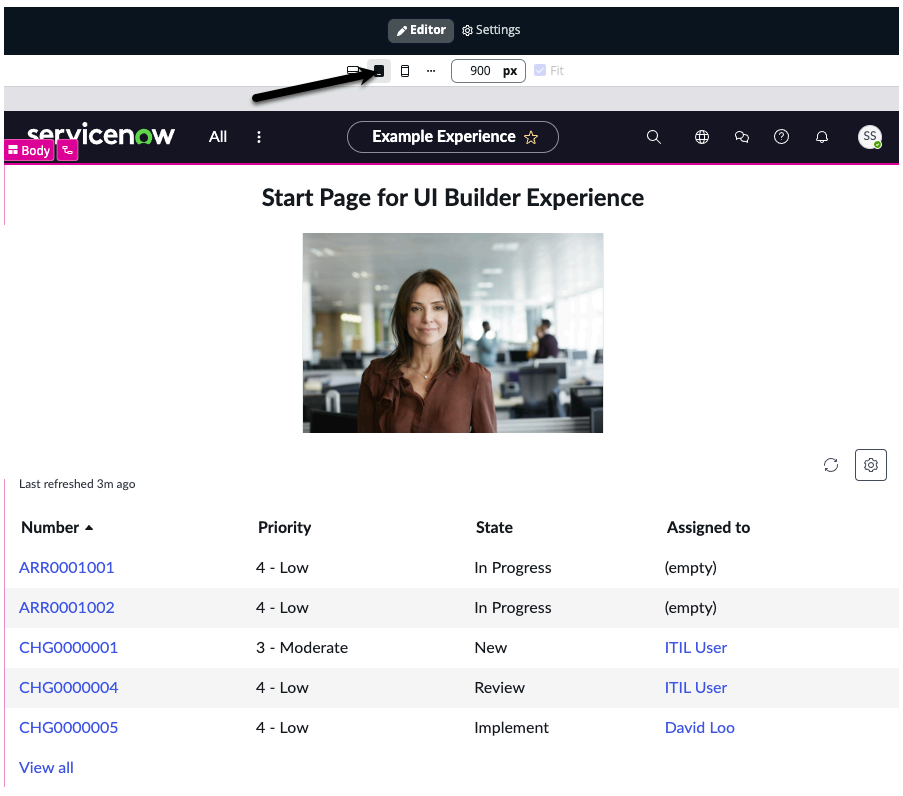
By default on the stage, you build pages for the desktop (1281 pixels to infinity). At any time, select another icon to see the page on the stage at a different form factor, such as tablet or mobile. As needed, edit the page so it displays appropriately at the new form factor.



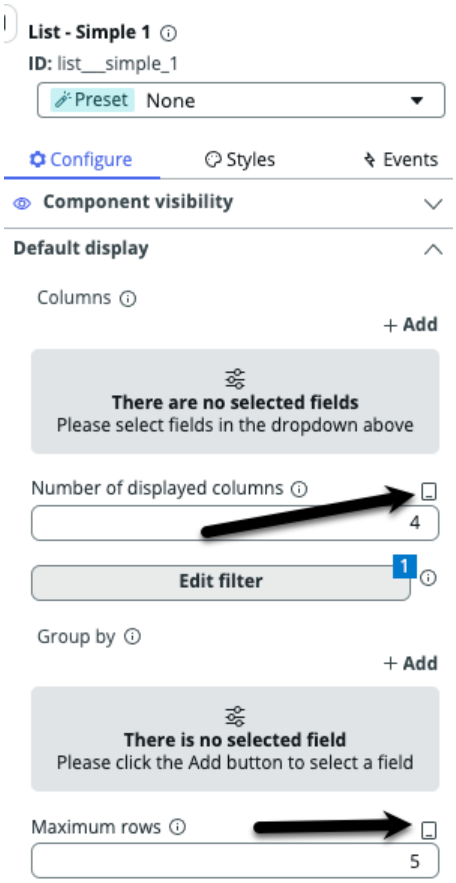
Here's what a sample page looks like at the desktop form factor.



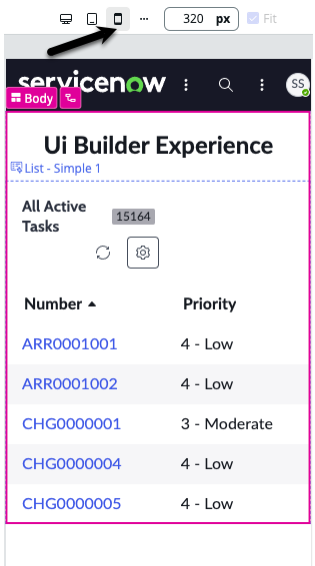
Here's the same page customized for the tablet form factor.



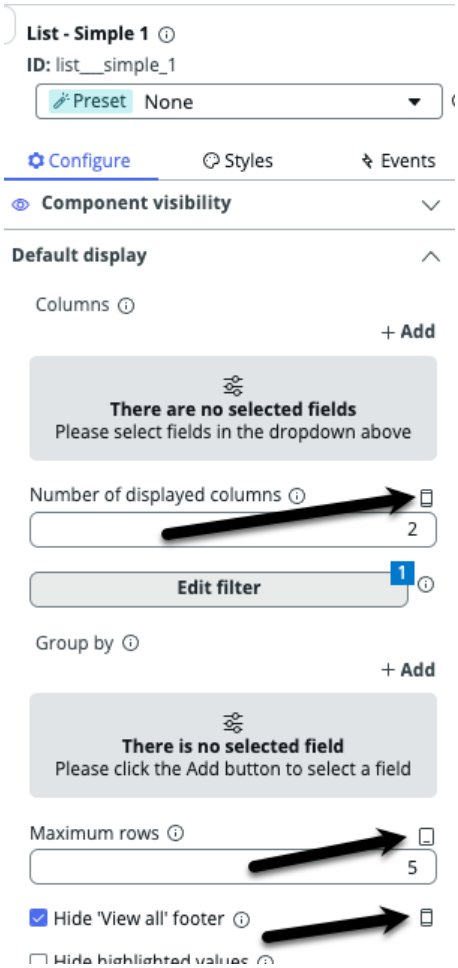
For tablet, the heading and image components have been reduced in size. The simple list component configuration was edited to show four columns instead of six and the maximum number of rows was set to 5. When editing a component for a form factor, the fields that have changed are marked with a cascading icon for that form factor (in this case, tablet). The icon enables you to determine the differences between the form factors for a given page easily.



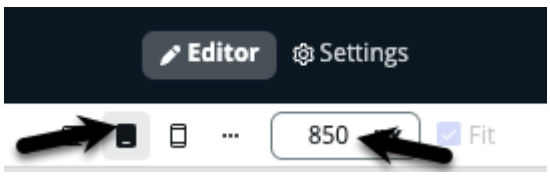
Here's the same page customized for the mobile form factor.



The number of words in the heading was reduced and the image component was hidden. The simple list component configuration was edited to show two columns instead of four and the option to hide the "view all" footer option was selected. The two fields customized specifically for mobile have a mobile cascading icon next to them. The **Maximum rows** field still retains the tablet cascading icon because that field is inheriting the tablet setting and wasn't customized for mobile.



In addition to the default form factors in the editor view, at any time you can manually enter a number in the pixel field. The stage adjusts to the nearest form factor based on range. For example, entering 850 pixels adjusts the stage to the tablet form factor because its range is defined as 1280 to 501 pixels.



Note:
Form factors and the ability to enter a pixel width are also available when previewing a page. For more information, see Learn how to view and test your UI Builder experience.

Adjusting component visibility in responsive authoring

When creating pages with responsive authoring for different form factors, learn how to show or hide components by completing steps to hide an image at mobile size.

Before you begin

Role required: ui_builder_admin

About this task

A method of increasing page usability is to hide components or show a different component across breakpoints. There are countless ways to use component visibility, but a few examples include:

- Use multiple button components horizontally across the top of a page for desktop and tablet size, but at mobile size, hide the buttons and show the dropdown component.
- Use a smaller button size for mobile size, but check that the buttons are large enough for users to press with a thumb. Consider changing the placement of buttons for mobile as well.
- Use images in desktop and tablet pages, but hide images, especially larger ones, in mobile.

In this procedure, show buttons across the top for the desktop and tablet form factors, but hide the buttons and use the dropdown component for mobile.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create > Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page from scratch with responsive authoring.
   For more information about how to create a page, see Create a page in UI Builder.
4. At the top, check that the desktop form factor icon is selected.

5. Add a column layout by selecting **+ Add content** under **Body** in the content tree.
6. On the **Layouts** tab, select **Single column**.
7. Add the first button component.

   a. Select the **+** icon in the center of the new column on the stage.

   b. On the **Components** tab, find and select the **Button** component.

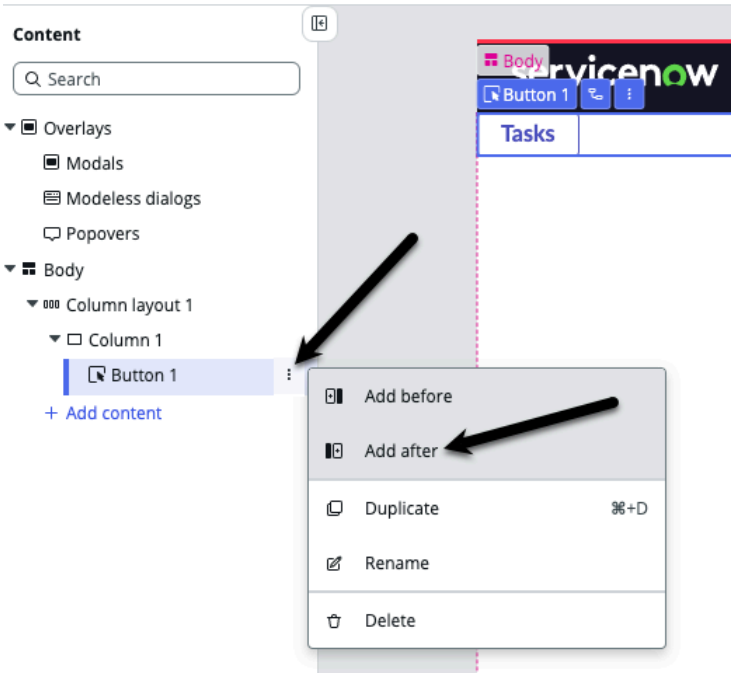
   c. In the configuration panel, select **None - Configure the component manually**.

   d. In the configuration panel, on the **Configure** tab, replace the default text in the **Label** field by entering `Tasks`.

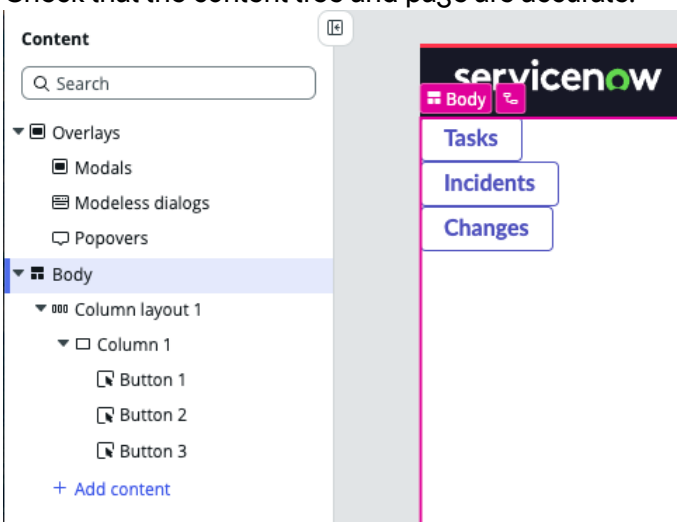
   e. Select **Save**.

8. Add two more buttons by repeating step 7 twice and in 7d name the buttons `Incidents` and `Changes`.

Note:
To add the buttons, point to **Button 1** in the content tree, select the menu icon, and then select **Add after**.



9. Check that the content tree and page are accurate.



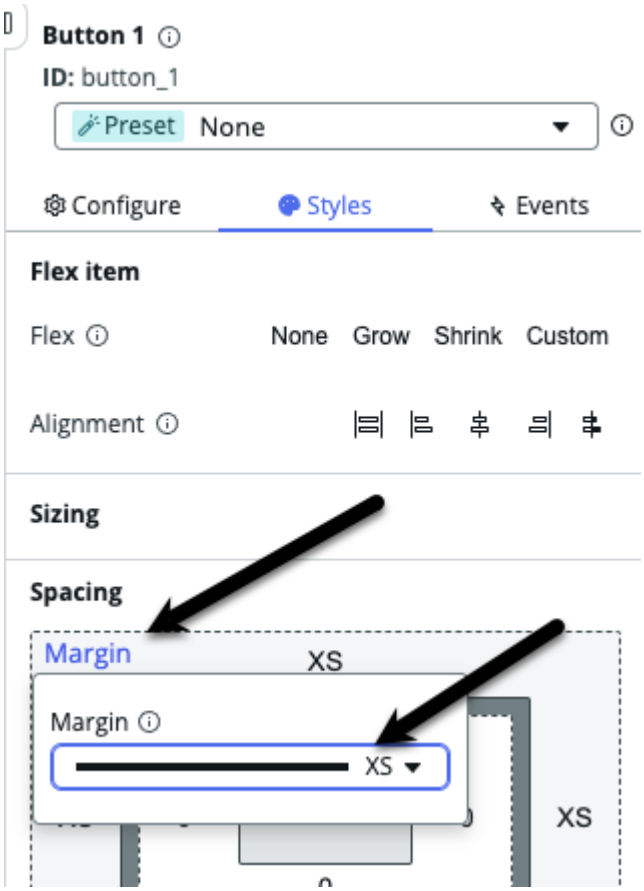
10. Add some space around each button.

    a. In the content tree, select **Button 1**.

    b. In the configuration panel, select the **Styles** tab.

    c. In **Spacing**, select **Margin**.

    d. In the menu, select **XS** (extra small).



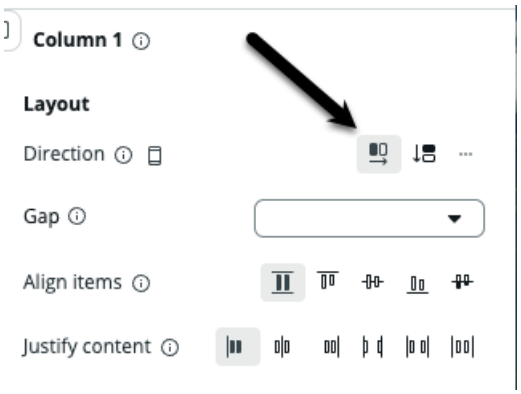
e. Select **Save**.

11. Add space around the other two buttons by repeating step 10 for each.

12. Change the buttons from the vertical direction to the horizontal direction.

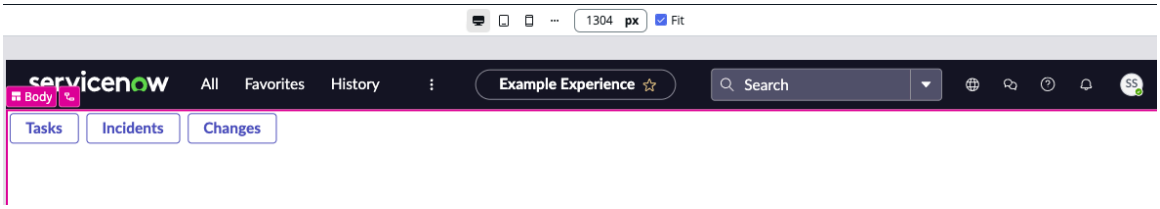
a. Select **Column 1** in the content tree.

b. On the configuration panel, in **Direction**, select the row icon.



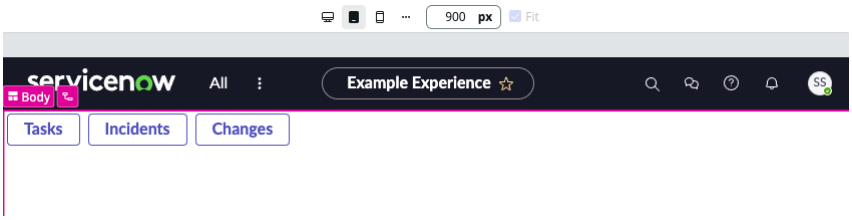
c. Select **Save**.

The page looks good at desktop width.



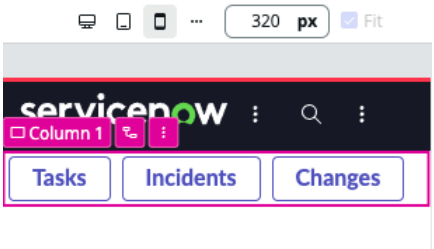
13. Select the tablet form factor icon.

The spacing and position of the buttons also looks good at tablet width.



14. Select the mobile responsive authoring icon.

The buttons use almost all the horizontal space at the smaller size.



15. Add the dropdown component.

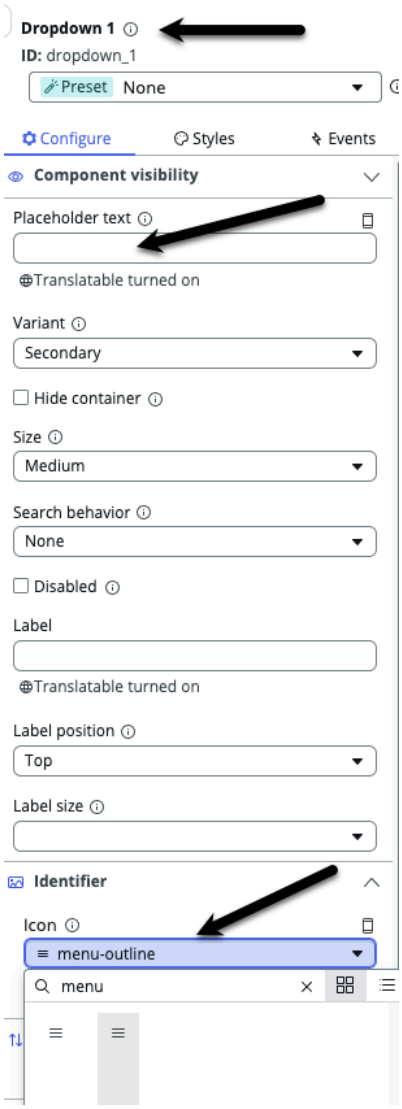
    a. Select the desktop form factor at the top of the stage.

    b. Point to **Button 3** in the content tree, select the menu icon, and then select **Add after**.

    c. On the **Components** tab, find and select the **Dropdown** component.

    d. In the configuration panel, select **None - Configure the component manually**.

    e. In the configuration panel, on the **Configure** tab, remove the default text in **Placeholder text** and select **menu-outline** in **Icon**.



f. Select **Save**.

16. Hide the dropdown component at the desktop and tablet form factors.

a. In the content tree, select **Dropdown 1**.

b. In the configuration panel, on the **Configure** tab, select **Component visibility** to show the options.

c. Select **Hide component**.

d. Select **Save**.

17. At the mobile form factor, hide the button components.

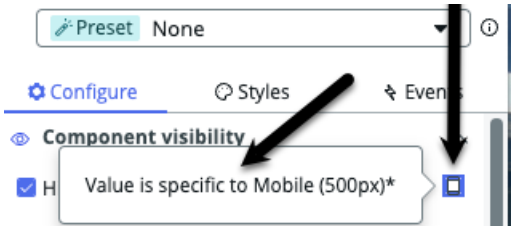
a. Select the mobile form factor icon at the top of the stage.

b. In the content tree, select **Button 1**.

c. In the configuration panel, on the **Configure** tab, select **Hide component**.

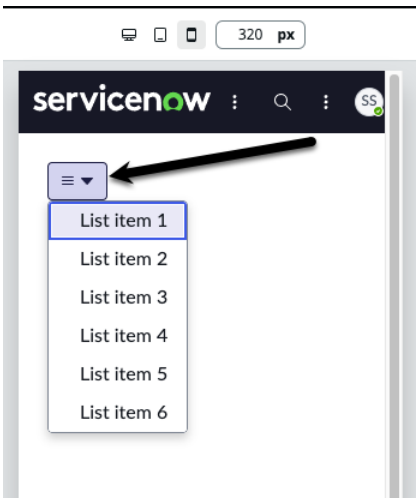
d. Repeat steps b-c for **Button 2** and **Button 3**.

e. Select **Save**.
Two locations show that the button components are hidden at mobile size. First, in the configuration panel, next to the **Hide component** option, select the mobile icon. A message is displayed to confirm that the value (hide component selected) is for the mobile size.



Second, in the content tree, the three button components are displayed with the hidden icon.

18. At the mobile form factor, show the dropdown component.
    a. In the content tree, select **Dropdown 1**.
    b. In the configuration panel, on the **Configure** tab, select **Hide component** to clear the field.
    c. Select **Save**.
19. Select **Preview**.
    The mobile form factor is displayed with the menu icon. If you select the arrow, the default options are displayed (List item 1, List item 2, and so on). You would configure the dropdown component to display **Tasks**, **Incidents**, and **Changes** just like the horizontal buttons available at the tablet and desktop form factors.



20. Select the desktop and tablet form factor icons at the top.
    The desktop and tablet form factors only show the horizontal buttons, not the menu icon.
21. Close the preview overlay by selecting the **X**.

Configuring components for responsive authoring

When creating pages with responsive authoring for different form factors, learn how adjusting some component configuration options can make pages look and work better at smaller sizes.

Before you begin

Role required: ui_builder_admin

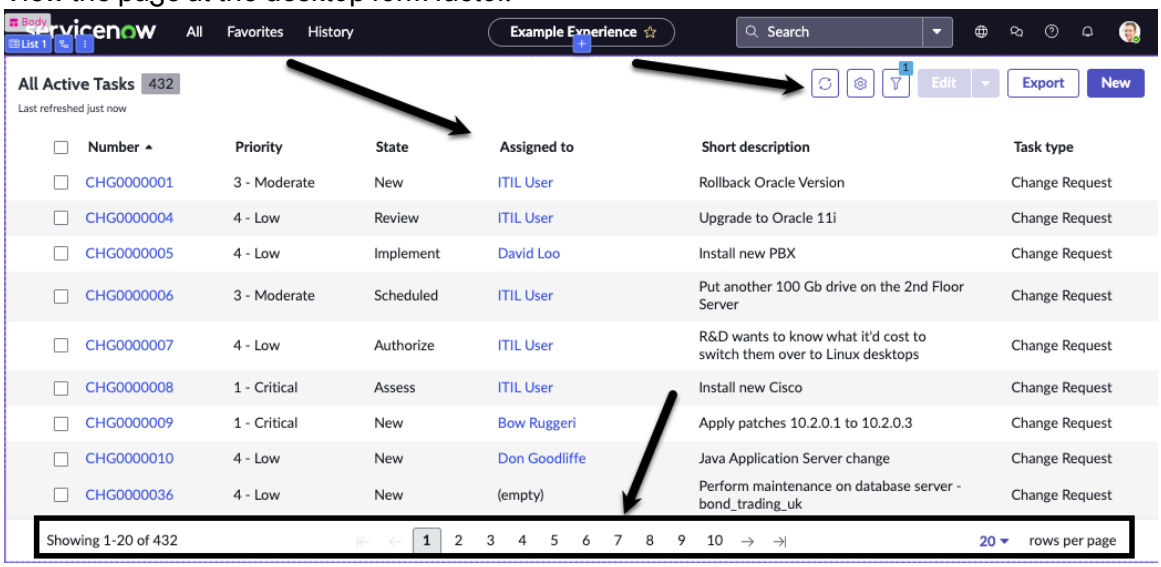
About this task

A method of increasing page usability is to tailor the look and feel of components using different configurations across breakpoints. There are countless ways to use component configuration. In this procedure, edit several configuration options for the List component to make it more suitable for smaller form factors.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create > Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page from scratch with responsive authoring.
   For more information about how to create a page, see Create a page in UI Builder.
4. At the top, check that the desktop form factor icon is selected.

5. On the stage, select **+ Add content**.
6. On the **Layouts** tab, select **Single column**.
7. Add the list component by selecting the **+** icon in the center of the new column.
8. On the **Components** tab, find and select the **List** component.
9. In the configuration panel, select **None - Configure the component manually**.
10. View the page at the desktop form factor.



Note the elements displayed, including the icons at the top, the number of columns, and the pagination information at the bottom.

11. Select the mobile form factor icon.

    At the mobile form factor, the list component is crowded and contains both vertical and horizontal scroll bars.

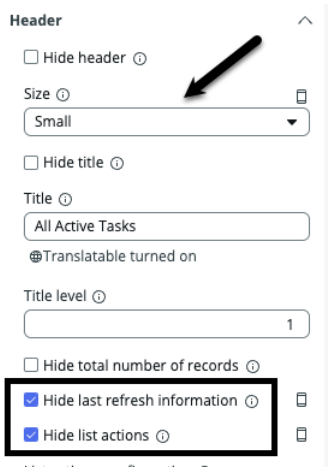
Make some simple configuration changes to improve the usability and appearance for the mobile form factor.

12. Select **List 1** in the content tree.
13. In the configuration panel, on the **Configure** tab, find the **Number of displayed columns** field and enter 1.
    Only the **Number** column is displayed. The horizontal scroll bar was removed.
14. In the configuration panel, on the **Configure** tab, scroll down to make the following changes in the **Header** section:

    a. Change the **Size** to **Small**.

    b. Select the **Hide last refresh information** option.

    c. Select the **Hide list actions** option.



As you made each change, the stage updated automatically. The header is a smaller size, the refresh time was removed, and the list actions icon was removed.

d. Select **Save**.

15. On the stage, scroll to the bottom of the mobile view.

16. In the configuration panel, on the **Configure** tab, scroll down and make the following changes in the **Pagination** section (if necessary, select **Pagination** to expand the field):

a. Select the **Hide range** option.

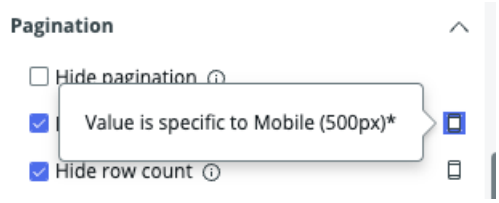
b. Select the **Hide row count** option.

c. Select the **Hide rows per page selector**.

d. Select **Save**.
The range, row count, and rows per page selector were removed. (The row count is still available at the top of the mobile screen).

In the configuration panel, the options and fields you edited are marked with the mobile cascade icon.

17. Select the mobile cascade icon next to any option or field to confirm that the value is for the mobile form factor.



18. Select the tablet and the desktop form factor icons at the top to confirm that no changes were made to the larger form factors.

Adjust styles for responsive authoring

When creating pages with responsive authoring for different form factors, learn how to change style options to increase the usability of the page at smaller sizes.

Before you begin

Role required: ui_builder_admin

About this task

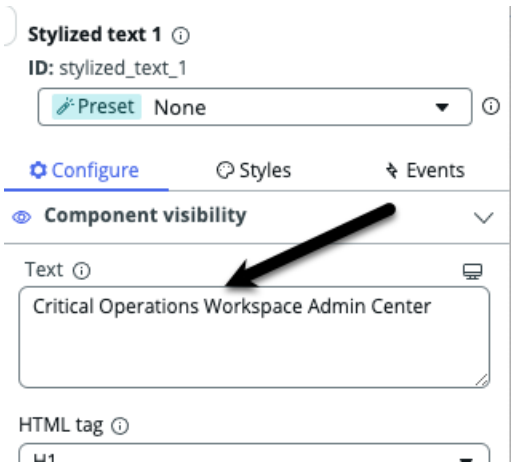
A method of increasing page usability is to tailor components using different styles across breakpoints. There are numerous options for editing styles. In this procedure, edit the margin around the stylized text component and reduce the text size so it uses less space on smaller form factors.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create > Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page from scratch with responsive authoring.
   For more information about how to create a page, see Create a page in UI Builder.
4. At the top, check that the desktop responsive authoring icon is selected.

5. On the stage, select **+ Add content**.
6. On the **Layouts** tab, select **Single column**.
7. Add the stylized text component.
   a. Select the **+** icon in the center of the column on the stage.
   b. On the **Components** tab, find and select the **Stylized text** component.
   c. In the configuration panel, select **None - Configure the component manually**.
   d. In the configuration panel, on the **Configure** tab, double-click (or use the keyboard shortcut) in the **Text** field to select the default text.

e. Replace the default text by entering `Critical Operations Workspace Admin Center`.



f. Select **Save**.

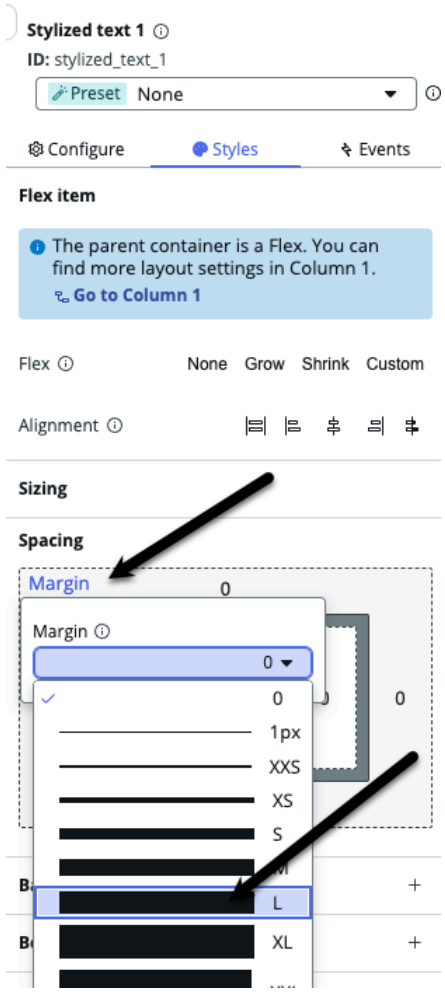
8. Add some space around the stylized text component and center it.

a. In the content tree, select **Stylized text 1**.

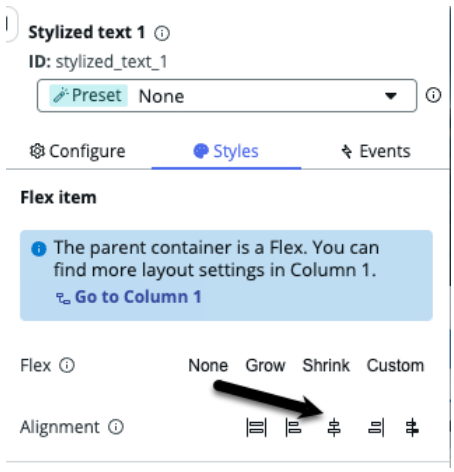
b. On the configuration panel, select the **Styles** tab.

c. In **Spacing**, select **Margin**.

d. Select **Large** in the list.



e. In **Alignment**, select the center icon.



f. Select **Save**.

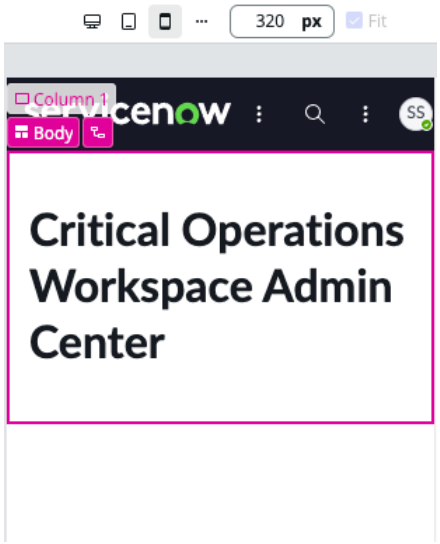
The stage updates automatically, showing the additional white space around the stylized text component and centering it.

9. Select the tablet form factor icon.

The spacing and heading size of the stylized text component looks good at tablet size.

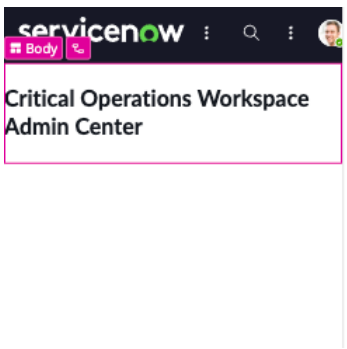
10. Select the mobile form factor icon.

The stylized text component uses a great deal of vertical space at the smaller size.



11. Remove the extra margin space and make the heading smaller just for the mobile form factor.
    a. In the content tree, select **Stylized text 1**.
    b. On the configuration panel, select the **Styles** tab.
    c. In **Spacing**, select **Margin**.
    d. Select **0** in the list.
    e. Select the **Configure** tab.
    f. In **HTML tab**, select **H3**.
    g. Select **Save**.

    The stage updates automatically showing that the stylized text component uses less space.



12. Select the tablet and the desktop form factor icons at the top to confirm that no changes were made to the larger form factors.

Adjust layout for responsive authoring

When creating pages with responsive authoring for different form factors, learn how to adjust the layout to improve the look and feel of the page at smaller sizes.

Before you begin

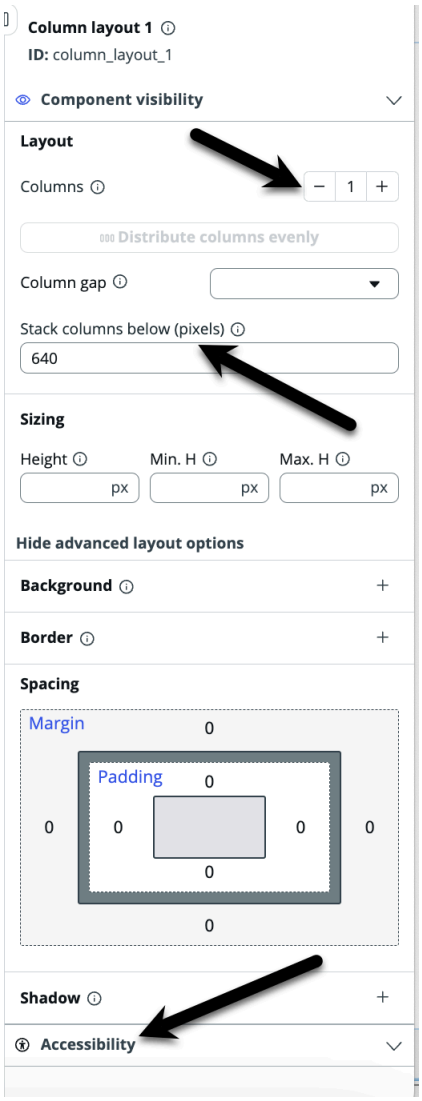
Role required: ui_builder_admin

About this task

A method of increasing page usability is to tailor components by adjusting the layout across breakpoints. There are numerous options for adjusting the layout. In this procedure, adjust the layout of the tabs component for the mobile form factor.

Most column layout options on the property pane can be edited for different form factors. However, the following options have global values across form factors:

- Number of columns
- **Stack columns below (pixels)** option
- All options under **Accessibility**



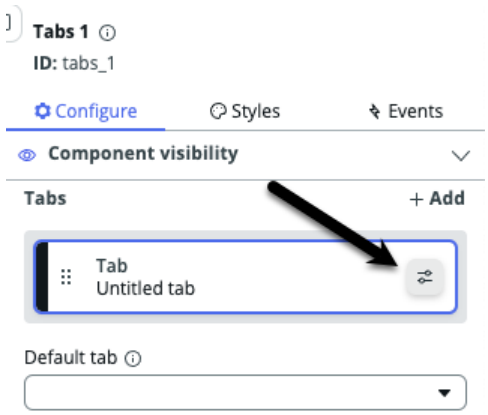
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create > Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page from scratch with responsive authoring.

For more information about how to create a page, see Create a page in UI Builder.

4. At the top, check that the desktop form factor icon is selected.

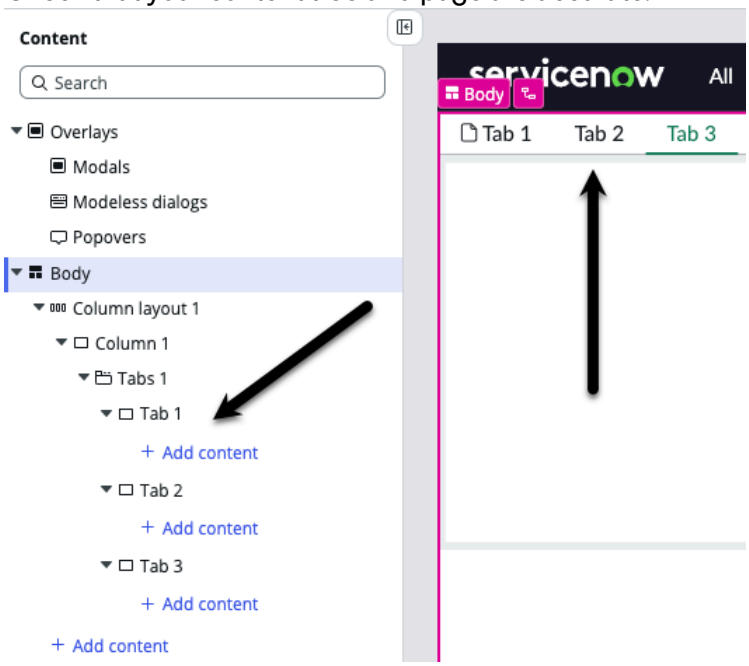
5. On the stage, select **+ Add content**.
6. On the **Layouts** tab, select **Single column**.
7. Add the tabs component.
   a. Select the **+** icon in the center of the column on the stage.
   b. On the **Components** tab, find and select the **Tabs** component.
   c. Select **Save**.
8. In the configuration panel, on the **Configure** tab, edit the name of the first tab by selecting the edit icon.



9. In **Tab label**, enter `Tab 1`.
10. In **Tab ID**, enter `tab_1`
11. Select **Save**.
12. Add a second tab.
    a. On the **Configure** tab, select **+ Add** next to **Tabs**.
    b. Select **Start from an empty container** and then select **Next**.
    c. In **Tab label**, enter `Tab 2`.
    d. Check that **Tab ID** has been automatically filled in with **tab_2**.

e. Select **Create**.

13. Add a third tab by repeating step 12 and in 12c name the tab `Tab 3`.
14. Check that your content tree and page are accurate.

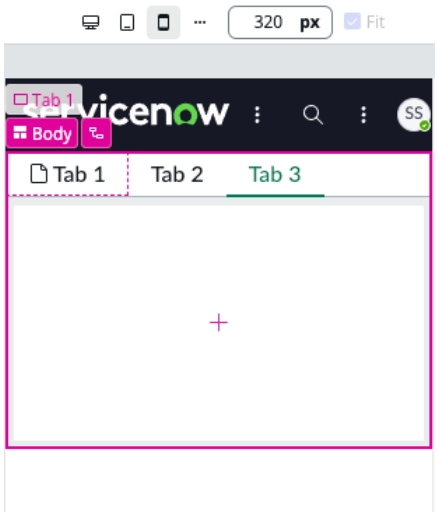


15. Select the tablet form factor icon.

The spacing and position of the tabs looks good at tablet width.

16. Select the mobile form factor icon.

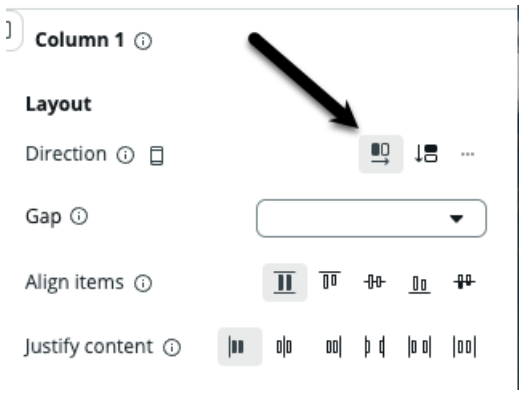
The tabs take more space at the smaller size.



17. Change the layout of the tabs just for the mobile size.

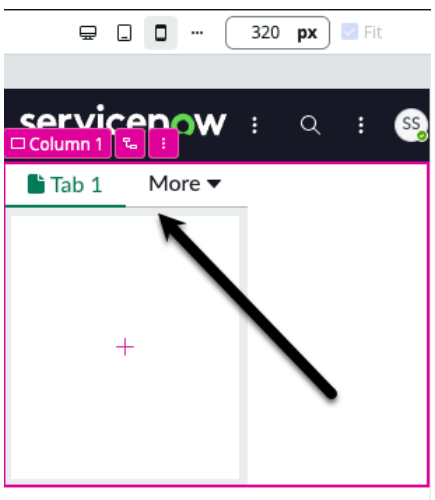
a. In the content tree, select **Column 1** under **Column layout 1**.

b. On the configuration panel, in **Direction**, select the row icon.

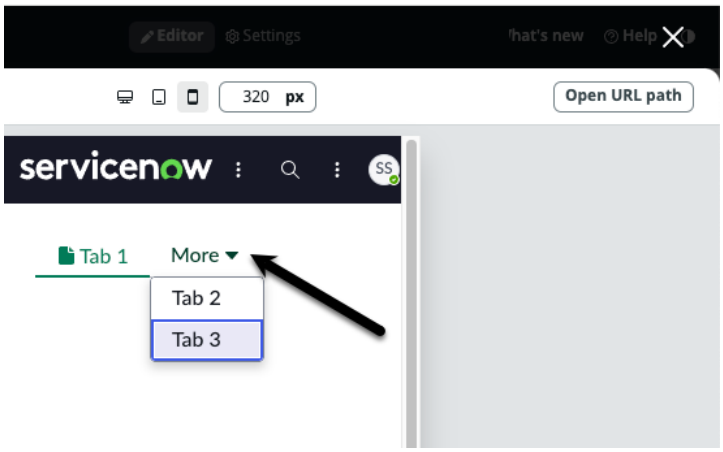


c. Select **Save**.

The stage updates automatically showing that tab 1 is visible and that there's a new dropdown menu.



18. Select **Preview**.
19. Select **More**.
    The other two tabs are available.



20. Select the desktop and tablet form factor icons to see that the More drop-down doesn't appear.
21. Select the **X** to close the **Preview** overlay.

Create a breakpoint for responsive authoring

Learn how to create custom breakpoints for responsive authoring to control the look and feel of a page at different form factors.

Before you begin

Role required: ui_builder_admin

About this task

UI Builder currently offers three default form factors:

- Desktop (1281 pixels and larger)
- Tablet (1280 pixels and smaller)
- Mobile (500 pixels and smaller)

Add up to three additional breakpoints. For example, there's a default form factor of 500 pixels and smaller for mobile devices, but you may need a breakpoint of 360 pixels.

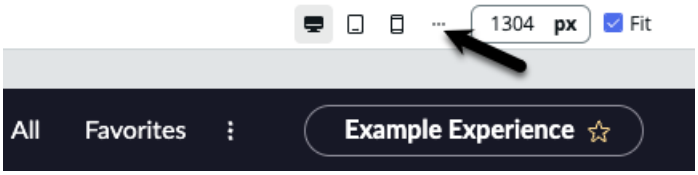
Note:
Custom breakpoints represent a range. If you create a breakpoint at 800 pixels, all changes apply to devices with a width at and lower than the new size. For example, a page opened on a screen 750 pixels wide uses the 800 pixel settings (properties and styles) unless there's another custom breakpoint at 750 pixels.

Procedure

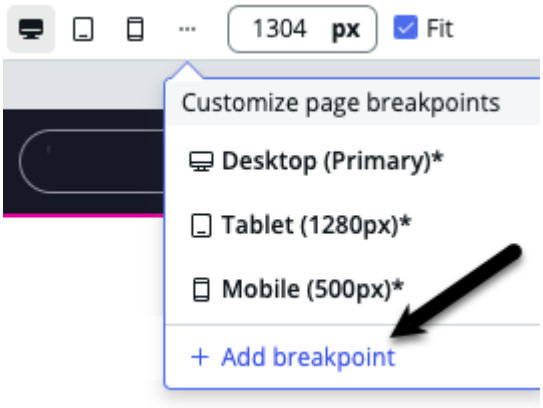
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create > Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Open an existing page created from scratch with responsive authoring or create a page from scratch with responsive authoring.

For more information about how to create a page, see Create a page in UI Builder.

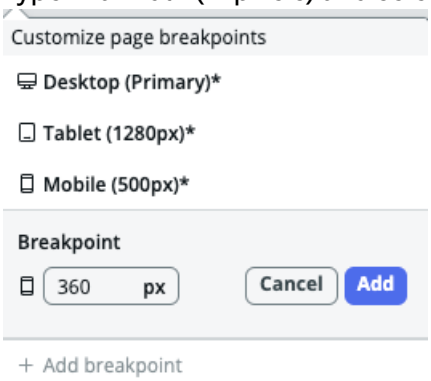
4. Select the menu icon next to the three form factor icons.



5. Select **+ Add breakpoint**.



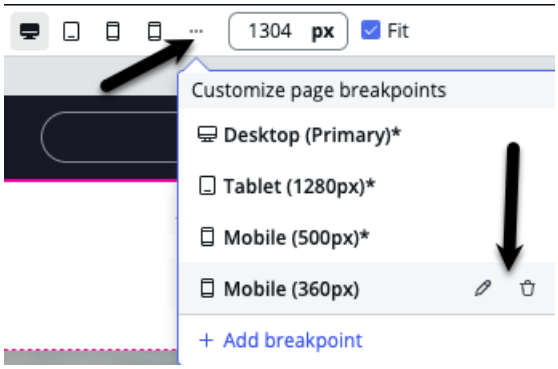
6. Type in a width (in pixels) and select **Add**.



The new breakpoint is saved and appears as a form factor icon.

As you build the page, select any of the form factor icons to view and edit the page at that size.

7. To edit or delete a custom breakpoint, select the menu icon, point to the breakpoint name, and select the edit or delete icon.



Note:
The default form factors (desktop, tablet, and mobile) can't be edited or removed.

Learn how to view and test your UI Builder experience

Preview your experience in UI Builder to see how it looks and functions while building an experience. Previewing helps ensure that your experience works as expected, that the data resources are available, and that the layouts are set up correctly.

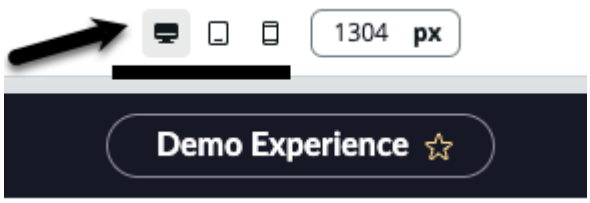
Test your page

You can test your page as the developer or see it as it would appear to an end user. Previewing doesn't require saving first.

Note:
Previewing inactive variants and page collections (sub pages) isn't currently supported.

You can test various aspects of your page.

- Test the variant that you're currently working on, including modals, viewports, and dynamic data by selecting the **Preview** button, which opens an overlay.
- Test with different data by changing the test values and selecting **Apply**. For more information, see Test values in a page.
- See what the variant looks like at different screen widths by selecting a form factor icon. For example, view the variant at tablet or mobile size. For more information about creating pages for different form factors, see Responsive authoring.



Note:
If you edit the test values or the form factor when previewing, the new test values or form factor are retained when you view the page variant in the editor. For example, if you changed the form factor to mobile while previewing, the page variant is displayed in the editor at the mobile form factor. You can always change to another size by selecting a form factor icon.

When you have finished testing, select the **X** in the upper right to close the overlay.

Test your page as an end user

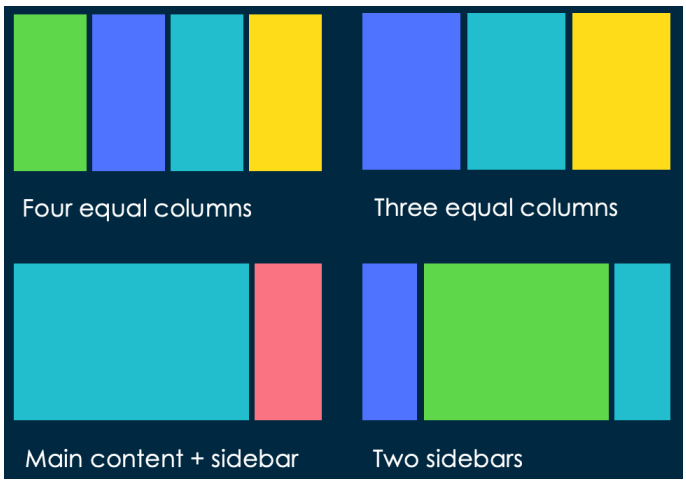
Test which variant users see by opening the URL path. Select the arrow next to the **Preview** button and in the drop-down list select **Open URL path**. UI Builder checks the audience, conditions, and condition order, and then opens the appropriate variant in a new browser tab. When you have finished testing, close the tab.

Organize components in UI Builder pages

Column layouts organize components on a UI Builder page. Learn how column layouts are used in UI Builder.

Column layouts enable you to create useful and visually appealing pages in an experience. A column layout is a type of flexible container that can hold components. Column layouts can have columns of equal or different widths. You can configure the column layout as a whole and the individual columns within the layout. For example, set a different border width and color for a column layout and for the individual columns within the layout. Column layouts can contain empty columns on a UI Builder page to create white space. Use multiple column layouts on a page. For example, a two-column layout could contain a header and image, then a three-column layout below it could hold more components like a list and form.

Think about the layout of your page before you begin building it. Analyze what you want to achieve and how complex the page layout must be. These questions determine what type of column layout or layouts you should use.



Column layouts in UI Builder use standards-based Cascading Style Sheets (CSS) rules and web layout technologies such as Flexbox, CSS grid, and absolute positioning. So whatever you can do in CSS you can do here. Visit Mozilla to learn more about CSS.

Note:
If you have existing UI Builder pages created in an earlier release (Utah or Tokyo), you can upgrade to Vancouver or Washington DC and add column layouts to the pages.

Column layouts

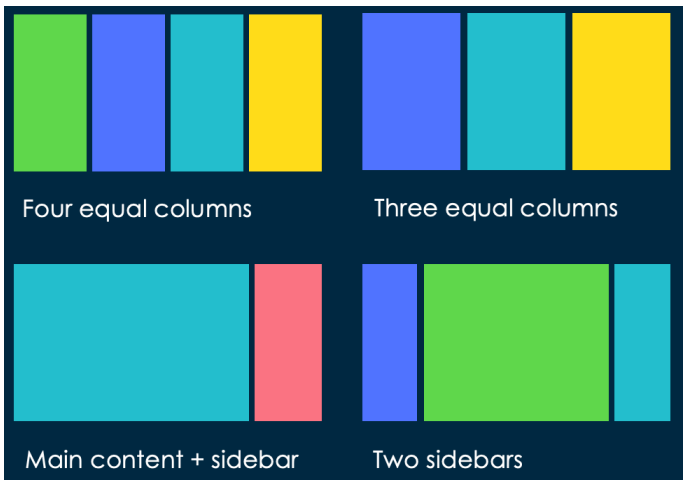
Column layouts are used to design and organize UI Builder pages.

This video shows you how to perform the following procedure. This video shows you how to add a column layout to a UI Builder page.

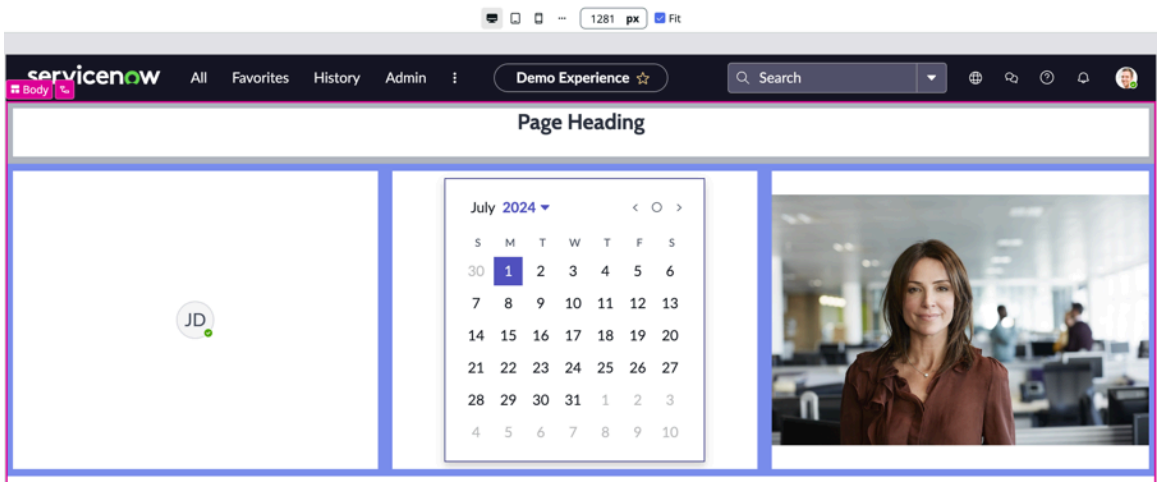
Column layouts enable you to create useful and visually appealing pages in an experience. A column layout is a type of flexible container that can hold components. Column layouts are

simple layouts that are preconfigured, enabling you to design an efficient and attractive page quickly. It's useful to define and set the structure of the page with column layouts before adding components.

Column layouts can have columns of equal or different widths.



You can configure the column layout as a whole and the individual columns within the layout. For example, set a different border width and color for a column layout and for the individual columns within the layout.



Note:
Currently, hiding/showing columns in a column layout based on conditions isn't supported.

Add a column layout

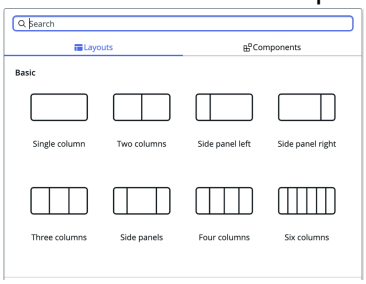
Add a column layout in UI Builder to build structure and organize components on an experience page.

Before you begin
Role required: ui_builder_admin

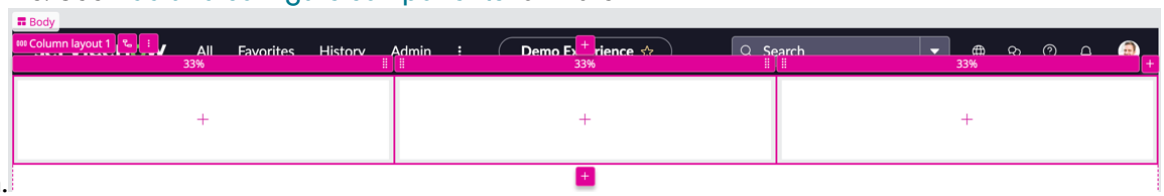
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.

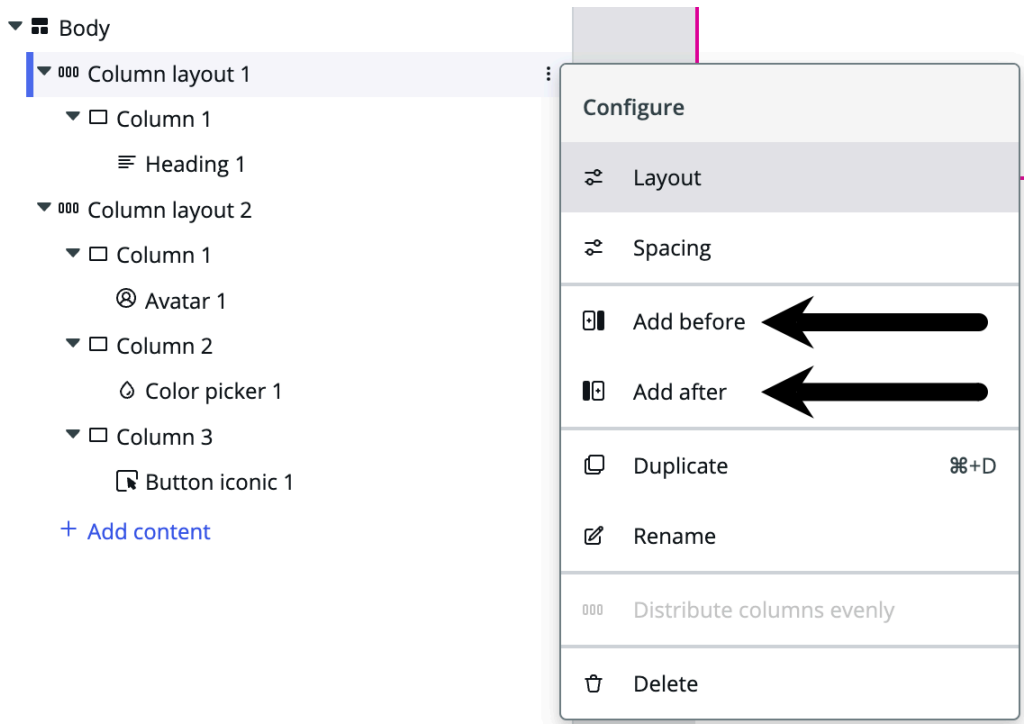
3. Create a page in UI Builder or open a page.
4. Select **+ Add content** in the content tree.
5. Select one of the **Basic** options on the **Layouts** tab.



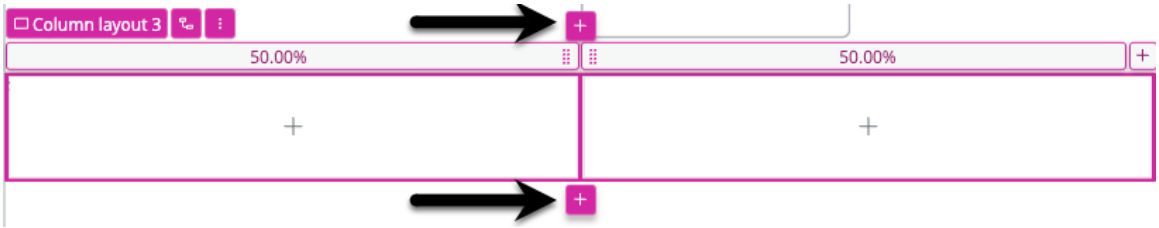
The column layout appears on the stage so you can add components to the columns. See Add and configure components for more information.



6. Add additional column layouts above or below.
   - In the content tree, select and hold (or right-click) on a column layout name or select the Menu icon for a column layout. Then, select **Add before** or **Add after** from the list and select a layout.



- On the stage, select a column layout, and then select the plus sign at the top or bottom.



Configure column layouts

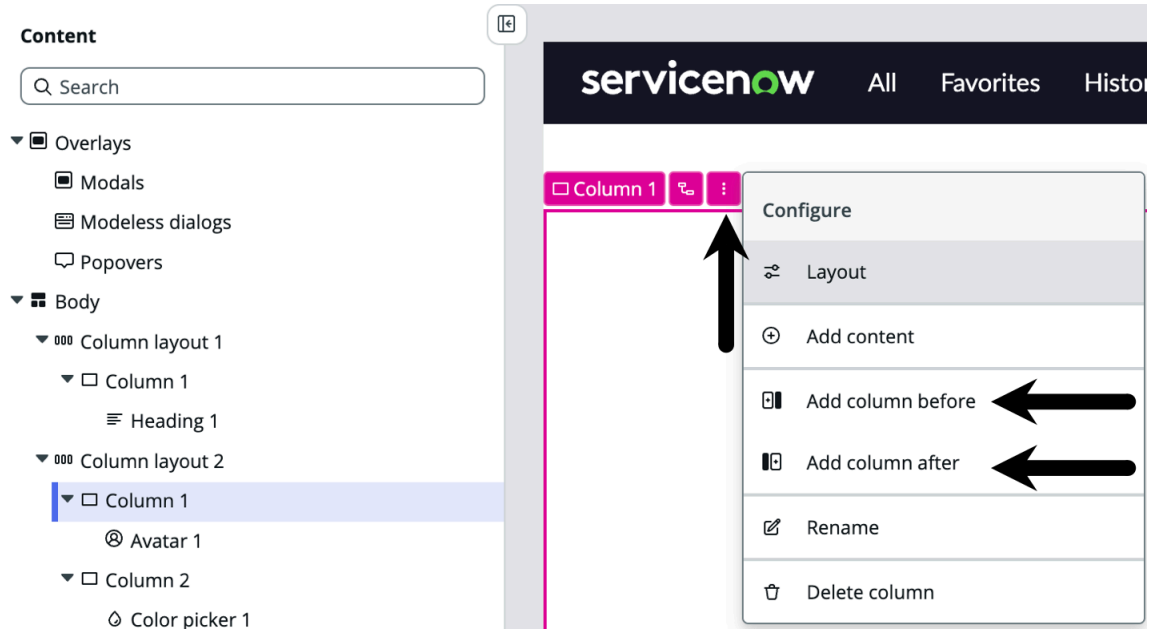
Configure column layouts in UI Builder to add the appropriate number of columns and the look you want on an experience page.

Before you begin
Role required: ui_builder_admin

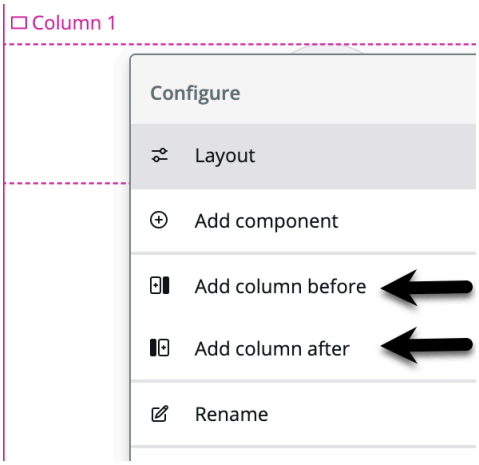
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page in UI Builder or open a page.
4. If the page doesn't already contain a column layout, Add a column layout.
5. Add (up to a maximum of six) columns using the content tree, the stage, or the configuration panel.
   - In the content tree, select and hold (or right-click) on a column name or select the Menu icon for a column and then select **Add column before** or **Add column after** from the list.

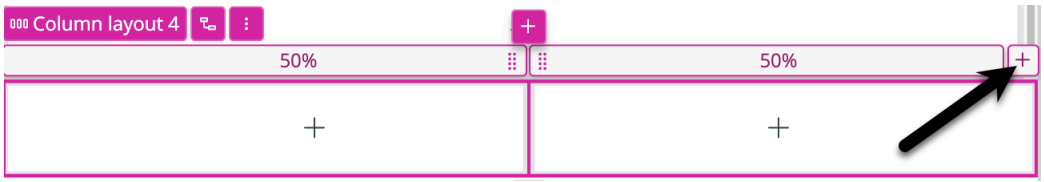
   - On the stage, select a single column, select the Menu icon next to the column name, and then select **Add column before** or **Add column after** from the list.



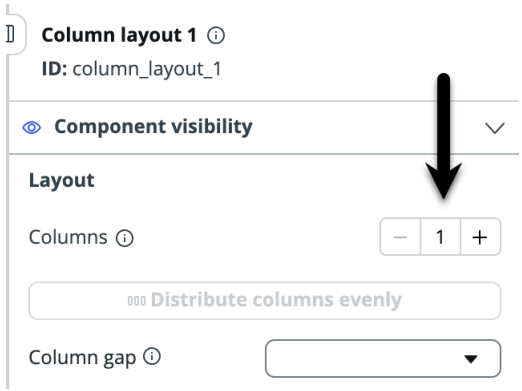
- On the stage, select and hold (or right-click) on a column and then select **Add column before** or **Add column after** from the list.



- In the content tree, select a column layout and then on the stage select the + plus icon to add columns to the right side of the column layout.

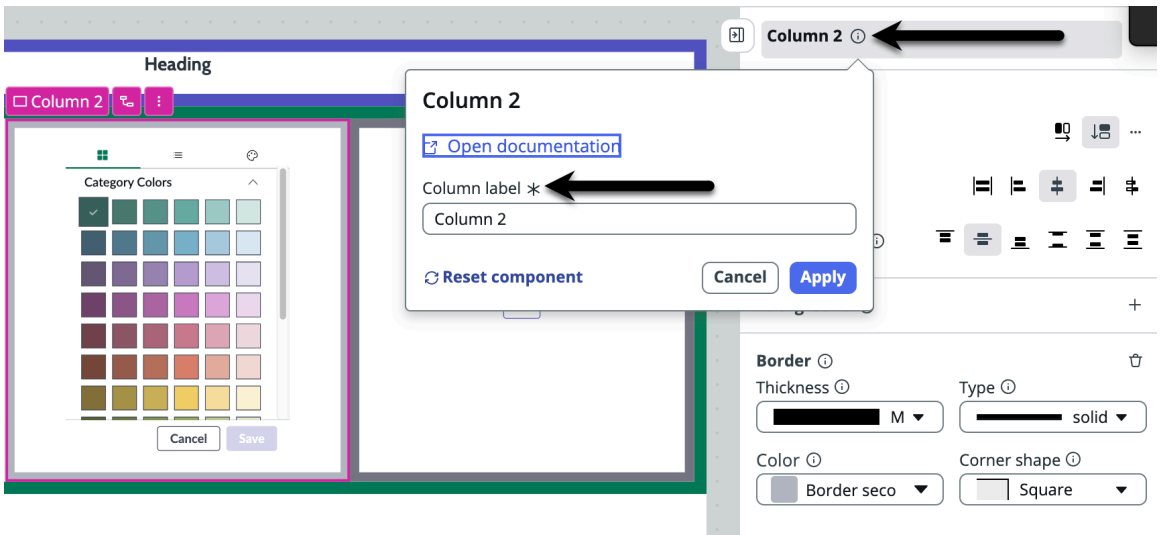


- In the content tree, select a column layout and then in the configuration panel use the + plus icon next to **Columns** to add columns to the right side of the column layout.



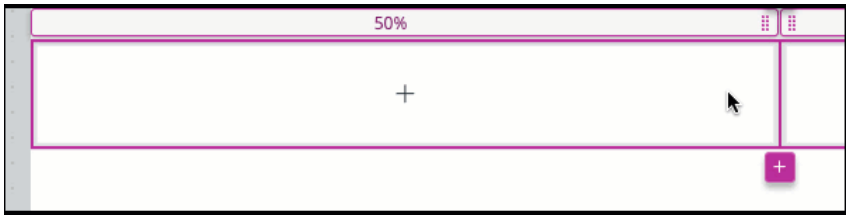
Note:
Columns can be nested inside one another, but this level of complexity isn't often required on pages.

6. Rename a column by editing the column label from the content tree, the stage, or the configuration panel.
   - In the content tree, select and hold (or right-click) on a column name or select the Menu icon for a column, select **Rename**.
   - On the stage, select the Menu icon next to a column name, select **Rename**.
   - In the configuration panel, select the information icon next to the column name.



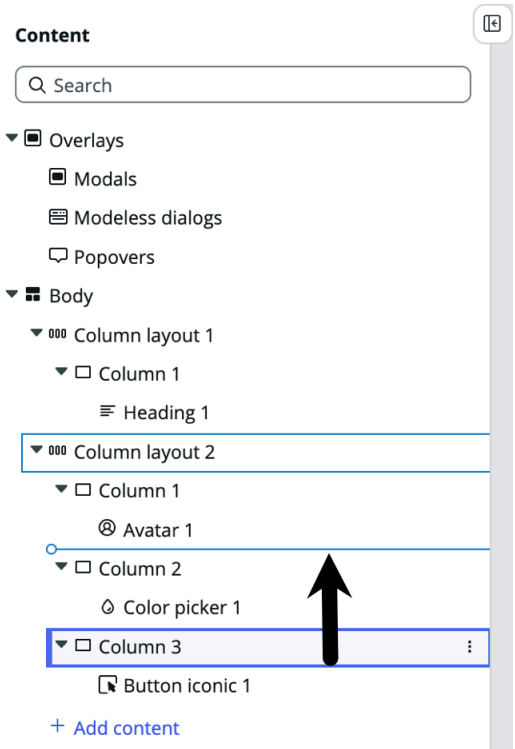
Renaming columns can help you distinguish between different columns on the stage and in the content tree. If you have a complex page with many column layouts and columns, it is useful to rename columns.

7. To change the width of a column in a layout, select the column layout (in the content tree or on the stage), then drag a column divider on the stage left or right to make the column narrower or wider.

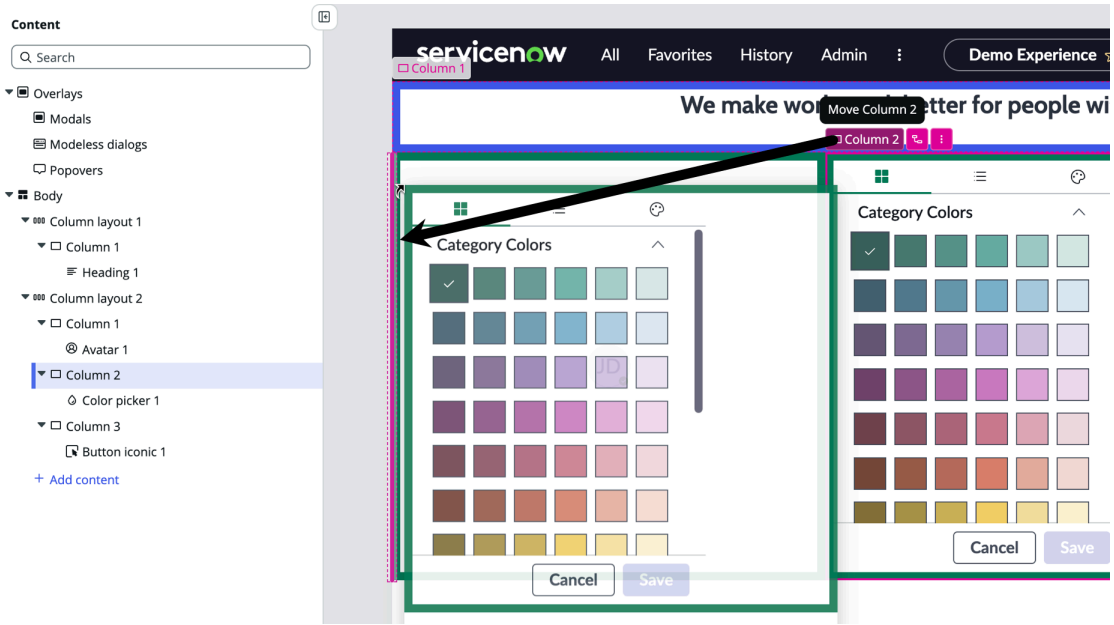


The width percentages at the top of the columns change automatically as you drag the column divider. The percentages add up to 100%. When resizing a column, be aware of how much space the component or components within the column need. For example, list and form components usually don't display well in narrow columns.

8. Distribute columns in a layout evenly across the horizontal using the content tree, the stage, or the configuration panel.
   - In the content tree, select and hold (or right-click) on a column layout name or select the Menu icon for a column layout, and then select **Distribute columns evenly** from the list.
   - On the stage, select a column layout, select the Menu icon next to the column layout name, and then select **Distribute columns evenly** from the list.
   - Select a column layout (in the content tree or on the stage) and in the configuration panel select **Distribute columns evenly**.
9. Reorder columns (including their contents) within a column layout using the content tree or the stage.
   - In the content tree, select the column and drag it to a different position (a blue horizontal line shows where the column can be dropped).



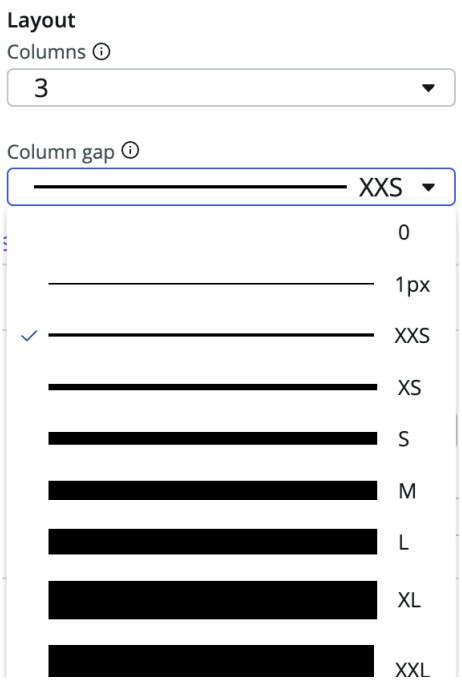
- On the stage, select a column header, drag the column to a different position, and drop the column into the drop zone defined by a vertical magenta line.



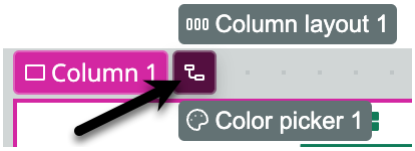
If you reorder the column in the content tree the stage updates, and if you reorder on the stage the content tree updates.

10. Specify the amount of space between columns from the content tree, the stage, or the configuration panel.

- In the content tree, select and hold (or right-click) on a column layout name or select the Menu icon for a column layout, select **Layout** from the list, and select a size option in **Column gap**.
- On the stage, select a column layout, select the Menu icon next to the column layout name, select **Layout** from the list, and select a size option in **Column gap**.
- Select a column layout (in the content tree or on the stage) and in the configuration panel select a size option in **Column gap**.



11. Select the Tree icon to navigate to a different layer of content, for example, from a column to the parent column layout or a child component.



12. Delete columns from the content tree or the stage.
    - In the content tree, select and hold (or right-click) on a column name or select the Menu icon for a column, and then select **Delete column** from the list.
    - On the stage, select a single column, select the Menu icon next to the column name, and then select **Delete column** from the list.
    - In the content tree, select a column layout and then in the configuration panel use the - minus icon next to **Columns** to remove columns from the right side of the column layout.

    For information about editing column spacing, see Set the gap between components in columns.

Set the gap between components in columns

In UI Builder, if a column contains multiple components, set the gap between the components.

Before you begin

Role required: ui_builder_admin

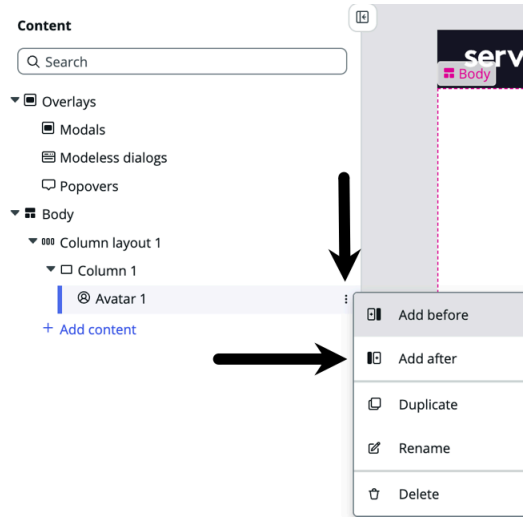
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page in UI Builder or open a page.
4. If the page doesn't already contain a column layout, Add a column layout.
5. Within a single column, add two components

    a. In the content tree, identify a column and select **+ Add content** under the column name.

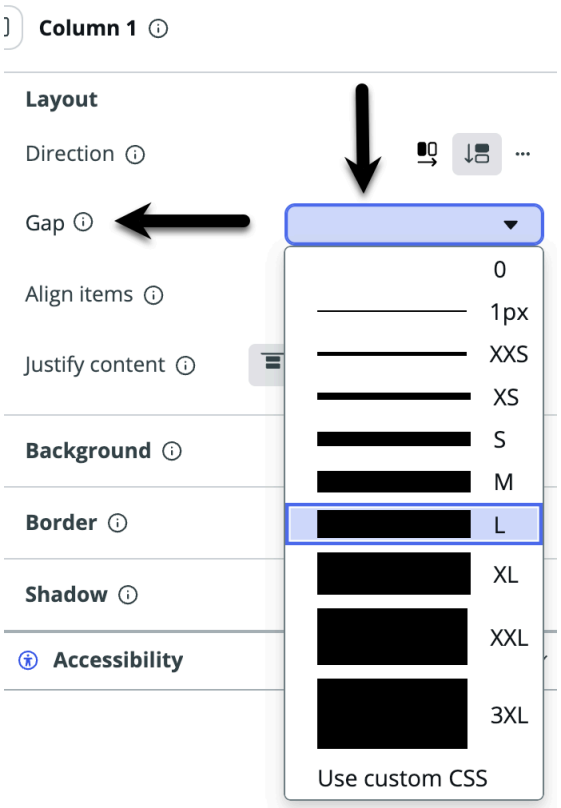
    b. In the toolbox window, select a component, for example, **Avatar**.

    c. In the content tree, move your mouse over the name of the component you just added, select the open menu (three vertical dots) icon, and select **Add after**.



d. In the toolbox window, select another component, for example, **Button**.

6. Select **Save**.
7. In the content tree, select the column to which you added the two components.
8. In the configuration panel, select a size option in **Gap**.



9. To specify an exact gap size in pixels, move your mouse over the **Gap** field, select the **Use custom value** (pencil) icon, and type in a number, for example, 300px.

10. To change between stacking the components and placing them next to each other in the column, select the **Row** or **Column** icon in **Direction**.

To reverse the order and placement of the components in the column, select the **Advanced** (three horizontal dots) icon in **Direction**, and then select the **Reverse** option.

Set advanced column layout options

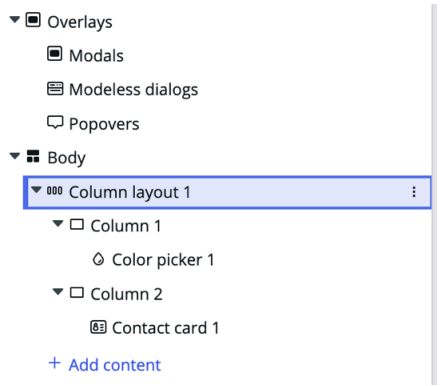
Set advanced column layout options in UI Builder including stack width and column layout height.

Before you begin

Role required: ui_builder_admin

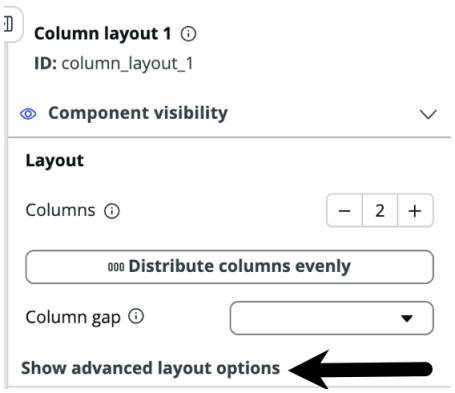
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page in UI Builder or open a page.
4. If the page doesn't already contain a column layout, Add a column layout.
5. Select a column layout containing two or more columns in the content tree.



6. To set a stack width, go to **Configuration panel > Layout** and select **Show advanced layout options**.

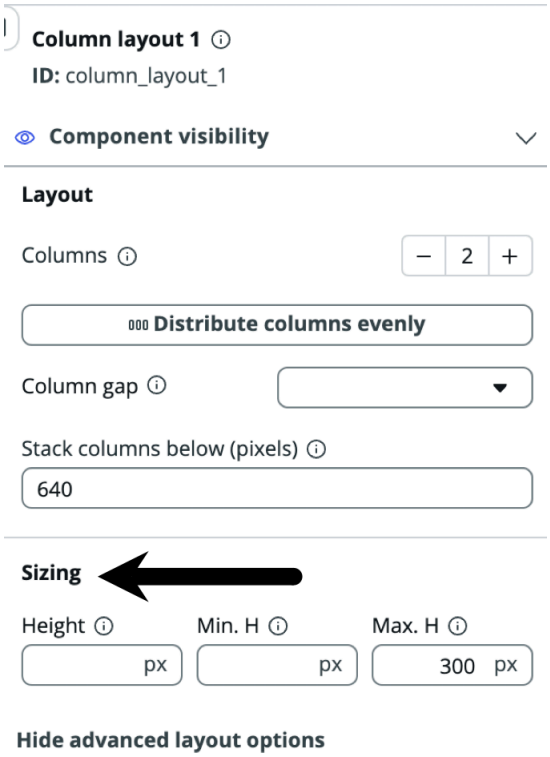
> **Note:**
> Setting a stack width enables you to control how a page with column layouts looks in a narrow browser window, tablet, or mobile device.



7. Type a width in **Stack columns below**.
8. Select **Save**.
9. To test the updated stack width, select the arrow next to **Preview** and select **Open URL path**.
10. Reduce the browser window width to less than the stack width that you specified to check that the columns on the right move below the first column.
11. Close the browser tab that opened with the URL path.
12. To control column layout height, select a column layout with two or more columns in the content tree, go to **Configuration panel > Layout**, and select **Show advanced layout options**.

> **Note:**
> Setting height is useful if your column layout contains a component that can be tall, like the List component.

13. Under **Sizing**, type numbers into one or more of the options (**Height**, **Min. H**, and **Max. H**), and set the sizing unit (for example, **px**, **%**, or **em**).



14. Select **Save**.
15. To test the updated sizing, select the arrow next to **Preview** and select **Open URL path**.
16. Reduce and expand the browser window height to test the specified values.
17. Close the browser tab that opened with the URL path.

Upgrading layouts in UI Builder

Upgrade layouts created in Quebec and Rome to the new layout system.

The UI Builder layout system was enhanced and updated in the San Diego release. This new layout system features a simplified content tree and a new styling panel for layout configuration and component styling. All newly created page variants use the new layout system. You have the option to upgrade to the new layout system for existing and custom pages.

The new layout system includes the following:

- A simplified content tree
- Improved styling panel for layout configuration and component styling
- Low-code UI for configuring CSS Flexbox and Grid layouts.
- Enhanced UI for component styling
- Updated layouts do not require slots

Things to look for after upgrading layouts

Variants and pages are upgraded individually.

A page/variant is made up of a layout, components, and subcomponents, that are wrapped in a container within a layout with data resources, event bindings, and composition. Only the layout of your page is upgraded when upgrading to the new layout system, so there is no impact to your data, components, or component styling.

All slots in the old layout system are migrated during the upgrade process to the new layout. The upgrade process changes how the component containers are structured on your page.

While component styling is not impacted, there may not be a one-to-one style migration of how components were positioned. Complex pages can have visual misalignments that occur through the upgrade process as styles are merged from slots to containers. Some issues must be resolved manually.

Upgrade your layout to the new layout system

Upgrade your UI Builder pages to the new layout system.

Before you begin

Role required: ui_builder_admin

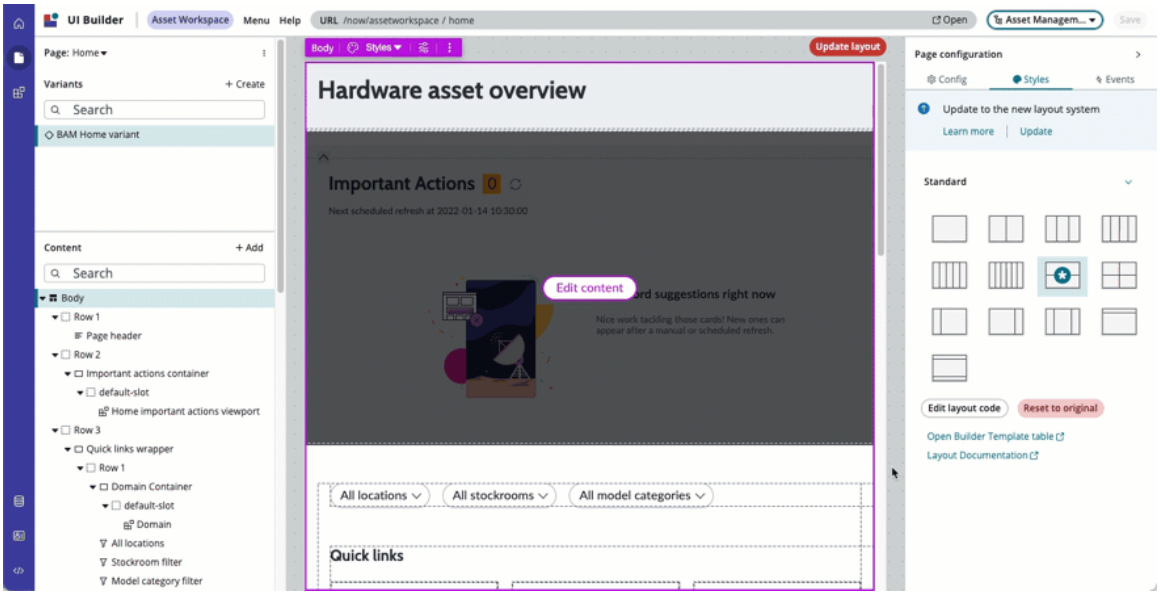
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience with the page you want to upgrade.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Select the page that you want to upgrade.

   You can find page variants that can be upgraded to the new layout system tagged with a red dot.

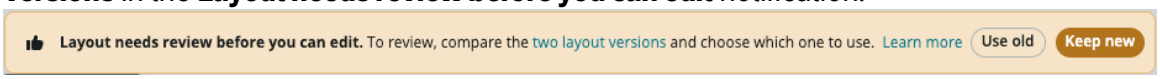
   Note:
   Legacy pages created using the pre-Quebec row/column layout system are not upgradable and must be rebuilt with the new layout system.

4. Select the **Update layout** button.



UI Builder begins updating your page layout to the new layout system. A notification appears when the process is complete.

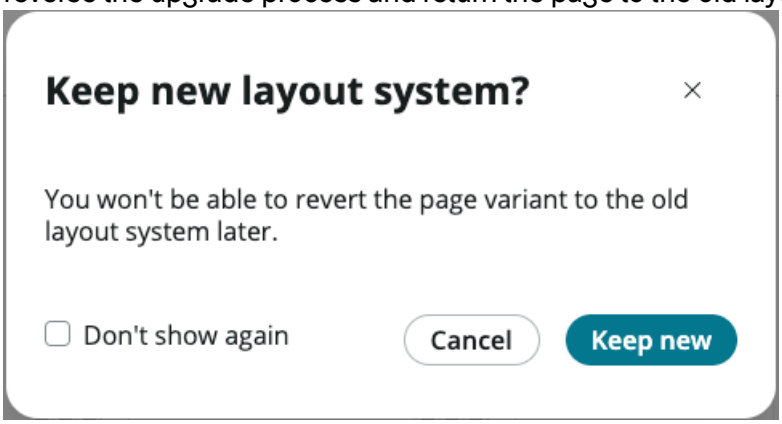
5. You can compare your old layout to the upgraded layout by selecting **compare the two layout versions** in the **Layout needs review before you can edit** notification.



Two browser tabs open, one displaying your current layout and one displaying the upgraded layout.

6. Select **Keep new** if you would like to update the page to the new layout system, or select **Use old** if you would like to keep the page layout as it was.
A modal appears asking you to confirm your selection.

7. Select **Keep new** to complete the upgrade to the new layout system, or select **Use old** to reverse the upgrade process and return the page to the old layout system.



8. The page reloads with the changes applied.

9. View and test your page by selecting the **Preview** button (

).

Using Flexbox layouts in UI Builder

Create a Flexbox layout in UI Builder to build powerful pages so that you can customize with cascading style sheets (CSS) and can improve your performance.

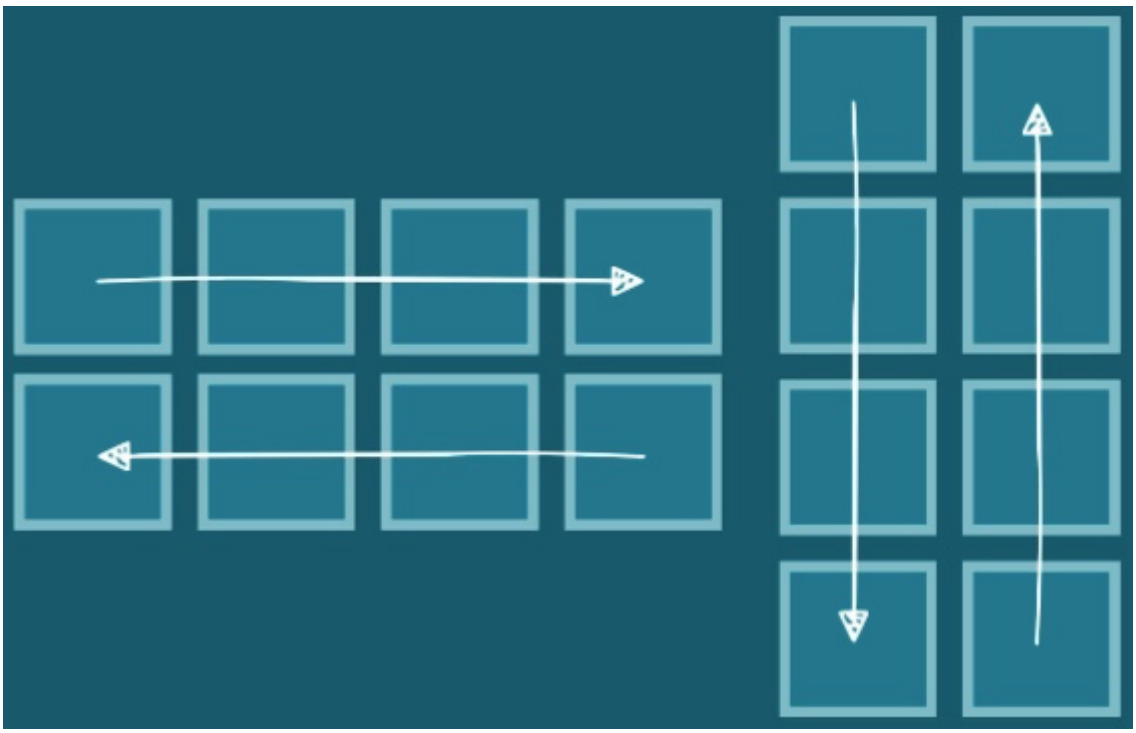
You can easily build custom pages with Flexbox layouts in UI Builder. Customizing the layout of your page lets you take full advantage of Flexbox so that you can achieve your overall page design. For more information, see Organize components in UI Builder pages.

Flexbox is a one-dimensional layout system in CSS. Flexbox is inherently flexible, which is useful for when you don't know the size of your content. If you plan to build complex pages, you can customize the layout of your page in the configuration panel styles tab or with CSS. Visit Mozilla to learn more about Flexbox.

You can change the direction of your content in the layout in the following ways:

- Row: Rows are organized left-to-right or right-to-left, depending on the direction of your browser's default language. Left/right is the case for an English browser.
- Row-reverse: Rows are organized in the reverse direction of your browser's default language, such as right-to-left or left-to-right.
- Column: Up/down or down/up
- Column-reverse: Down/up

Flexbox row and column directions



- Justify content: Defines the alignment along the main axis. Choices are as follows:
  - Flex-start: Items are at the start of the flex direction, similar to left-justified content. This is the default setting.
  - Flex-end: Items are at the end of the flex direction, similar to right-justified content.
  - Space-between: Items are distributed evenly.
  - Space-around: Items are distributed evenly with equal space around them.
  - Space-evenly: The spacing between items is equal.
- Align items: Defines how you want your flex content displayed along the cross axis. Choices are as follows:

- Stretch: Stretch your content to fill the container. This is the default setting
- Flex-start: Place your content at the start of the cross axis.
- Flex-end: Place your content at the end of the cross axis.
- Center: Center your content in the cross axis.
- Base system: Align your content the same as your baseline alignment.

- Height: Set the height automatically or manually.
- Width: Set the height of your flexbox items automatically or manually.
- Margin: Set your minimal distance between flexbox items.
- Padding: Set the padding for each side of your flexbox items.

Create a Flexbox layout with the new layout system

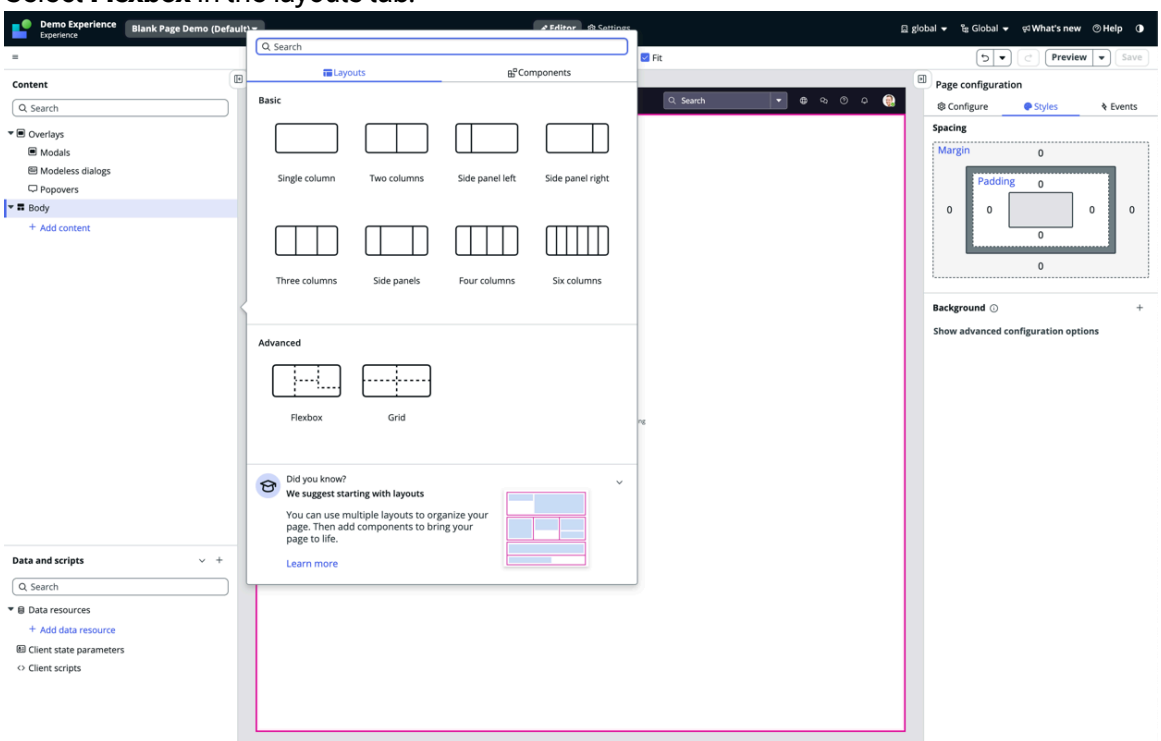
Create a Flexbox layout in UI Builder to build powerful pages in a low-code environment.

Before you begin

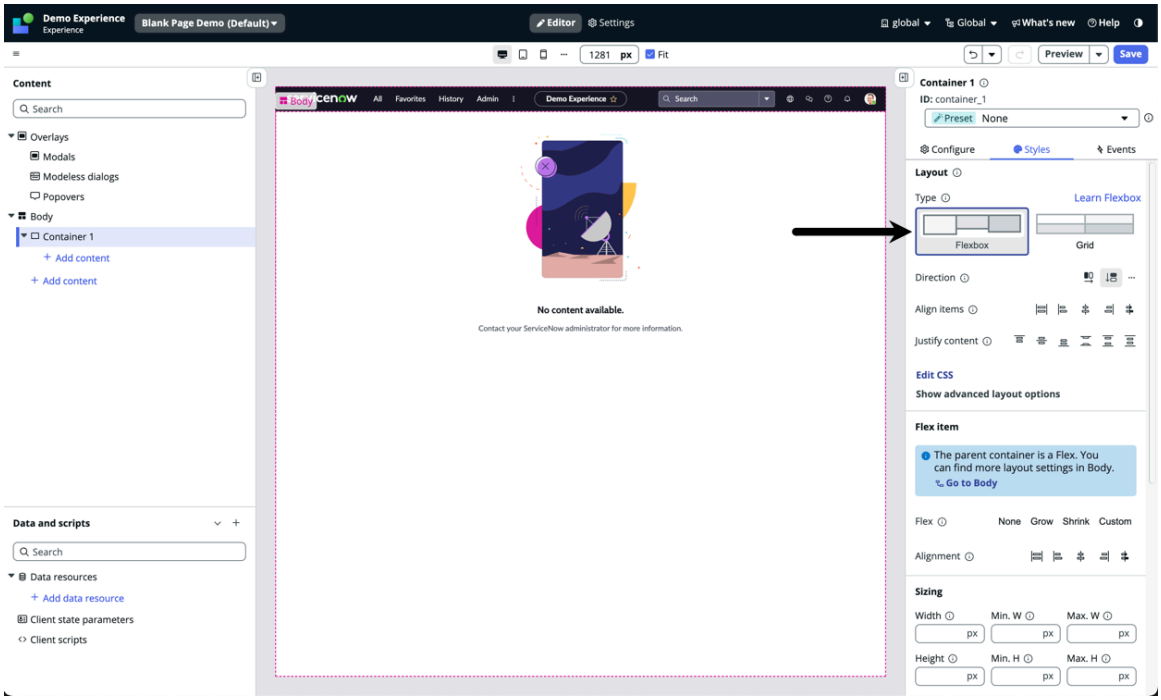
Role required: admin

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page in UI Builder.
4. Select the **+ Add content** button in the UI Builder stage.
5. Select **Flexbox** in the layouts tab.



6. Select the **Styles** tab in the configuration panel.
7. In the **Layout** section, you should see **Flexbox** highlighted.



8. In the **Layout** section of the styles tab, you can change the following:

   Direction

   Define how you want components to stack, horizontally or vertically.

   Align Items

   Define how components within containers align as a group.

   Justify content

   Define how to pack or space apart the components within the container.

   > **Note:**
   > Select **Show advanced layout options** to see the next two options.

   Gap

   Set the size of the gap between rows and columns.

   Wrap child elements to multiple lines

   Set whether components are forced onto one line or overflow onto multiple lines.

   Visit Mozilla to learn more about Flexbox layout configurations.

9. **Optional:** You can edit the CSS code by selecting **Show advanced configuration options** at the bottom of the **Styles** tab, and then selecting the **View and edit CSS** option.
10. Select **Save**.
    Your page refreshes and displays the changes made to the layout.
11. Add components to your page.
    See Add and configure components for more information.
12. View and test your page by selecting Preview.

Create a Flexbox layout with the old layout system

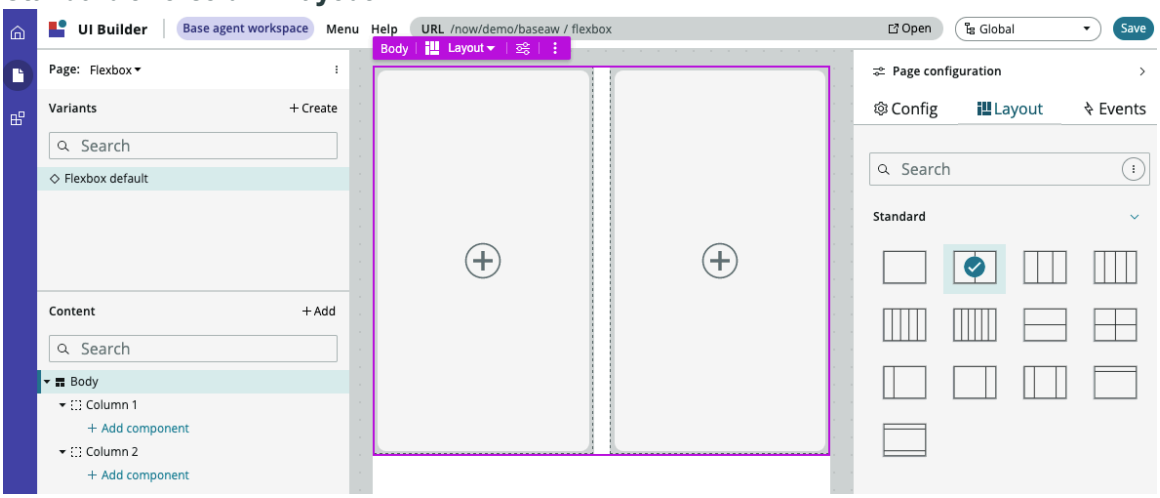
Create a Flexbox layout in UI Builder to build powerful pages so that you can customize with cascading style sheets (CSS) and can improve your performance.

Before you begin
Role required: admin

About this task
In the following procedure, you learn how to use Flexbox to change the CSS code to customize the layout of your page.

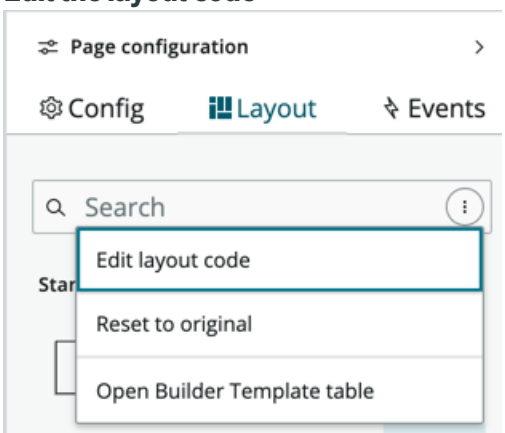
Procedure
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page in UI Builder or open a page.
4. Click the **Layout** tab and choose the two-column layout.

Standard two-column-layout



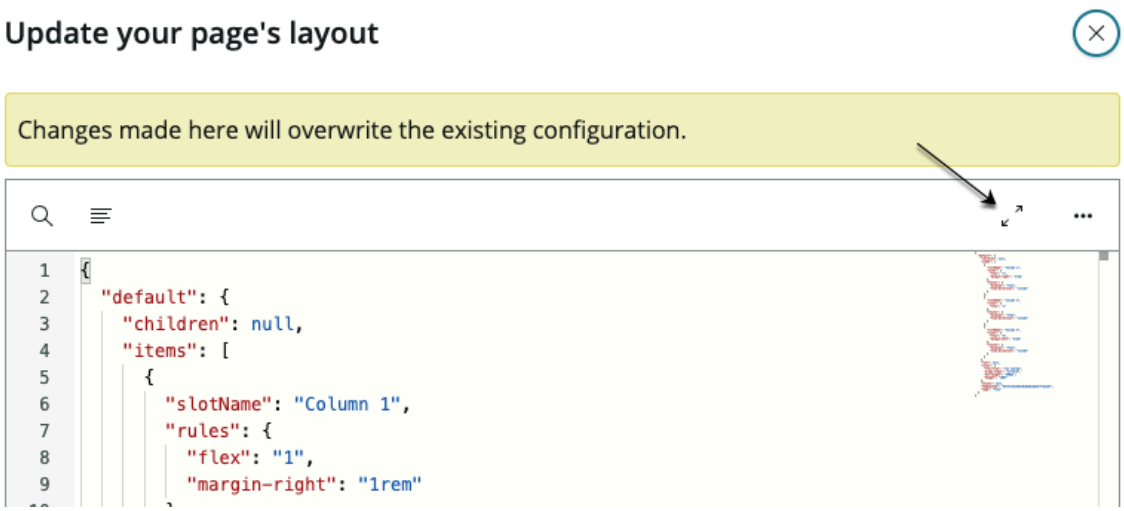
5. Click **Edit layout code**.

Edit the layout code



6. Expand the code editor so that you can easily view the CSS code.

Expand the code editor



7. Add another slot to the layout by copying the CSS code for an existing slot.

   Copying the code is easier than typing it into the layout.

Copy the CSS code for a slot

8. Below the code that you copied, place a comma and then paste the following CSS code:
   a. Change the *"slotName"* property to `"Column 3",`.
   b. Change the *"flex"* property to `"2"`.
   c. Add `"margin-left": "1rem"`.

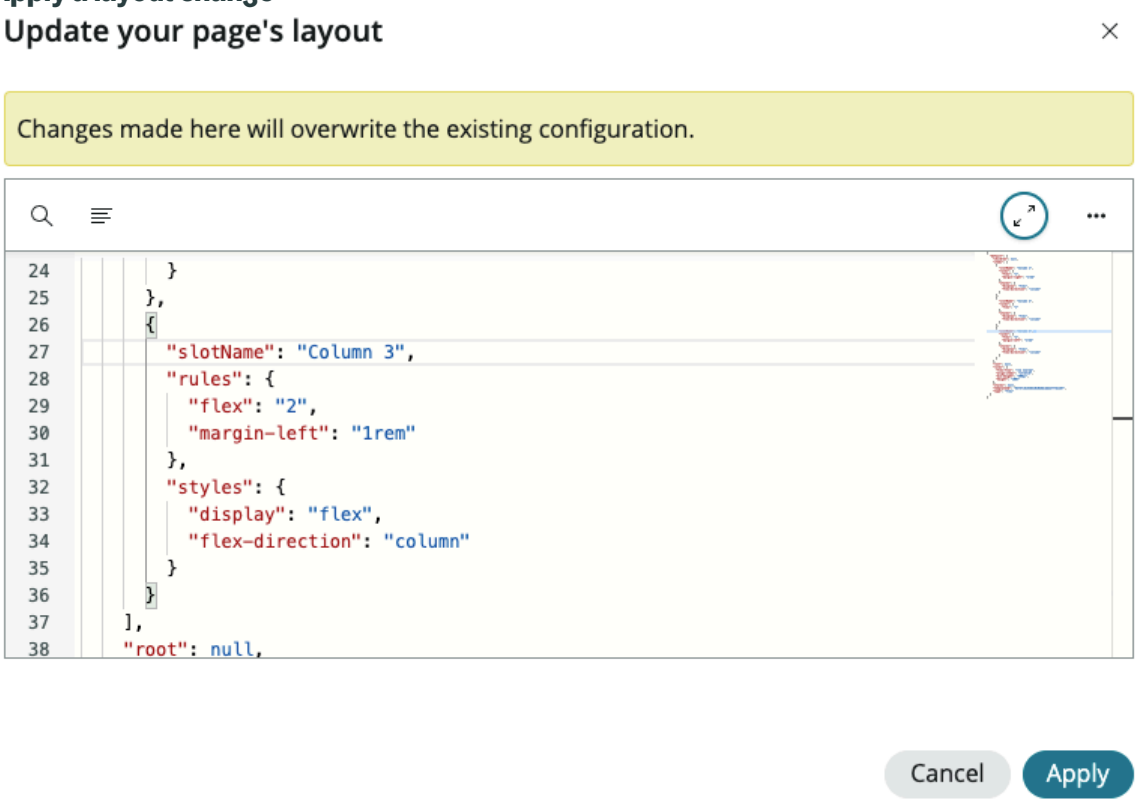
Paste the CSS code

```
        "flex": "1"
      },
      "styles": {
        "display": "flex",
        "flex-direction": "column"
      }
    },
    {
      "slotName": "Column 3",
      "rules": {
        "flex": "2",
        "margin-left": "1rem"
      },
      "styles": {
        "display": "flex",
        "flex-direction": "column"
      }
    }
  ],
  "root": null,
  "rules": {
    "flex-flow": "row nowrap",
    "align-items": "stretch",
    "min-height": "400px",
    "height": "100%"
```

Changing the *"flex"* property increases the size of the column. By using *"margin-left"*, you add space between the previous columns.

9. Collapse the expanded view, and then click **Apply**.

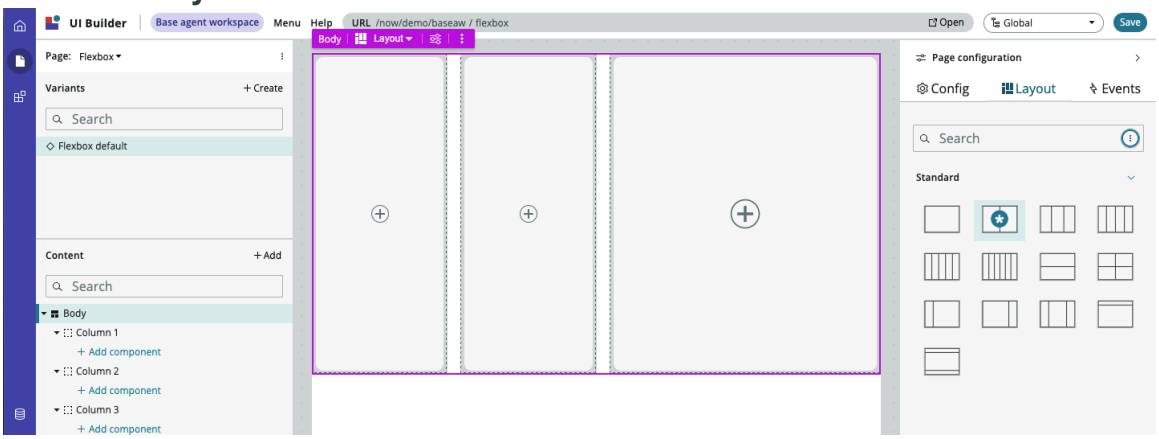
Apply a layout change



Result

The new Flexbox layout that you created shows the new slot that you added to the original two-column layout.

New custom layout



Click **Reset to original** to reset layout changes back to the original.

Reset a layout

Create a CSS Grid layout with the old layout system

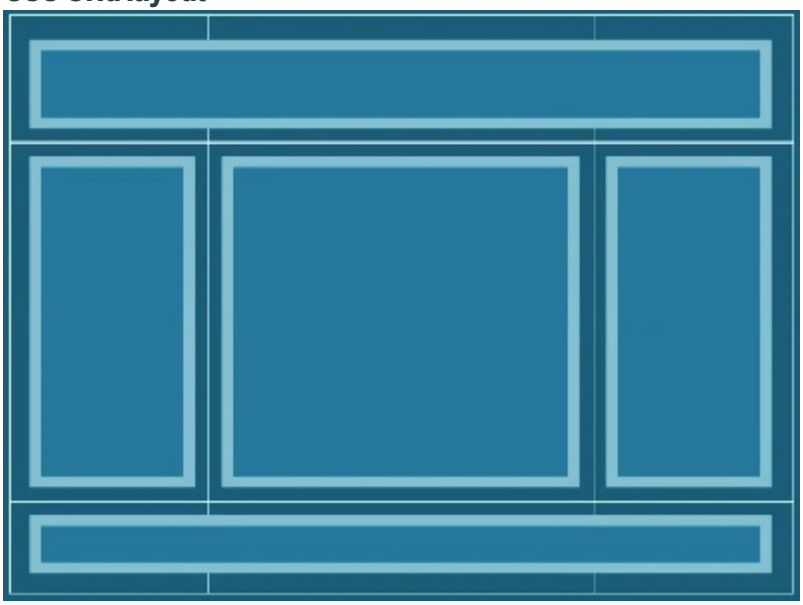
Using CSS Grid layouts to build a page

Create a CSS Grid layout in UI Builder to build powerful pages so that you can customize with cascading style sheets (CSS) and can improve your performance.

CSS Grid is the most powerful layout system in CSS. CSS Grid is built on top of a two-dimensional grid. CSS Grid gives you control over how you create your pages. Use UI Builder to implement a CSS Grid layout using low-code layout configuration properties. For advanced layouts, you can view and edit CSS code to customize your layouts. Visit Mozilla to learn more about CSS Grid.

For example, you can have a grid with three columns and three rows to make a grid nine cells. You can place components inside these cells or make the component span multiple cells.

CSS Grid layout



Customizing the layout of your page lets you take full advantage of CSS Grid so that you can achieve your overall page design. For more information, see Organize components in UI Builder pages.

To find out more about CSS layouts within your UI Builder instance, you can find them in the [sys_uib_template] table.

Create a CSS Grid layout with the new layout system

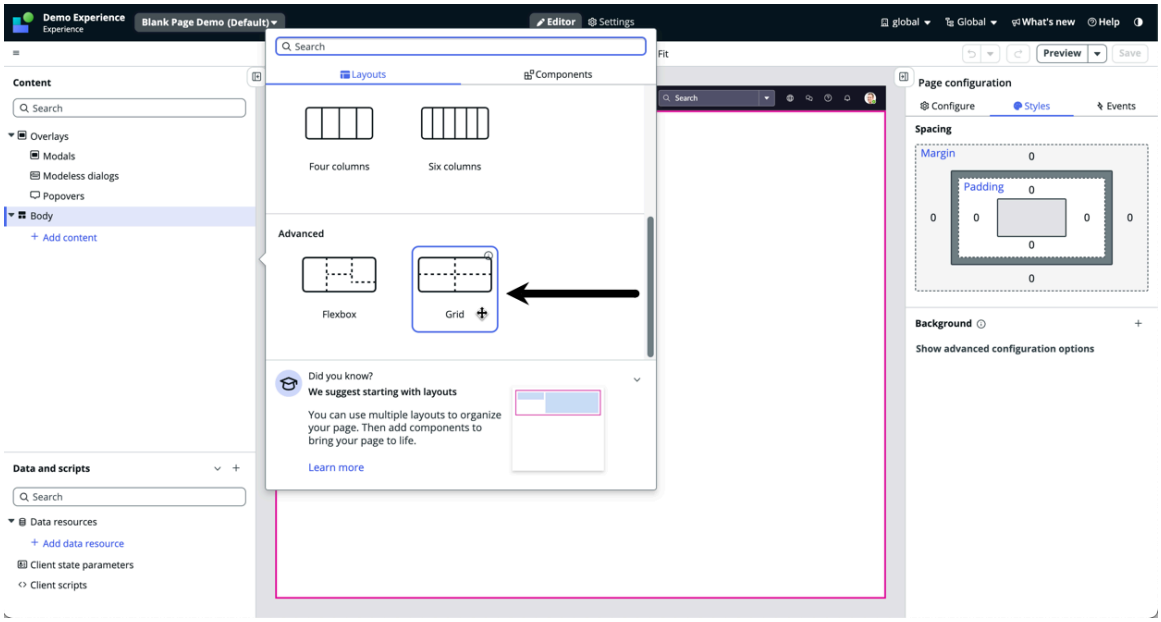
Create a CSS Grid layout in UI Builder to build powerful pages in a low-code environment.

Before you begin

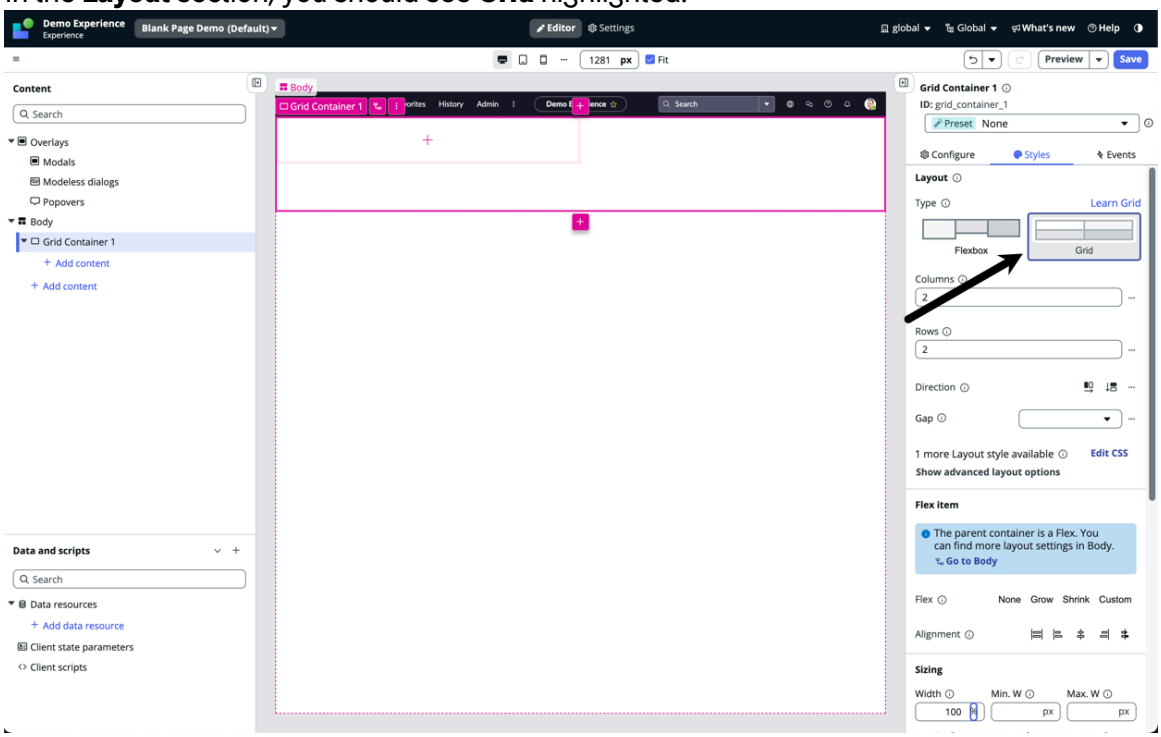
Role required: admin

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page in UI Builder.
4. Select the **+ Add content** button in the UI Builder stage.
5. Select **Grid** in the layouts tab.



6. Select the **Styles** tab in the configuration panel.
7. In the **Layout** section, you should see **Grid** highlighted.



8. In the **Layout** section of the styles tab, you can change the following:

Columns

Defines the number, order, and width of grid columns.

Rows

Defines the number, order, and width of grid rows.

Direction

Sets whether newly added components are stacked horizontally or vertically.

Gap

Sets the size of the gap between rows and columns.

Note:
Select **Show advanced layout options** to see the next four options.

Align items

Defines how components within the container align as a group.

Justify items

Defines how the browser distributes space between and around content items along the inline axis of a grid container.

Align content

Sets the distribution of space between and around content items along a grid's block axis.

Justify content

Defines how to pack or space apart the components within the container.

Visit Mozilla to learn more about CSS Grid layout configurations.

9. **Optional:** You can edit the CSS code by selecting **Show advanced configuration options** at the bottom of the **Styles** tab, and then selecting the **View and edit CSS** option.
10. Select **Save**.
    Your page refreshes and displays the changes made to the layout.
11. Add components to your page.
    See Add and configure components for more information.
12. View and test your page by selecting Preview.

Create a CSS Grid layout with the old layout system

Create a CSS Grid layout in UI Builder to build powerful pages so that you can customize with cascading style sheets (CSS) and can improve your performance.

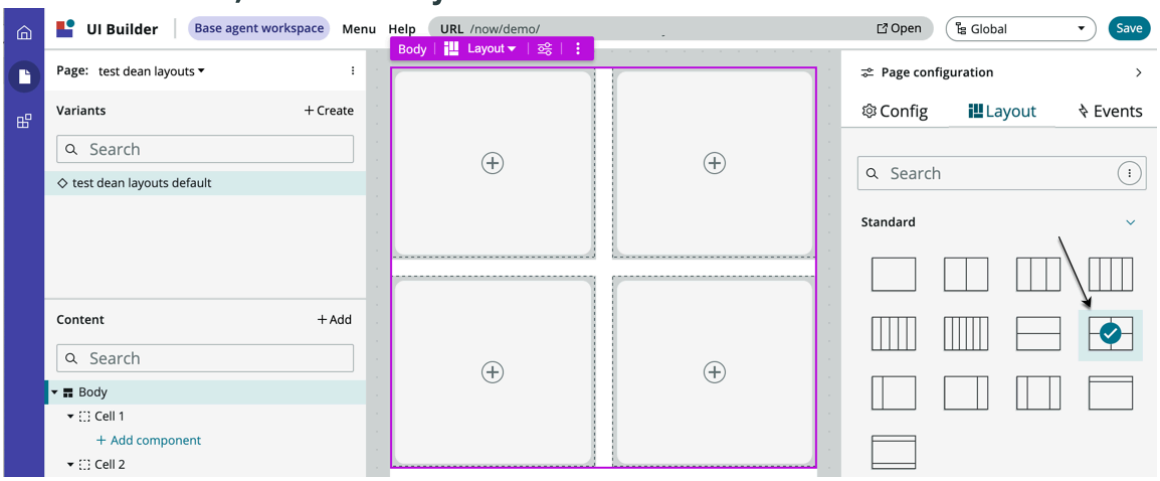
Before you begin
Role required: admin

About this task
In the following procedure, you learn how to use CSS Grid to modify your CSS to customize the layout of your page.

Procedure

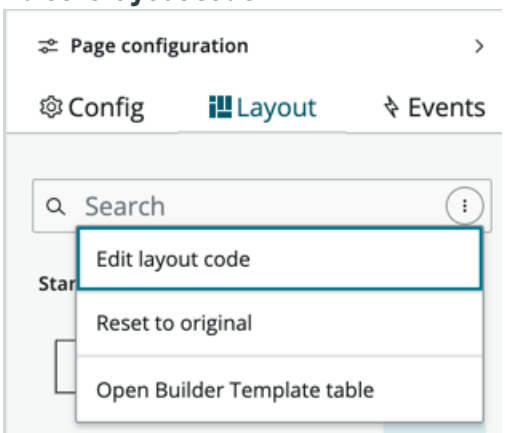
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page in UI Builder or open a page.
4. Click the **Layout** tab and choose the two-row by two-column layout.

Standard two-row, two-column layout



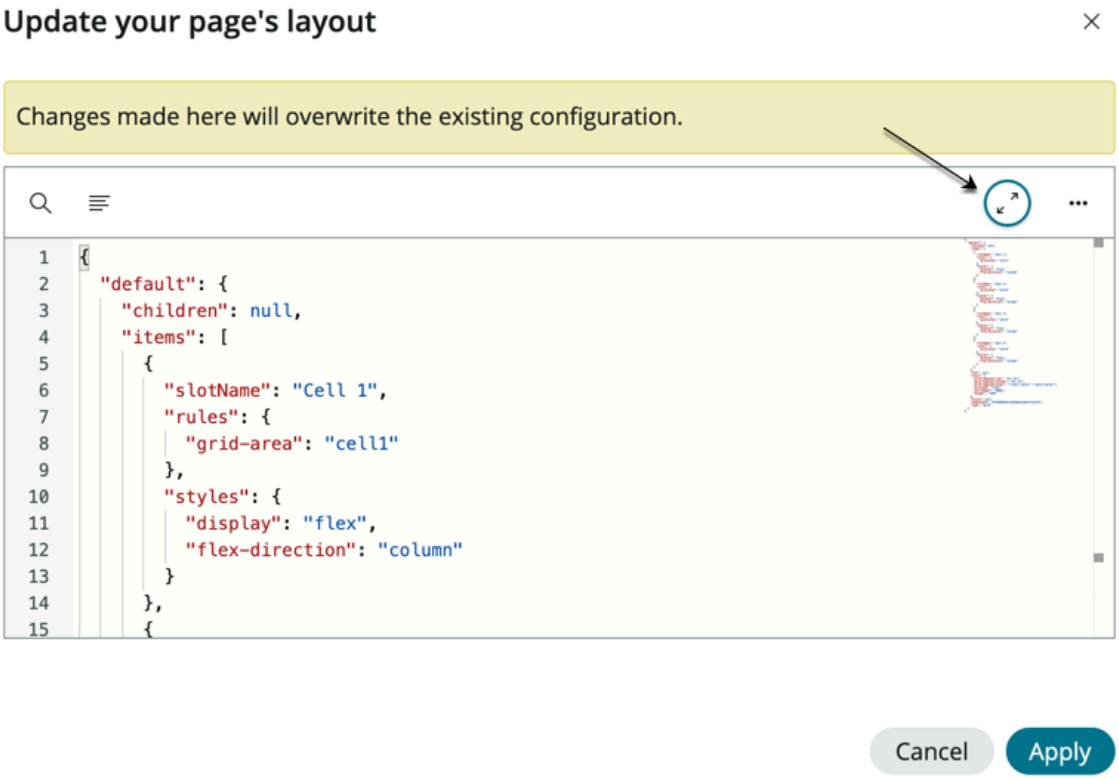
5. Click **Edit layout code**.

Edit the layout code



6. Expand the code editor so that you can easily view the CSS code.

Expand the code editor



7. Add another slot to the layout by copying the CSS code for an existing slot.

   Copying the CSS code is easier than typing it into the layout.

Copy the CSS code for a slot

```
23          }
24        },
25        {
26          "slotName": "Cell 3",
27          "rules": {
28            "grid-area": "cell3"
29          },
30          "styles": {
31            "display": "flex",
32            "flex-direction": "column"
33          }
34        },
35        {
36          "slotName": "Cell 4",
37          "rules": {
38            "grid-area": "cell4"
39          },
40          "styles": {
41            "display": "flex",
42            "flex-direction": "column"
43          }
44        }
45      ],
46      "root": null,
47      "rules": {
48        "grid-template-rows": "1fr 1fr",
49        "grid-template-columns": "1fr 1fr",
50        "grid-template-areas": "\"cell1 cell2\" \"cell3 cell4\"",
51        "grid-gap": "1rem",
52        "min-height": "400px",
53        "height": "100%"
54      },
55      "styles": null,
56      "templateId": "b719698953c31010e6bcddeeff7b1275",
57      "type": "grid"
58    }
59  }
```

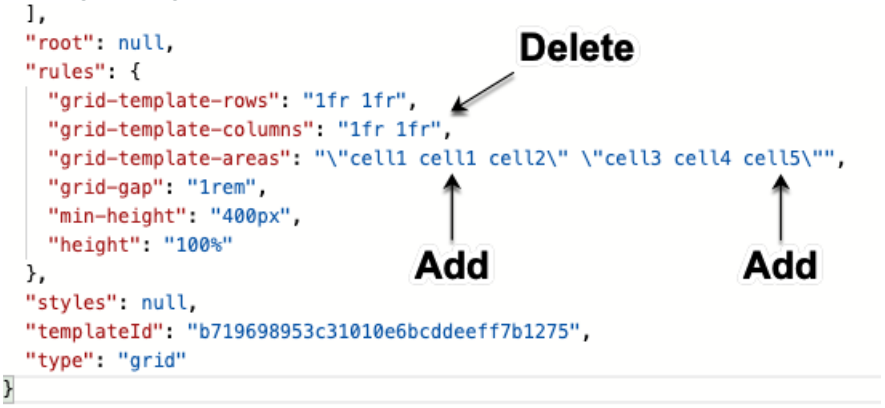
8. Paste the CSS code below the code that you copied and change the *`slotName`* and *`grid-area`* to a unique value.

Paste the CSS code

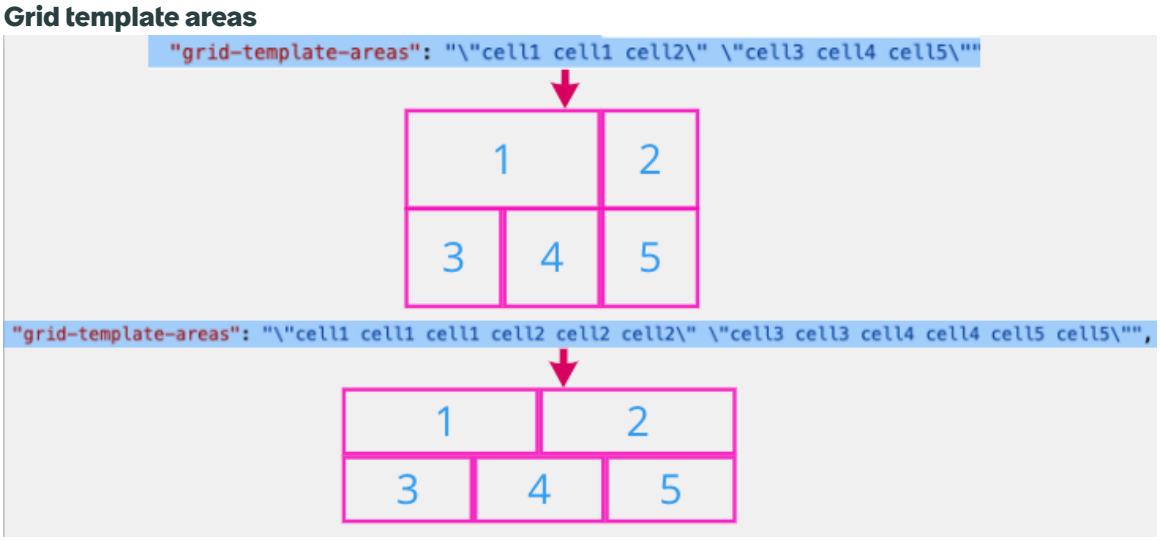
```
{
  "slotName": "Cell 4",
  "rules": {
    "grid-area": "cell4"
  },
  "styles": {
    "display": "flex",
    "flex-direction": "column"
  }
},
{
  "slotName": "Cell 5",
  "rules": {
    "grid-area": "cell5"
  },
  "styles": {
    "display": "flex",
    "flex-direction": "column"
  }
}
```

9. Modify the layout rules to include the new column and template area, as follows:
   a. Delete the `"Grid-template-columns": "1fr 1fr",` line.
   b. Add a second `cell1` after `cell1`, and then add `cell5` after `cell4`.

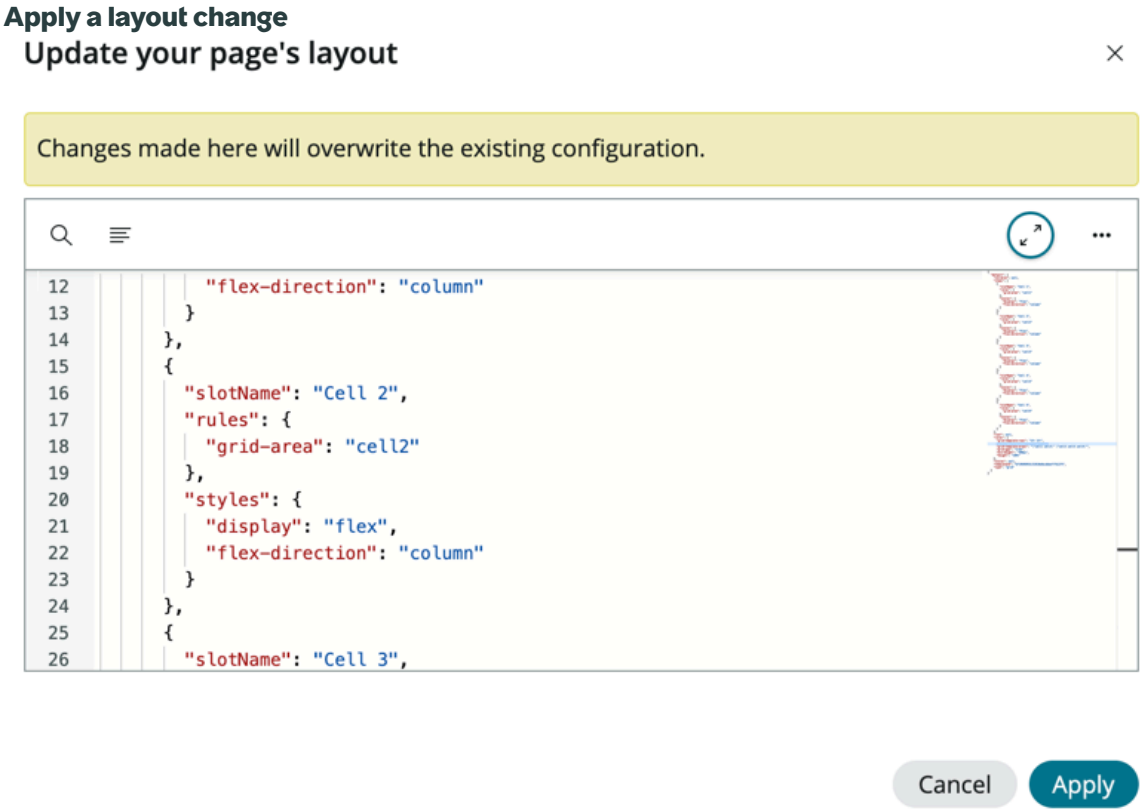
Modify the layout rules



You can set many different configurations. In this example, there are the two resulting grids from two different grid template areas. The *"grid-template-areas"* property being modified is setting the CSS property of the same name. For more information, see MDN grid-templates-areas.



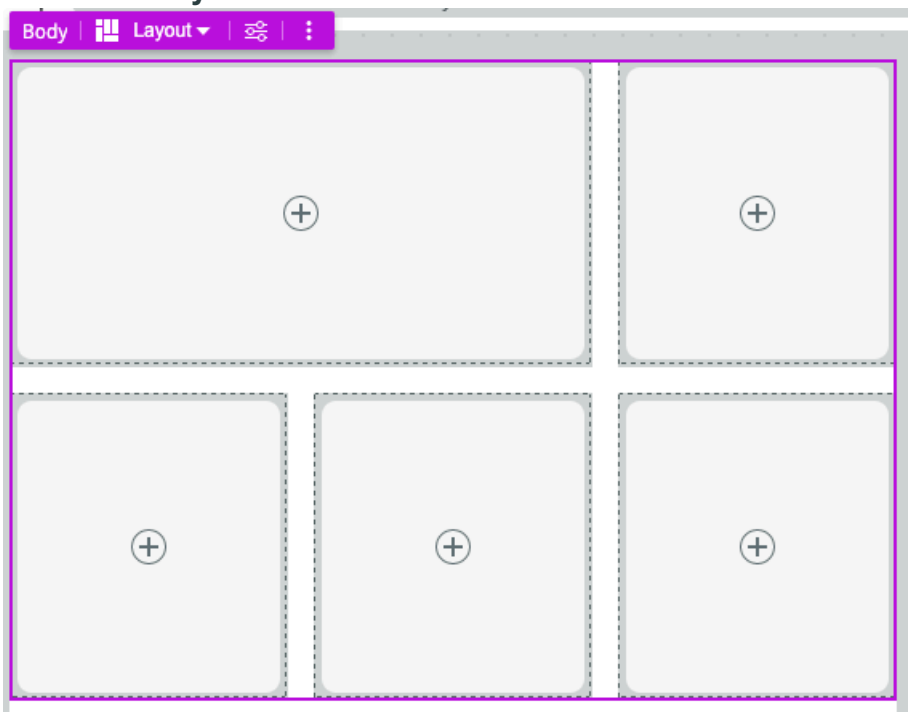
10. Collapse the expanded view, and then click **Apply**.



Result

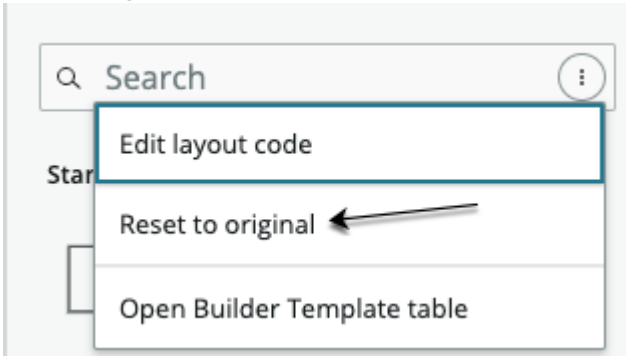
The new CSS Grid layout shows that the new slot was added to the original two-row, two-column layout.

New custom layout



Click **Reset to original** to reset the layout changes back to the original at any time.

Reset a layout



Related topics

Create a Flexbox layout with the old layout system

Change the layout of a page created in Quebec or Rome

Add and modify your layout design to change the way your page looks. Choose how components are displayed on a page through Cascading Style Sheets (CSS) web layout technologies, such as Flexbox and CSS Grid.

Before you begin

Role required: ui_builder_admin

About this task

Layouts control what containers and components are available on a page, and where they are. CSS rules apply to them. You can change the layout as follows.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page.
4. Select the **Layout** tab.
5. Depending on the type of page, do one of the following to select a container to update. If you are starting a new page, you can select the layout at the page level, and later at the container level. If you are not the owner of an existing page, be aware of the impact of changing the layout at the page level.
6. Change the layout of your container.

   a. In the Page configuration pane, select the **Layout** tab to select the layout that you want to use.

      You can change the current layout of an existing page into a new one. For example, in a three-column layout, you can click the four-column layout to change the layout.

      You can also set the layout for a container. The following image shows the layout options for the UI Builder.

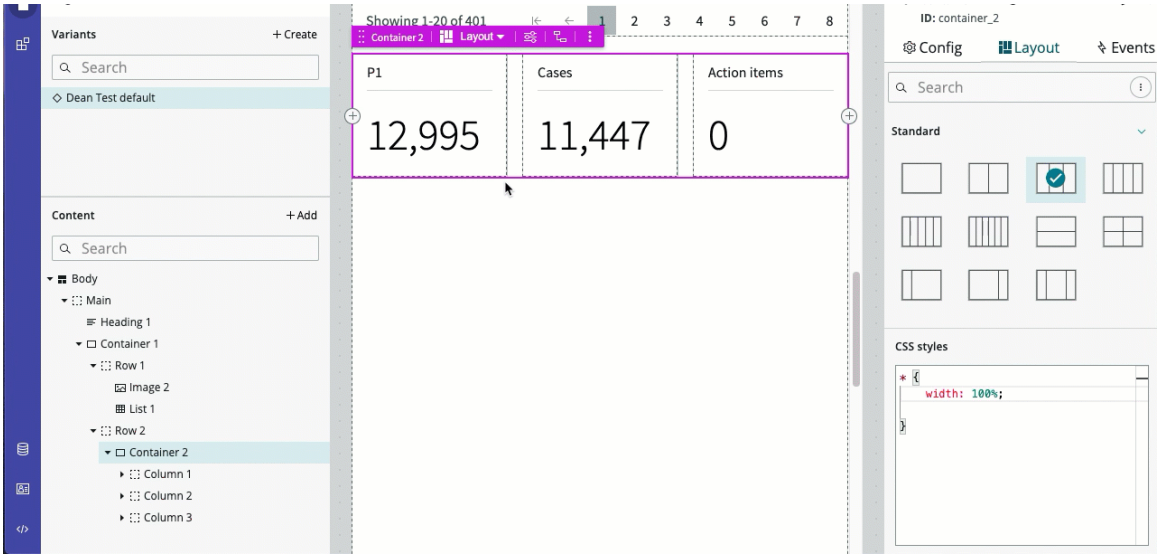
   b. If you are creating a page, add components to the new areas in your layout.

   c. Click **Save**.

   d. View and test your page by selecting Preview.

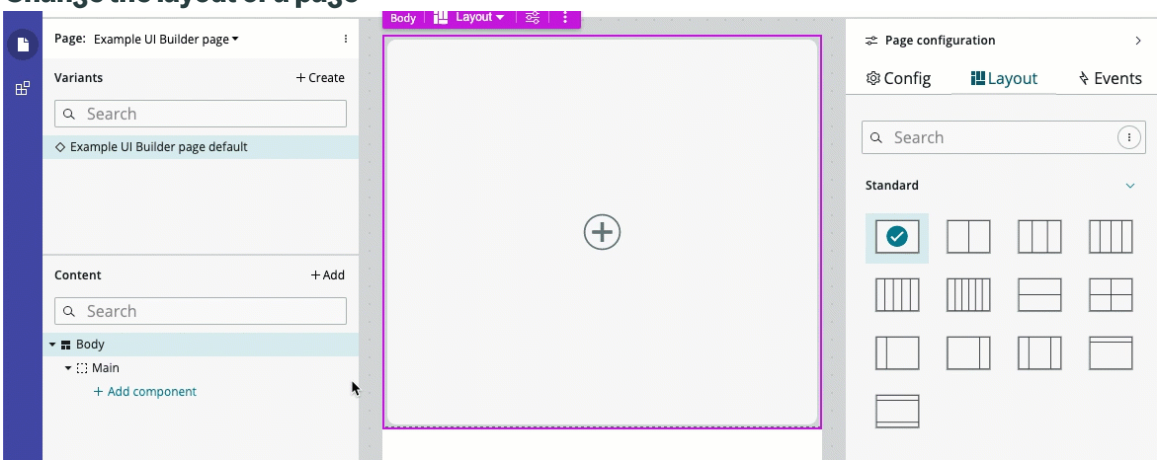
Example

For changing an existing page, the following video shows how you can change the container layout from three to four columns, and then add a new component to the fourth column.



For setting the layout of a new page, the following video shows you how to set the layout that you want for the page. For example, you can set your page to have two slots or columns. Then, you can add containers to each slot and change the layout for each container. You can also set the layout at the container level after you add containers to your page.

Change the layout of a page



7. Add components to slots.
   You build your page with containers components. See Customize UI Builder pages using components for more information.

   You can add components by using any of the following ways.

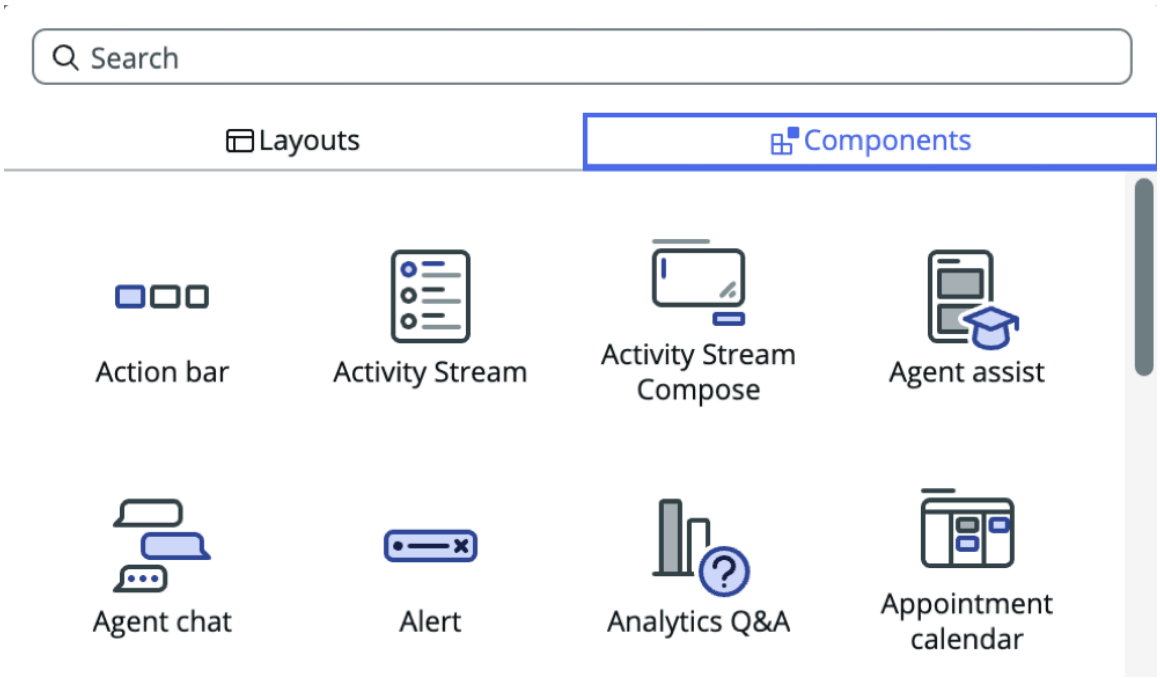
8. Modify the layout styling options in any of the following ways.

Customize UI Builder pages using components

Learn what a component is in UI Builder. Also, see how components work within UI Builder.

Components are the base elements of your UI Builder page. Components range from core elements like buttons and labels to more complex experience components like lists and forms.

You can add these components to your UI Builder page to build or customize your workspace or portal experience. For example, adding an **Activity stream** component to your page that lets users see their travel request activity.



You can add components to your UI Builder page in the following ways.

Ways to add a component to a page

Location	Example
Directly from a page in UI Builder (option 1)	Select the add content (plus) icon, select the **Components** tab, and then select a component. Directly from a page in UI Builder (option 2)	On a column layout or component, select the add before (plus) or add after (plus) icon, and then select a component.

Ways to add a component to a page (continued)

Location	Example
	From the **Content** tree in UI Builder	In the content tree, select **+ Add content** and then select a component. From the floating menu above the page in UI Builder	On a column layout or component, select the Menu icon, select **Add before** or **Add after**, and then select a component.

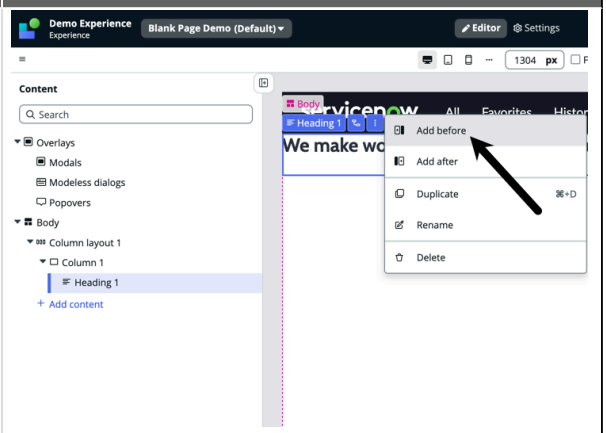
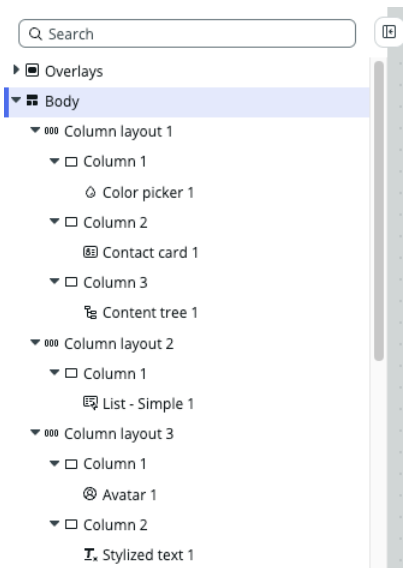
Ways to add a component to a page (continued)

Location	Example
	


Column layouts in UI Builder

Add column layouts and columns to your UI Builder page first. Then add components to the columns in a column layout to build and customize your page. Think of a column layout as a defined part of the screen where you add components like lists and headings. You can have as many column layouts on a UI Builder page as you want, with as many as six columns in any column layout. Multiple components can be added to a single column. View the structure of your page in the **Content** tree.



For more information, see Column layouts.

Configure components in UI Builder

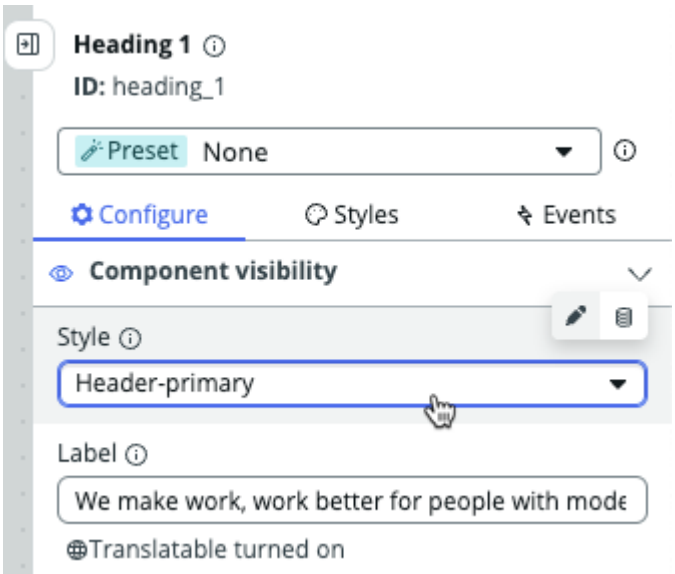
There are three ways to configure a component in the configuration panel.

- Configure the component properties.
- Add CSS style overrides.
- Set up event handlers for the components.

Configure tab

Component properties vary based on each component. Component configuration can be simple, as is the case with simple elements like buttons, headings, and labels. Components like lists and forms require significant configuration. For icon and image components, select from a variety of options or use a custom icon or image. You can modify component properties with UI Builder's low-code JSON editor. For more information about configuring components, see Next Experience Components.

For each property in the component configure tab, you can choose from the following options.



- Static: Use data from a list, or enter your own data. The data doesn't connect to an external data source.
- Dynamic data binding: A way to bind a component property to a data resource, page property, or client state.
- Script: Enter JavaScript code to populate a property value.

Styles tab

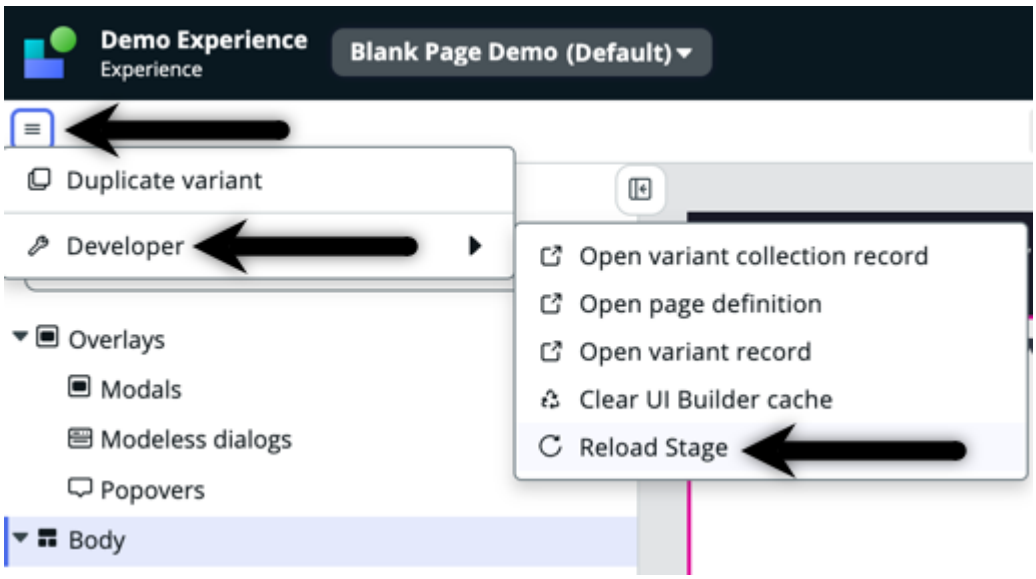
You can change the Cascading Style Sheets (CSS) styles for individual components. Change color borders, font size, and so on.

Events tab

Configure page-level and variant-level event mappings. Also add dispatched events and handled events for your variant. The more complex, experience components rely heavily on dynamic data that is provided by a data resource. Binding dynamic data to a component is an important feature. You dynamically expose data from tables, records, or other elements on your page. Exposing data enables you to reuse your components. Also, you can point to the configuration fields to see icons data or scripting options for each field.

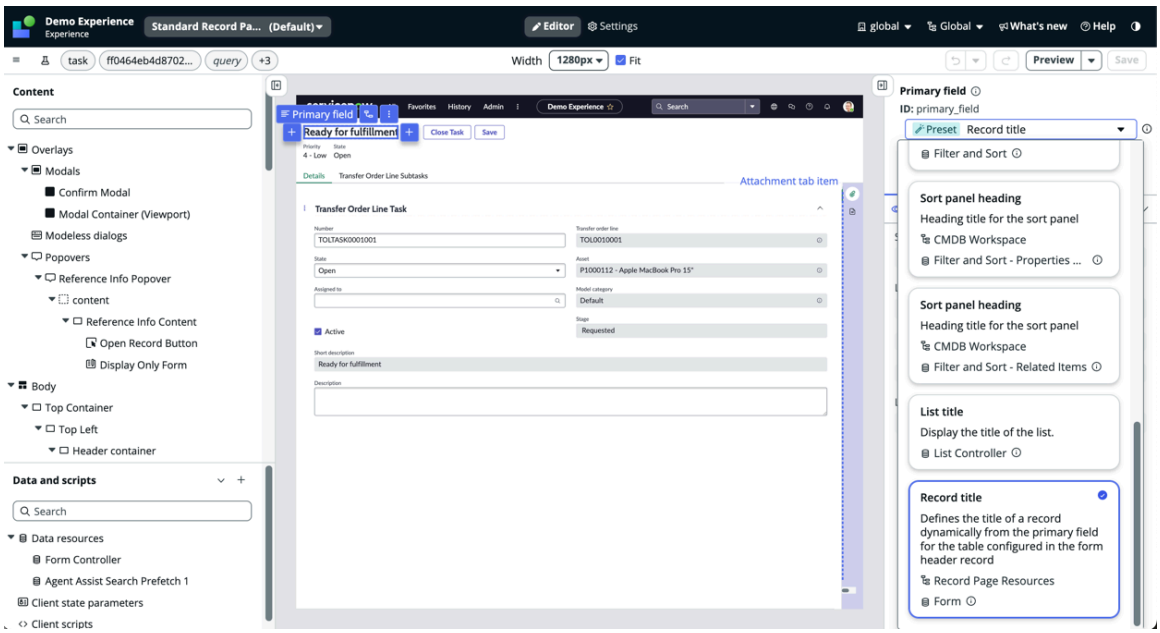
As you add and configure components on the page, the stage shows your work. If you make changes and the updates do not load on the stage, select the **Open menu** icon and then select

Developer > Reload Stage. Reloading the stage shows your changes, but does not save them. To save your work, select **Save** at the top right.



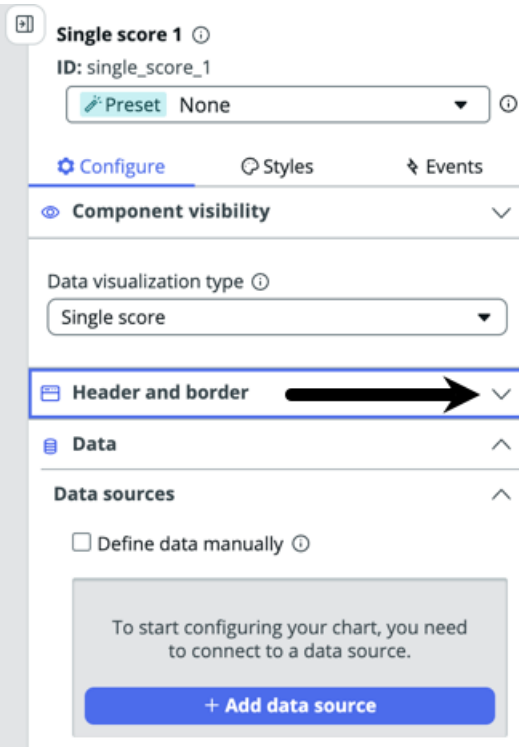
Component Presets in UI Builder

Use component presets to automatically configure components on compatible pages. UI Builder page templates contain controllers that presets use to define component configuration values. For more information, see Automatically configure components using presets.



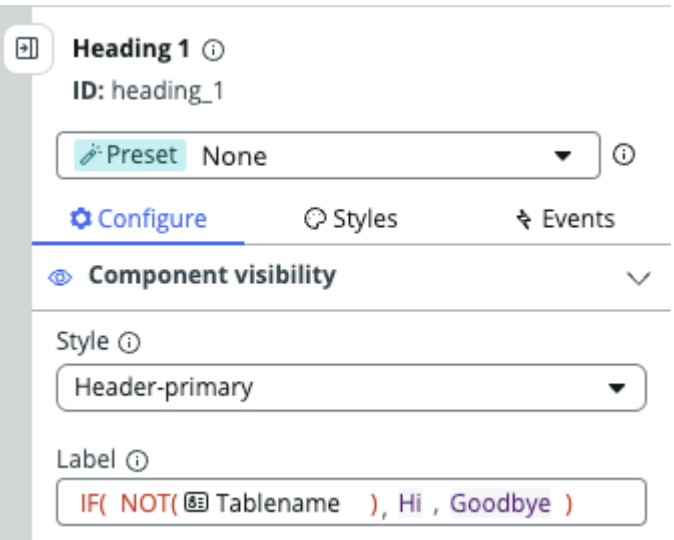
Component properties sections

Component properties are grouped into sections of similar properties. Open and close sections by selecting the arrows to the right of the property headings. UI Builder admins can select which component configuration properties are displayed or hidden based on UI policies.



Component formula editor

Use the UI Builder component formula editor in the configuration panel to bind or modify formulas. You can enter text, data bindings, and/or formulas. Formulas can consist of any combination of the three input types. The component formula editor supports logical, arithmetic, comparison, negation, and functional transform types.

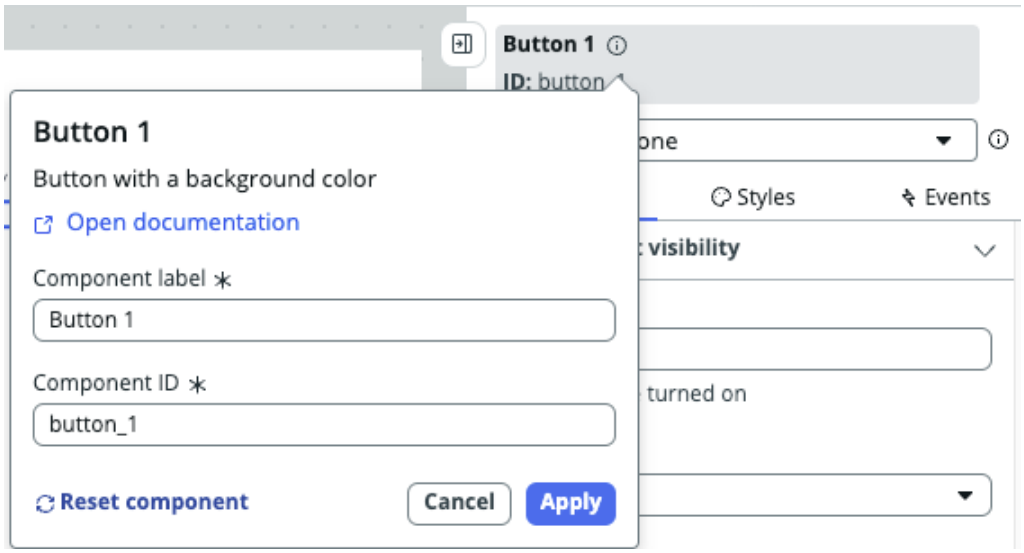


Each function added to the component formula editor auto-completes. The component formula editor displays a label for each input of the function so you know what parameters each function requires. For more information about the supported functions in the component formula editor, see Supported functions in the UI Builder component formula editor.

Component ID

Use the component ID when you add a script or bind data to the component as a way to reference the component. A component ID is automatically created and is based on the

component label when you add a component to a page. You can change the component ID to anything you want, as long as it is unique. Select the name of the component in the configuration panel to see the component ID.

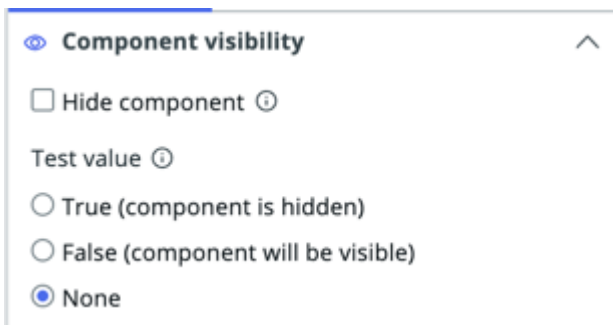


Component visibility

Select the eye icon in the configuration panel to set component visibility. Component visibility is based on a property of the component itself, not who is viewing it. You could show or hide a component based on conditions. For example, hiding an image if it has a broken link.

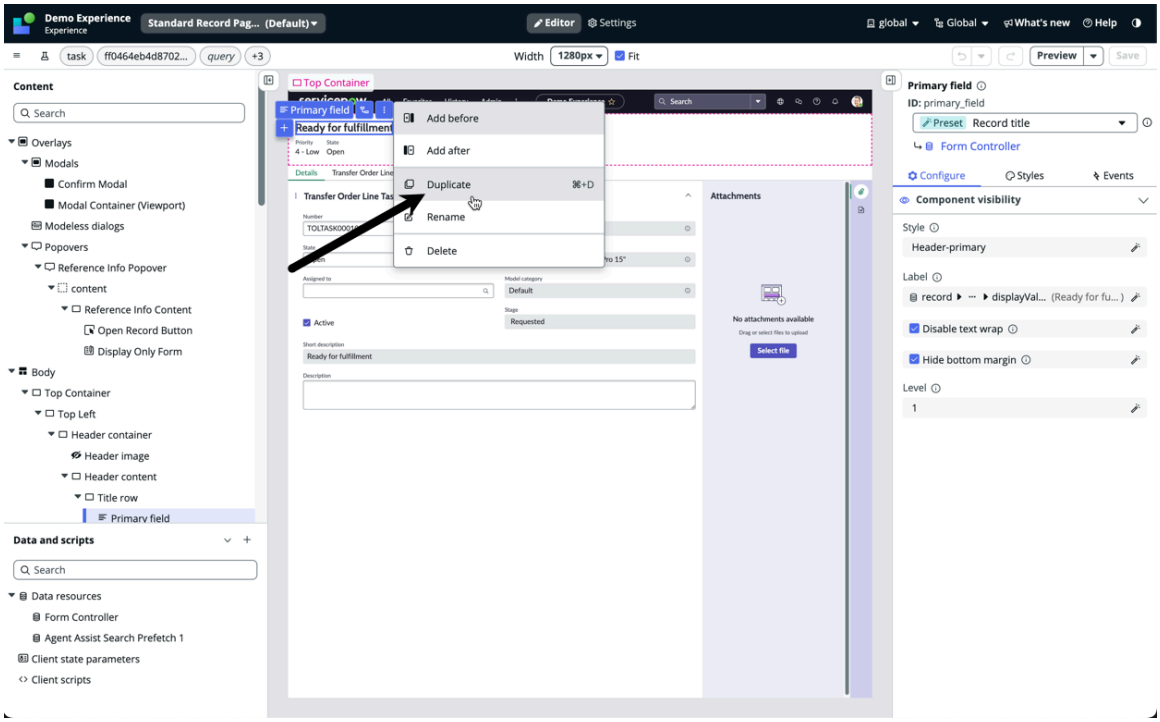
You can set the visibility based on dynamic data binding, or by editing a scripted property value.

Set the **Test value** to test what happens when the visibility is set to true, false, or none.



Duplicate components

Create an exact copy of a configured component on your UI Builder page except for the name and ID. A duplicated component copies all properties, bindings, and events. For more information, see Duplicate a component.



Automatically configure components using presets

Use component presets to automatically configure components on compatible pages.

Use component presets to apply predefined configuration values and event mappings to components. UI Builder page templates contain controllers that presets use to define component configuration values.

Presets apply pre-built configurations to component properties and event handlers and are only available for certain components. They are based on common use cases for components, such as configuring a **Form** component with fields that are typically included on a record page.

Applying a preset automatically configures components to work immediately, simplifying page creation and maintenance for page authors.

Presets offer the following benefits to page authors:

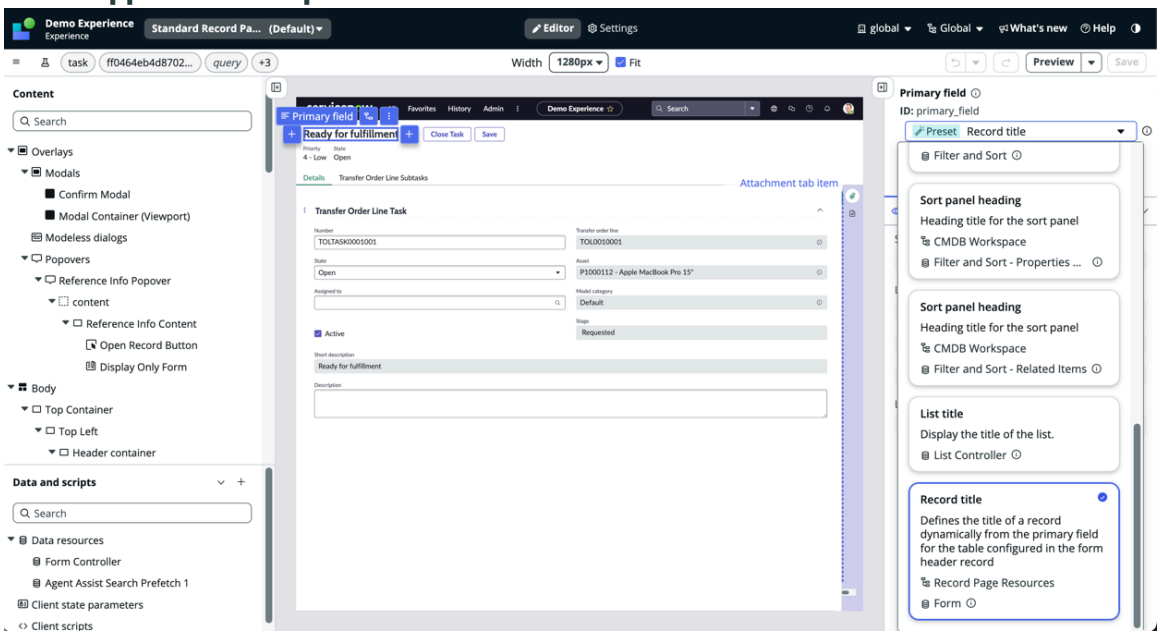
- Handling of complex data and event binding for components
- Reduced cost of ownership and maintenance due to being defined external to pages

From the Configuration pane, you can select whether to apply a preset to the selected component or instead manually configure it. Default presets are automatically applied for components when a page is created from a template or the controller required for the preset is already added to the page. Any properties or events configured by the preset display as read-only when a preset is applied.

You can override values configured by a preset but in doing so you assume ownership of the component configuration and maintenance.

Sub-pages do not inherit controllers and are not able to use presets in Xanadu.

Preset applied to a component



Data and event bindings

Presets can include bindings to:

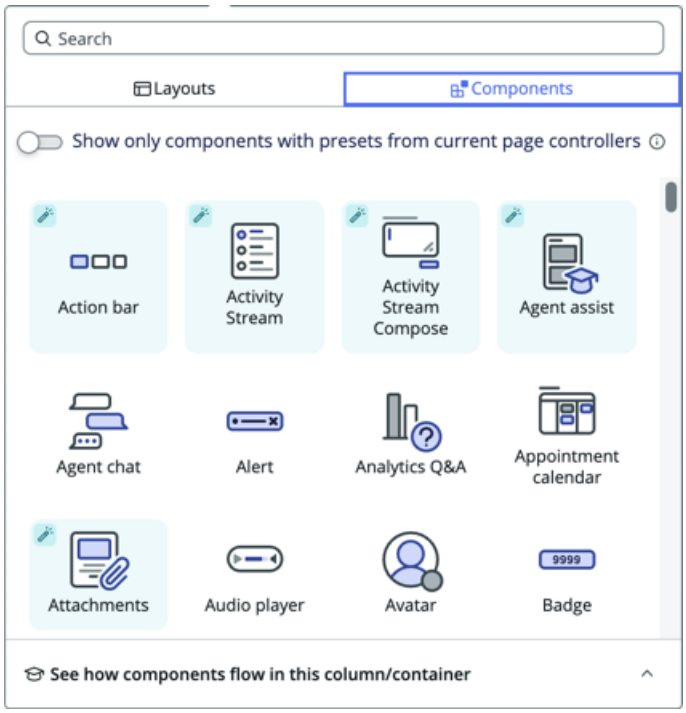
- Controller output properties (@data)
- Event payloads (@payload)
- Session context (@context.session)
- Complex formulas (client transforms)

Presets can also include event mappings to a controller's handled events. For more information, see Manage actions in UI Builder pages.

Controllers

Presets connect components to data and event mappings using a controller. If the controller required by a preset is not already on the page, the preset prompts you to configure the controller's required properties and adds the controller. After a controller is added to a page, components that have presets associated with the controller appear highlighted in the components list. For more information, see Bind data to UI Builder pages using controllers (advanced feature).

Components with presets



Select a component preset

Choose a component preset when adding a component to your page.

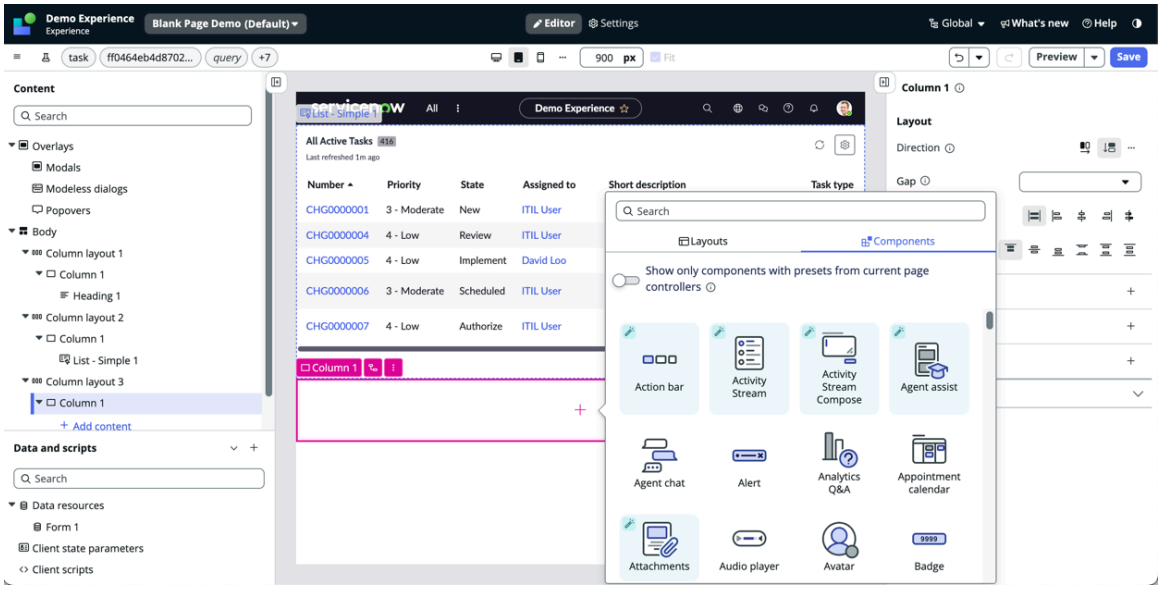
Before you begin

Role required: admin

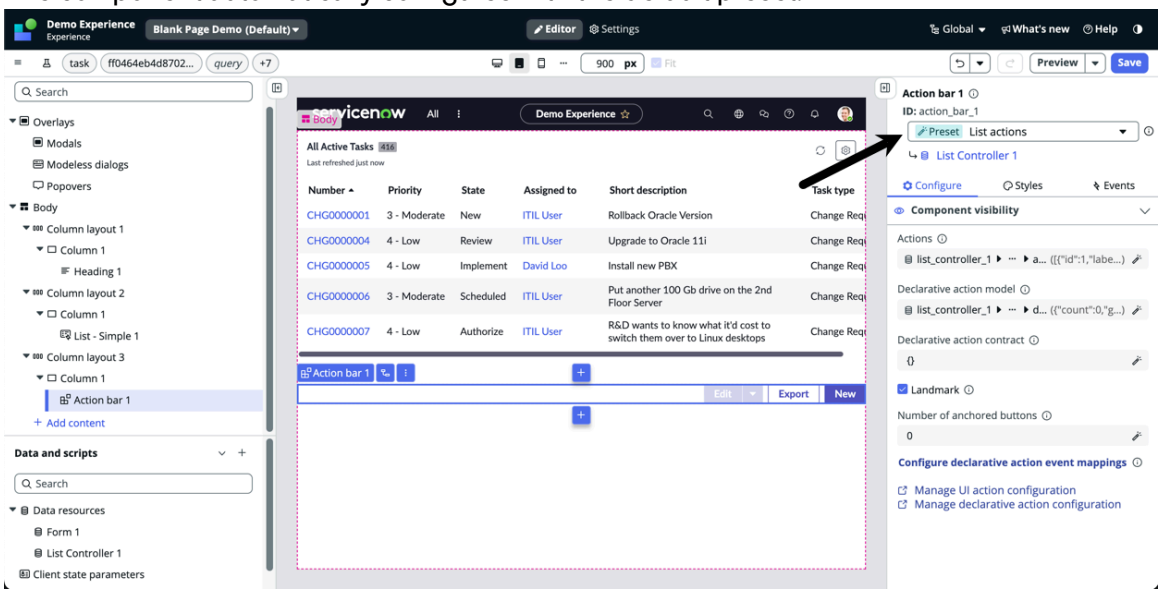
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page or page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Open the toolbox.
5. Add a component highlighted in green to your page.

   Components highlighted in green have presets available.

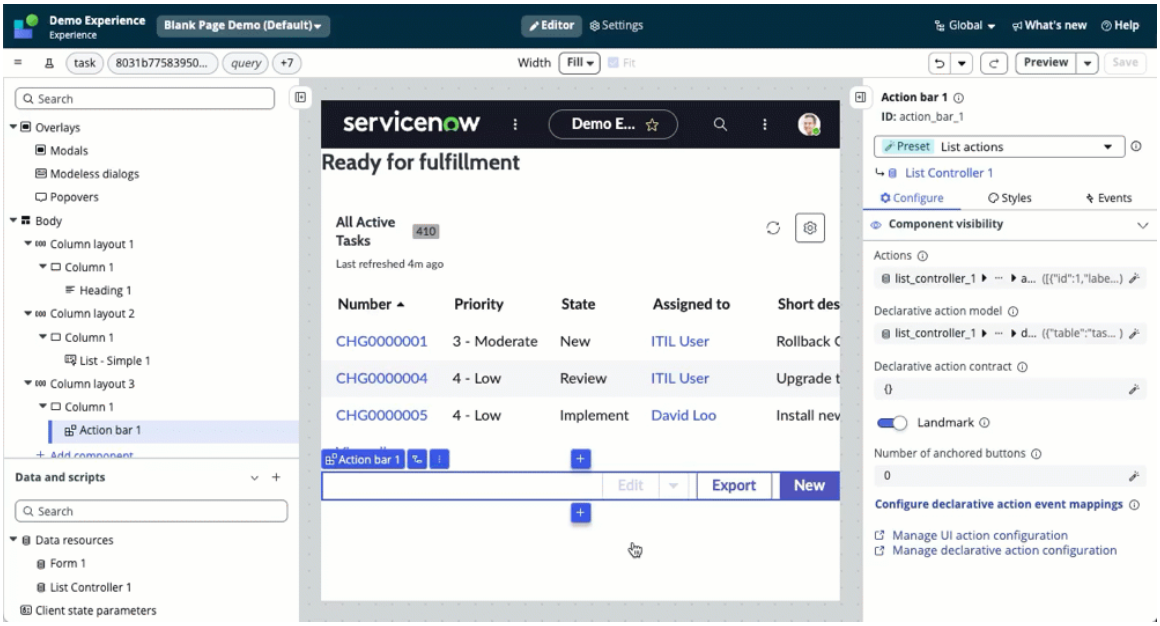


6. The component automatically configures with the default preset.



7. **Optional:** Select a different preset from the list in the configuration panel. You can configure a component not to use a preset by selecting **Remove**.

   a. Select **Continue** to replace the existing preset.



8. Click **Save**.

Override a component preset

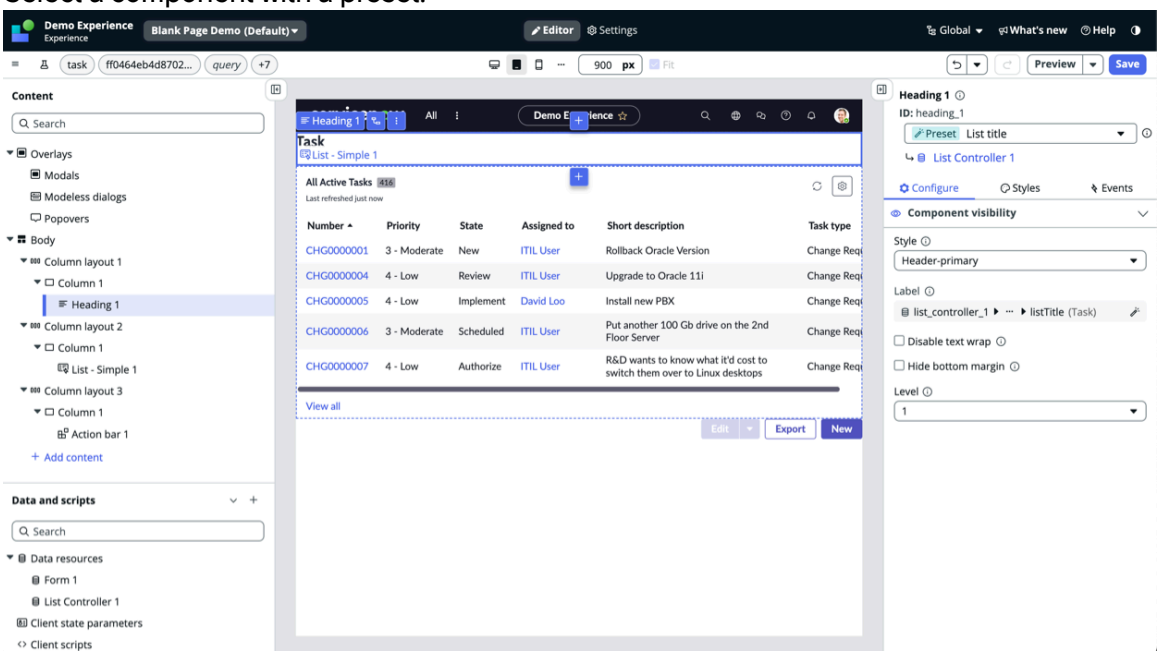
Override a component preset to enter your own custom values.

Before you begin

Role required: admin

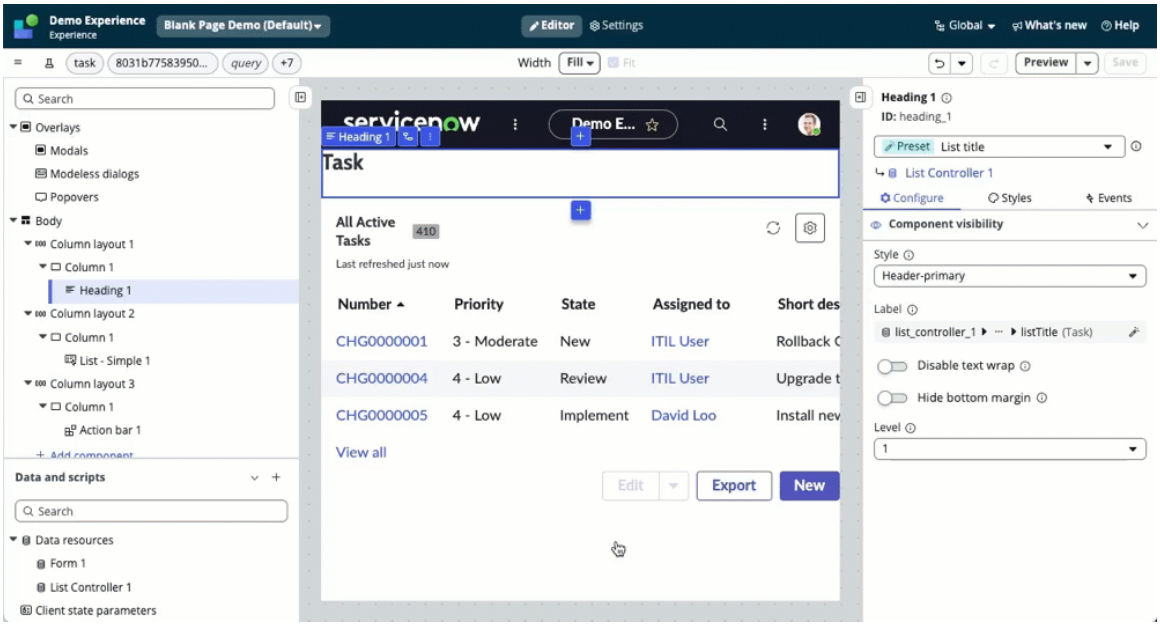
Procedure

1. Select a component with a preset.



2. Find the data value that you want to override in the configuration panel.
3. Click the lock icon in the data field.
4. Enter the data value that you want to override the preset value.

5. Select **Save**.



Result

The configuration panel displays the custom value in the field.

Reset a component

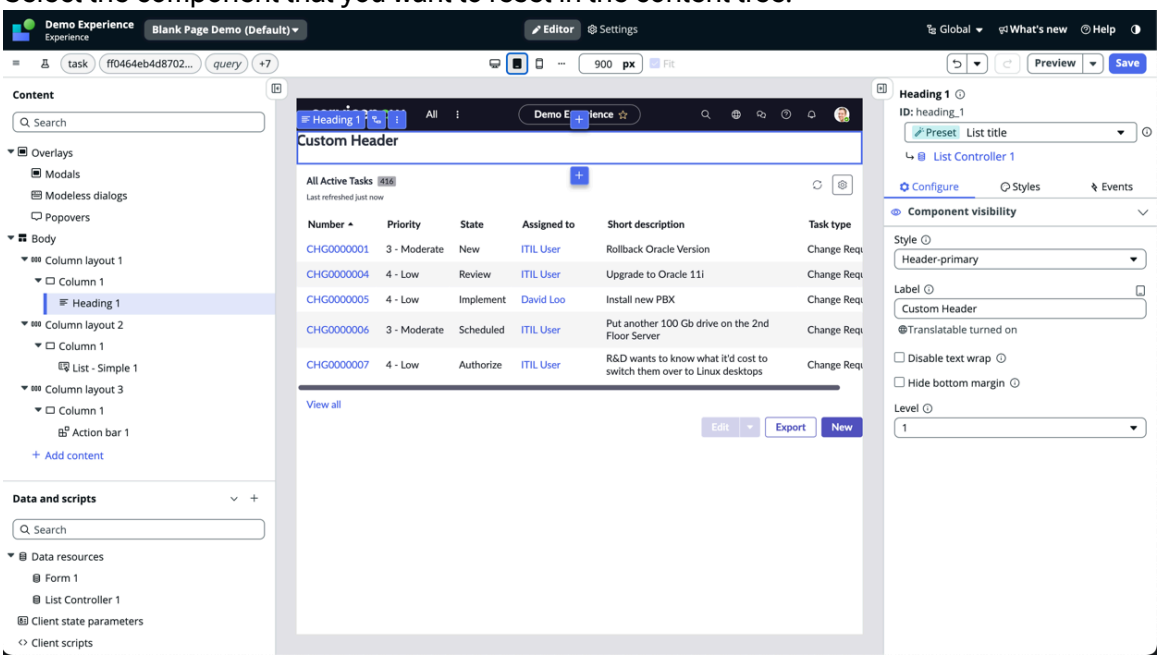
Reset component presets to their default values.

Before you begin

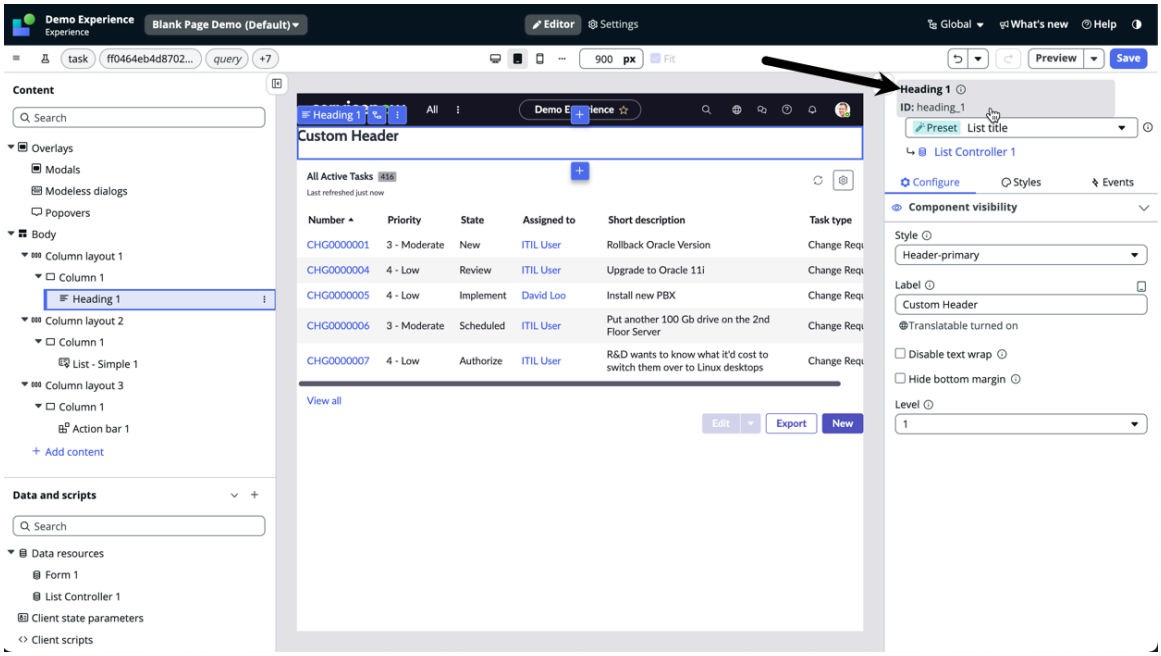
Role required: admin

Procedure

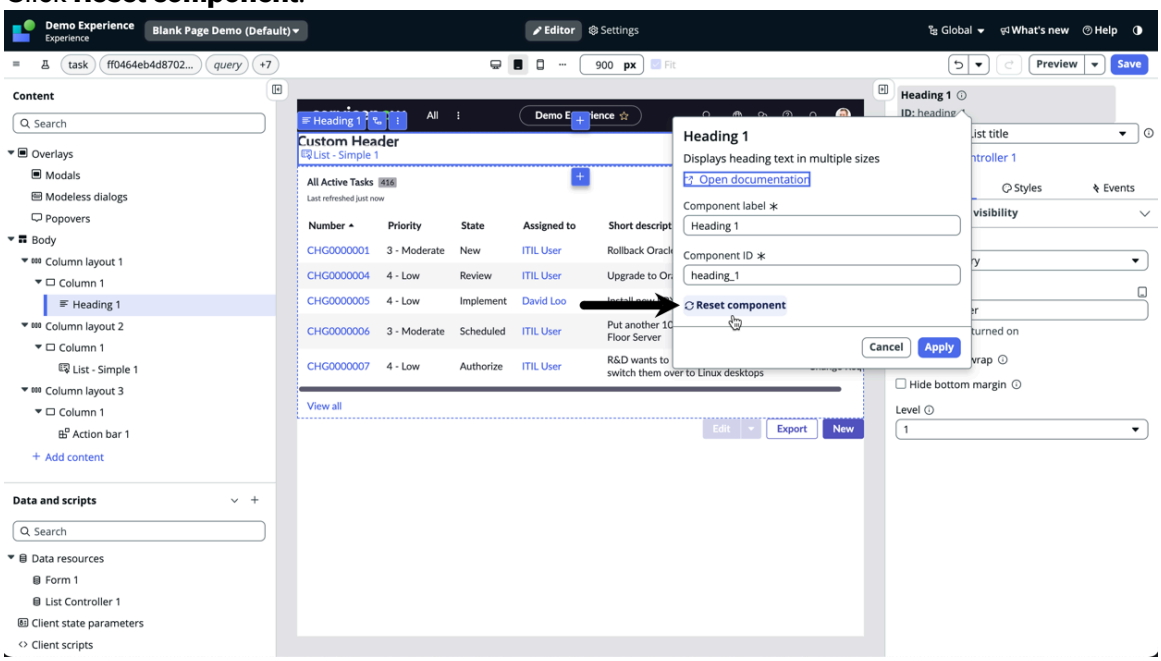
1. Select the component that you want to reset in the content tree.



2. Select the component name in the configuration panel.



3. Click **Reset component**.



4. Click **Reset**.

Result

The component preset resets to the default values.

Change the default appearance of components

Set the styles for components and wrappers to change the default appearance.

This video shows you how to perform the following procedure. This video shows you how to change the default appearance of components on a UI Builder page.

Before you begin

Role required: ui_builder_admin

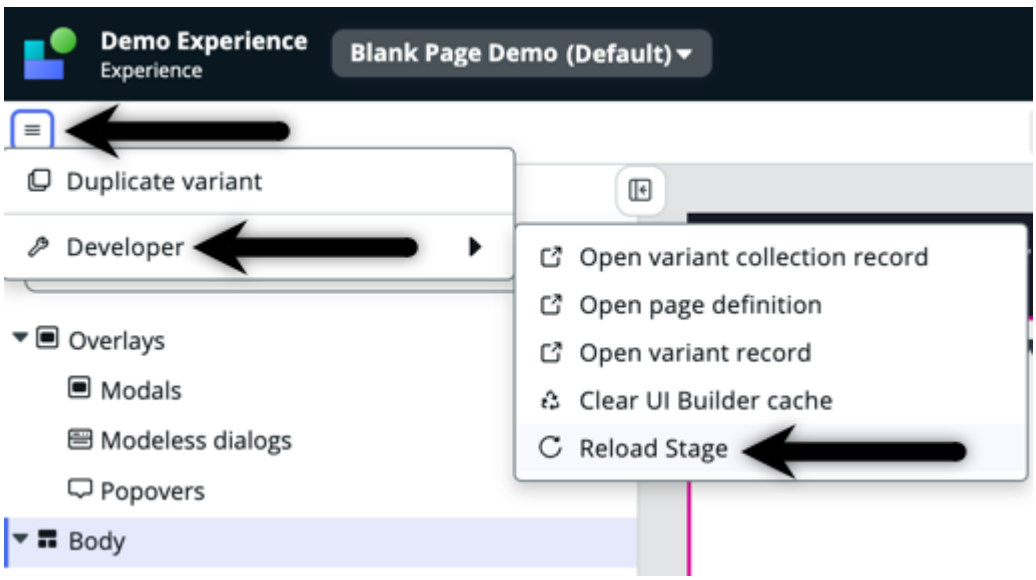
About this task

This task describes how to add styles to components and the wrappers (such as Body, column layouts, or a column) containing components. Customize component styling by selecting the component in the Content tree or apply styles to multiple components by placing components inside a wrapper.

For information about adding styling to your entire experience, see Manage the visual style of UI Builder experiences.

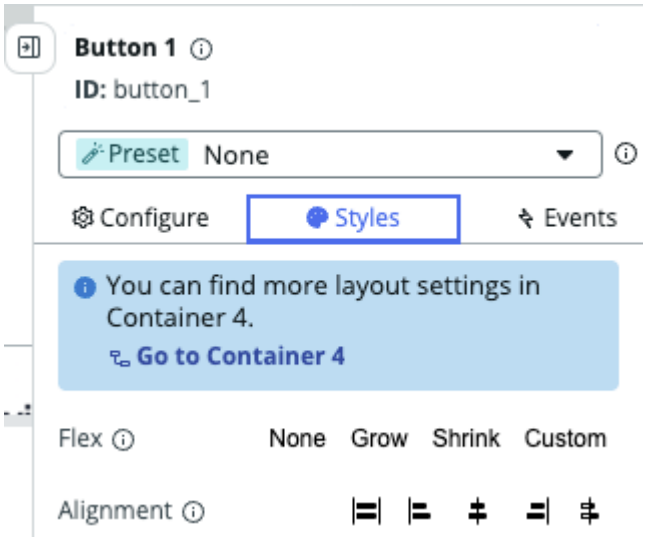
This task applies to the new layout system introduced in Xanadu. If your page is using the old layout system, see Add styling to a component using the old layout system for more information.

Note:
As you add and configure components on the page, the stage shows your work. If you make changes and the updates do not load on the stage, select the **Open menu** icon and then select **Developer > Reload Stage**. Reloading the stage shows your changes, but does not save them. To save your work, select **Save** at the top right.



Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page or page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. In the Content panel, select a component or wrapper (for example, Body, a column layout, or a column) for which you want to add styling.
5. For Body or a component, select the **Styles** tab in the configuration panel.



6. Use the visual representations on the **Styles** tab to decide what is best for the look and feel of your page.

Accessibility (Column layout and Column)

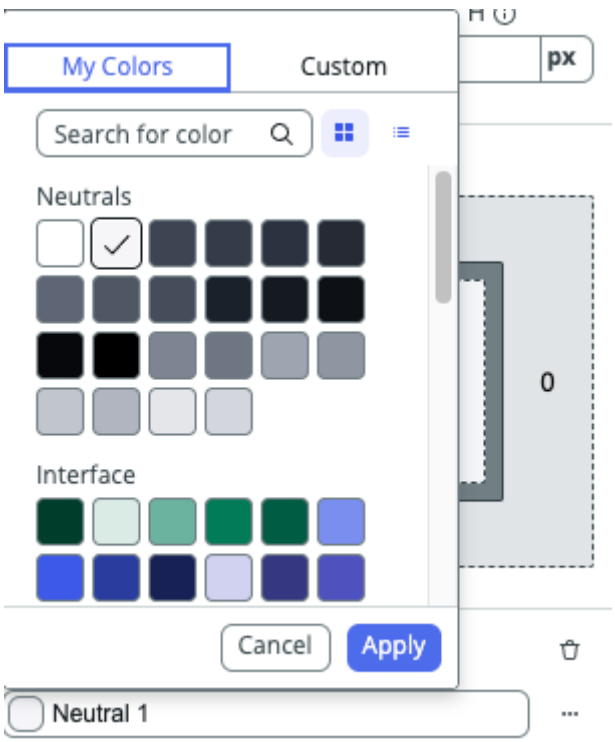
Specifies accessibility settings such as ARIA Region Name, ARIA Region Heading Level, ARIA Role, and inclusion of ARIA Heading. For detailed information, see the ARIA documentation on developer.servicenow.com.

Alignment (Column and Component)

For a column, defines how components align within the column as a group. For a component, defines how the component aligns within the parent layout element, such as a column or column layout.

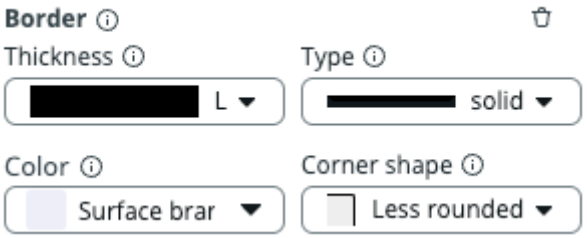
Background (Body, Column layout, Column, and Component)

Sets the background color behind the layout element. Select a color from the color picker **My Colors** tab where you can view available colors in a grid or a list. Alternatively, use the **Custom** tab to specify any color in HEX, RGB, or HSL.



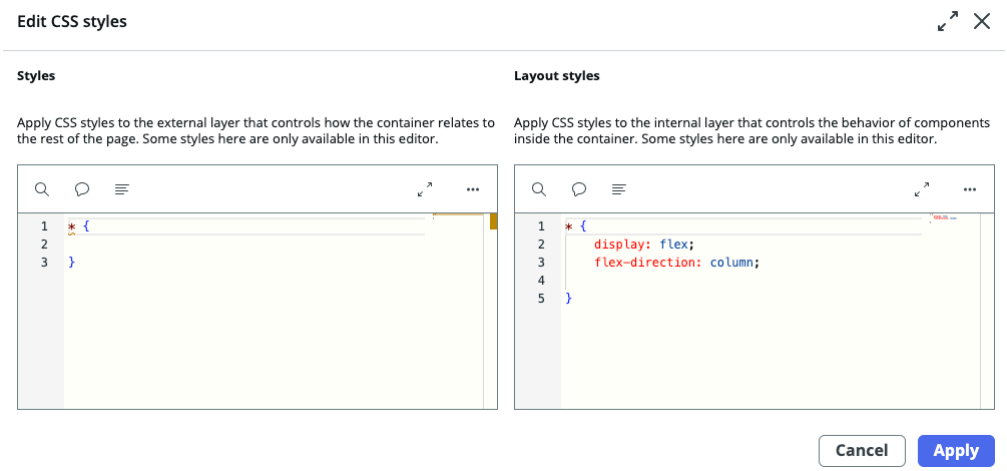
Border (Column layout, Column, and Component)

Adds a border around the content. The border is placed on the immediate inside of the margin and the immediate outside of the padding. Specify the border thickness, type, color, and corner shape. For components, you have the option to use custom CSS for the border.



Layout (Body, Column layout, Column, and Component)

For body and column, specifies direction, alignment, and content justification. For column layout, specifies the number of columns and the column gap (space between columns). For some components, such as Card Base Container, select **Edit CSS** to apply specific CSS styles to the container layer and to the internal layer controlling components within the container.



Shadow (Column layout, Column, and Component)

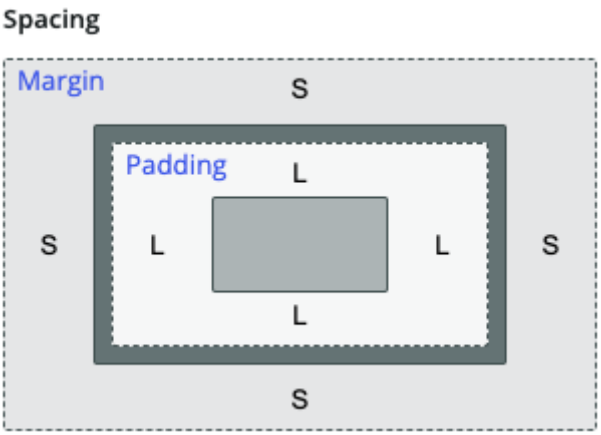
Adds shadow effects around the content. You have the option to use custom CSS.

Sizing (Component)

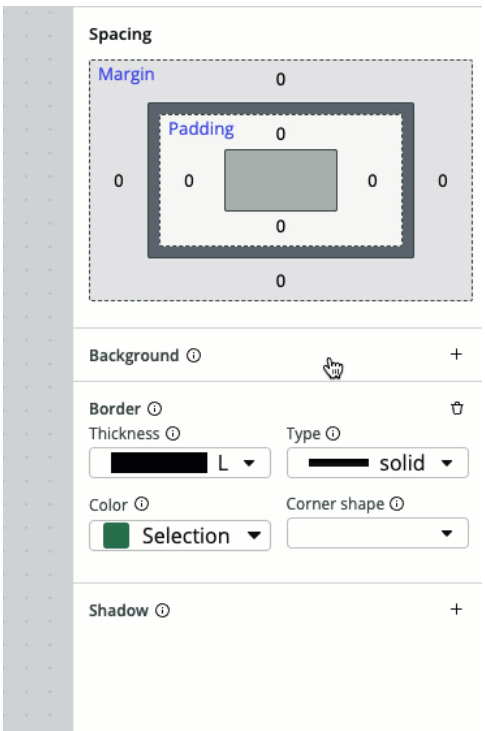
For applicable components, sets the default, minimum, and maximum height and width for the component (in px, %, em, rem, or a custom value). This value is relevant for when the browser window is resized.

Spacing (Body, Column layout, and Component)

Margin sets the size of the space on the immediate inside of the body, column layout, or component. Padding sets the size of the space on the immediate outside of the body, column layout, or component. Select Margin or Padding to set the same size for all four sides.

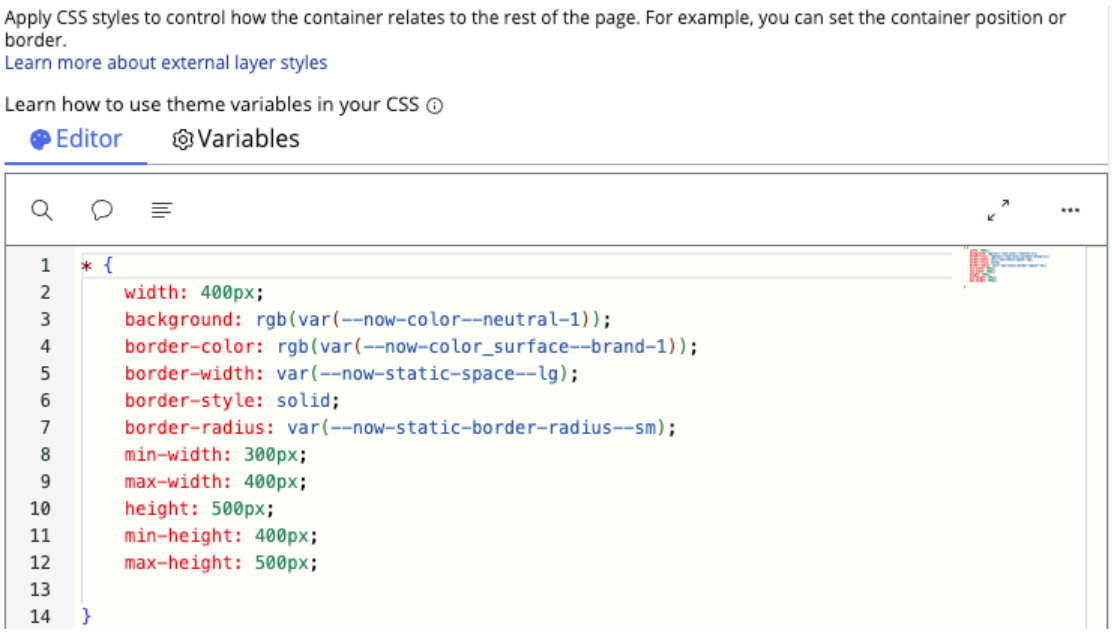


You can set the size for each margin or padding side by selecting the current setting and then selecting an option.



7. **Optional:** For Body and components, you can edit the CSS code by selecting the **View and edit CSS** link at the bottom of the **Styles** tab.
   The **Styles tab** displays a **CSS styles** code editor. The following CSS properties are the most commonly used:
   - `background-color`
   - `background-image`
   - `border-style`
   - `border-width`
   - `border-color`

- `border-radius`
- `box-shadow`
- `height`
- `min-height`
- `max-height`
- `margin`
- `overflow`
- `padding`
- `width`
- `min-width`
- `max-width`
- `z-index`



Important:
Some components contain built-in styling configurations that you can't override with CSS in UI Builder. For information about overriding these style configurations, see Manage the visual style of UI Builder experiences.

8. In the main header, select **Save** to save your changes.

Add styling to a component using the old layout system

Set CSS styles for a component to change its default appearance.

Before you begin

Role required: ui_builder_admin

About this task

This task describes how to add styles to the wrapper containing your component, which is generally recommended instead of applying styles to the component directly. Make sure that the component whose styles that you want to define is placed within a container component to put

the component in a wrapper. Your component's wrapper is one level higher than the component in the Content hierarchy and is labeled by default as `Main`.

To add styling to an entire page, you can use standards-based CSS in the wrapper for the page. For information about adding styling to your entire experience, see Manage the visual style of UI Builder experiences.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page or page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.

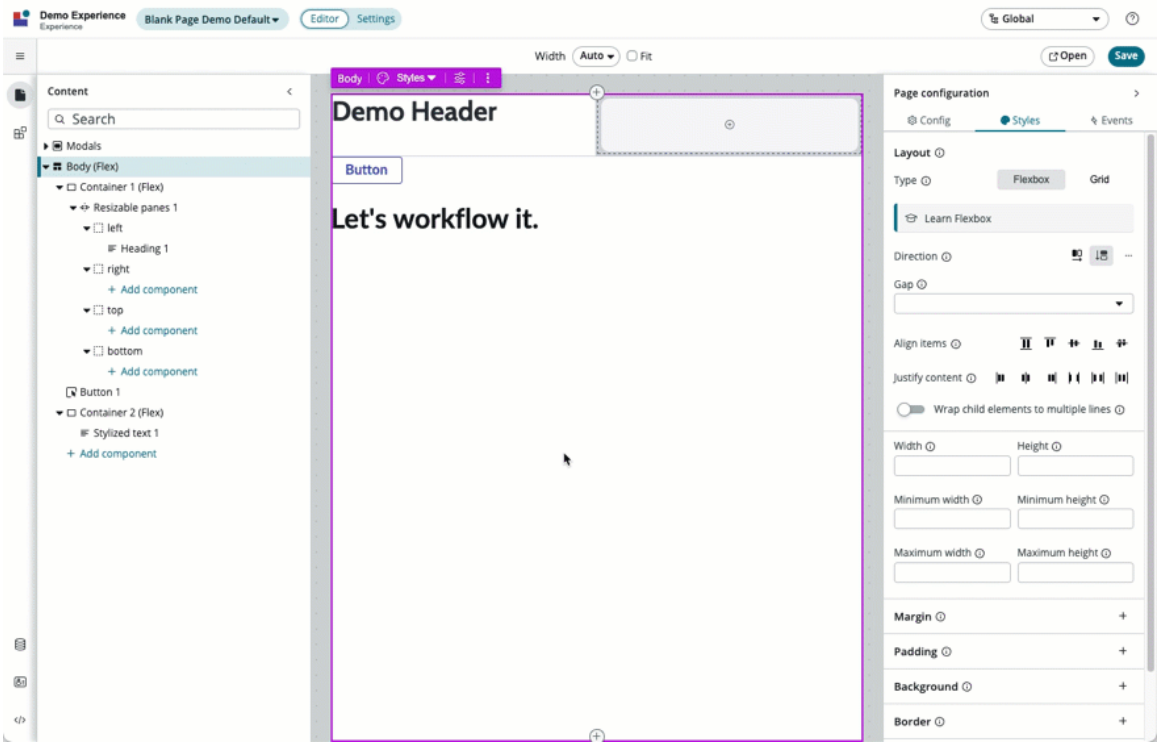
   Note:
   A component must be placed in a container before adding styles to the component.

4. Select the container holding the component you want to add styling to.
   The container is typically one level higher than the component in the content tree.
   The Styles tab appears in the configuration panel.
5. In the CSS Styles window, enter standards-based CSS properties and values.
   The following CSS properties are the most commonly used to apply styles for components within containers:
   - `background-color`
   - `background-image`
   - `border-style`
   - `border-width`
   - `border-color`
   - `border-radius`
   - `box-shadow`
   - `height`
   - `min-height`
   - `max-height`
   - `margin`
   - `overflow`
   - `padding`
   - `width`
   - `min-width`
   - `max-width`
   - `z-index`

Important:
Some components contain built-in styling configurations that you cannot override with CSS in UI Builder. For information about overriding these style configurations, see Manage the visual style of UI Builder experiences.

6. In the main header, select **Save** to save your changes.

Add styling to a component in the Styles configuration panel



Duplicate a component

Duplicate a configured component to reuse on a page.

Before you begin

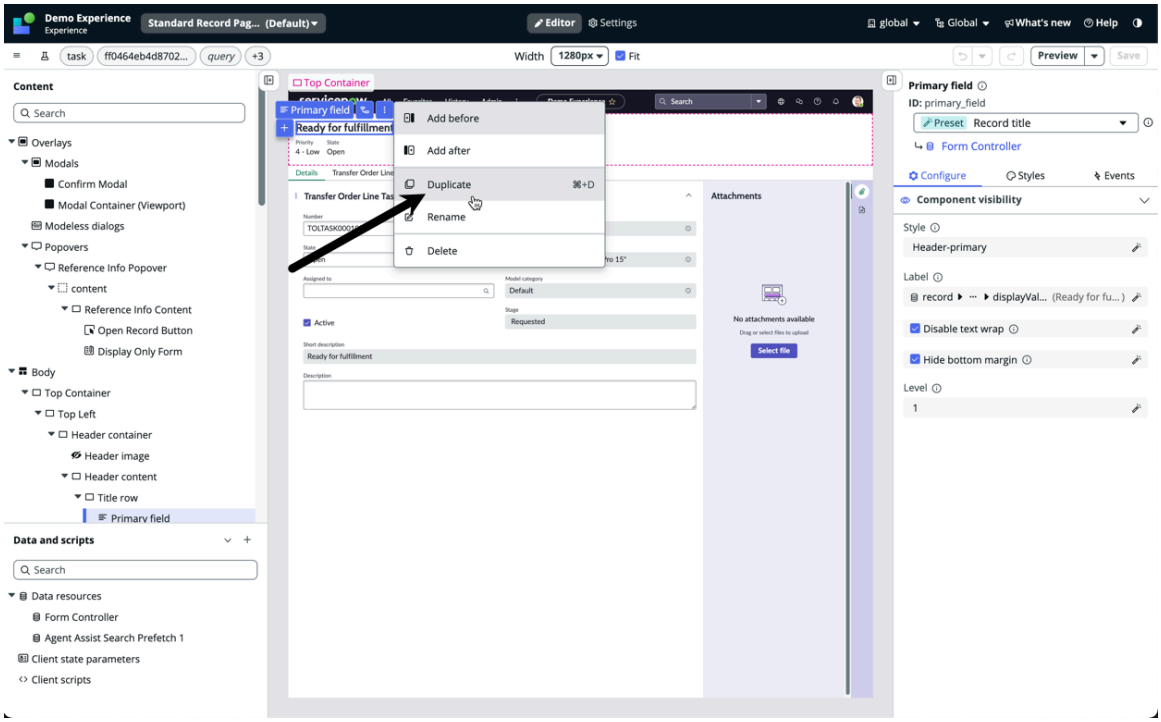
Role required: ui_builder_admin or admin

About this task

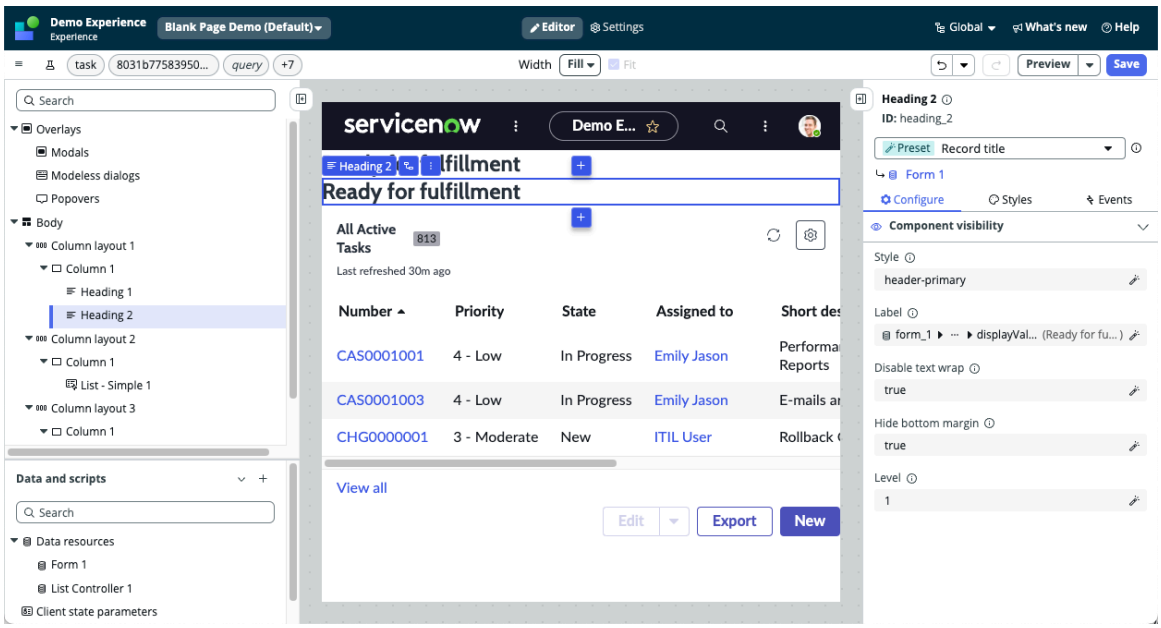
Create an exact copy of a configured component on your page except for the name and ID. A duplicated component copies all properties, bindings, and events. The duplicated component appears directly after the component that is copied. If a tabs component is duplicated, all tabs and their children are copied as well as their names and IDs are made unique.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Open the page variant with the component you want to duplicate.
4. Select the component that you want to duplicate.
5. Right-click the component.
6. Select **Duplicate**.
   You can also use the keyboard shortcut **cmd + D** (Mac) or **ctrl + D** (Windows).



The duplicated component appears below the copied component in the content tree.



7. Select **Save**.

Page collections

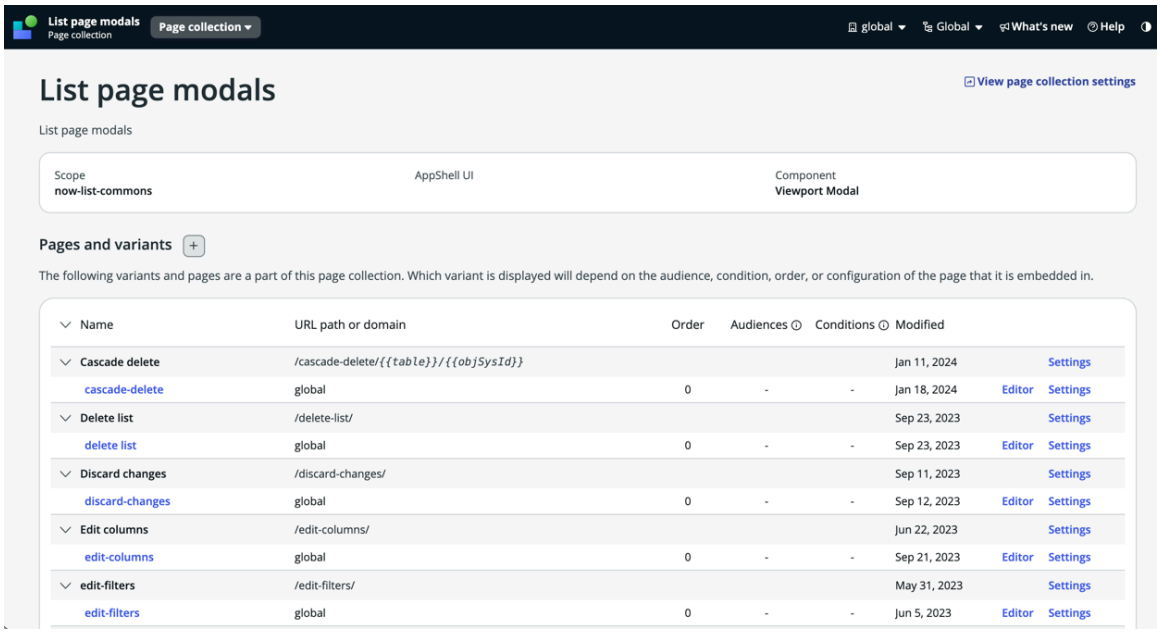
Page Collections are groups of pages that can be used across multiple experiences.

What is a page collection

Page Collections (sys_ux_extension_point) are groups of pages that are meant to be re-used across multiple experiences. These sets of pages can be used in a modal viewport or in a tabs component. These pages are sandboxed and do not have access to things like URL params or data resources from the page that is calling them. All they have access to is the Controller record

that is specified on the Page Collection record and that is passed down by the calling page in runtime.

Page collections are sandboxed inside of the pages they are within, this means that they do not have direct access to change the parent page. However, because of the way seismic works, your page collection page can dispatch an event that the calling page can listen for to take action. This is the only way to achieve a change in the calling page.



Why should you use page collections

Page collections allow you to reuse custom pages across experiences. This will save you time if you need to replicate a page for multiple experiences and help pass information to different groups of users.

You can also use page collections to provide additional information within an existing topic by using a viewport modal. A viewport modal will allow your audience to view pages outside of their experience to make changes without leaving the parent page.

Create collection of tabs that can be shared across experiences. Each tab is an individual page in a page collection.

Where can you use page collections

You can access a page collection from the UI Builder home screen. The list of page collections details which component and type each page collection is.

You can create a page collection from the UI Builder home screen, or from a component that uses page collections.

Page collections can be used with the following components:

- Viewports
- Viewport Modals
- Tabs

Things to consider

The page collection creation screen requires a component and controller selection.

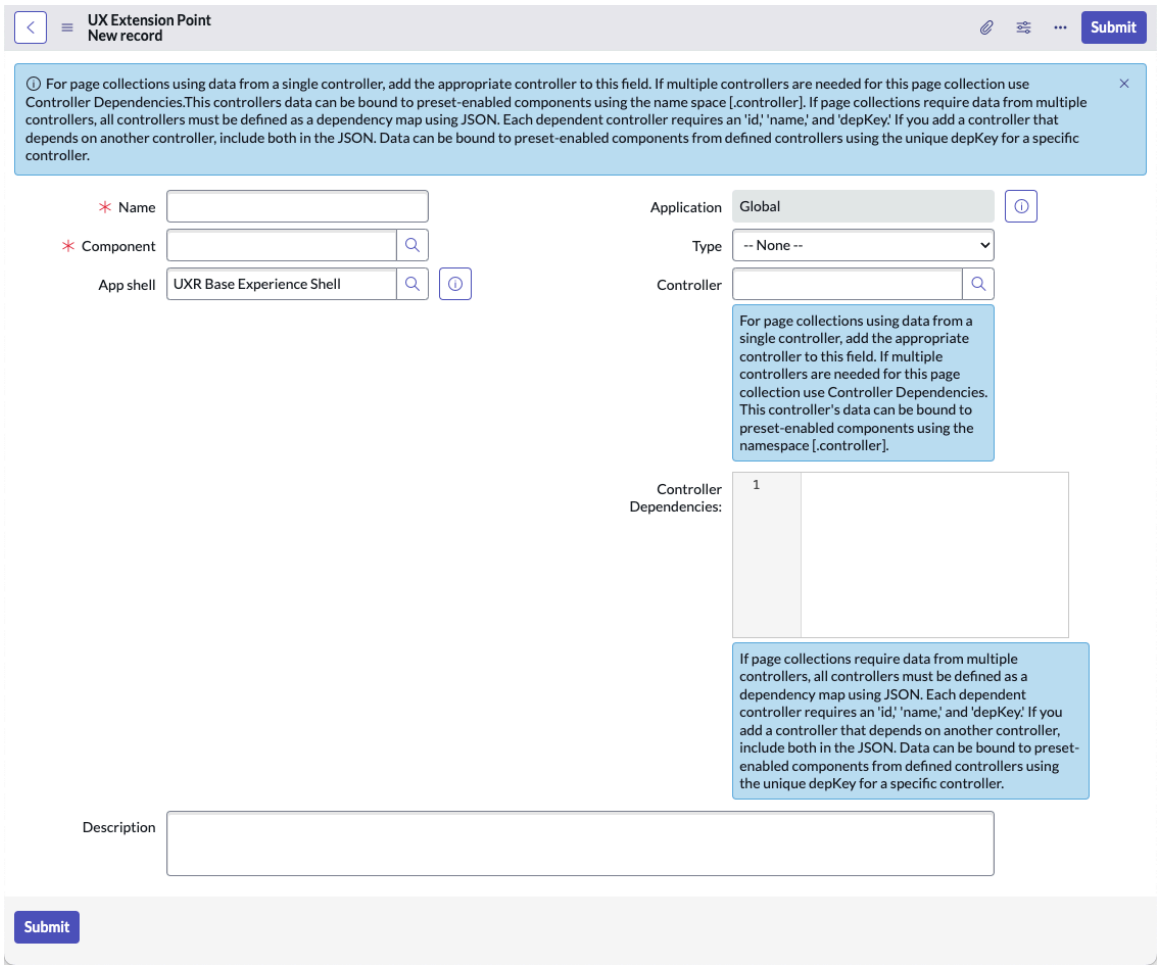
Data resources need to be selected to pass information to a page collection. Need to bind data from the parent page.

Need to route to the page in a page collection you want to display in a viewport.

Add a link to creating a page collection.

Page collection on the platform

You create a page collection within the ServiceNow platform. At this time, only the Tab and Viewport component can be used when creating a page collection. You can select a controller or pass controller dependencies using JSON.



Create a page collection across multiple UI pages

Create a page collection to accommodate tabbed content that can be used across experiences.

Before you begin

Role required: admin

About this task

Use page collections to create tabbed content in your experiences with the Tabs component in UI Builder.

Pages within a page collection don’t have access to the parent page's URL parameters or data resources. You can set conditions for pages in a page collection to define which page to display to certain audiences. Page templates are not supported inside a page collection.

Procedure

1. Click **Create** > **Page collection**.
2. On the form, fill in the fields.

Create a page collection form

Field	Description
Name	Name to track your page collection internally.
Controller	Controller that defines the data for the page collection.
App shell UI	Type of app shell UI that you want to use with the page collection. The app shell is the wrapper of the page contents, which is similar to the functionality of a web page. The app shell can show things like the logo of your company, user preferences, and the search icon. For more information, see Define UI experiences using app shells.
Description	Short description to help find your page collection. Write a description that helps page builders understand what content is included in the page collection.
Application scope	Application scope defines which application that the page collection is part of. To create a page collection in a different application scope, change the application scope in the platform and then create a page collection in UI Builder.

3. Click **Create**.
4. Click **Edit page collection**.
   A new tab opens to the page collection editing screen.
5. Click **Start editing**.
6. Click **Create a page**
7. Enter a unique name for the page in the **Name** field.
8. Specify a path for your page in the **Path** field. UI Builder generates a default path based on the name that you provided in the previous step.

   Note:
   The application scope defaults to the scope that the user is in. For more information about the application scope, see Learn about security and roles.

9. Click **Create**.
10. **Optional:** Set advanced settings such as required and optional parameters, as well as variant settings.

a. Select **Add required parameters** to add any required parameters to your page URL.

A required parameter is a piece of data that your page requires, such as a sys_id, table, or query. Required parameters are useful for components, because they can bind to the value of the required parameter.

For more information, see Manage UI Builder pages and page variants.

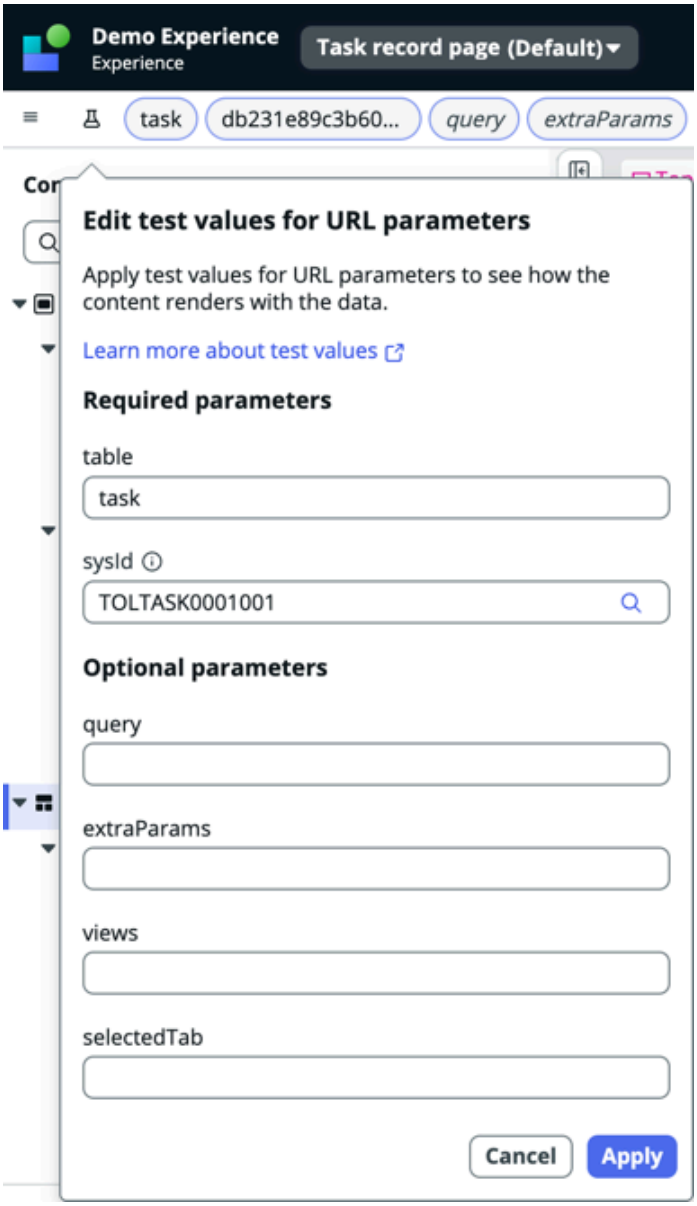
b. Select **Add optional parameters** to add any optional pieces of data that you want to add to the URL of your page.

Unlike required parameters, optional parameters are always name and value pairs that work regardless of the order they're provided in.

For more information, see Manage UI Builder pages and page variants.

c. Click the required or optional parameter in the URL, and in the **Test values** field type a value, such as `incident`.

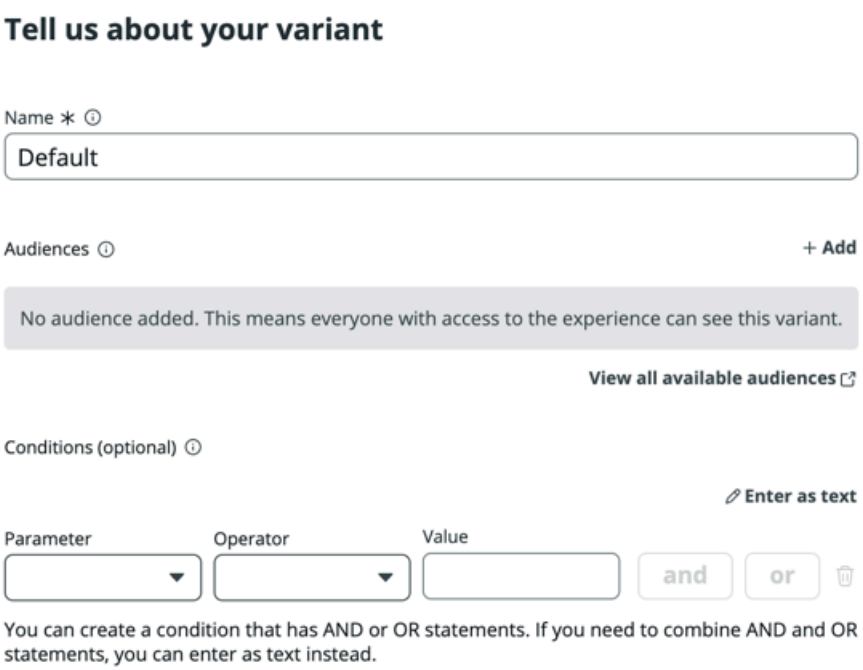
You add a test value to your page to populate data into the page as a way to test it. For example, if you add a table as a required parameter, you could add a test value of incident to bring in test data on the incident for that table.



For more information on test values, see Test values in a page.

d. Select the **Variant** tab to set the audience and conditions settings for your page.

(Optional) When you create a page, UI Builder also creates a variant of the page for you by default. A page variant is a variation of your page at the same path that lets you target experiences for different audiences using user criteria. For example, a page for managers, and a variant of that page for the manager's direct reports. For more information about creating a variant, see Create a page variant.



For more information about audiences, see Learn about audiences.

e. Click **Done**.

11. Click **Done**.

12. Add and configure components on your page.

13. Click **Save**.

14. Optional: Add more pages to your page collection.

a. Click **Menu**.

b. Select **Create page**.

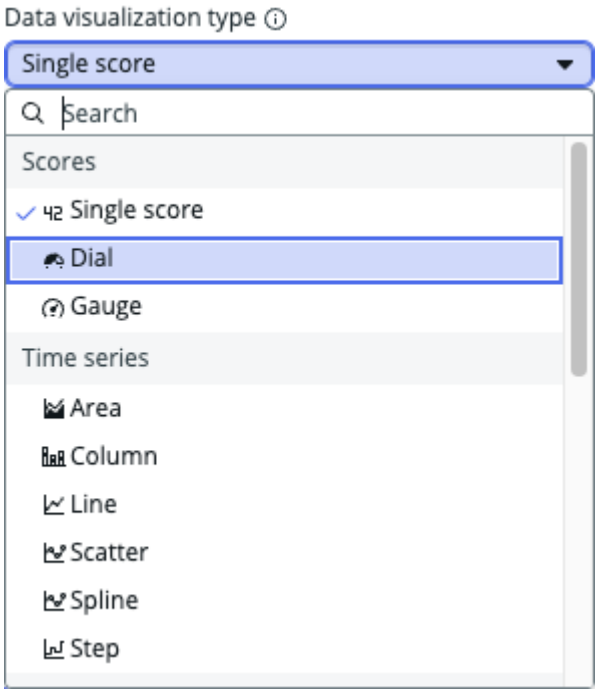
c. Repeat steps 6 through 13.

15. Close the page collection window.

Change data visualizations in UI Builder

Change data visualizations in real time using a drop-down list to preview data in your experience.

You can change data visualization types via a drop-down in the configuration panel to preview different data visualization types. Each data visualization can be configured to display different data depending on who is using your experience. Select the drop-down under **Data visualization type** to preview different types of data visualization.



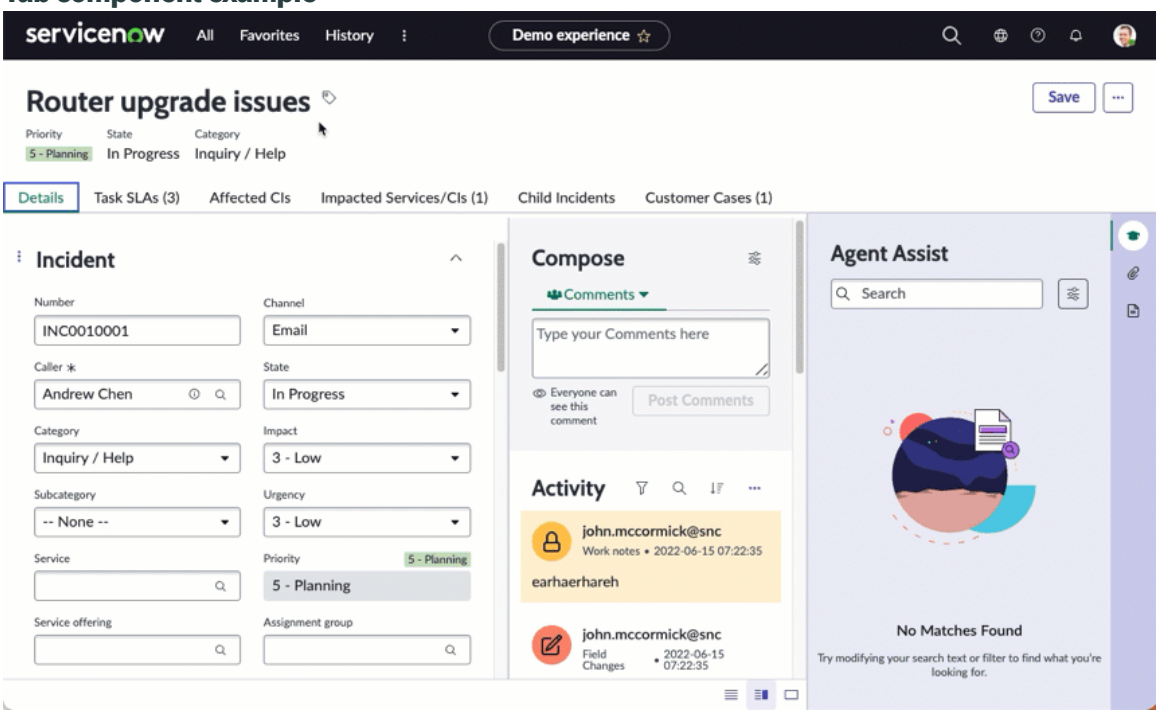
A preview of the data visualization you selected appears in your page. For information about adding data visualization components to your experience, see Add and configure components.

Add tabbed content to UI Builder pages

Use the Tabs component to add tabbed content to pages in UI Builder.

Create additional navigation on your UI Builder page by adding a Tabs component to your page. Use the Tabs component to nest components within tabs on your page. Tabs can be configured as either horizontal tabs at the top of the content, or as vertical tabs on the left or right side of the content.

Tab component example



Tabs can be organized in the configuration panel to reorder how they are displayed on the UI Builder page. Add custom labels and icons to tabs to provide unique visual identifiers for navigating across tabs. These changes can be viewed in real-time as you edit the Tabs component.

You can add one of the following types of tabs to your UI Builder page:

- Empty container tab
- Repeater tab
- Related list tab
- Page collection tabs

The tabs component supports any combination of static tabs, repeated tabs, related list tabs, and page collection tabs. Alternatively, you can still use the Viewport tab mode to add a series of viewports.

Add empty container tabs

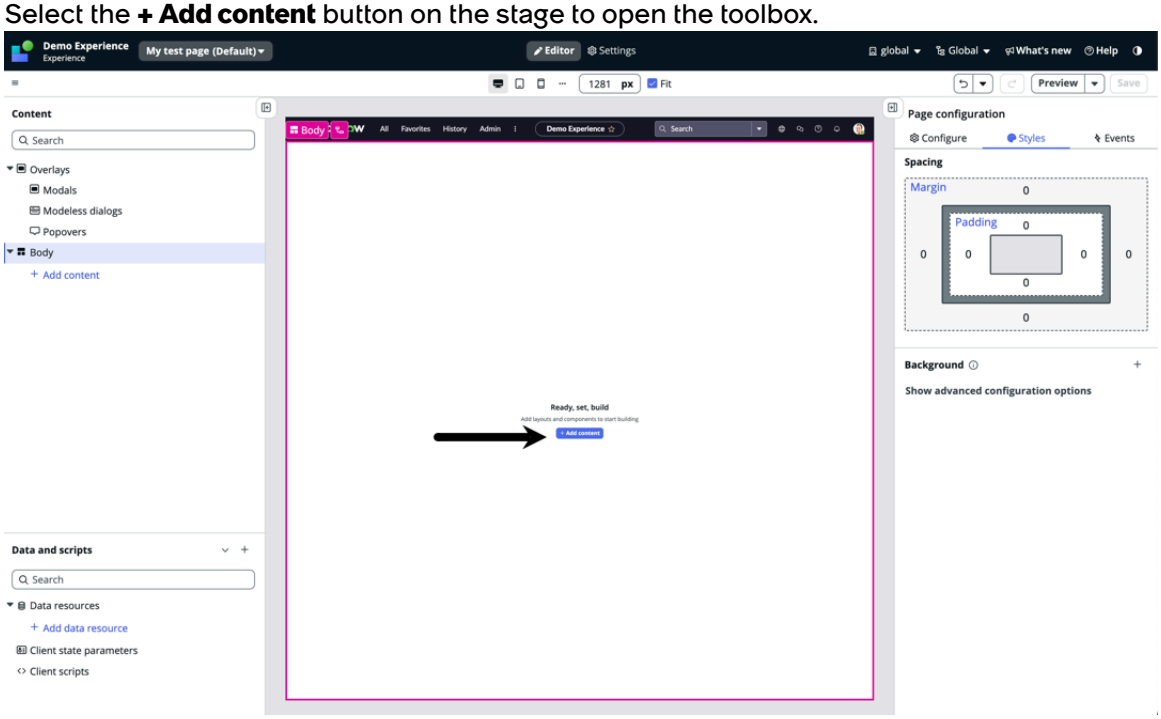
Use an empty container tab to manually create a static set of tabs on your page.

Before you begin

Role required: admin

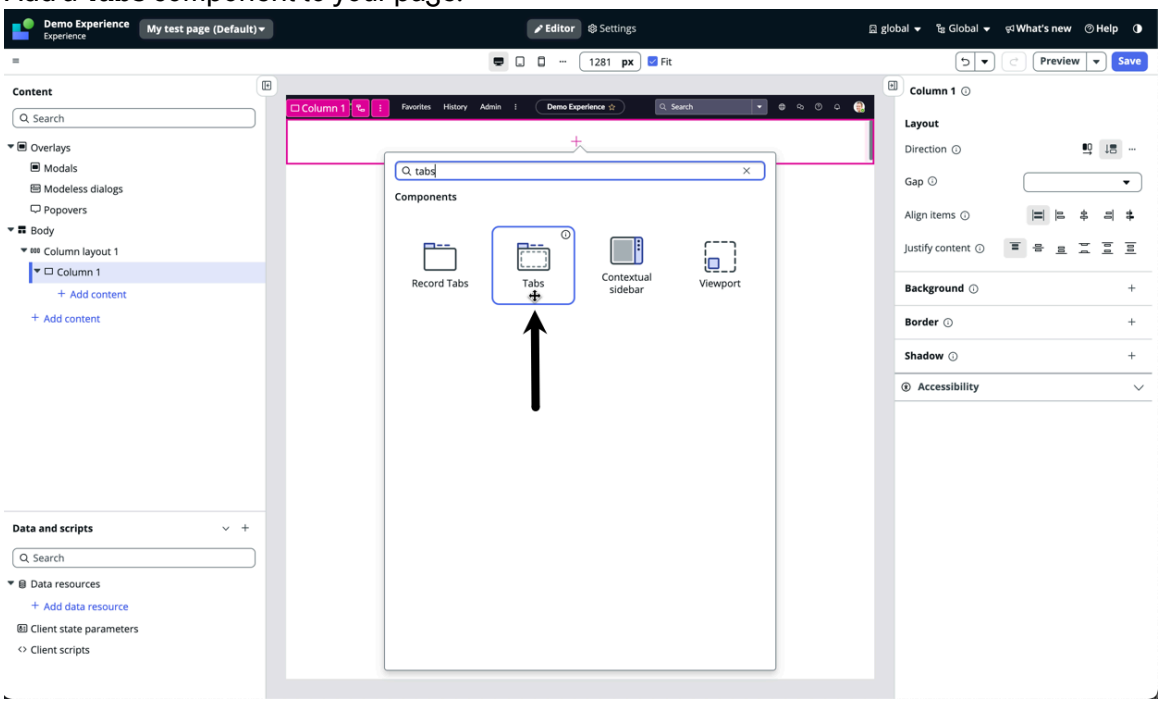
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page or page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Select the **+ Add content** button on the stage to open the toolbox.



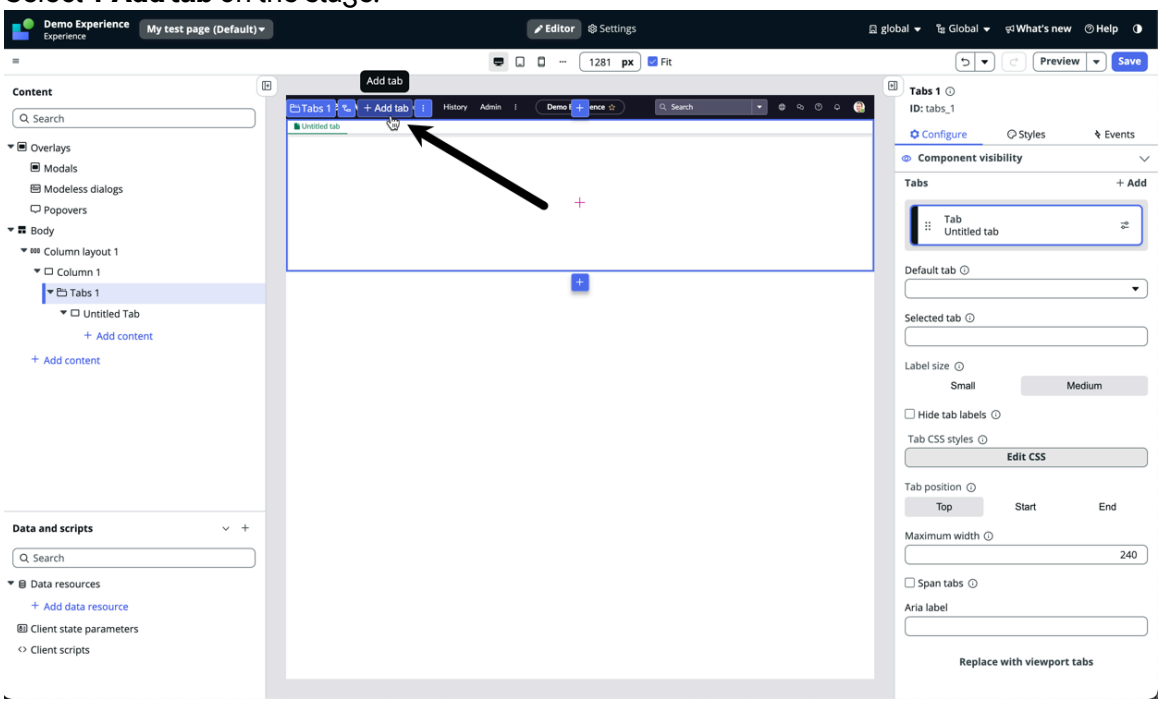
5. Select a **Single column** layout.
6. Next, select the **+** icon in the column to open the toolbox.

7. Add a **Tabs** component to your page.

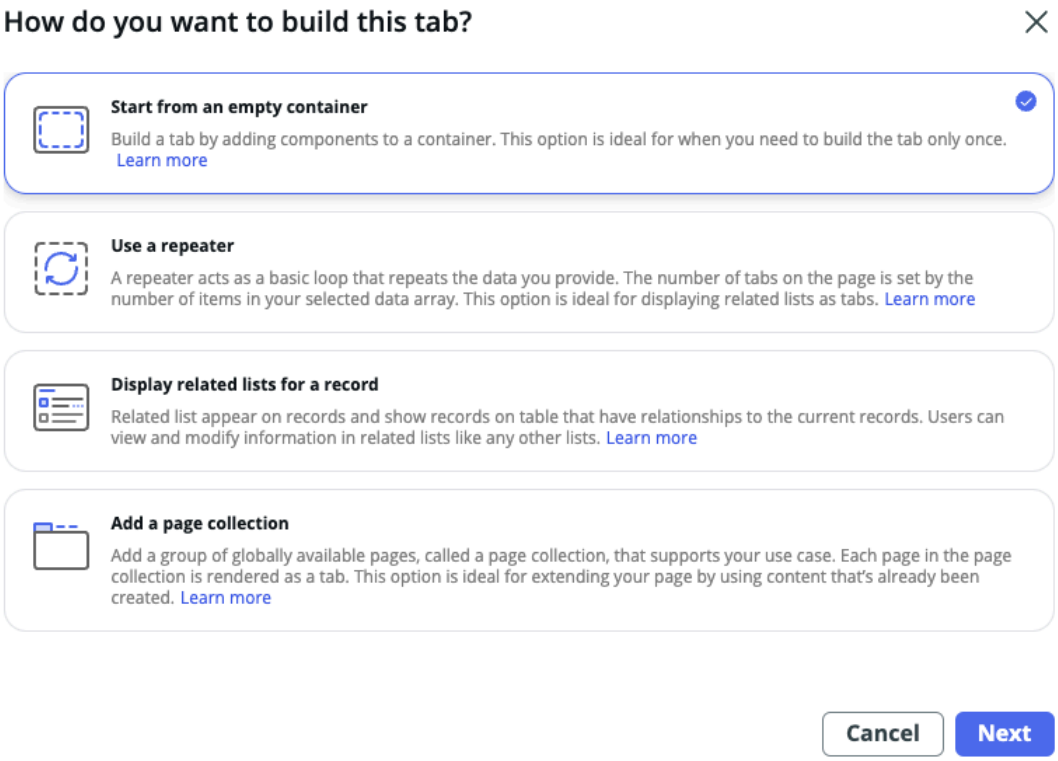


For more information on how to add a component to a page, see Add and configure components.

8. Select **+ Add tab** on the stage.



9. Select **Start from an empty container**.

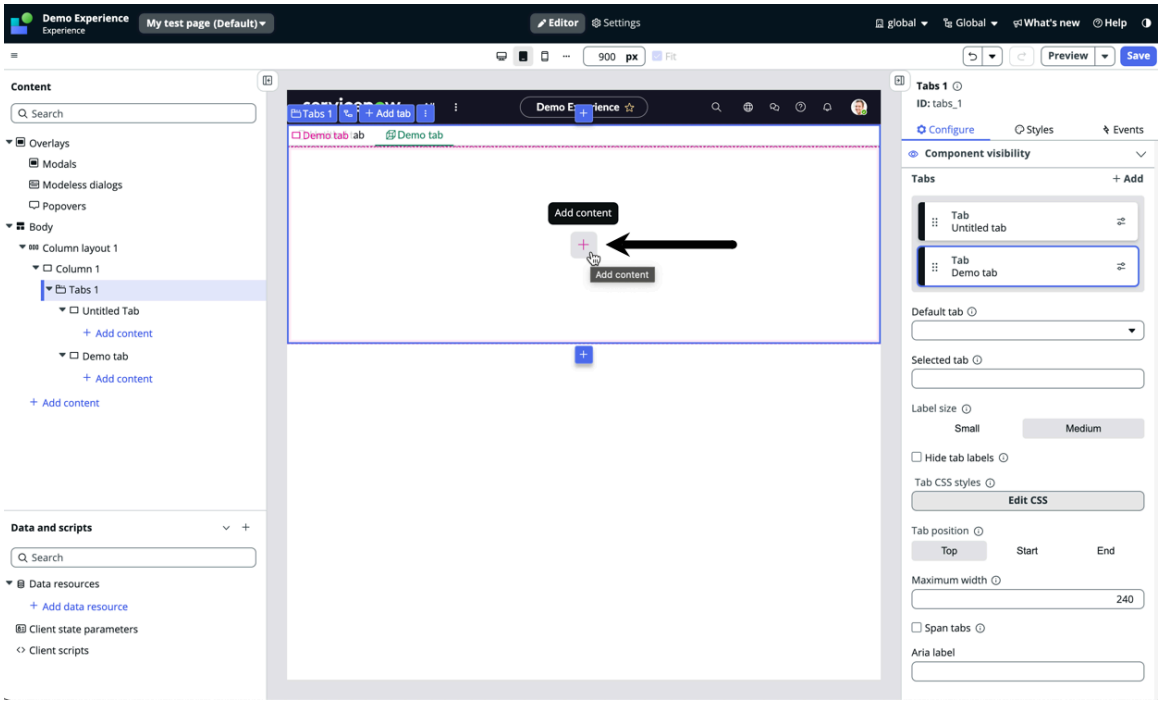


10. Select **Next**.
11. On the form, fill in the fields.

Tab settings form

Field	Description
Tab label	Label for the tab to display on your page.
Icon	Icon to appear next to the tab label. Icons are not required.
Hide tab	Whether to hide or display the tab.

12. Select **Create**.
    The new tab displays in the **Tabs** component.
13. Select the new tab.
14. Select **+** icon.



15. Select the component that you want to add to the tab.
    Components display under the tab in which they're nested in the content tree. For more information, see Add and configure components.

Result

Your page shows the two tabs that you created. Select each tab to further configure them, add styling, or add an event handler. For more information on styling, see Change the default appearance of components. For more information on adding an event handler, see Manage actions in UI Builder pages.

Add repeater tabs

Use the Tabs component to create a set of repeater tabs by linking tabs to a data array.

Before you begin

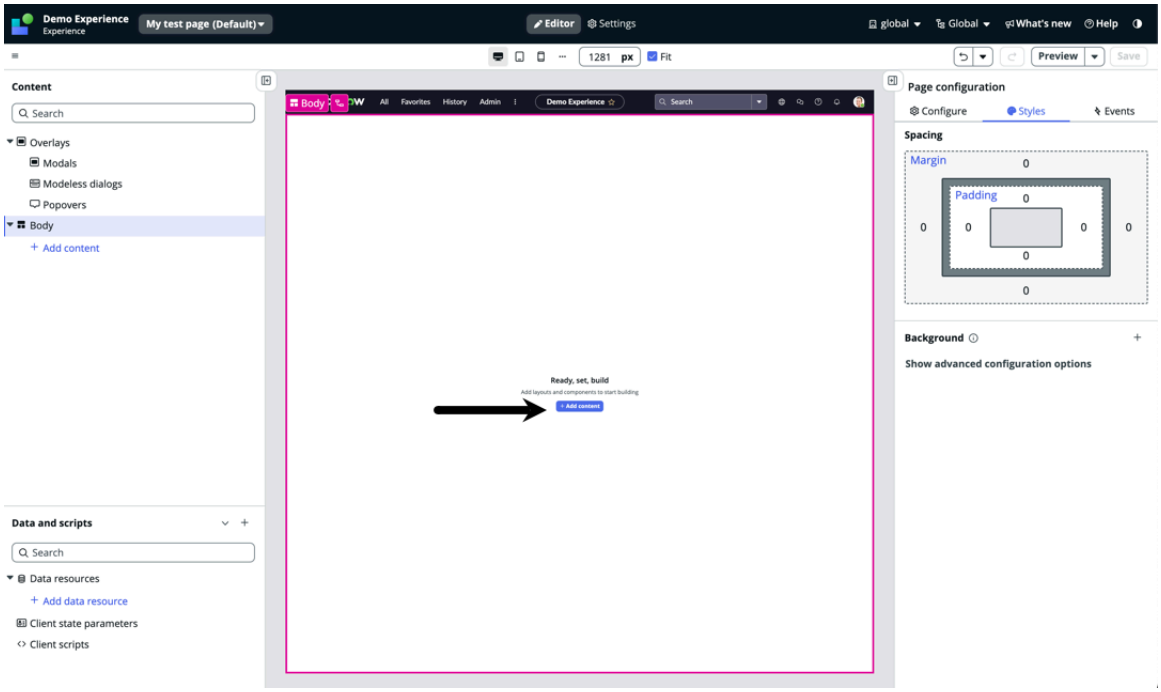
Role required: admin

About this task

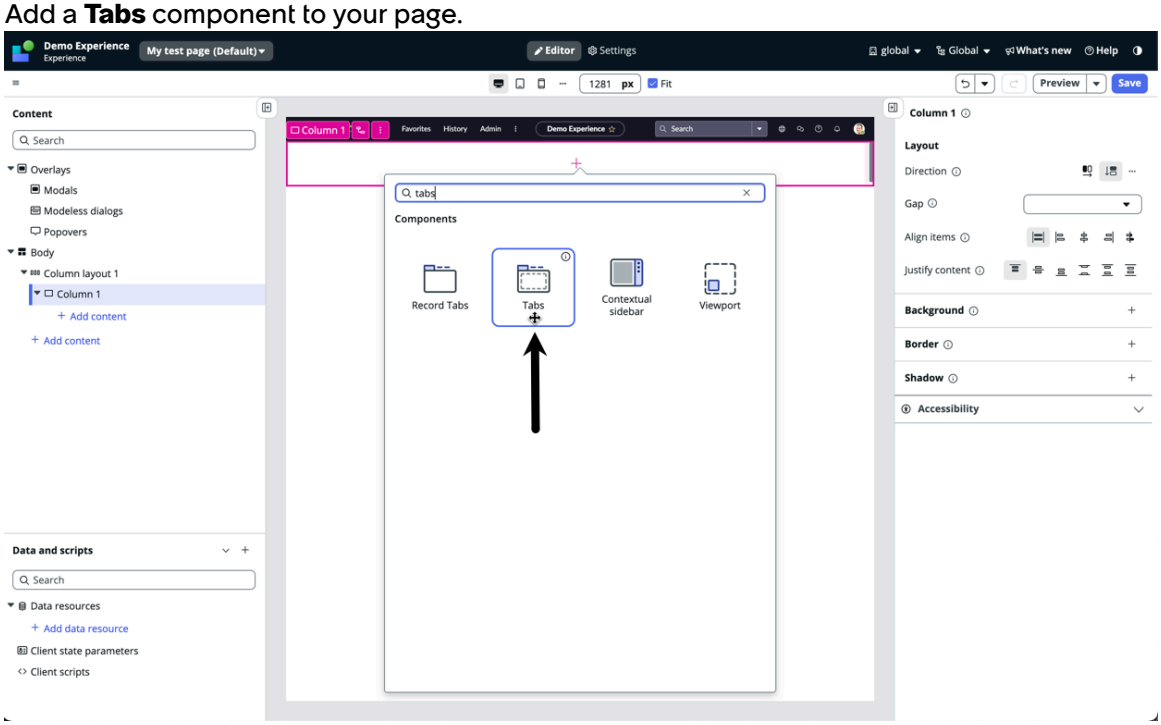
You can use repeater tabs to create multiple tabs based on the data array you provide. You can pass the icon, label, count, and fields as a key in the object. Use the label key to add names to tabs. Use the field key to pass information to repeater tabs. You can bind a data broker, client state, or a client script to the data array provider to return the array of objects with the correct schema.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page or page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Select the **+ Add content** button on the stage to open the toolbox.

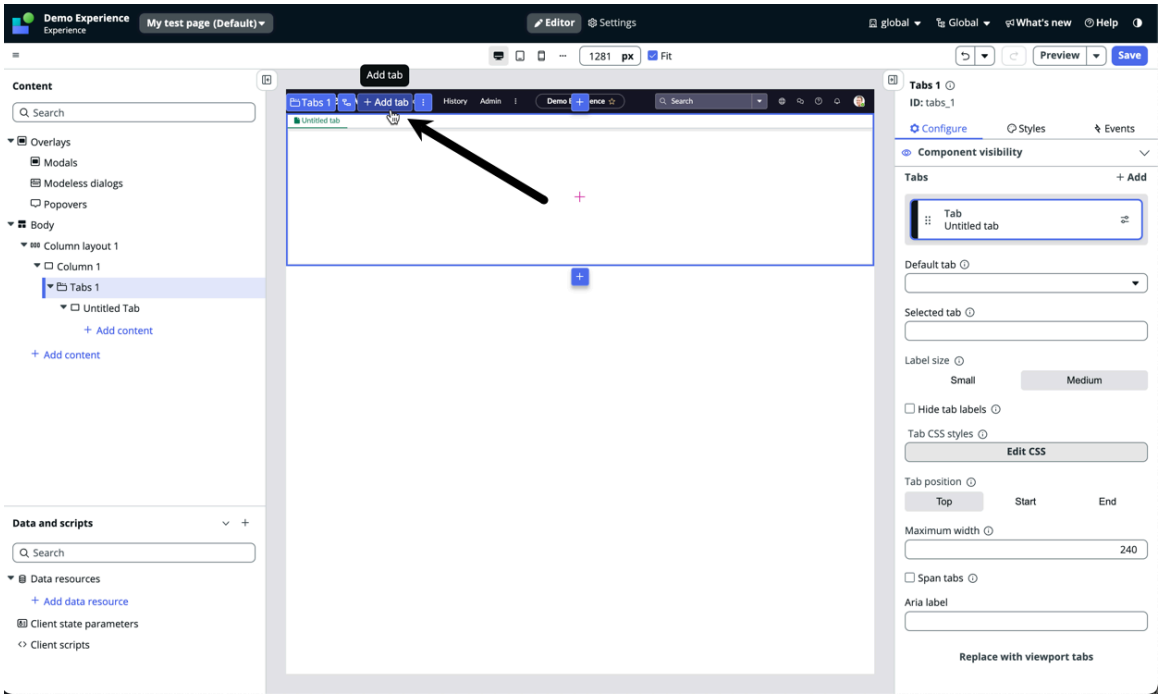


5. Select a **Single column** layout.
6. Next, select the **+** icon in the column to open the toolbox.
7. Add a **Tabs** component to your page.

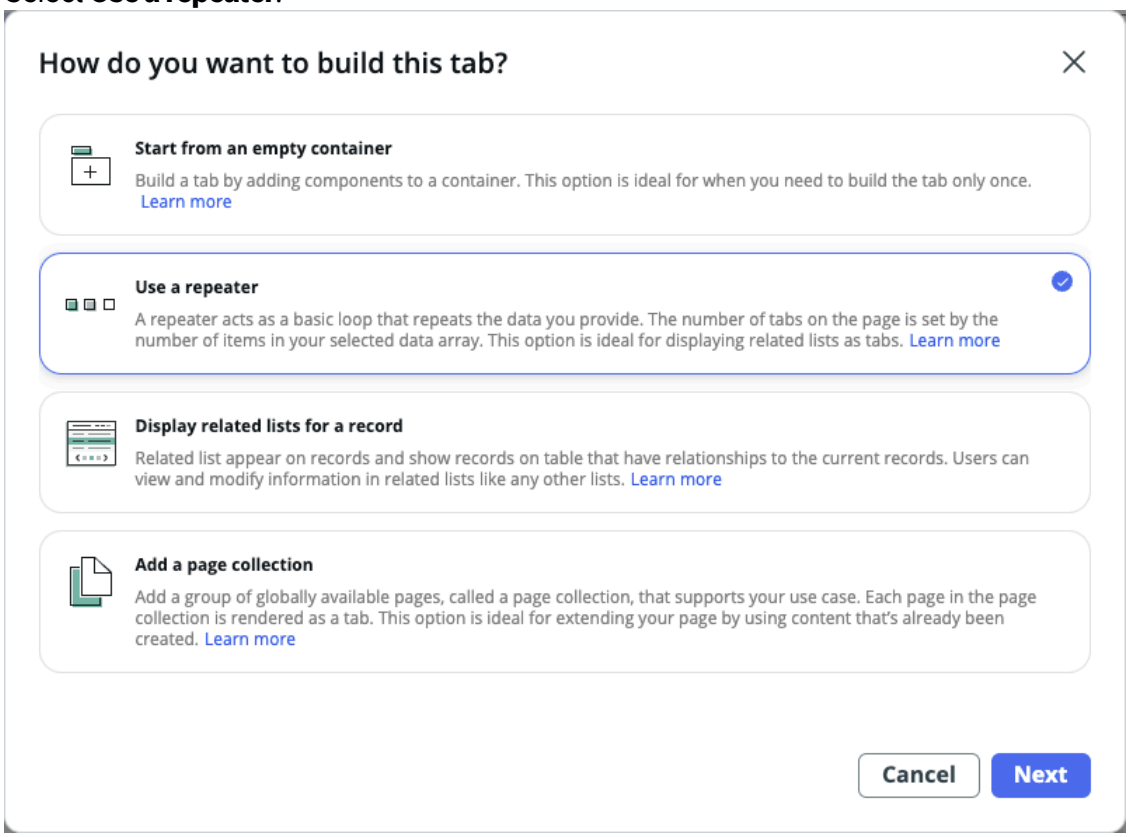


For more information on how to add a component to a page, see Add and configure components.

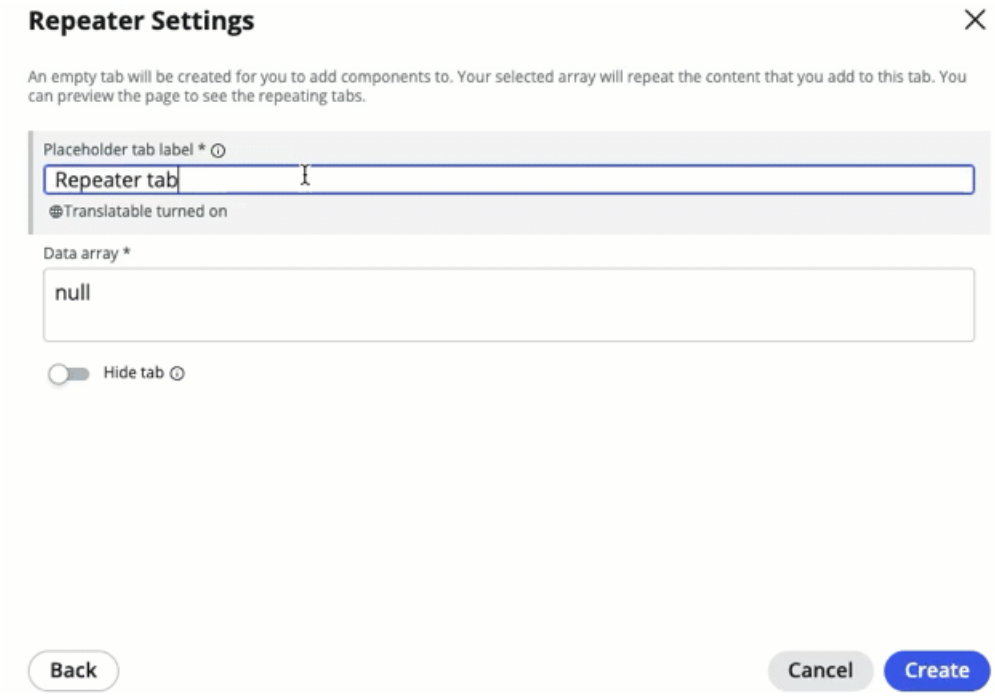
8. Select **+ Add tab** on the stage.



9. Select **Use a repeater**.



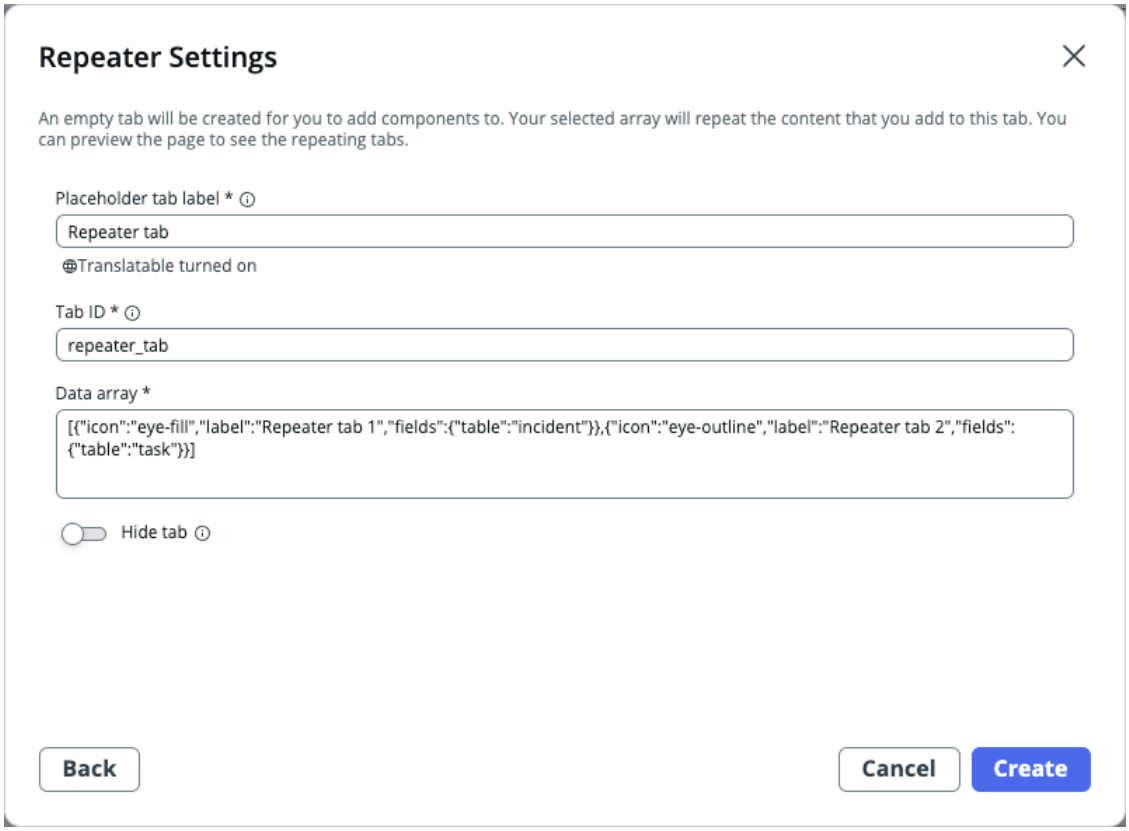
10. Select **Next**.
11. Enter a label for the repeater tab in the **Placeholder tab label** field.
    This label is assigned to the first repeater tab and is the only tab displayed in the page preview.
12. Select **Edit** in the **Data array** field.



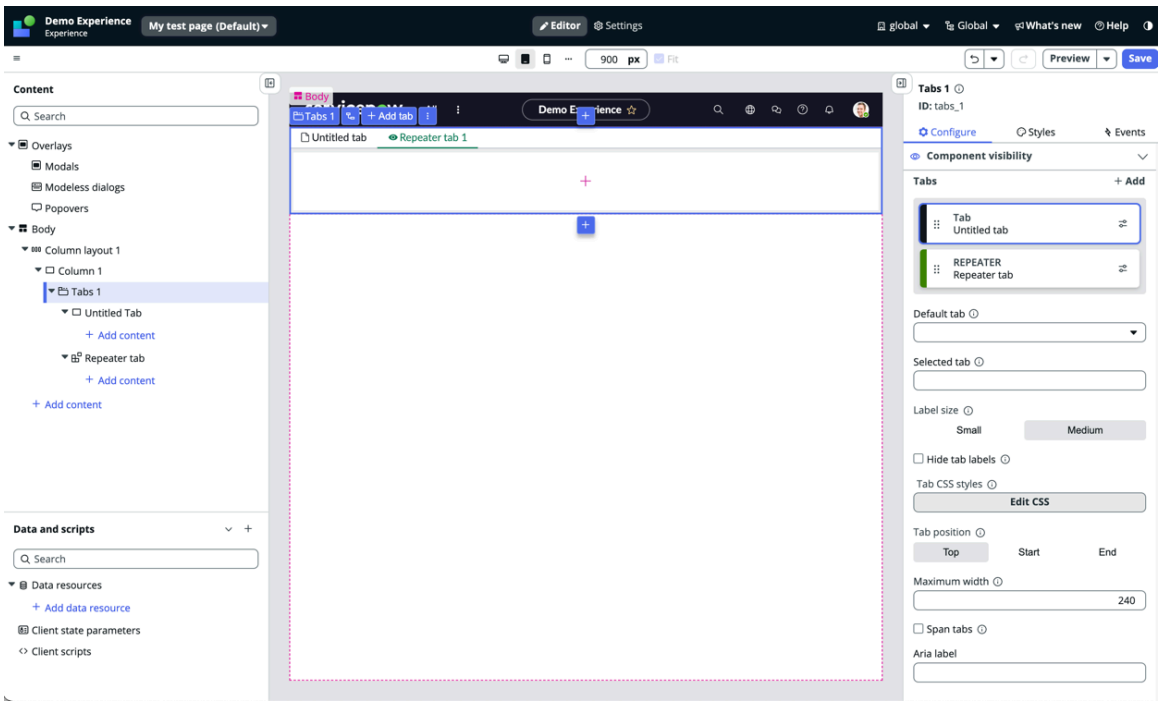
13. Configure the data array in the JSON editor.

Key	Data type	Description
icon	String	Name of the icon that appears in UI Builder.
label	String	Required. Display name of the tab in UI Builder.
count	Number	Value to provide on the tab label. Dynamically bind to a data broker or a client script that will be displayed on the label.
fields	Object	Object that can be used to store information and to pass down to the components in the tabs.

14. Select **Apply**.
The data array field displays the data array configuration.



15. Select **Create**.
    The new repeater tab appears on the page and in the content tree.



16. Select **Save**.
17. Add components to the repeater tab.
18. Select Preview to verify that the repeater tabs display correctly on your page.

Add related list tabs

Create a set of tabs on a page by linking to a related list.

Before you begin

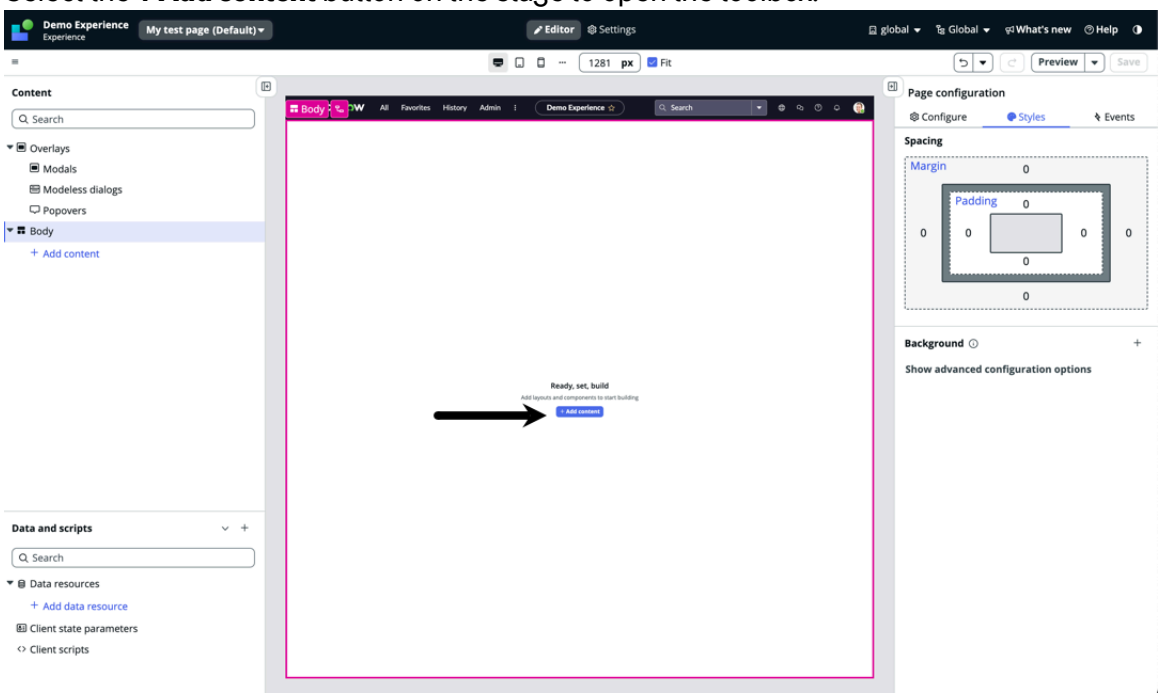
Role required: admin

About this task

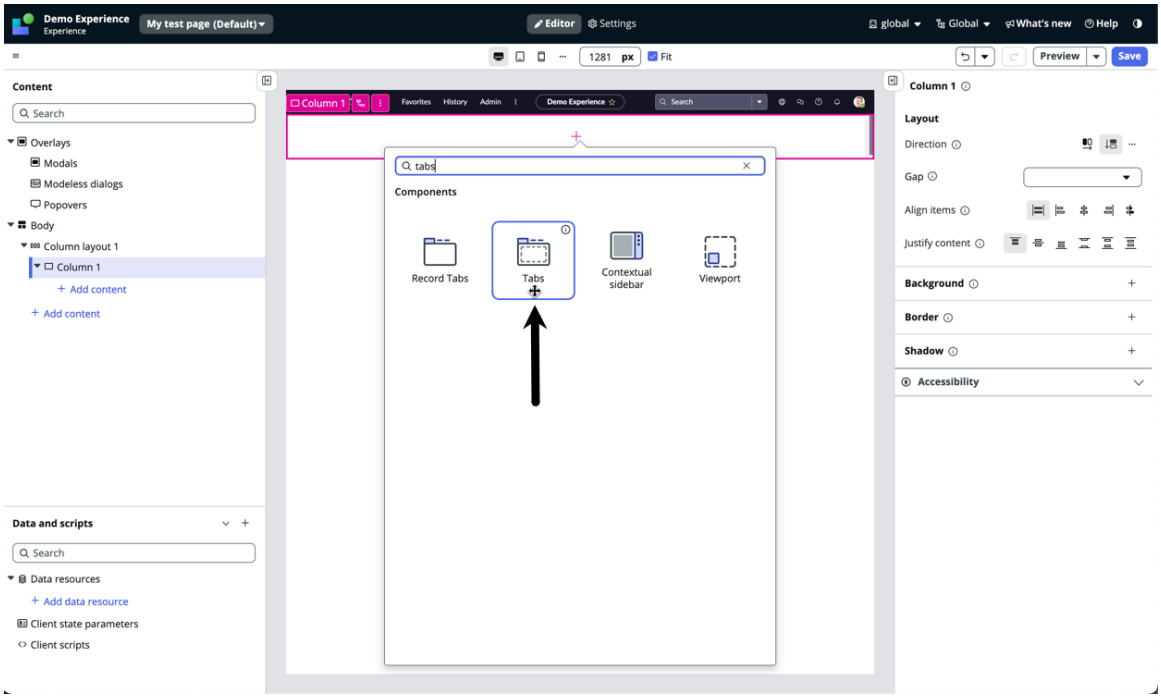
The related list tab automatically populates tabs based on the record that your page is displaying. For example, by default the related lists for the user table are Roles, Groups, Delegates, and Visibility domains. If your page is displaying a user record, then creating a related list tab adds all four of these related lists as tabs on your page. You can preview the page to see the related lists that were added. A record controller is required to create related list tabs. To add a controller to your page, see Bind data to UI Builder pages using controllers (advanced feature) for more information.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page or page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Select the **+ Add content** button on the stage to open the toolbox.

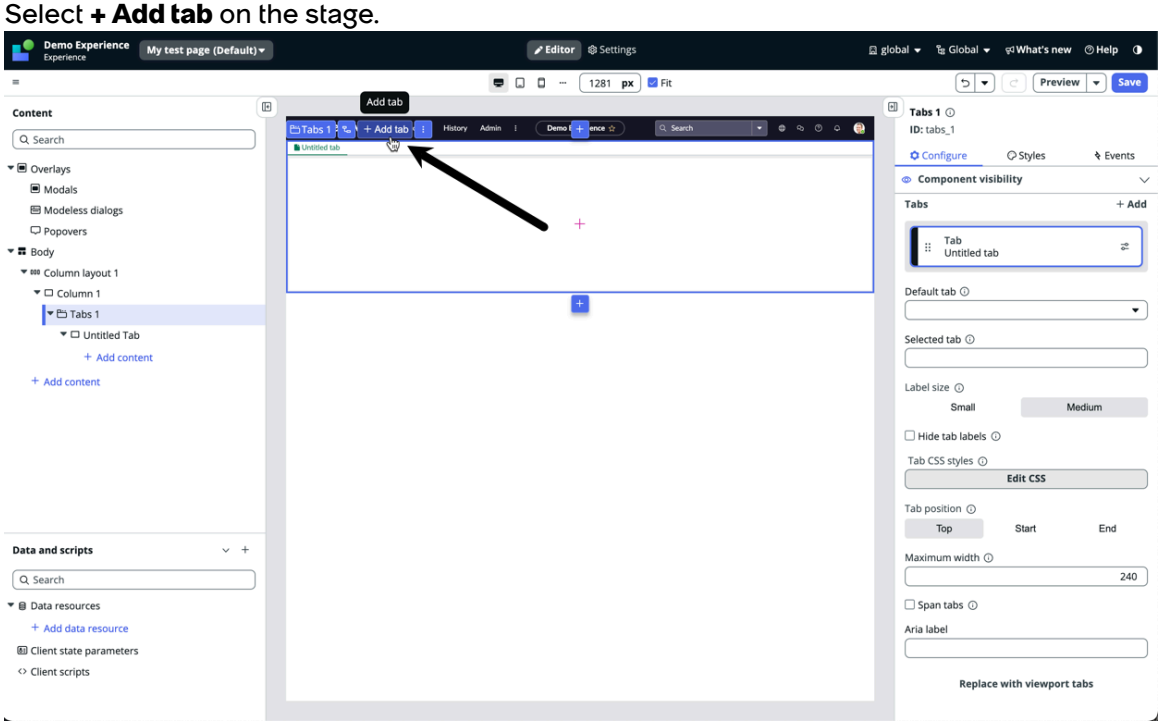


5. Select a **Single column** layout.
6. Next, select the **+** icon in the column to open the toolbox.
7. Add a **Tabs** component to your page.

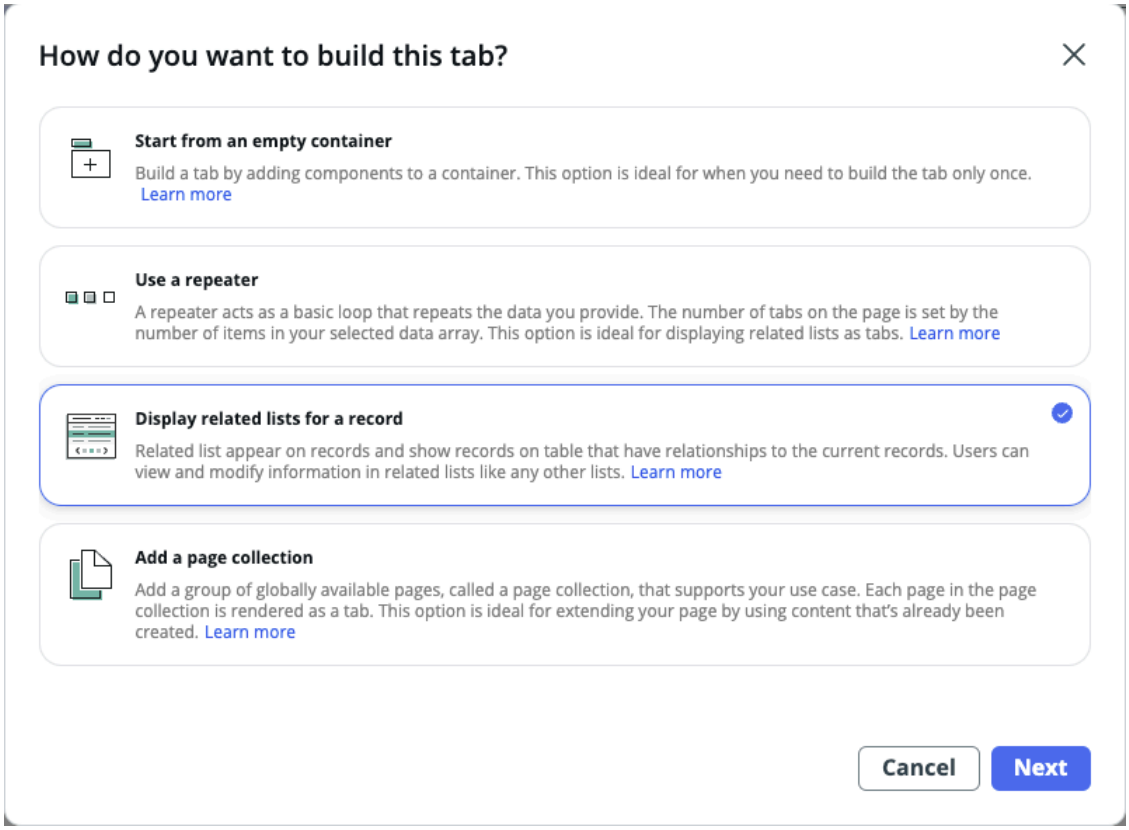


For more information on how to add a component to a page, see Add and configure components.

8. Select **+ Add tab** on the stage.



9. Select **Display related lists for a record**.

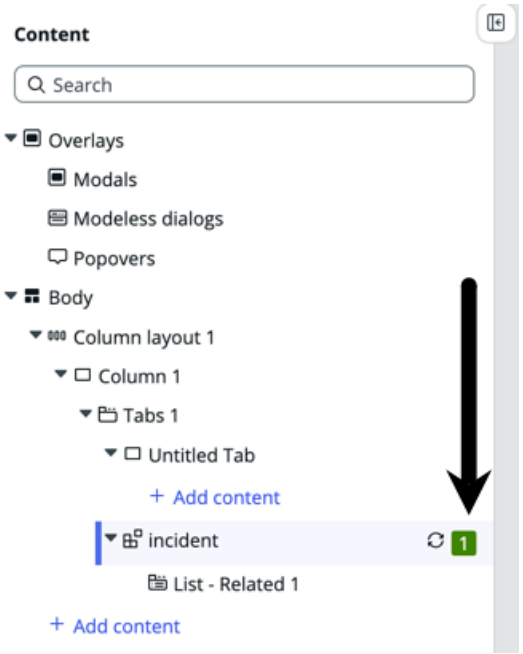


10. Select **Next**.
11. On the form, fill in the fields.

Tab settings form

Field	Description
Placeholder tab label	Placeholder label to appear on the preview tab of your page.
Hide tab	Whether you want to hide or display the tab.
Record Controller	Record controller with the related list.

12. Select **Create**.
    The new related list tab displays in the **Tabs** section of the configuration panel. Only one placeholder tab appears in the page preview. The green icon next to the related list tab in the content tree shows how many tabs appear on your page.



13. Select **Save**.
14. View and test your page by selecting Preview.

Add page collection tabs

Use page collection tabs to recreate the same tabs across multiple pages in UI Builder.

Before you begin

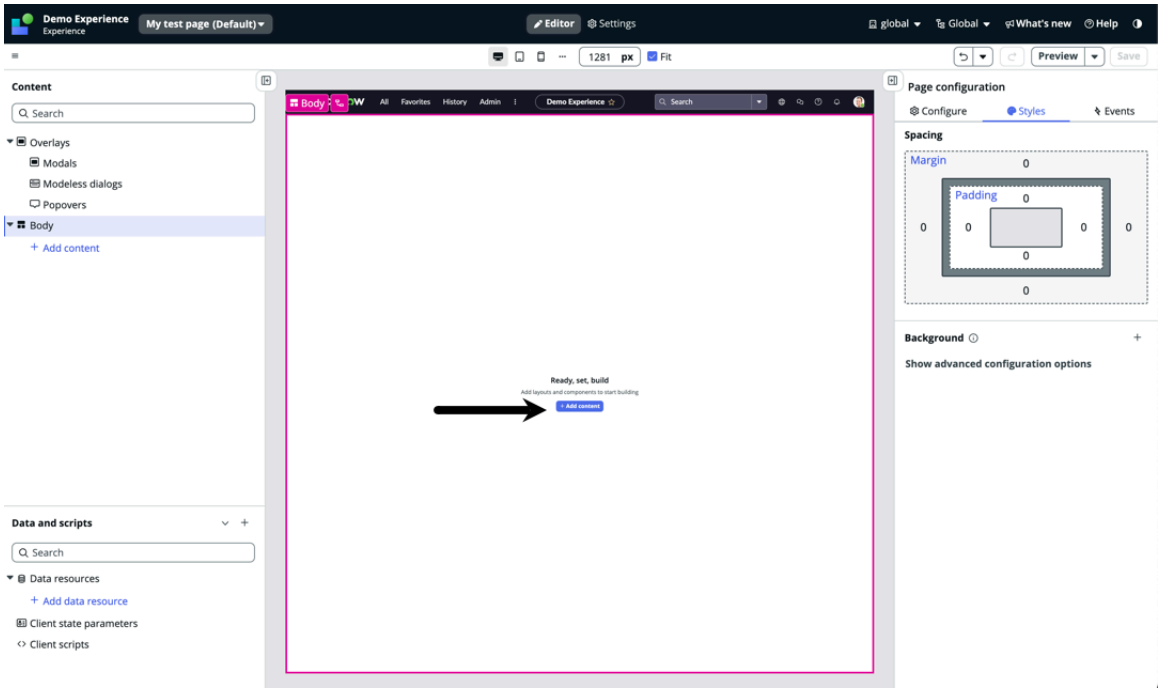
Role required: admin

About this task

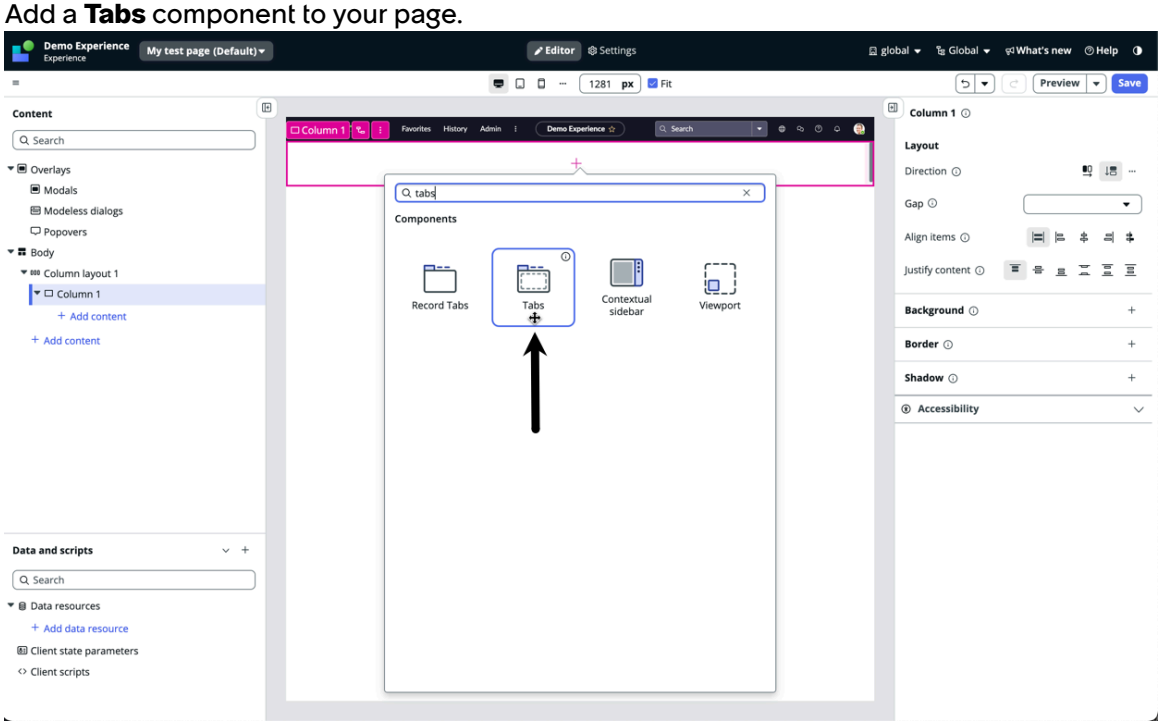
A page collection is a group of prebuilt globally available pages. Use page collection tabs to render each page in a page collection as a tab. You can select an existing page collection or can create your own. A controller is required to add a page collection. For more information about page collections, see Page collections.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page or page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Select the **+ Add content** button on the stage to open the toolbox.

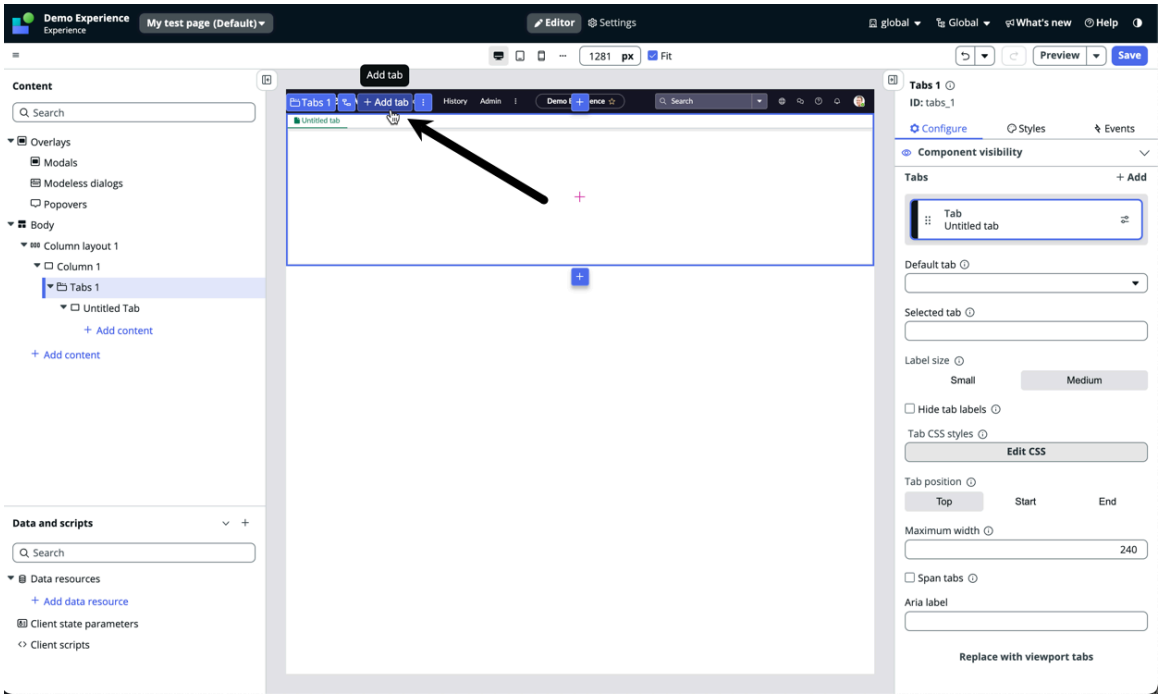


5. Select a **Single column** layout.
6. Next, select the **+** icon in the column to open the toolbox.
7. Add a **Tabs** component to your page.

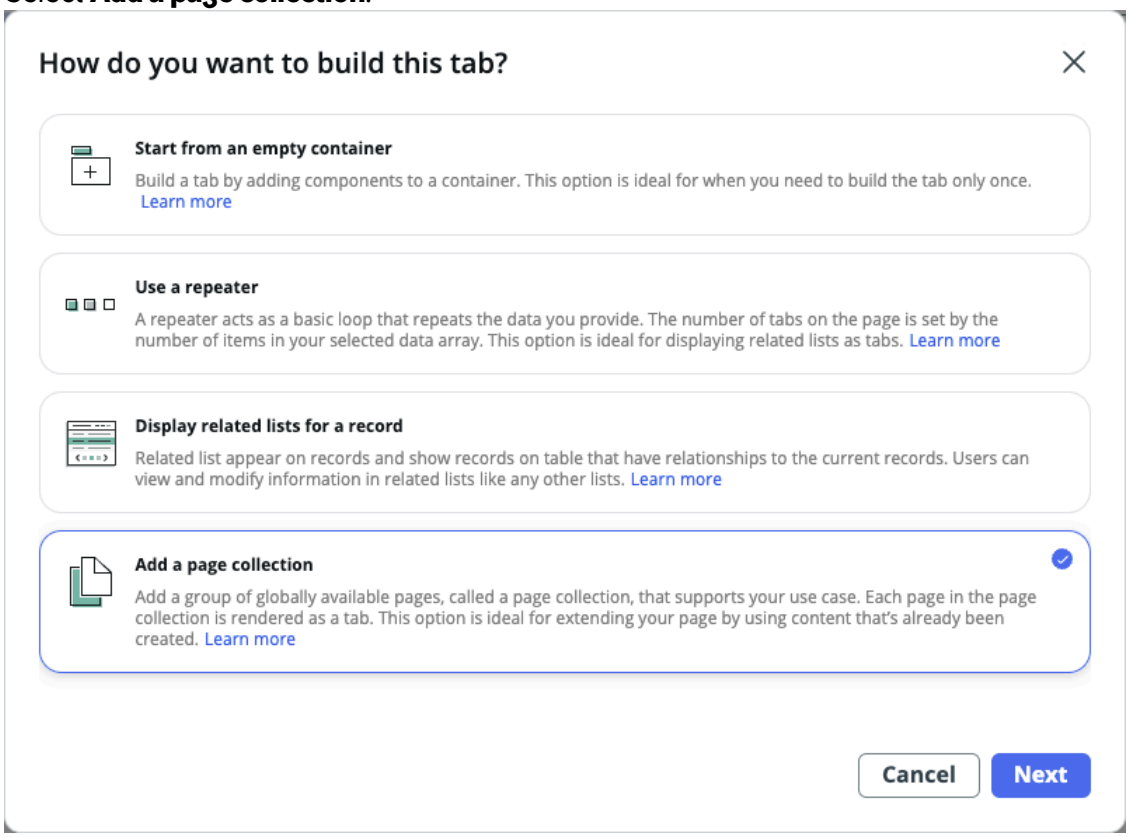


For more information on how to add a component to a page, see Add and configure components.

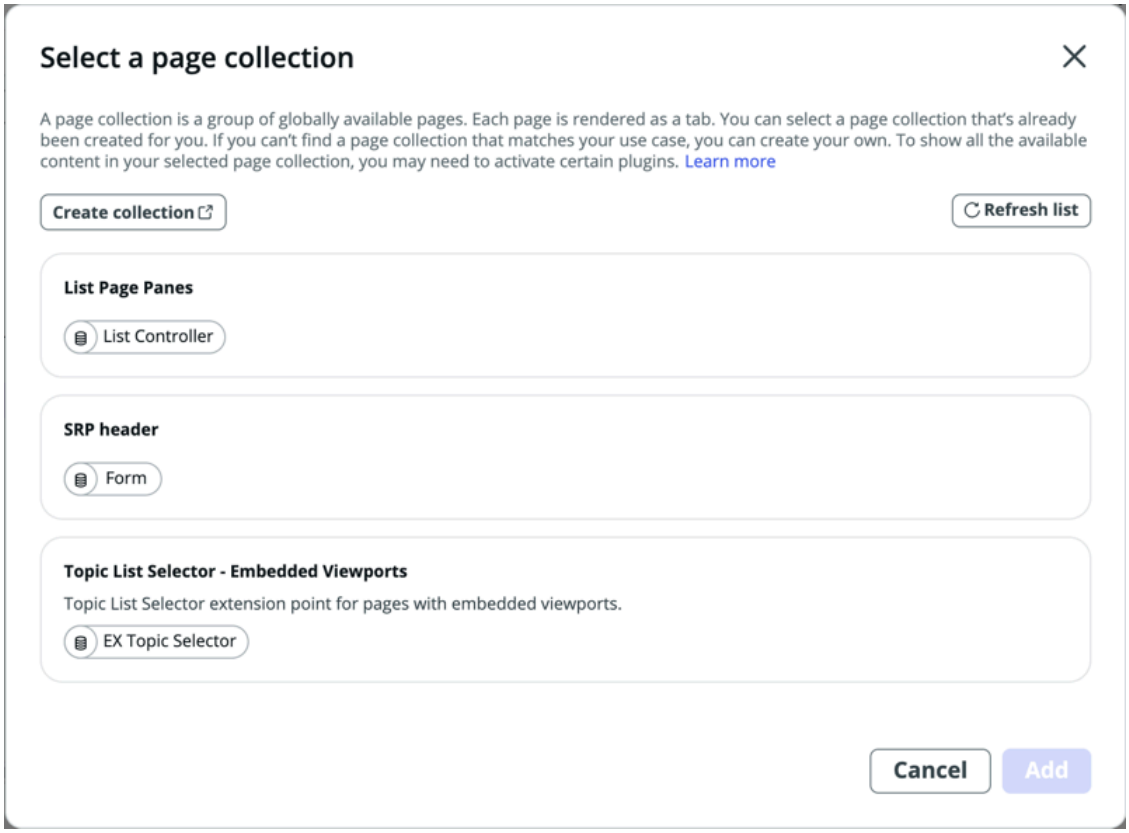
8. Select **+ Add tab** on the stage.



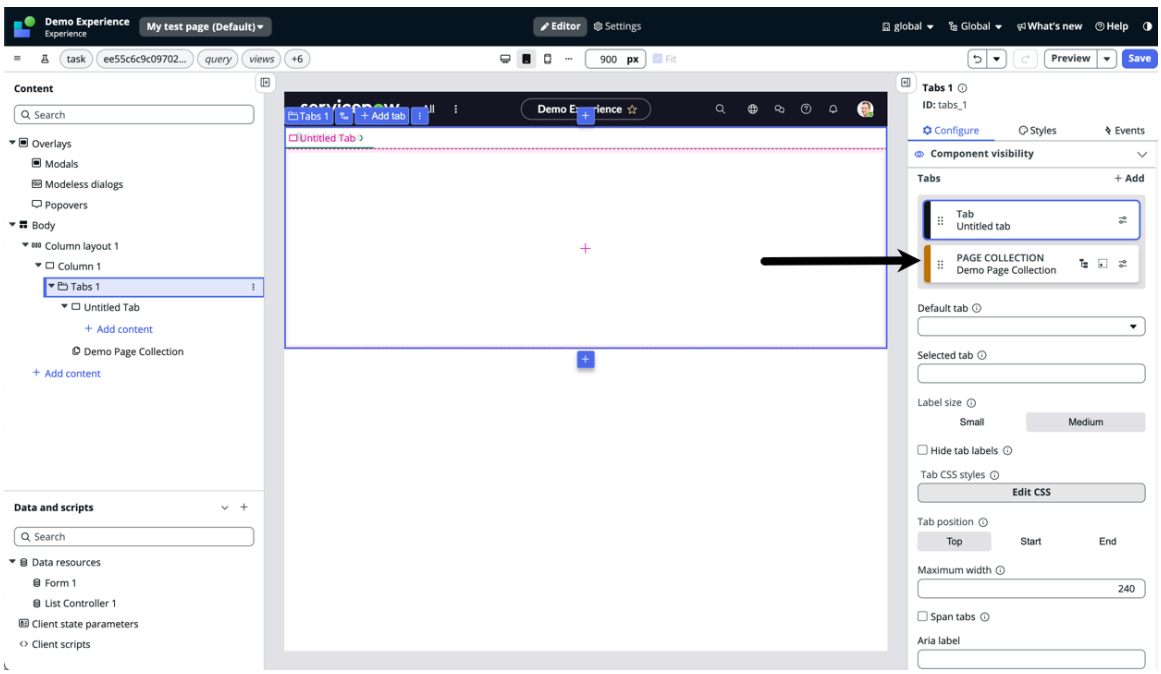
9. Select **Add a page collection**.



10. Select **Next**.
11. Select a page collection from the list or create a collection by selecting **+ Create collection**. To create your own page collection, see Create a page collection across multiple UI pages.



12. Select **Add**.
The new page collection tab displays in the **Tabs** section of the configuration panel. Only one placeholder tab displays in the page preview.



13. Select **Save**.

14. View and test your page by selecting Preview.

Add a contextual sidebar

Add a contextual sidebar to a page with UI Builder to display related content using a vertical tab structure.

Before you begin

Role required: ui_builder_admin

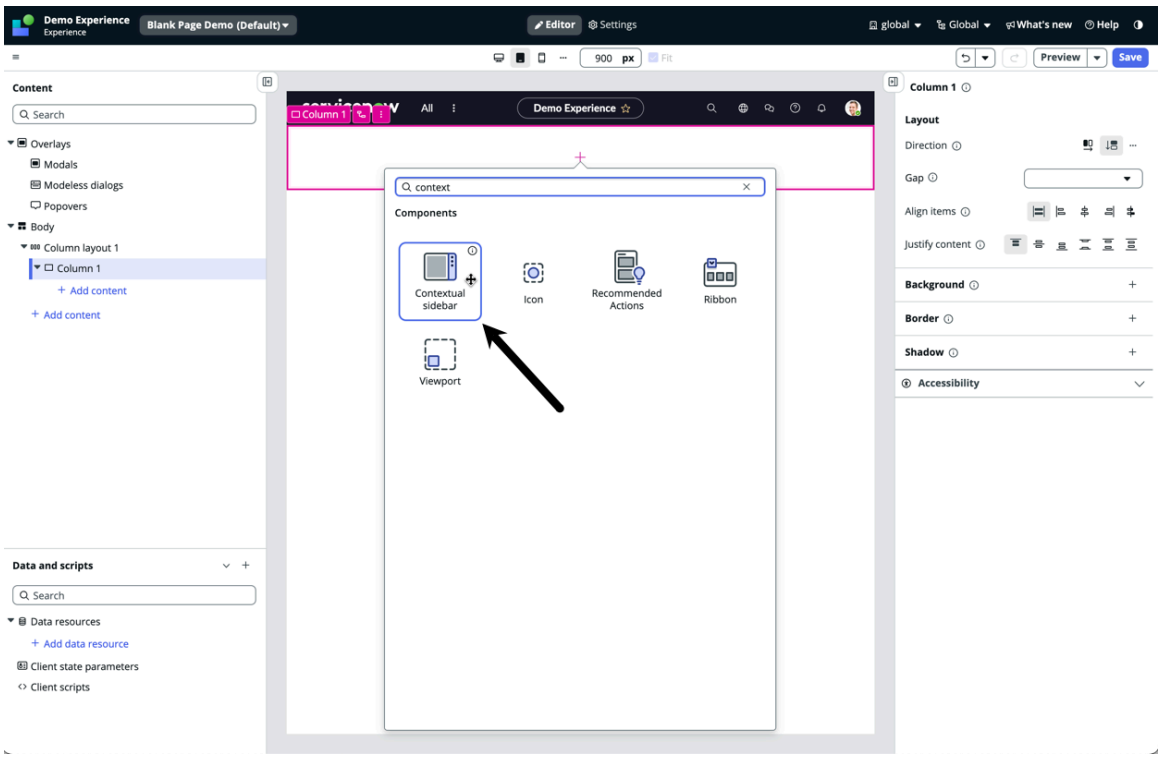
About this task

You can configure the contextual sidebar in the same way you would configure a tab component. Each vertical tab in the contextual sidebar renders custom content. You can place components in each tab for quick access directly from the page.

For example, a document creation page might have the attachments component on one tab, enabling you to attach files related to the document that you're working on. On another tab, there could be a nested comments component, enabling you to add and view comments related to the document.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page or page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder. For information about creating a page variant, see Create a page variant
4. On the stage, open the toolbox by selecting the **+ Add content** button.
5. Select the **Single column** layout tile.
6. In the column, open the toolbox by selecting the **+** icon.
7. Select the **Contextual sidebar** component to add it to your page.



The contextual sidebar appears on the stage, and the Tabs section appears in the configuration panel.

8. In the configuration panel under the Tabs section, select the settings icon (⚙) to configure the tab.

   a. On the form, fill in the fields.

   Tab settings form

Field	Description
Tab label	Label that displays on the tab for your page.
Icon	Icon that appears next to the tab label. **Note:** Icons aren't required.
Hide tab	Option to hide or display the tab.

   b. Select **Save**.

9. On the stage in the contextual sidebar, open the toolbox by selecting the **+** icon.
10. Select the component that you want to add to the tab.
    The component displays under the tab in the content tree. For more information, see Add and configure components.
11. **Optional:** To add another tab, select **+ Add** under the Tabs section.

What to do next

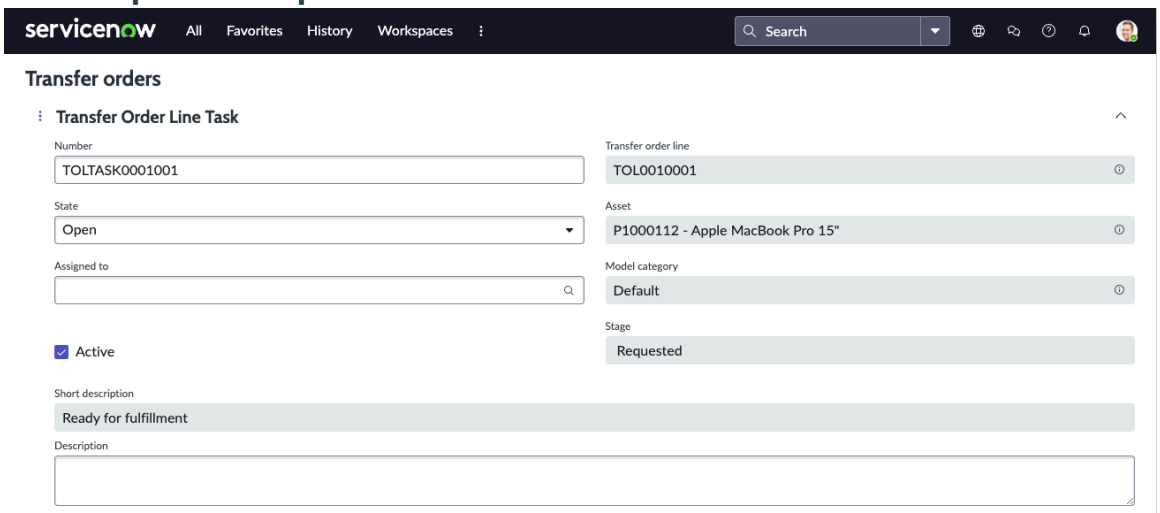
For detailed information about the configuration of the contextual sidebar and its properties, see Tabs UIB Setup on the ServiceNow Developer Site.

Add forms to UI Builder pages

Use the Form component to add one or more forms to UI Builder pages.

Add functionality to your UI Builder pages by including forms. You define the fields on the form and their properties, such as making them required. Then, collect data as the form is completed and submitted.

Form component example

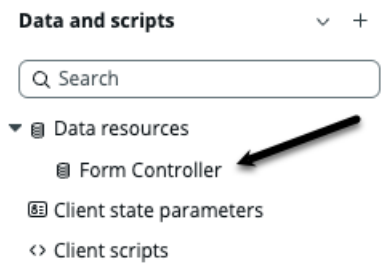


You can add more than one form to a single page. You can also add a form to a page that already contains a component with a nested form. Sample use cases include:

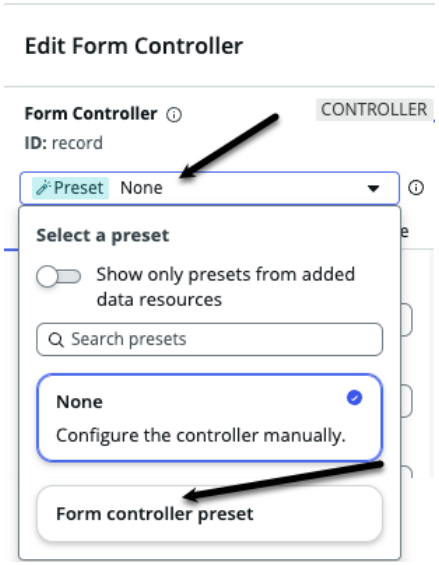
- Extend record pages by adding an inline tab with a form using its own form controller instance.
- Add modals with a form on a record page.

For existing pages with forms created in a pre-Xanadu ServiceNow release, you must apply a preset to the original form before adding another form to the page. Applying the preset is a prerequisite to adding multiple forms to a page and enables multiple forms to work as expected on a page. The form controller preset should be applied onto all form controllers.

1. Open the page containing an existing form.
2. In the data drawer, expand the **Data resources** list and select the original form controller.



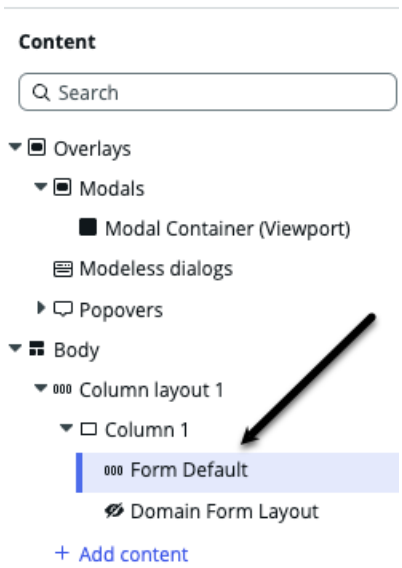
3. Select the **Preset** field.
4. Select **Form controller preset**.



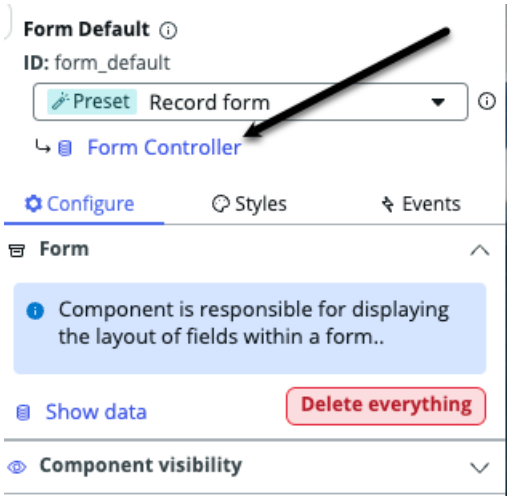
5. Select **Apply**.
6. Select the **X** to close the **Edit Form Controller** pop-up.

   Exactly one of your form controllers should have the **Is mapped to app Shell** property set to true. This property is used to specify the primary form on the page. The primary form is responsible for handling global events. You shouldn't set the property to true for more than one form controller or have zero form controllers with the property set to true.

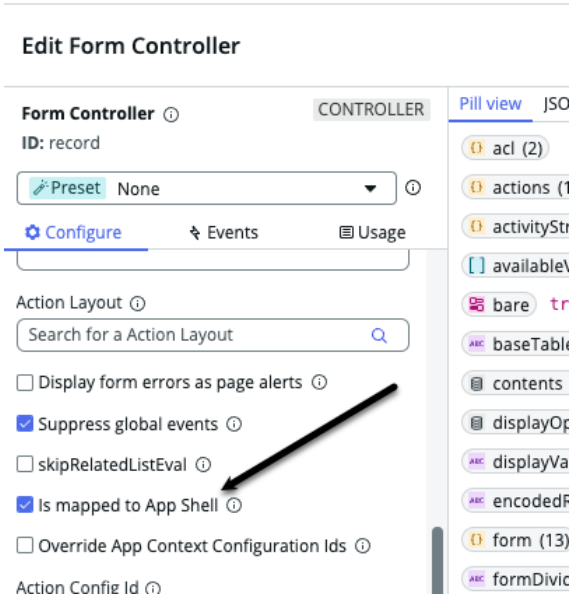
7. Open the page containing one or more forms.
8. In the content tree, select a form.



9. In the configuration panel, on the **Configure** tab, select **Form Controller**.



10. On the **Edit Form Controller** pop-up, scroll down in the **Form Controller** list to find the **Is mapped to App Shell** option.



11. Select or clear the option for each form component on the page to confirm that exactly one form controller is mapped to the app shell.

Advanced form event handling

Experienced developers with knowledge of conflict event handling may find the following details useful.

If isMapped to app shell is set to true, the form handles these events automatically:

Screen Status Changed

- Description: Action to indicate that a form is dirty.
- Output: `CTRL_RECORD#SCREEN_STATUS_CHANGED`

Update Configuration Menu Requested

- Description: Action to set record configuration menu items on the avatar menu.
- Output: `CTRL_RECORD#UPDATE_CONFIGURATION_MENU_REQUEST`

Phone Requested

- Description: Action to make a call when the CTI plugin is enabled.
- Output: `CTRL_RECORD#PHONE_REQUESTED`

Form Loading State Changed

- Description: Action to show a loading spinning when that form is loading data.
- Output: `CTRL_RECORD#FORM_LOADING_STATE_CHANGED`

For detailed information about the Form component and its properties, see Form Overview on the ServiceNow Developer Site.

Create modals in UI Builder

Use modals in UI Builder with components to provide alerts or calls to action for a user. UI Builder comes with modals to save time and effort.

What Modals are

Modals, also known as dialogs, are windows that overlay another content window. Modals take control of the user experience. Users cannot interact with the overlaid window until the modal is closed. Modals can contain different types of content such as:

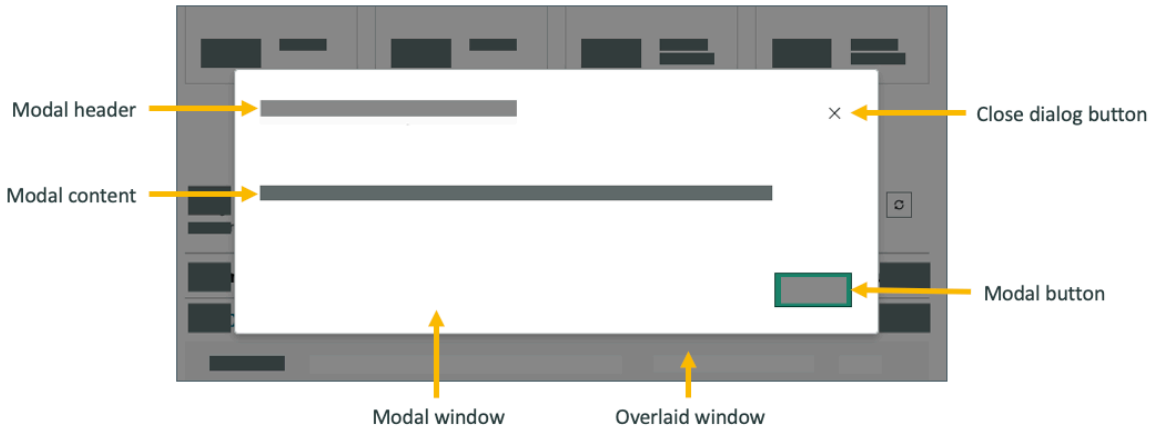
- Static text
- Dynamic text
- Forms
- Images
- Buttons

UI Builder has preconfigured modals available. You can add a modal to your component. Then, configure the content of the modal, and how it displays on the screen. Add an event handler to the modal to perform an action when a user selects it. The action can alert a user about something, or ask a user to confirm an action. A modal is a way to ensure that a user knows what is happening. For example, a modal may ask a user to confirm a selection before continuing whatever action they are performing on the main page.

Modal Anatomy

Modals in UI Builder can have:

- Modal header
- Modal content
- Close dialog button (no action taken by the modal)
- At least one Modal button (action can be taken by the modal)



Modal types

Different types of modals are available in UI Builder, as shown in the following table.

Modal type	Description
Alert	An Alert modal provides information relating to the component action. For example, when a user presses a delete button, you could have an alert pop-up that lets the user know they cannot undo a delete action.
Confirm	A Confirm modal asks a user to confirm the component action. For example, when a user presses a delete button, the user would have to confirm the deletion of data. You can choose the confirm options from the primary and secondary button label fields, such as Yes/Cancel.
Confirm and destroy	A Confirm and destroy modal is more directive, usually relating to deleting or erasing content. It lets the user know the seriousness of an action, and asks them whether they want to proceed with the action.
Custom	Custom modals address scenarios that are not handled using the standard modals. Custom modals can be thought of as a container component on a modal. You can add a custom layout, components, events, and data resources just like you do on a page. The custom modal uses layouts to let you fully design what information you want in the modal. Layouts also decide where the information sits within the modal screen. You can use Cascading Style Sheets (CSS) styling to change the visual look of the modal.
iframe	Use iframe to bring content into your modal from existing iframe content from a URL and data.

Modal type	Description
Modal viewport	Dynamically pass content into your viewport modal through an event binding using a client script.

Event handlers and modals

Expose events to modals to handle call-to-action events. For example, a primary action, secondary action, and so on. You configure the data by adding an event handler and invoking a data resource. It is as simple as adding a new event handler for the component that has a modal. Or you can add an event handler to the modal itself. You select the event that you want associated with the component or modal and add it. See Add modal to component for detailed instructions.

Add modal to component

Learn how to add a modal in UI Builder. A modal is a window that appears when you click a component. For example, a modal might display when a delete button component is clicked, prompting the user to confirm deleting a record.

Before you begin

Role required: ui_builder_admin

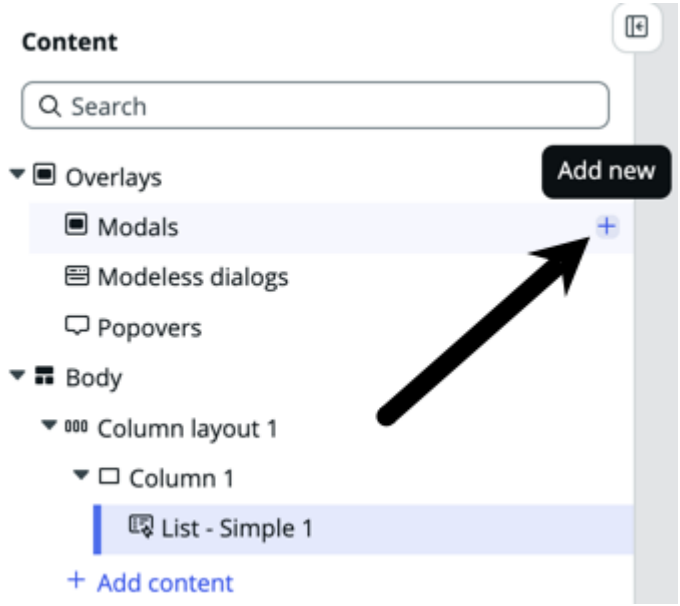
About this task

A modal is a screen that appears when an event handler is triggered by an event such as a button being clicked. The following procedure shows an example of how to add a Confirm modal and an associated event handler to a button component.

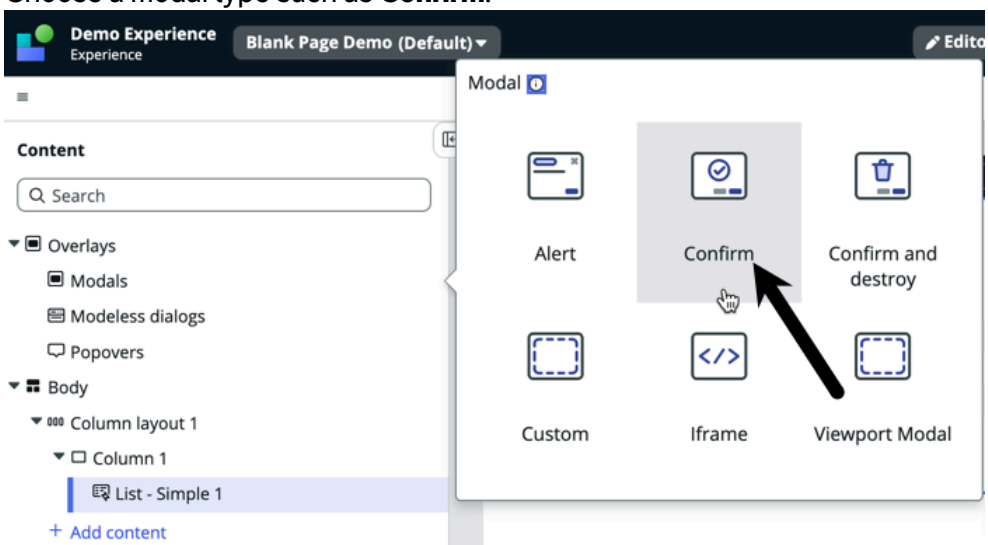
Procedure

1. Navigate to **All** > **Now experience framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Open or create a page or page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Add a modal to the page.

a. Select the **+** icon in the content tree next to **Modals and popovers**.



b. Choose a modal type such as **Confirm**.



Modal type	Description
Alert	An Alert modal provides information relating to the component action. For example, when a user presses a delete button, you could have an alert pop-up that lets the user know they cannot undo a delete action.
Confirm	A Confirm modal asks a user to confirm the component action. For example, when a user presses a delete button, the user would have to confirm the deletion of data. You can choose the confirm options from the primary and secondary button label fields, such as Yes/Cancel.

Modal type	Description
Confirm and destroy	A Confirm and destroy modal is more directive, usually relating to deleting or erasing content. It lets the user know the seriousness of an action, and asks them whether they want to proceed with the action.
Custom	The Custom modal uses layouts to let you fully design what information you want in the modal. Layouts also decide where the information sits within the modal screen. You can use Cascading Style Sheets (CSS) styling to change the visual look of the modal, such as background color.
iframe	Use iframe to bring content into your modal using existing iframe content from a URL and data.
Modal viewport	Dynamically pass content into your viewport modal through an event binding using a client script. See Bind an event to a component for more information on binding an event to a component.

c. Configure the modals as shown in the table.

Configure each modal differently, depending on what the modal requires. Change what information goes into the modal, the size of the modal, and how it looks. You can add an event handler to the modal that performs the action for the modal, such as opening or closing the modal.

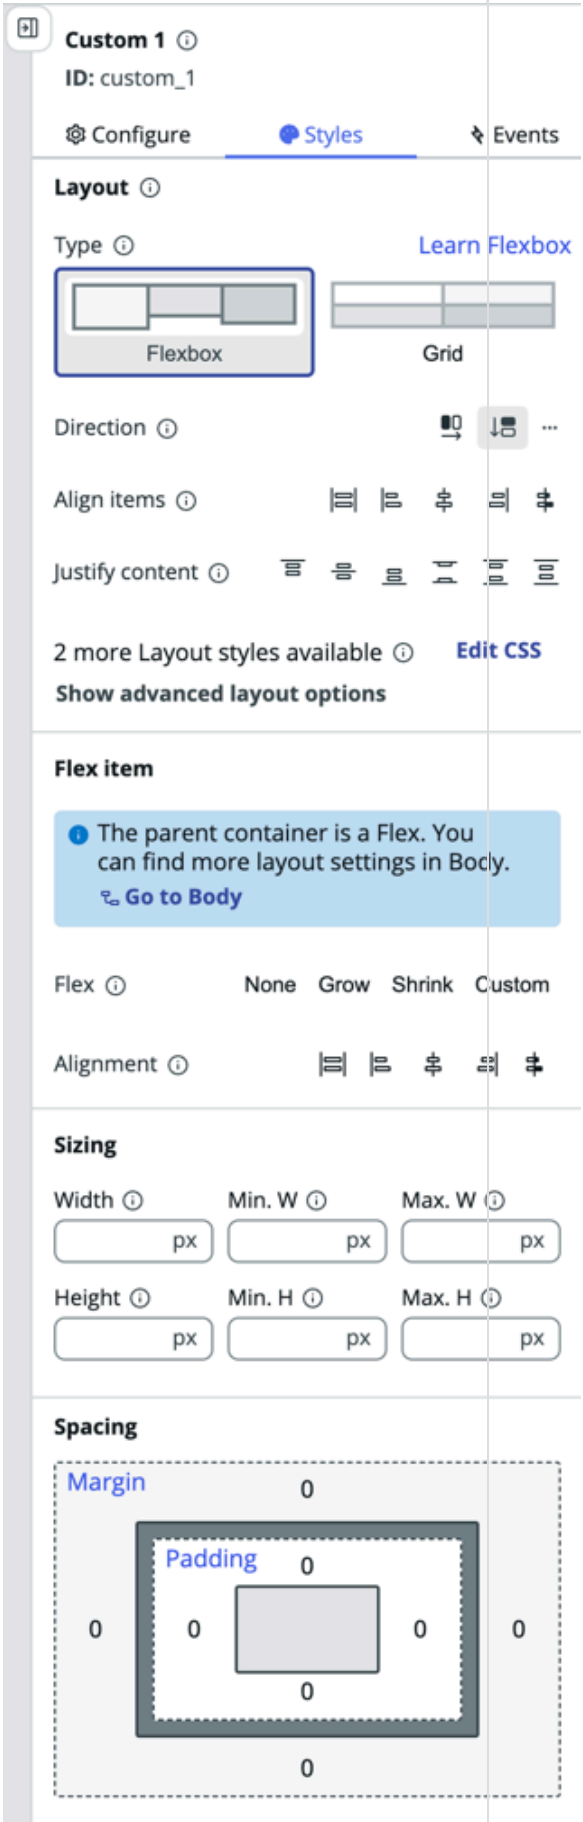
Modal	Configuration
Alert	▪ Add a header, which is the title of the modal. ▪ Write the content that you want displayed in the modal. The content tells the user what the alert is. ▪ Add text for the button label. It can be anything you want, such as **OK**, **Yes**, and so on. ▪ Choose the size of the modal on the screen. Select **Small**, **Medium**, **Large**, or **Fullscreen**. ▪ Enable or disable **Prevent Default Button Action**, depending on whether you want the modal to close based on the default action. ▪ Enable or disable **Defer modal content loading**. If you disable it, the modal loads with the page. If you enable it, the modal doesn't load when the page loads.

Modal	Configuration
	▪ Select **Events** > **Add event mapping** to add an event handler to the modal. ▪ Select an event handler to apply to the modal, then select **Add** to add it to the page. Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the user session for GraphQL, or a user session for Transform.
Confirm	▪ Add a header, which is the title of the modal. ▪ Write the content that you want displayed in the modal. The content tells the user what the alert is. ▪ Add text for the primary button. The primary button is the main action button for users, such as **Yes**, **Add**, and so on. ▪ Add text for the secondary button. The secondary button is usually the no choice for users, such as **Cancel**, **No**, and so on. ▪ Choose the size of the modal on the screen. Select **Small**, **Medium**, **Large**, or **Fullscreen**. ▪ Enable or disable **Prevent Default Primary Button Action**, depending on whether you want the modal to close based on the default action. ▪ Enable or disable **Prevent Default Secondary Button Action**, depending

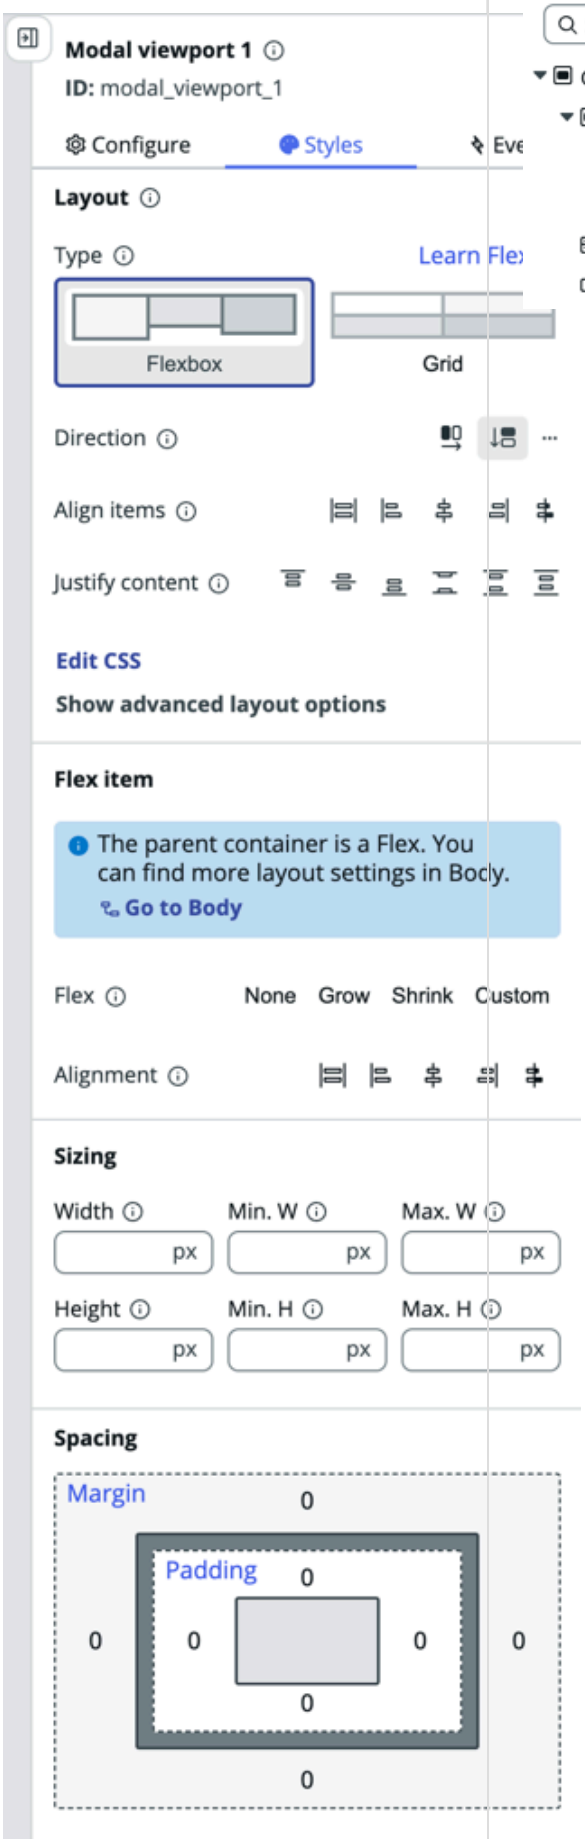
Modal	Configuration
 	on whether you want the modal to close based on the default action. ▪ Enable or disable **Defer modal content loading**. If you disable it, the modal loads with the page. If you enable it, the modal doesn't load when the page loads. ▪ Select **Events** > **Add event mapping** to add an event handler to the modal. ▪ Select an event handler to apply to the modal. Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the user session for GraphQL, or a user session for Transform.
Confirm or destroy	▪ Add a header, which is the title of the modal. ▪ Write the content that you want displayed in the modal. The content tells the user what the alert is. ▪ Add text for the primary button. Primary is the main action button for users, such as **Delete** or **Erase**. ▪ Add text for the secondary button. The secondary button is usually the no choice for users, such as **Cancel**, **No**, and so on. ▪ Choose the size of the modal on the screen. Select **Small**, **Medium**, **Large**, or **Fullscreen**.

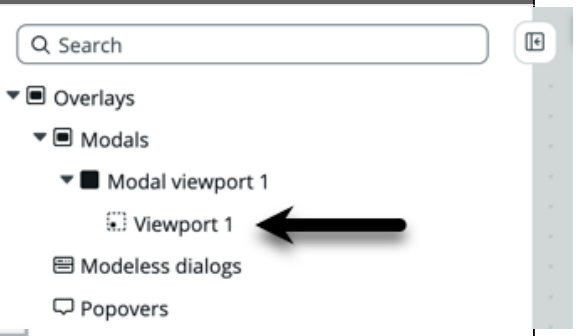
Modal	Configuration
 	▪ Enable or disable **Prevent Default Primary Button Action**, depending on whether you want the modal to close based on the default action. ▪ Enable or disable **Prevent Default Secondary Button Action**, depending on whether you want the modal to close based on the default action. ▪ Enable or disable **Defer modal content loading**. If you disable it, the modal loads with the page. If you enable it, the modal doesn't load when the page loads. ▪ Select **Events** > **Add event mapping** to add an event handler to the modal. ▪ Select an event handler to apply to the modal. Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the user session for GraphQL, or a user session for Transform.
Custom	▪ Choose a layout for your modal. You can use a flexbox or CSS grid layout. These layouts let you add content in your modal however you want. ▪ Use styling options to change how your modal looks. You can apply any standard CSS styling to your modal, such as background color and padding. For more information about styling, see Change the default appearance of components.

Modal	Configuration
	▪ Add components to the containers within the custom modal. ▪ Select **Events** > **Add event mapping** to add an event handler to the modal. ▪ Select an event handler to apply to the modal. Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the user session for GraphQL, or a user session for Transform. 
Modal	Configuration



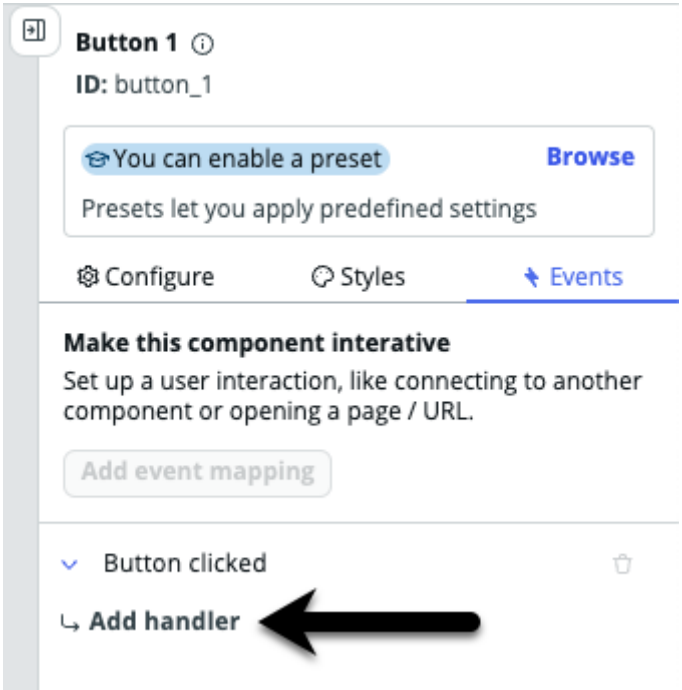
Modal	Configuration
iframe 	▪ Add a header, which is the title of the modal. ▪ Add a source URL that points to your existing iframe content. ▪ Set the parameters and initial data that you want to iframe. ▪ Choose the size of the modal on the screen. Select **Small**, **Medium**, **Large**, or **Fullscreen**. ▪ Turn on **disable sandbox** to lift the following restrictions: allow-forms, allow-modals, allow-popups, allow-presentation, allow-same-origin, allow-scripts, and allow-downloads options. Turn off the **disable sandbox** to only lift the allow-scripts option. ▪ Enable or disable **Defer modal content loading**. If you disable it, the modal loads with the page. If you enable it, the modal doesn't load when the page loads. ▪ Select **Events** > **Add event mapping** to add an event handler to the modal. ▪ Select an event handler to apply to the modal. Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the user session for GraphQL, or a user session for Transform. 
Modal	Configuration
Modal viewport	▪ Choose the size of the modal on the screen. Select **Small**, **Medium**, **Large**, or **Fullscreen**. ▪ Enable or disable **Hide Padding**. ▪ Enable or disable **Hide Close Button**. If you enable it, the close button does not display in the modal. ▪ Enable or disable **Defer modal content loading**. If you disable it, the modal loads with the page. If you enable it, the modal doesn't load when the page loads. ▪ Select **Events** > **Add event mapping** to add an event handler to the modal. ▪ Select an event handler to apply to the modal. Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the user session for GraphQL, or a user session for Transform.  ▪ Select the viewport component within the modal viewport.

Modal	Configuration
	


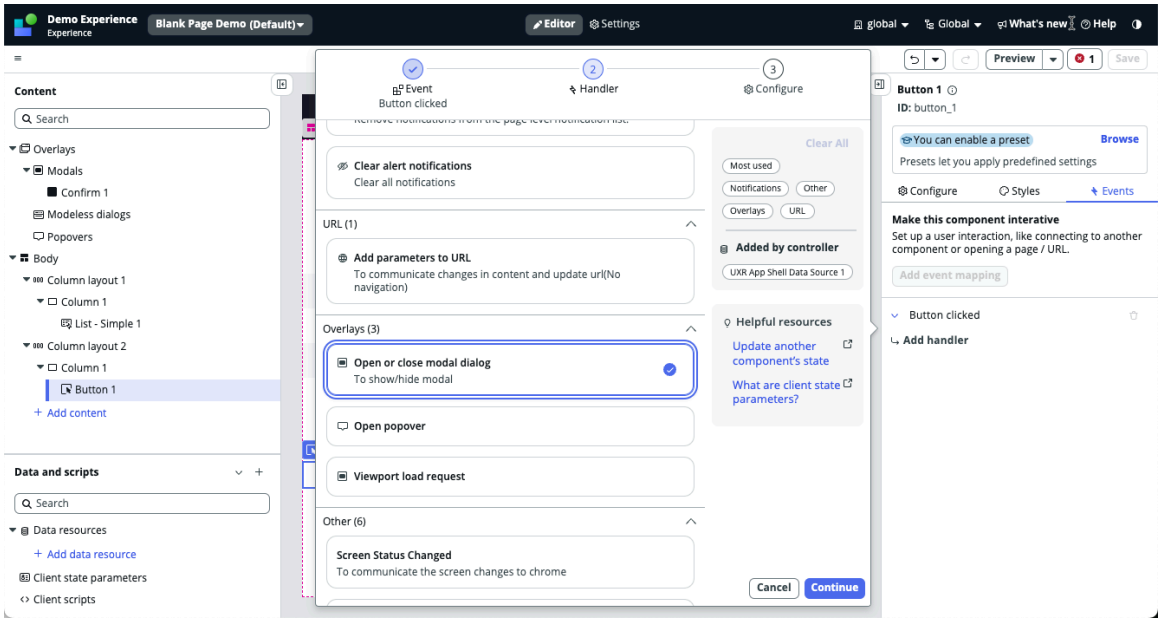


Modal	Configuration
	▪ Select **+ Add** in the Configure tab to add a page collection to the viewport. ▪ Select a page collection from the list and click **Add**.

5. Add a component to your page to trigger the modal you just added, such as a button component.
   See Add and configure components for more information.
6. Select the **Events** tab in the configuration panel.
7. Select **+ Add event handler**.

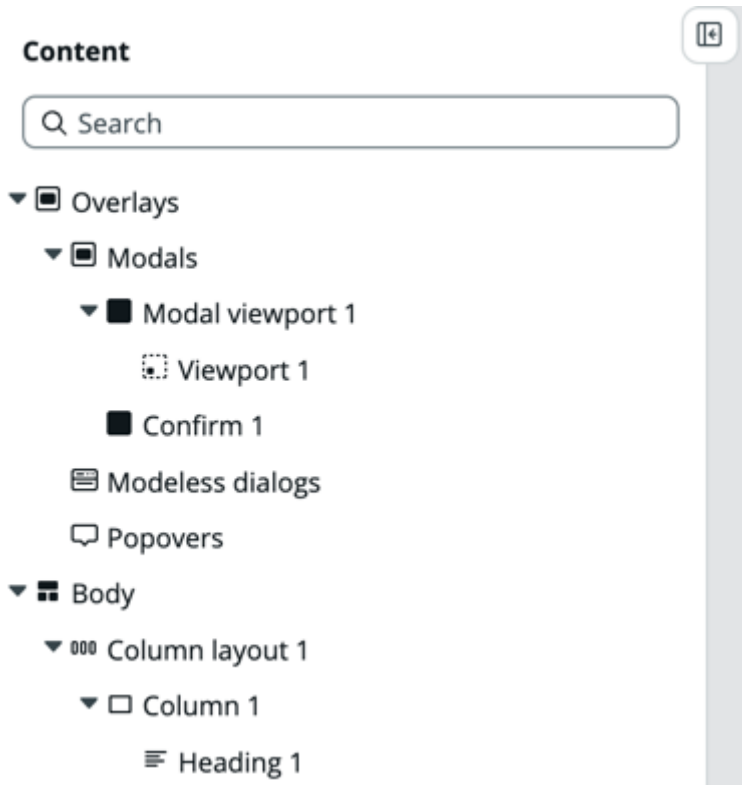


8. Select **Open or close modal dialog**.
9. Select the modal you created in the previous steps using the **Modal** drop-down.
10. Click **Add**.



11. When you finish configuring the modal, close it.

Notice in the content tree that the modals you create sit above the body of your page structure.



12. Click **Save**.

Extend your UI experience with viewport components

Viewports are specialized components that enable you to extend your experience without needing to own the parent page in UI Builder. You can work with viewports in three ways. You can add a viewport component or a viewport-enabled tab to a page, or add a viewport to the Contextual sidebar component.

Add a viewport component to your page to create separate content even if you do not own the content of the page itself. Create subpages, specify audiences, or customize content with

different data, routes, and screens. For more information about viewport components, see Add a viewport component to your page.

You can replace Tabs components with Viewport-enabled tabs as a way to display third-party custom data, assign audiences, and create variants. For more information about viewport-enabled tabs, see Replace a tab with a viewport-enabled tab.

Use the **Edit content** mode of UI Builder to add viewports or tab sets to a page or Contextual sidebar component. Edit tabs in a Contextual sidebar component as you would on a page using the **Config** panel. The main difference is, when you are in the **Edit content** mode of a tab, the page management area changes to **Tab management**.

Select the menu icon ⋮ to edit your tab settings, or change the required or optional parameters.

Add viewport modals to your experience to embed subpages or other experiences within a modal in your parent page/experience. For more information about adding viewport modals to your experience, see Add a viewport modal to your experience.

Add a viewport component to your page

Add a viewport component to your page and create a subpage to create separate content on the page.

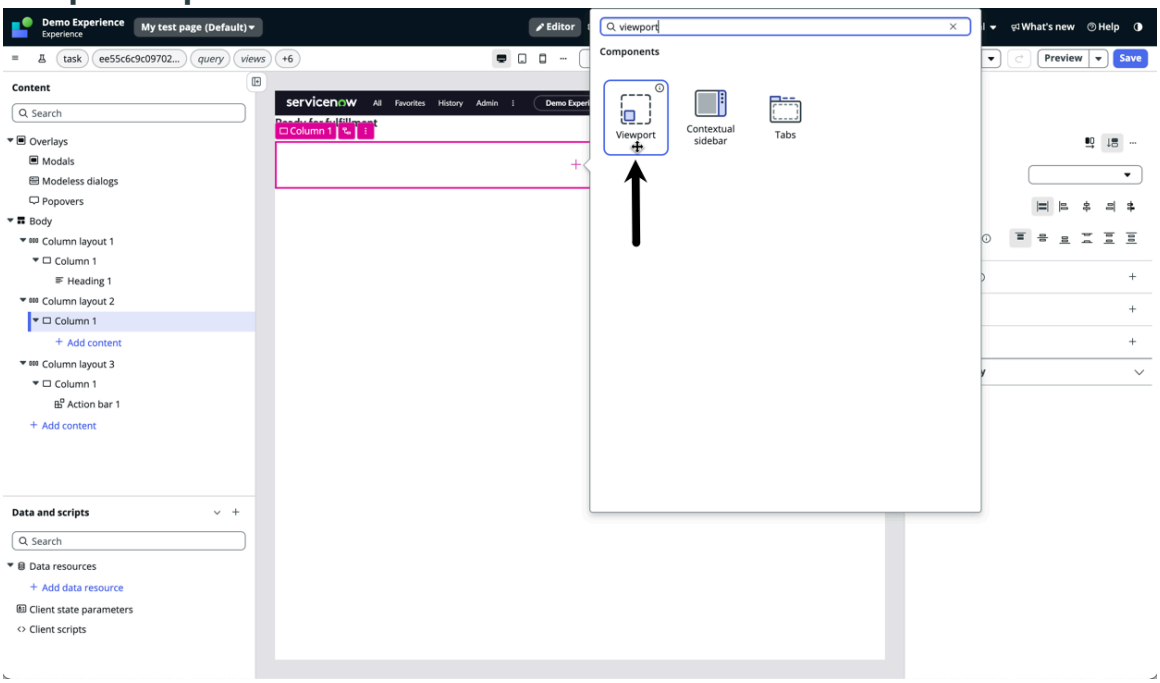
Before you begin

Role required: ui_builder_admin

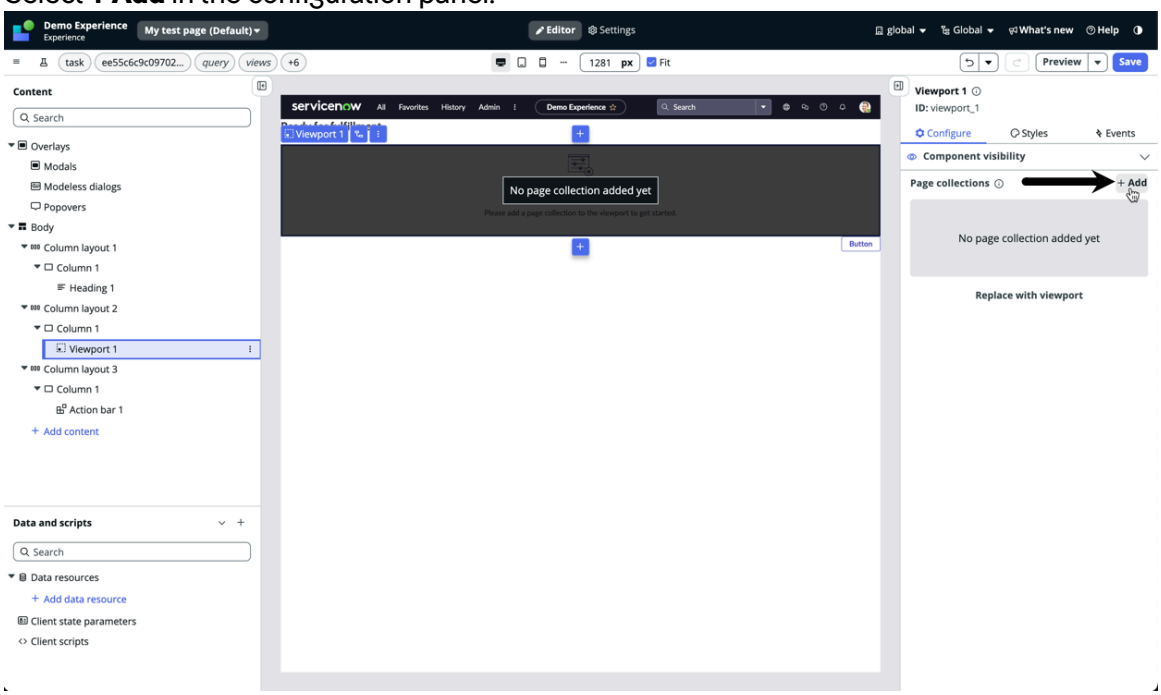
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Open the editor for the page variant that you want to add the viewport to. If you haven't created a page for your experience, follow the steps to Create a page in UI Builder.
4. Select **+ Add content** in the content tree.
5. Select a **Single column** layout.
6. Next, select the **+** icon in the column to open the toolbox.
7. Enter `viewport` in the search box.
8. Select **Viewport**.

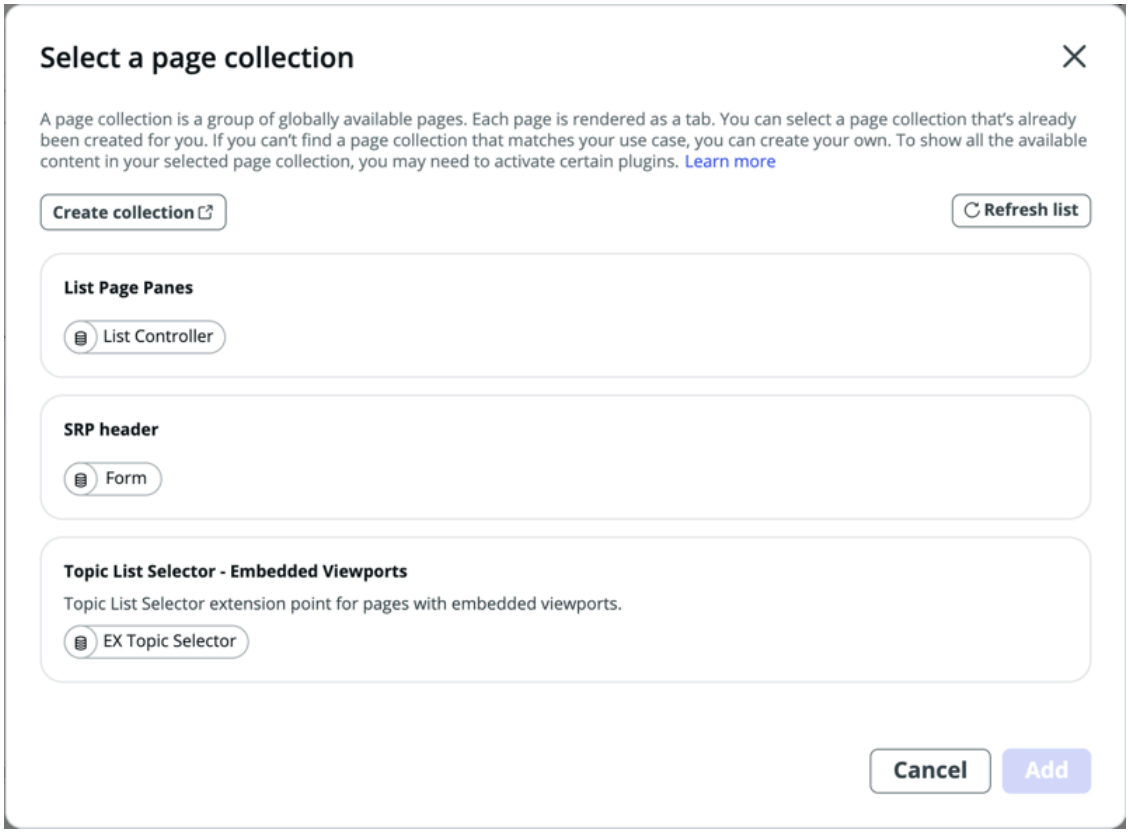
Viewport component



9. Select the viewport component in the content tree.
10. Select **+ Add** in the configuration panel.



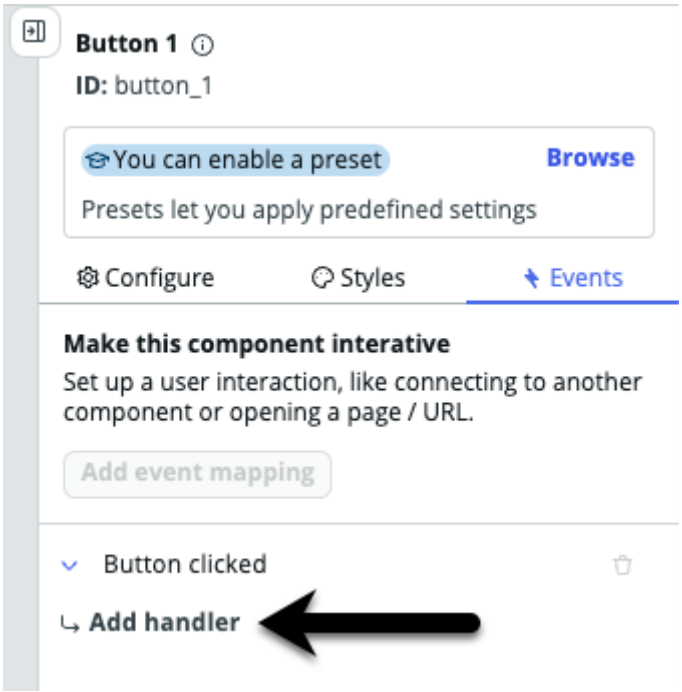
11. Select a page collection from the list or create a collection by selecting **+ Create collection**. For more information on creating your own page collection, see Create a page collection across multiple UI pages.



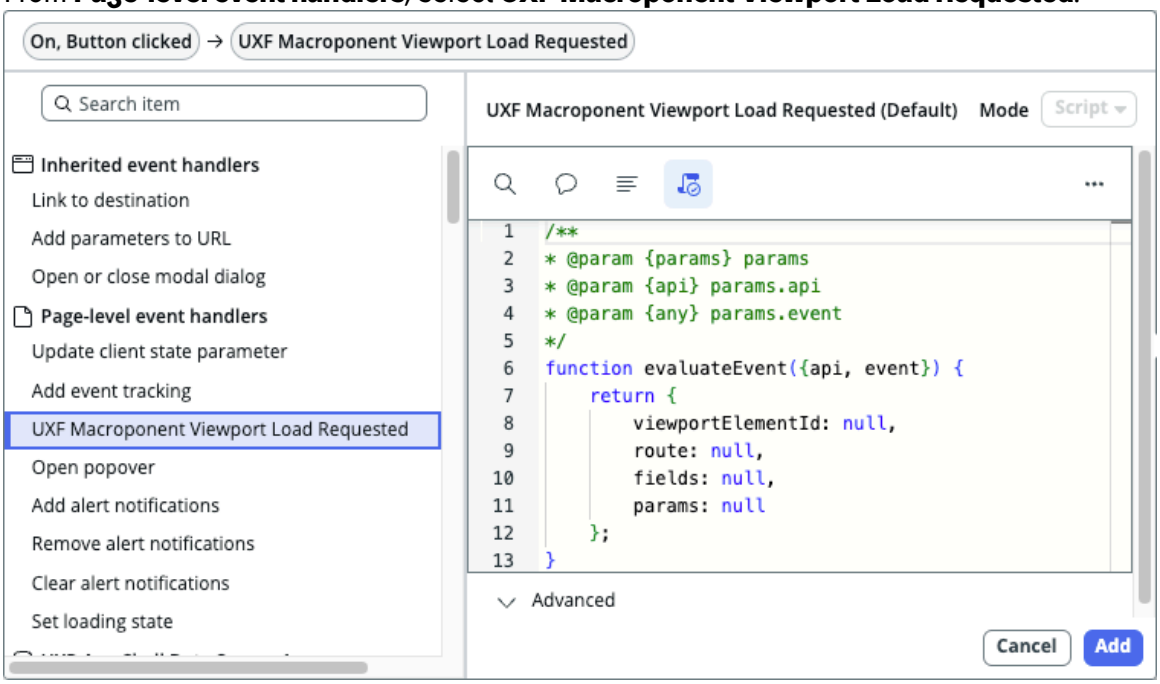
12. Select **Add**.
    The page collection displays in the **Page collections** section of the configuration panel. Only one page of the page collection displays in the staging area.
13. Select **Save**.
14. Locate the viewport ID and route.

    You can see the ID and route in the Config panel as shown in the following figure.

15. Add a component to your page to open the viewport you just added, such as a button component.
    For more information, see Add and configure components.
16. Select the **Events** tab in the configuration panel.
17. Select **+ Add event handler** to view the viewport.

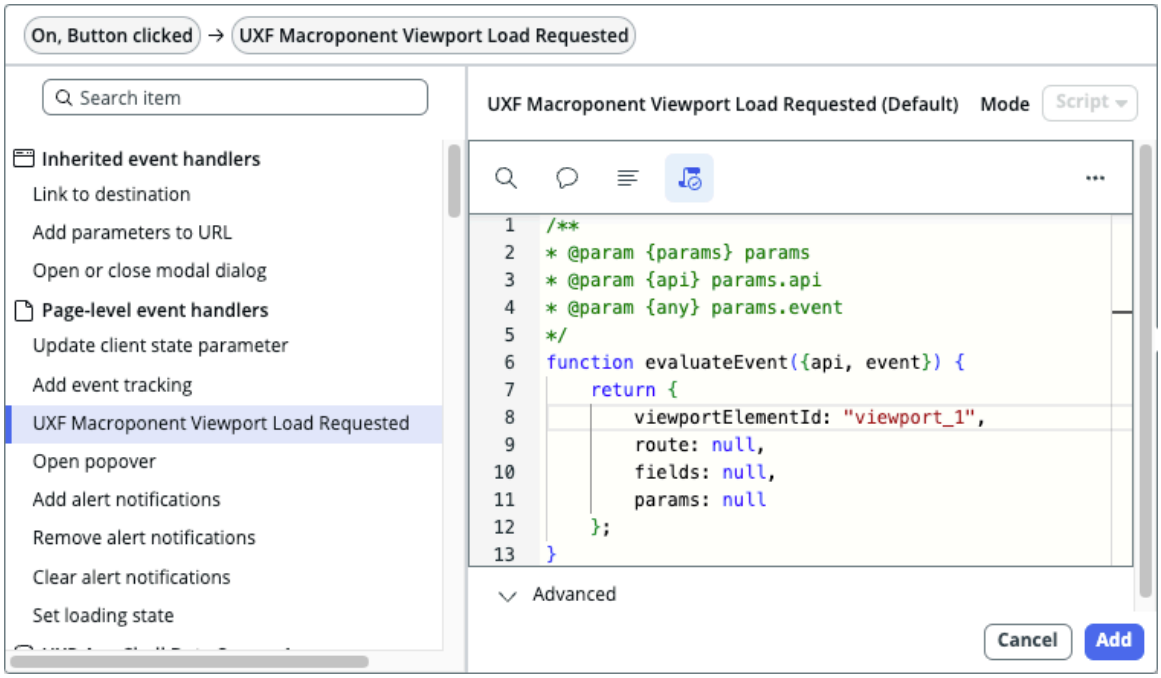


18. From **Page-level event handlers**, select **UXF Macroponent Viewport Load Requested**.



19. In the **viewportElementID** element, replace the `null` value with the viewport ID that you located in a previous step.
In this example, it is, `"viewport_1"`.

20. Select **Add**.



21. Select **Save**.
22. View and test your page by selecting Preview.

Add a viewport modal to your experience

Add a viewport within a modal in your experience.

Before you begin

Role required: ui_builder_admin

About this task

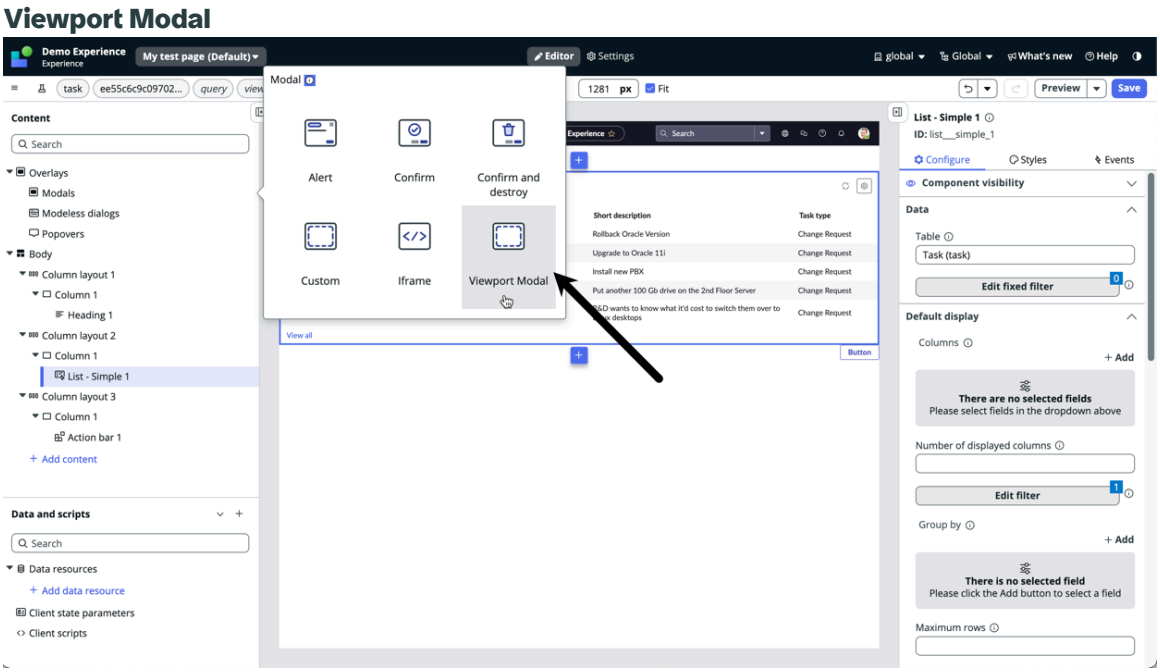
Use viewport modals to embed subpages or other experiences within a modal in your parent page or experience. Viewport modals can be opened via events or scripts. Viewport modals are limited to one subroute per viewport modal. You can create additional viewport modals for extra routes.

Note:
Legacy viewport modals cannot be upgraded and must be recreated to take advantage of the new functionality.

Procedure

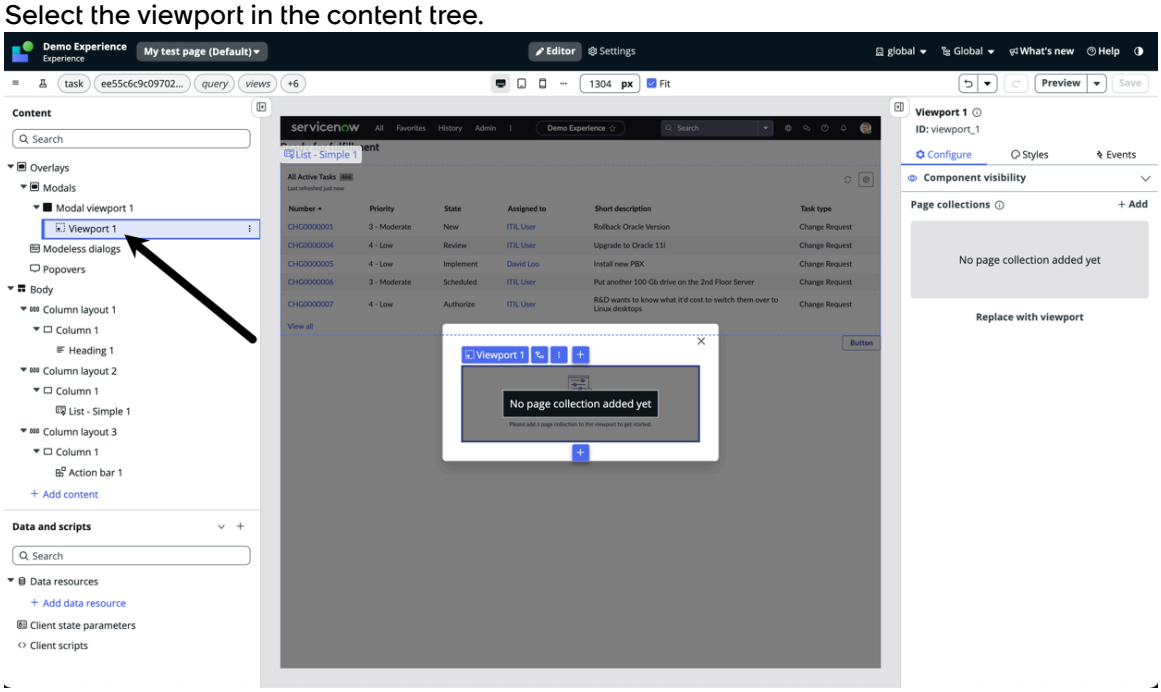
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information.
3. Open or create a page.
   If you open an existing page, ensure you are in the same scope as the original page. If not, change the scope before you start editing the page. Application scoping protects applications by identifying and restricting access to application files and data. Administrators set the scope to specify what parts of an application are accessible to other applications. Application scope protects data and application files. See Learn about security and roles for more information on application scope.
4. Select **+ Add content** in the content tree.
5. Select a **Single column** layout.

6. Select **+** next to **Modals** in the content tree.
7. Select **Viewport Modal** in the list.

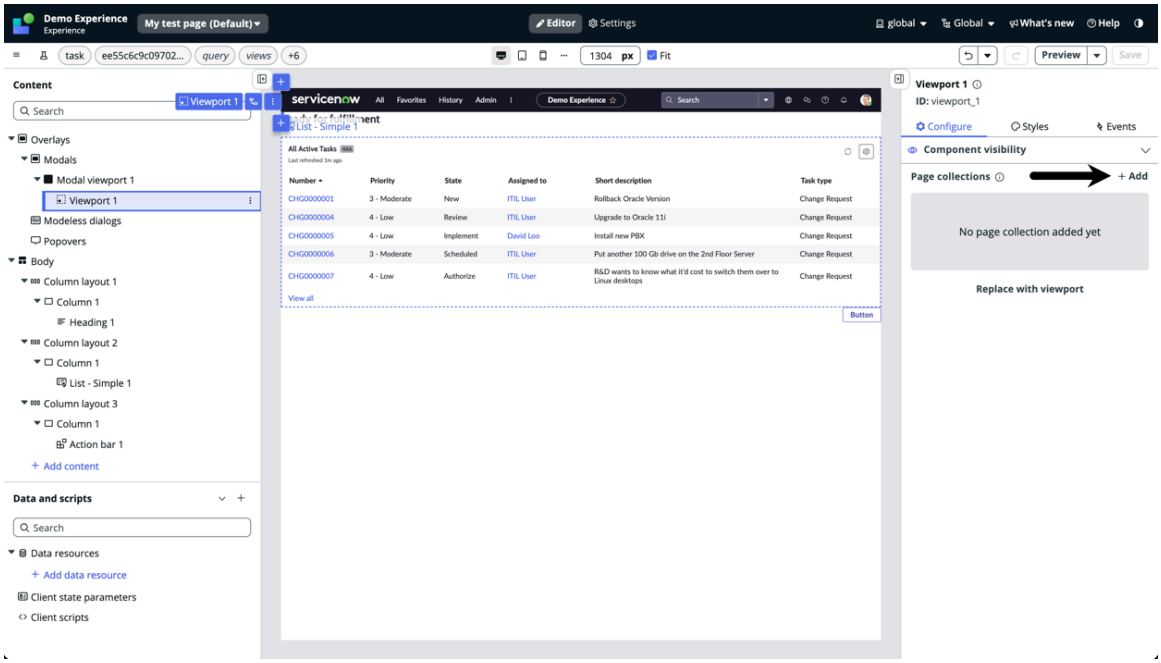


A viewport model appears above your page.

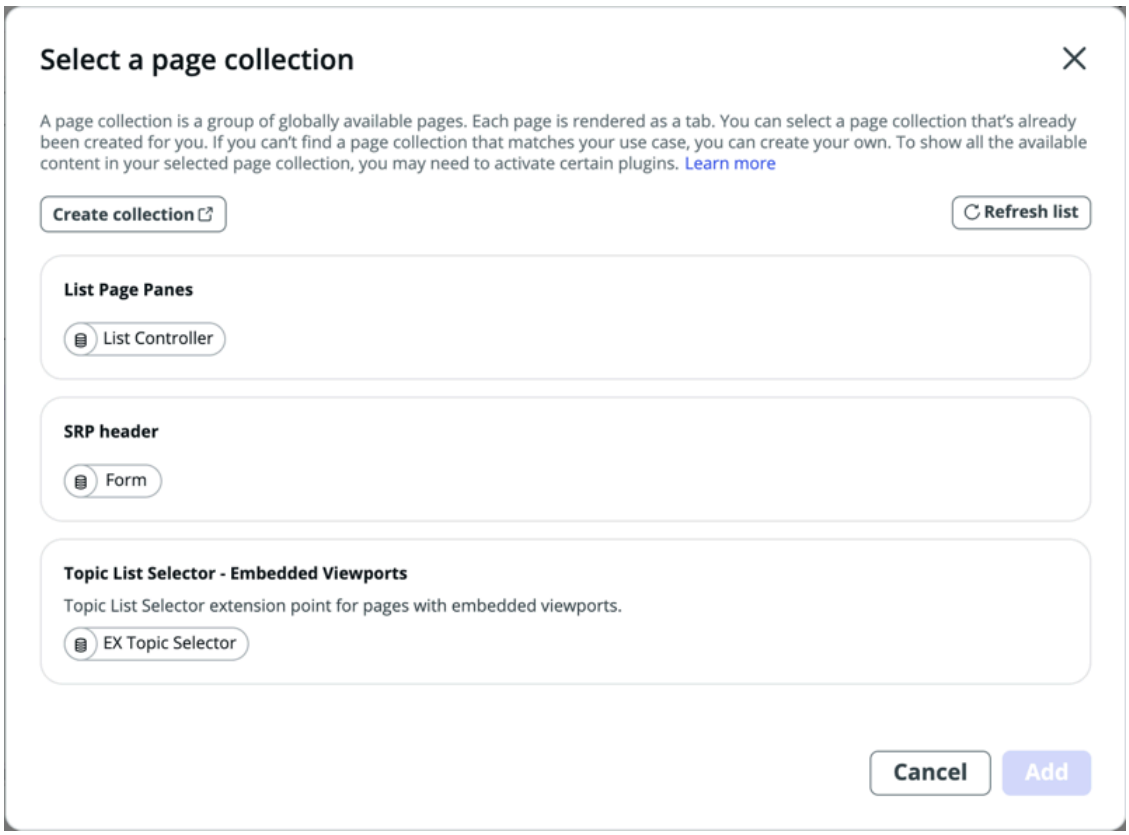
8. Click **Save**.
9. Select the viewport in the content tree.



10. Select **+ Add** next to **Page collections** in the configure tab.

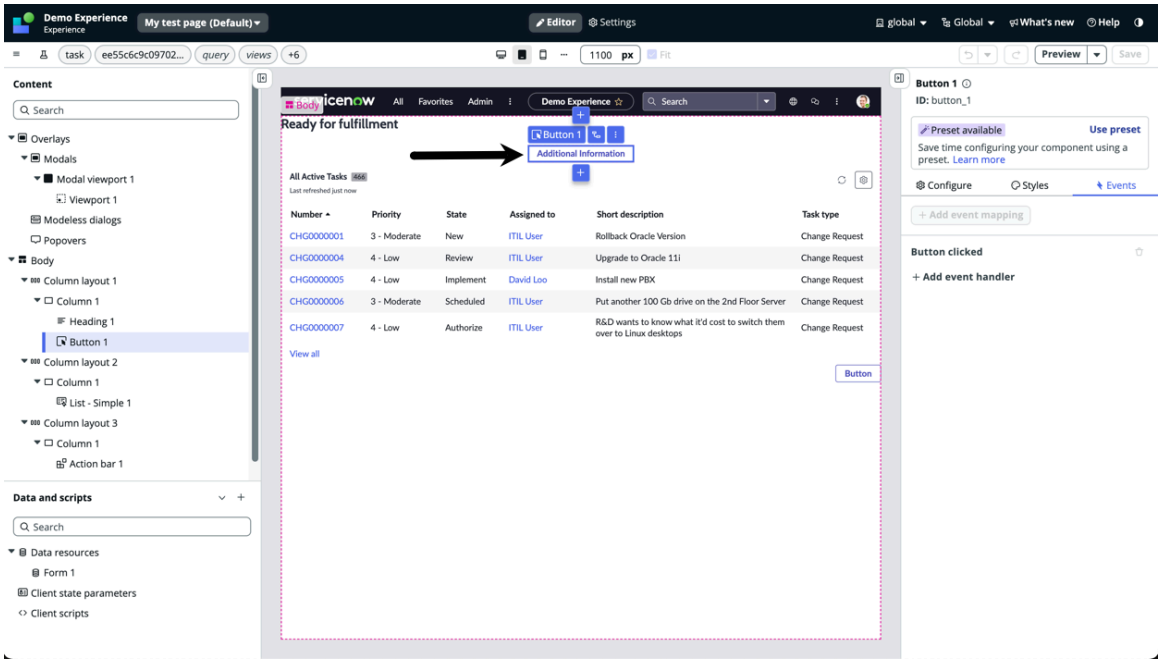


11. Select a page collection or create a new one.
    For more information, see Create a page collection across multiple UI pages.

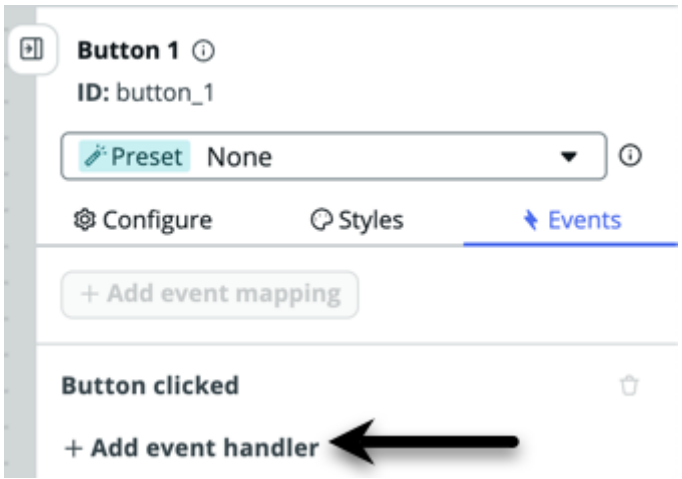


12. Click **Add**.
13. Click **Save**.
14. Add a component that opens the viewport modal.

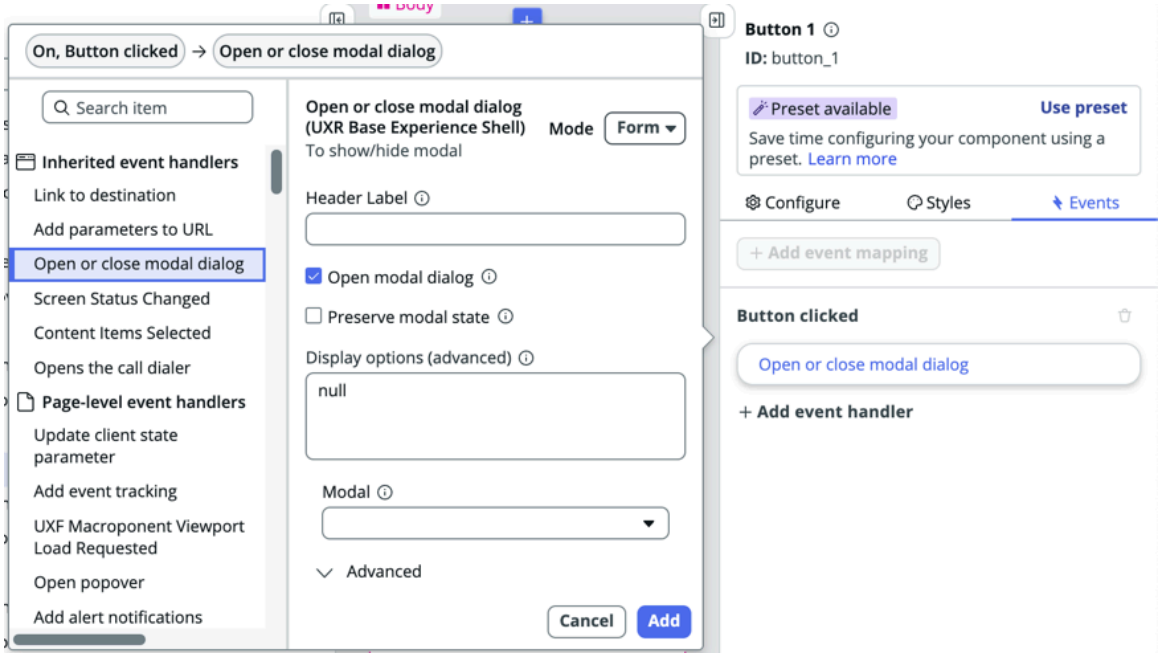
    The following example uses a button to open the viewport modal.



15. Select the **Events** tab.
16. Select **+ Add event handler**.



17. Select **Open or close modal dialog**.
18. Enable **Open modal dialog**.
19. Select the viewport modal that you created in the **Modal** dropdown.



The **Viewport ID** auto populates.

20. Select **Add**.
21. Select **Save**.
22. View and test your page by selecting Preview.

Replace a tab with a viewport-enabled tab

Convert a tab on a page to a viewport-enabled tab. Use viewport-enabled tabs to display third-party custom data, assign audiences, and create variants.

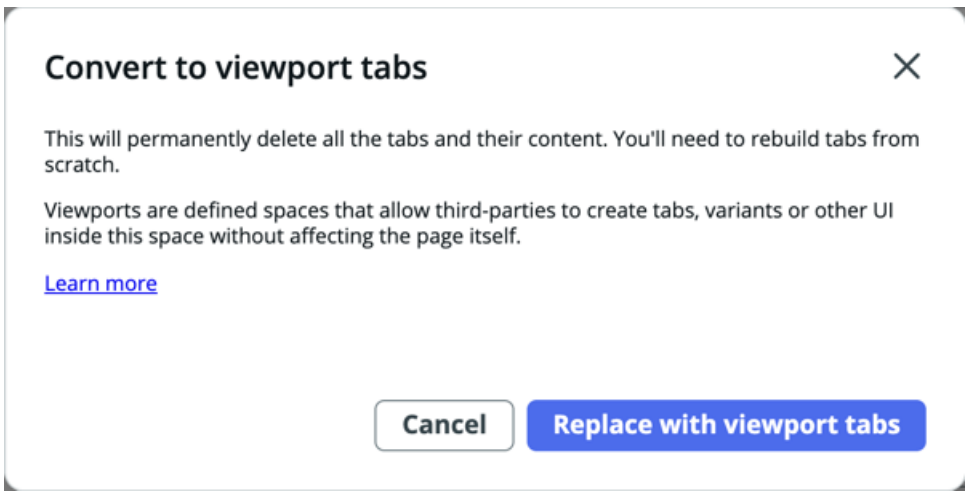
Before you begin

Role required: admin

About this task

Replace your tab or tabs with viewport-enabled tabs.

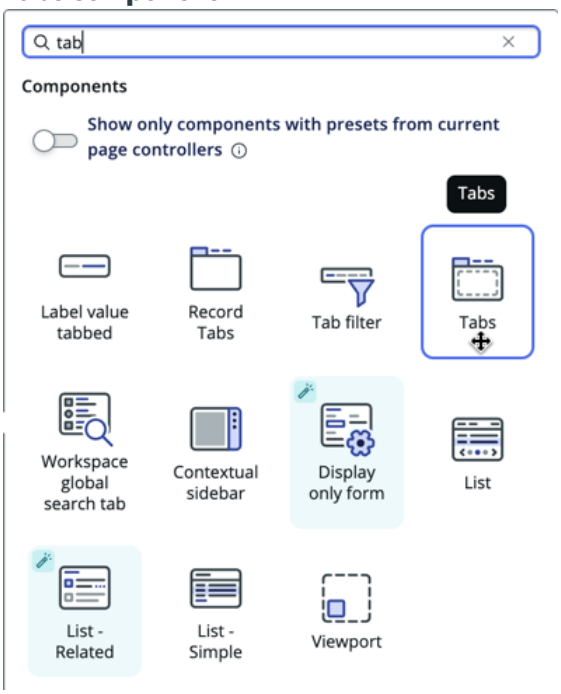
Note:
Replacing a tab with a viewport-enabled tab is a permanent and one-way process. You lose any existing tab content and must recreate the viewport tab content.



Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page with existing tabs, or add a **Tabs** component to your page.

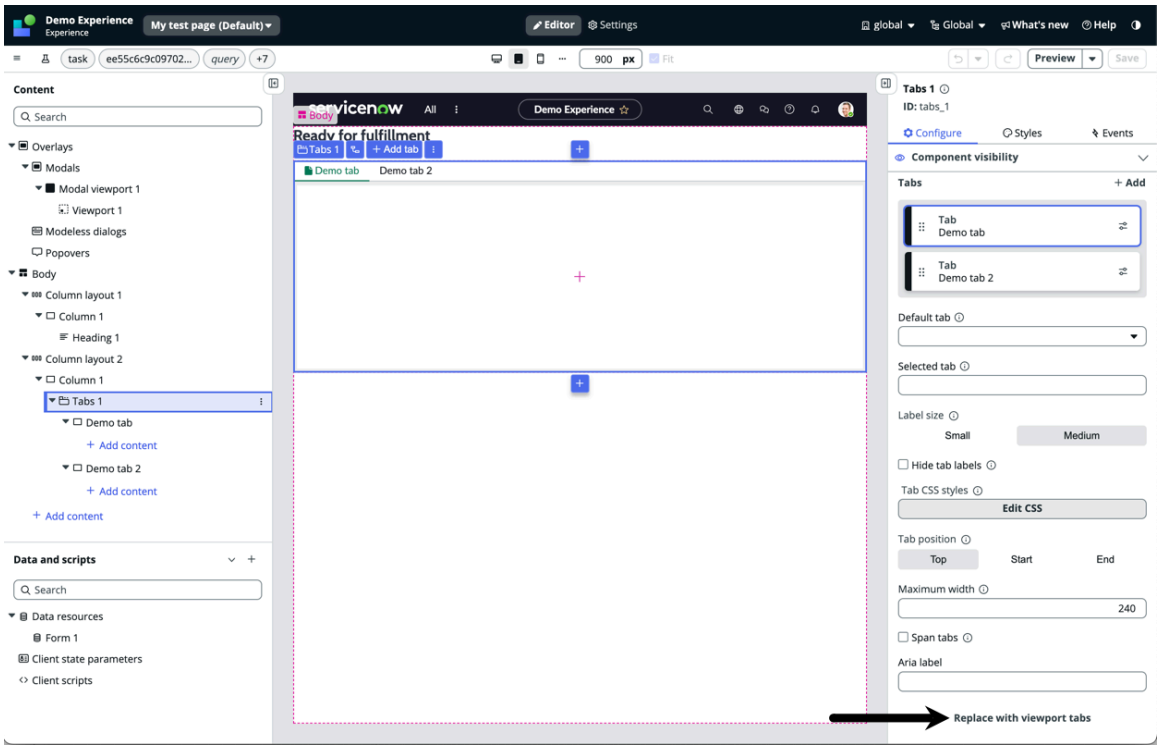
Tabs component



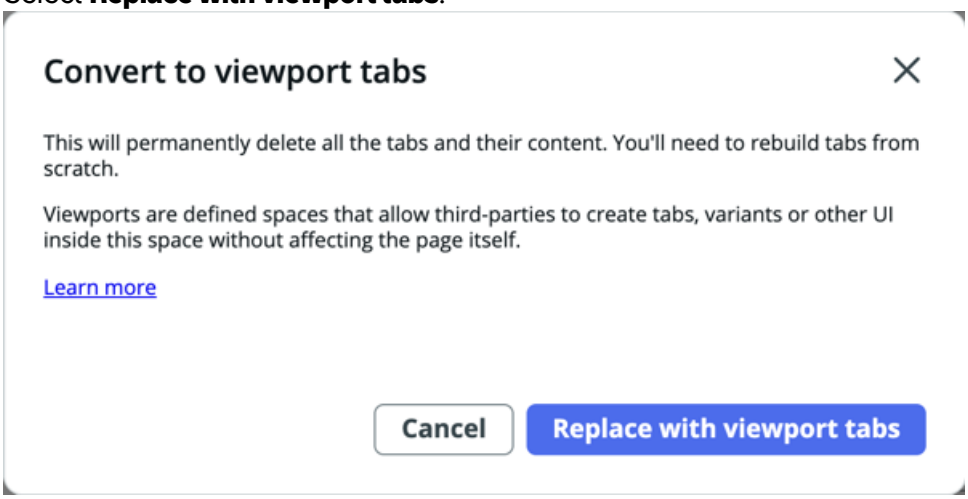
For more information on how to add a Tabs component to a page, see Add tabbed content to UI Builder pages.

4. Select the tabs component that you want to replace with viewport tabs in the content tree.
5. Select **Replace with viewport tabs** in the configuration panel.

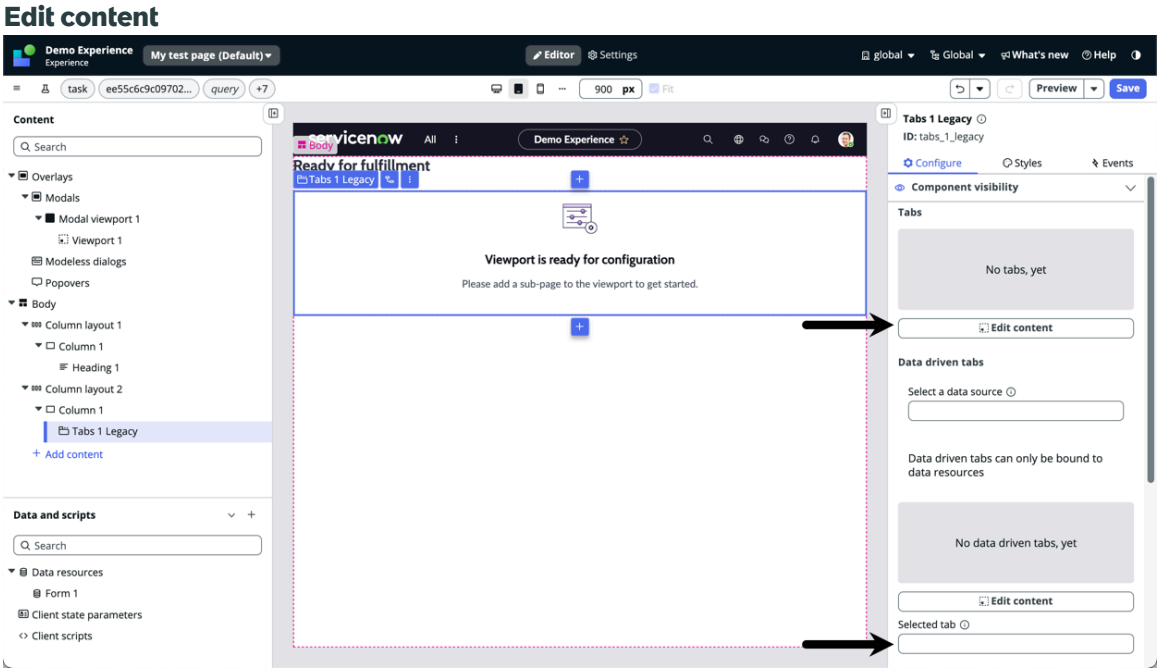
Note:
Replacing a tab with a viewport-enabled tab is a permanent and one-way process. You lose any existing tab content and must recreate the viewport tab content.



6. Select **Replace with viewport tabs**.



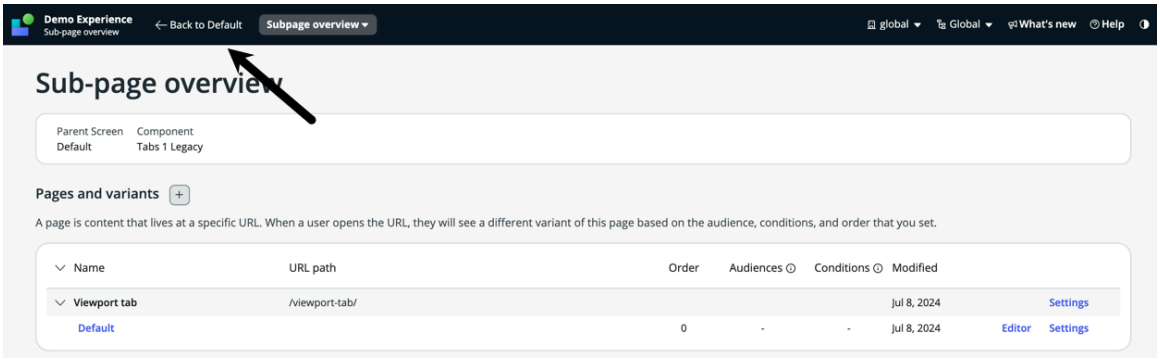
7. Click **Edit content** to add a viewport-enabled tab.



For more information on viewport components, see Add a viewport component to your page.

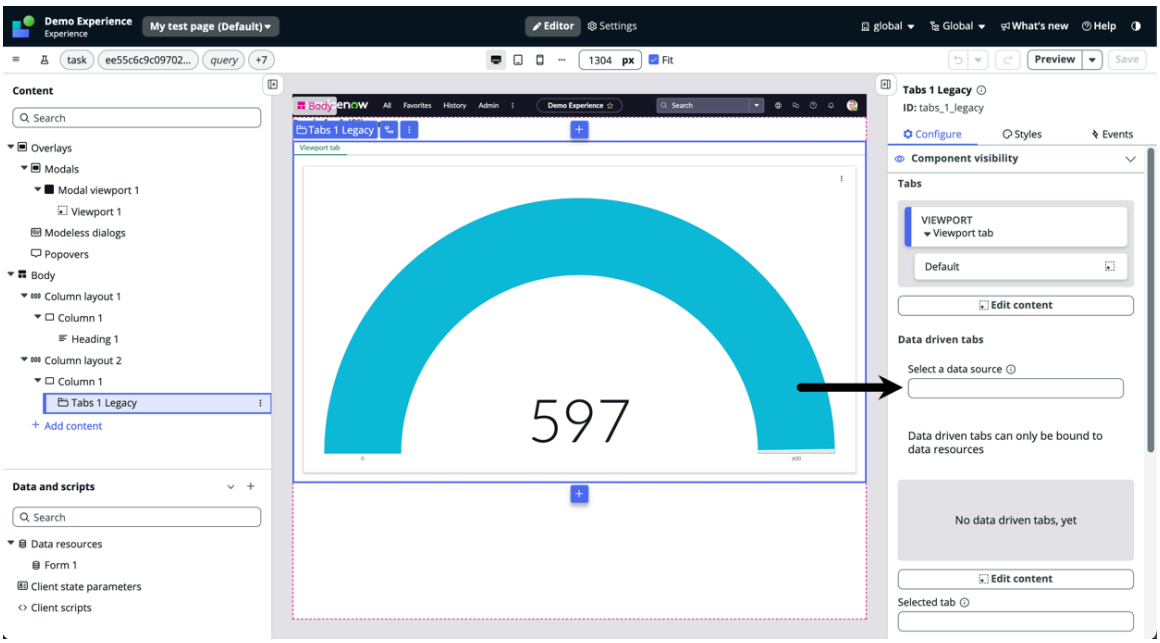
8. Select **Save and continue**.
   The sub-page overview page appears.
9. Select **Create new page.**
10. In the **Name** field, enter a name for your viewport-enabled tab.
11. Keep the default path, or change it to your preference.
12. Select **Continue**.
13. In the **Name** field, enter a name for the page variant or leave it as **Default**.
14. Add one or more audiences for this page.
    If an audience you need is not listed, you can choose the **View all available audiences** to create one.
15. **Optional:** Declare conditions for when to display the page or tab by either using the provided dropdown menus or writing an encoded query string.

    (Optional) For more information on writing encoded queries, see Encoded query strings.
16. Select **Open in editor**.
17. Add components to your tab as you would to a page.
18. Add an event handler to any components to make them perform actions, such as loading page content.
    For more information about event handlers, see Manage actions in UI Builder pages.
19. Select **← Back to (name of page)** to return to your original page.

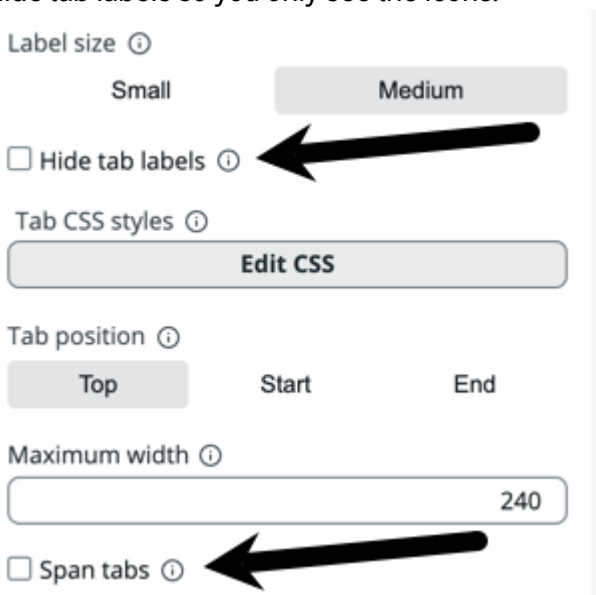


20. In **Data driven tabs**, select a data source to bind data to your viewport-enabled tab using data resources to dynamically expose your data from tables and records.

You then bind these data properties to components in your tab. For more information about using data resources, see Dynamically expose data in UI Builder pages (advanced feature).



21. Choose where the viewport-enabled tab labels appear on the page and decide whether to hide tab labels so you only see the icons.



Create popovers in UI Builder

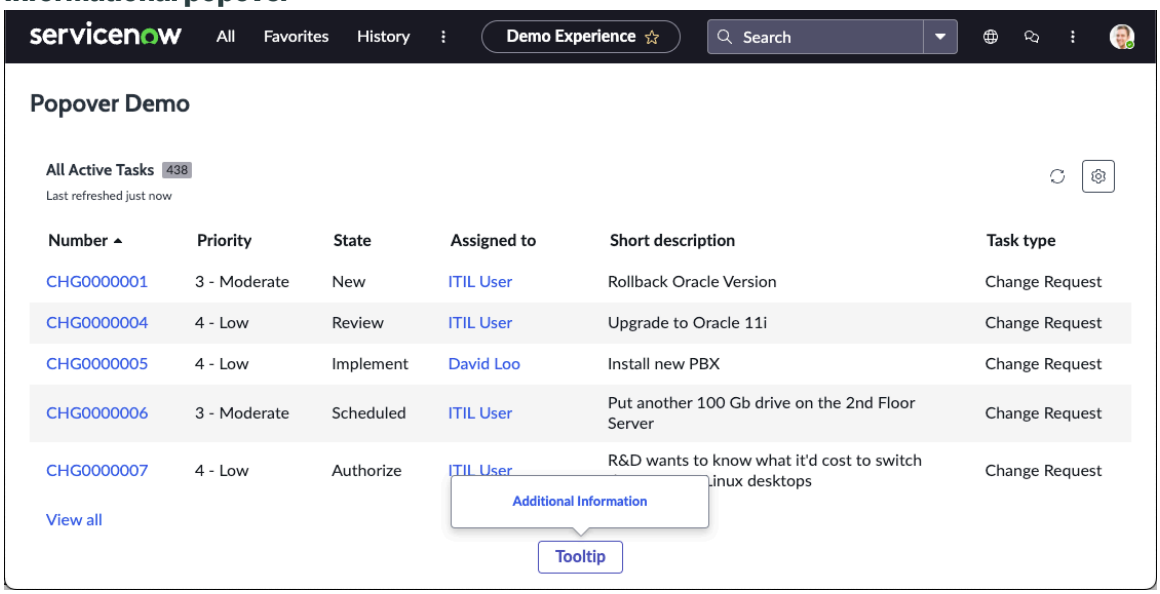
Use popovers on a UI Builder page to overlay contextual information or functionality to help users complete tasks.

A popover is a small window or dialog box that appears above a UI Builder page and contains additional information, options, or actions related to the content or task at hand. Add components to a popover in the same way you add modals to a page.

You can place popovers anywhere on a UI Builder page where you think additional information helps the users. Popovers are intended to provide small pieces of information or links to related content, so you should limit the amount of information or functionality within a popover because the popover only displays when a user is interacting with it.

You can make popovers visible or hidden with event mapping, such as triggering a popover to appear when selecting a button or pointing to a part of the page. For more information, see Define map events.

Informational popover



Add popover to a UI Builder page

Learn how to add a popover in UI Builder. A popover is a container that appears above a page when you click a component. For example, a popover might display contact information when selecting a persons name in a list.

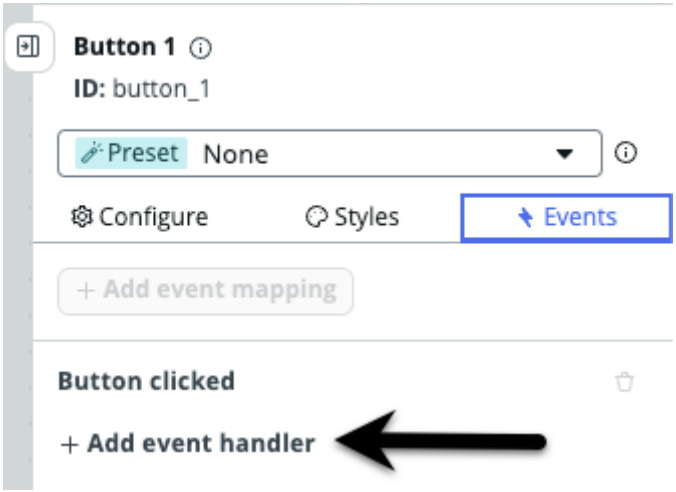
Before you begin

Role required: admin

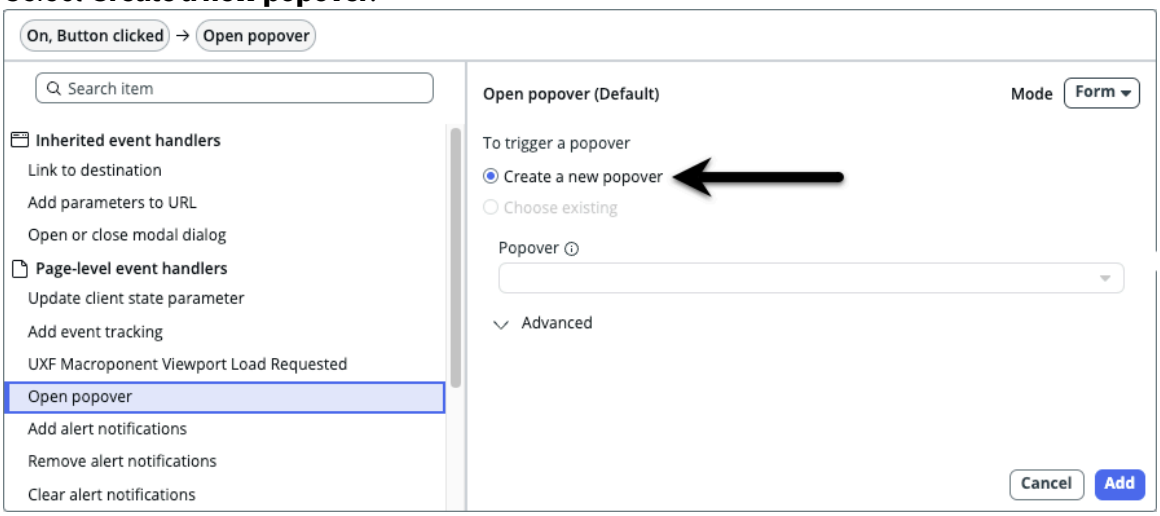
Procedure

1. Navigate to **All** > **Now experience framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Open or create a page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Add a component to your page that you want to trigger a popover, such as a button component.
   See Add and configure components for more information.

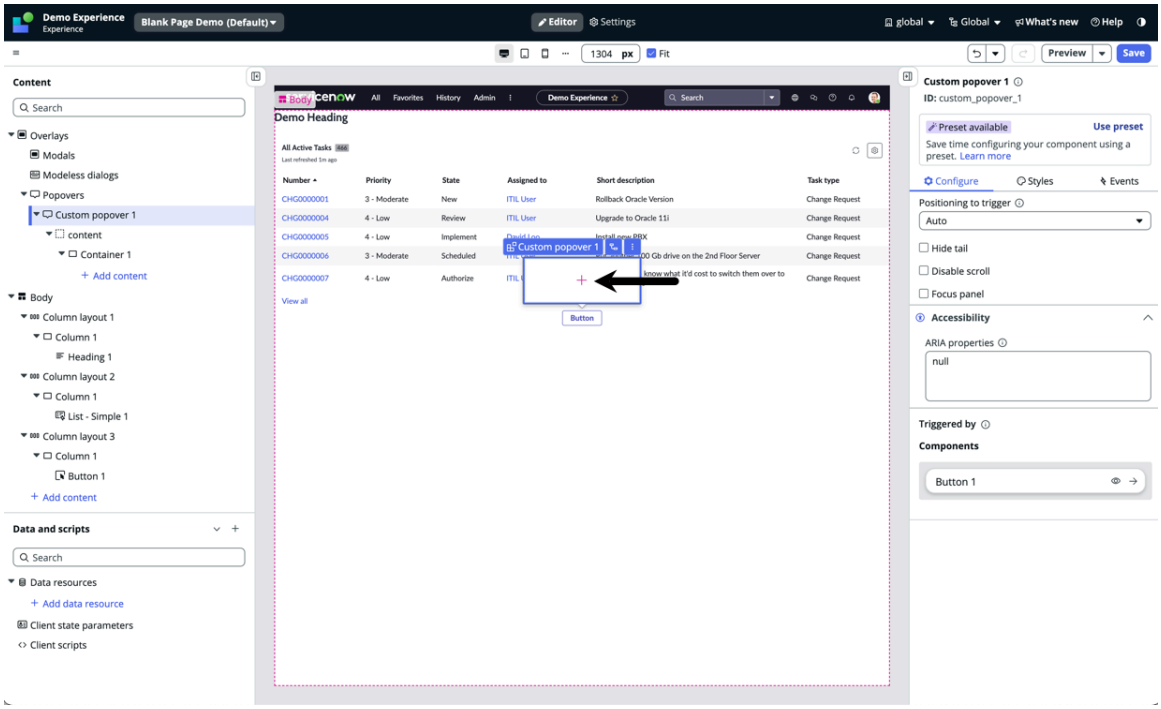
5. Select the **Events** tab in the configuration panel.
6. Select **+ Add event handler**.



7. Select **Open Popover**.
8. Select **Create a new popover**.

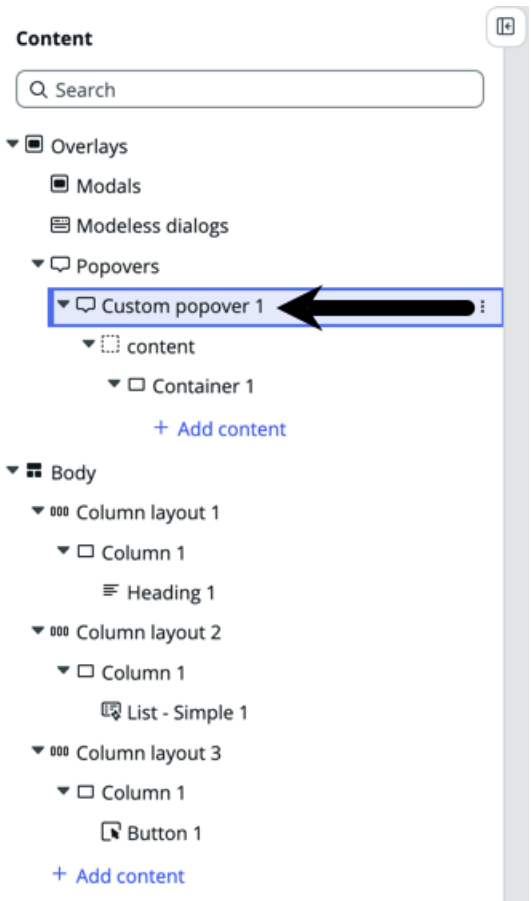


9. Select **Add**.
   The popover appears above the stage.
10. Add components to the popover by selecting the **+** icon.



11. When you finish configuring the popover, close it.

Notice in the content tree that the popovers you create sit above the body of your page structure.



12. Click **Save**.

13. Select **Preview** in the UI Builder header.
14. Click on the button to test the popover.

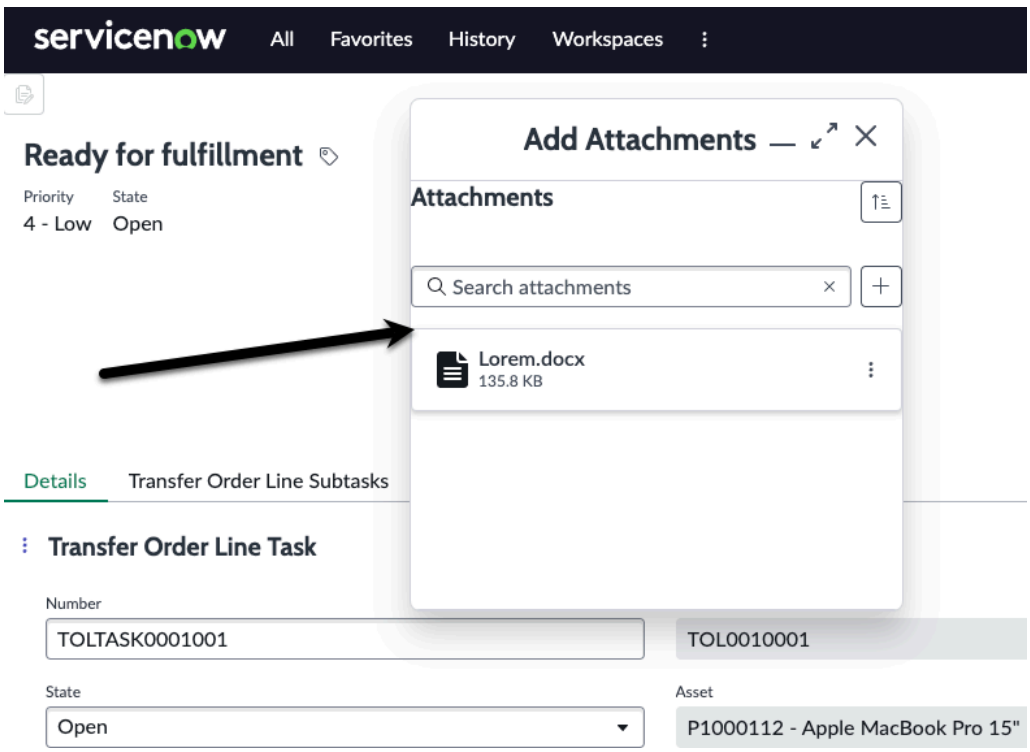
Create modeless dialogs in UI Builder

Use modeless dialogs on a UI Builder page to add a floating window that enables you to interact with both the window content and the page content below.

The Modeless Dialog component is a floating window containing components and content that appears over a UI Builder page. You can do actions in the modeless dialog while still viewing and interacting with the page below. Multiple modeless dialog windows can be added to a single page. Modeless dialogs can be resized, moved to a new position on a page, and minimized.

Modeless dialogs are different than modals, which pop up but block interaction with the page until the modal is closed. Modeless dialogs are also different than popovers, which close after you click outside the popover.

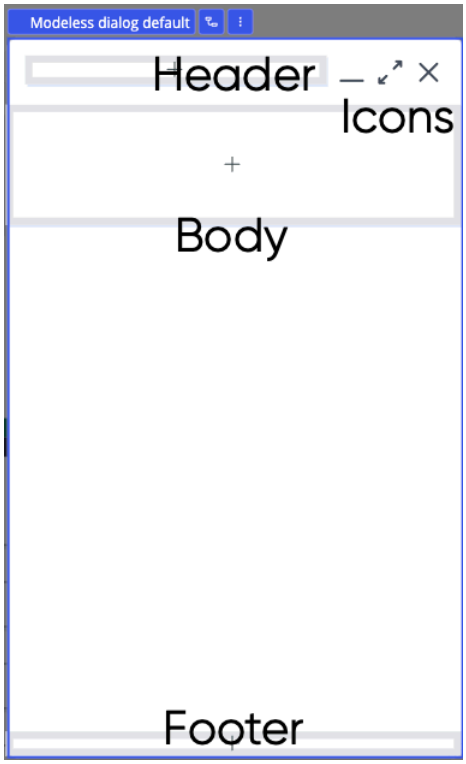
Common modeless dialog use cases include creating a record, composing an email, using chat, adding work notes or comments, reading help information, or adding/viewing attachments in the modeless dialog.



Anatomy of a modeless dialog

A modeless dialog consists of three parts:

- When you add a modeless dialog to a page, the header includes a preconfigured minimize icon, expand icon, and close icon. Other actions can be configured if needed, for example, configure an action in a button to open the modeless dialog in a new tab.
- Add any component from the UI Builder toolbox, for example, Email composer, Attachments, or Agent chat, into the body. You can apply layouts and configure the component as if you were adding the component to a page.
- If needed, provide additional buttons or content in the footer at the bottom of the modeless dialog.



Add modeless dialog to a UI Builder page

Learn how to add a modeless dialog in UI Builder. A modeless dialog is a floating window containing content above a page.

Before you begin

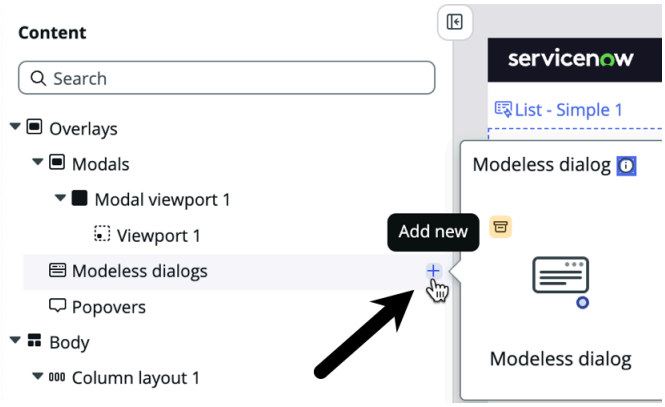
Role required: ui_builder_admin

The following steps walk you through the process of configuring a button to open a modeless dialog containing the Attachments component.

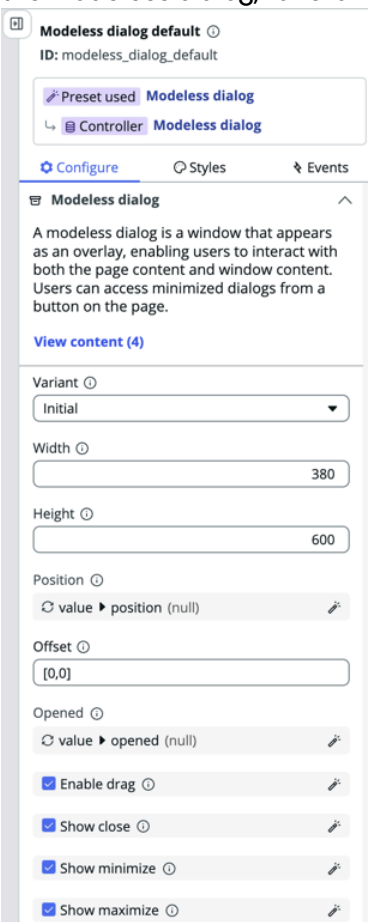
Note:
The procedure outlined here is just one example of how to use modeless dialogs. There are infinite possibilities. Add and configure modeless dialogs to meet your business needs.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Open or create a page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. In the content tree, move your mouse to **Modeless dialogs**, select the + icon, and select the **Modeless dialog** component.



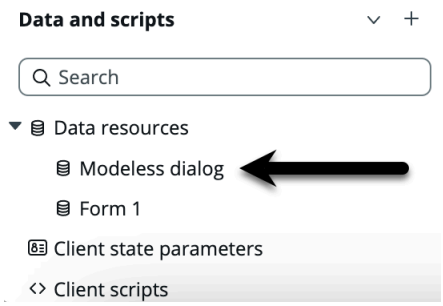
5. If the modeless dialog doesn't appear on the stage automatically, select the new modeless dialog named **Modeless dialog default** in the content tree.
6. In the configuration panel **Configure** tab, view the presets that were added automatically with the modeless dialog, for example, the width, height, position, and enable drag setting.



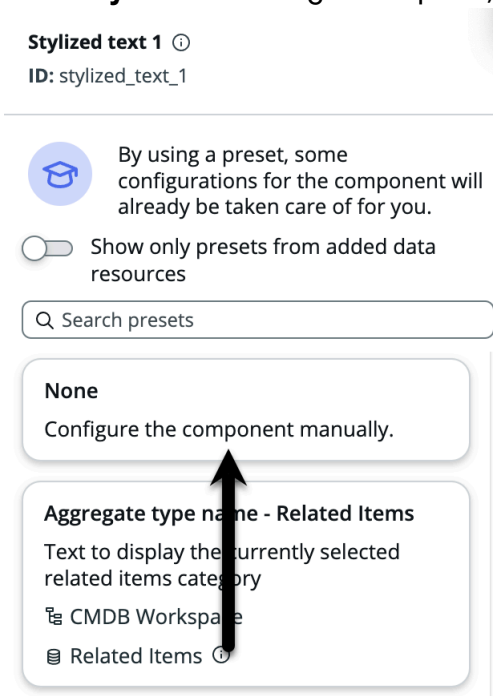
All of these preset properties can be edited, if necessary.

Note:
For more information about Modeless Dialogs advanced properties, see the ServiceNow Developer site.

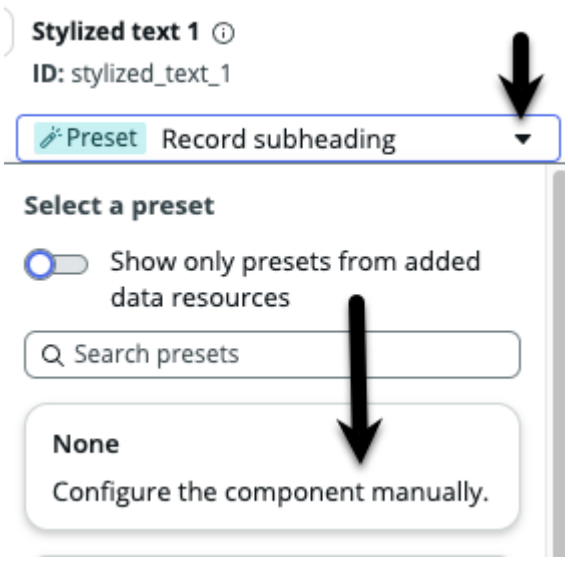
7. In the data resources drawer, the **Modeless dialog** controller was added automatically.



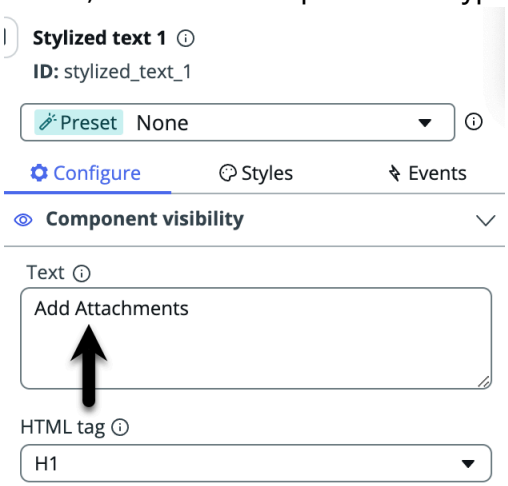
8. In the content tree, select **+ Add content** under **Modeless dialog default > actions** to add content to the modeless dialog header.
9. Search for and select the **Stylized text** component.
10. In the **Stylized text** configuration panel, select **None** to configure the component manually.



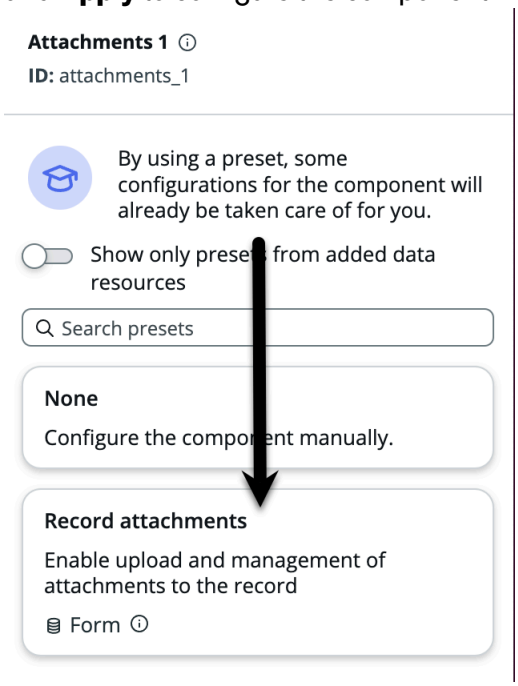
If the **Record subheading** preset was automatically added, select the drop-down arrow, select **None**, and select **Remove** on the **Configure** tab.



11. If not open already, select **Configure** to open the configure tab.
12. In **Text**, remove the sample text and type `Add Attachments`.



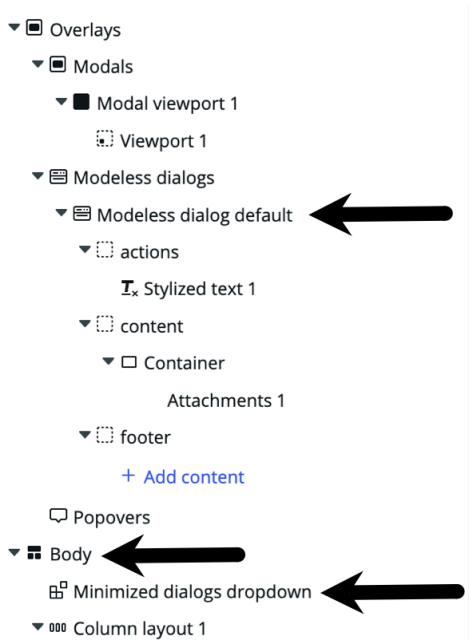
13. Select **Save** in the UI Builder header.
14. In the content tree, select **+ Add content** under **Modeless dialog default > content > Container** to add content to the modeless dialog body.
15. Select the **Attachments** component.
16. In the **Attachments** configuration panel, if not selected already, select **Record attachments** and **Apply** to configure the component with a preset.



For more information about configuring the Attachments component, see the ServiceNow Developer site.

17. You could add content to the modeless dialog footer, but in this example leave the footer empty.
18. Select **Save**.
Notice in the content tree that the modeless dialog and all of its components are listed above the **Body** of your page structure. Also, the **Minimized dialogs dropdown** component is added

to the page automatically (and is listed under the **Body** in the content tree) to provide the functionality for the minimize icon in the modeless dialog header.



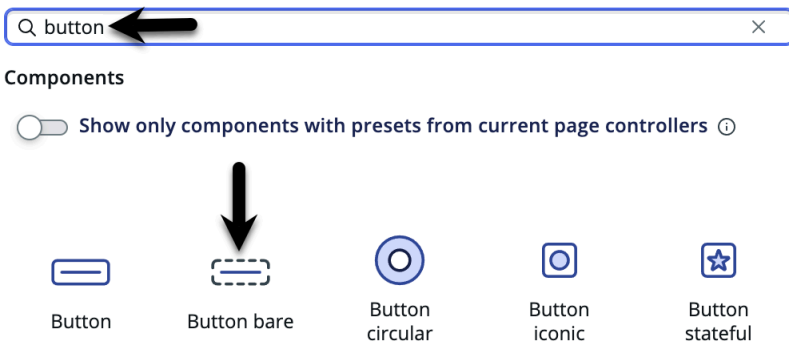
19. In the content tree, select **Body**.
20. Add a button component and configure it to open the modeless dialog.

    a. In the content tree, select the **Menu** icon next to **Body** and select **Add content**.

    b. On the **Layouts** tab, select **Single column**.
    A new column layout containing a single column is added to the bottom of the page.

    c. On the stage, select the + icon in the new column layout.

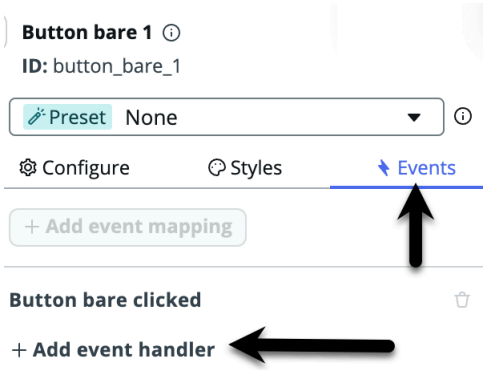
    d. Search for and select the **Button bare** component.



e. In the configuration panel, on the **Configure** tab, select **None** to configure the component manually.

f. Select the **Events** tab in the configuration panel.

g. Select **+ Add event handler**.

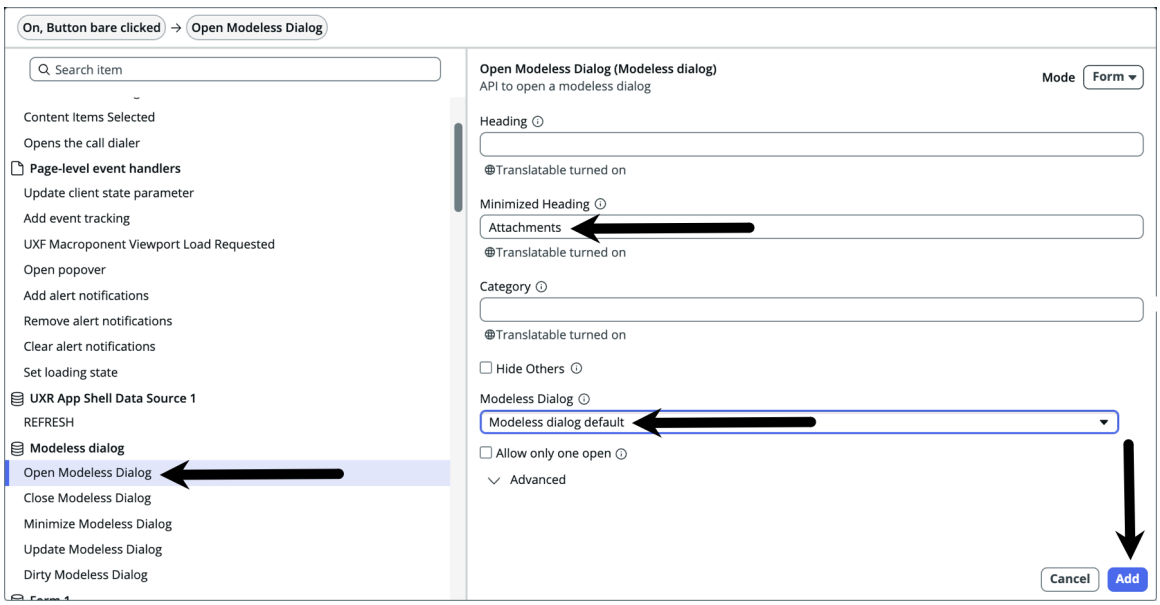


h. In the list at left, select **Open Modeless dialog** (you may need to scroll down in the list).

i. Type `Attachments` in **Minimized Heading**.

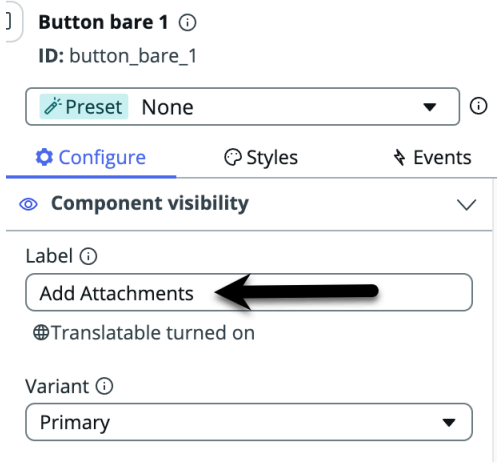
j. Select **Modeless dialog default** in **Modeless dialog**.
There are other options that can be configured here, including a heading and a category.

k. Select **Add**.



l. Select the **Configure** tab.

m. Type `Add Attachments` in **Label**.



21. Select **Save**.
22. Select the drop-down arrow next to **Preview** in the UI Builder header and select **Open URL path** in the list.
23. Select the **Add Attachments** button to test the modeless dialog.
    The modeless dialog opens above the main page with the heading at the top and the Attachments component below.
24. To test the minimize functionality, select the minimize icon on the modeless dialog.

    The modeless dialog is minimized and can be accessed from the Minimized dialogs drop down.
25. Select the minimized dialogs icon and then select **Attachments** to open the modeless dialog window again.

Add modeless dialog event to a UI Builder page

Learn how to add and configure a modeless dialog event, such as open, close, or minimize in UI Builder. A modeless dialog is a floating window containing content above a page.

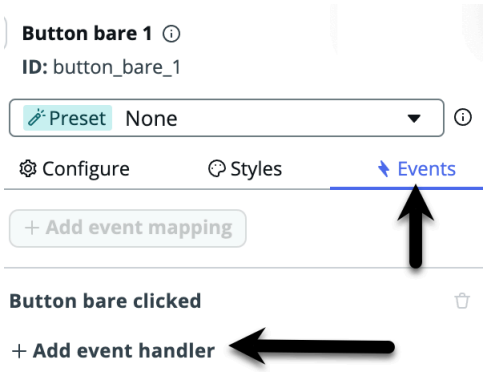
Before you begin

Role required: ui_builder_admin

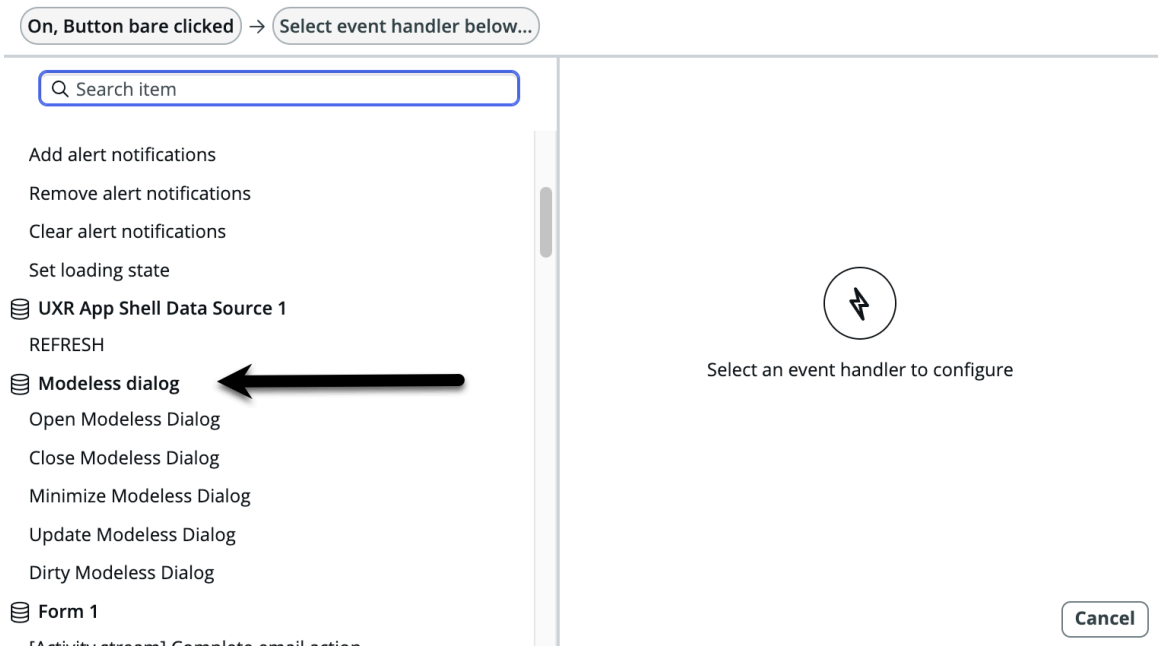
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.

3. Open or create a page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Add a modeless dialog to the page.
   For more information about how to create a modeless dialog, see Add modeless dialog to a UI Builder page.
5. Add a component to the page, such as a button, to take action on the modeless dialog.
   For more information about how to create a button that interacts with a modeless dialog, see Add modeless dialog to a UI Builder page.
6. Select the button component in the content tree or on the stage.
7. In the configuration panel, select the **Events** tab.
8. Select **+ Add event handler**.



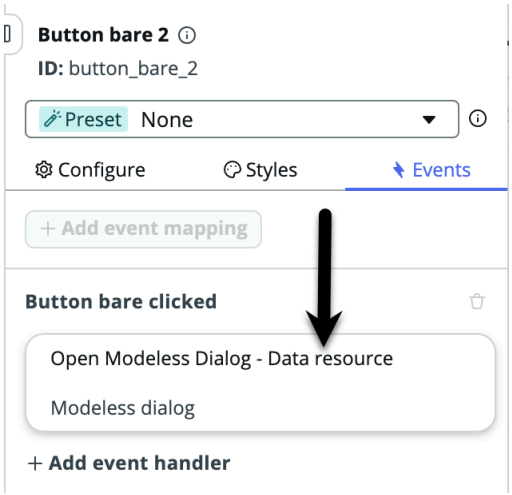
9. From the Event handler preview window, select an action to assign to the button.
   There are five modeless dialog event handlers available.



Note:
For any of the event handlers, select **Script** in the **Mode** drop-down if you prefer to work in the script editor.

10. Select **Add**.

Result
The configured event handler displays in the configuration panel **Events** tab for the component.



Manage actions in UI Builder pages

Learn how to work with events so that you can add actions to components, pages, data resources, and declarative actions in UI Builder.

Actions in UI Builder

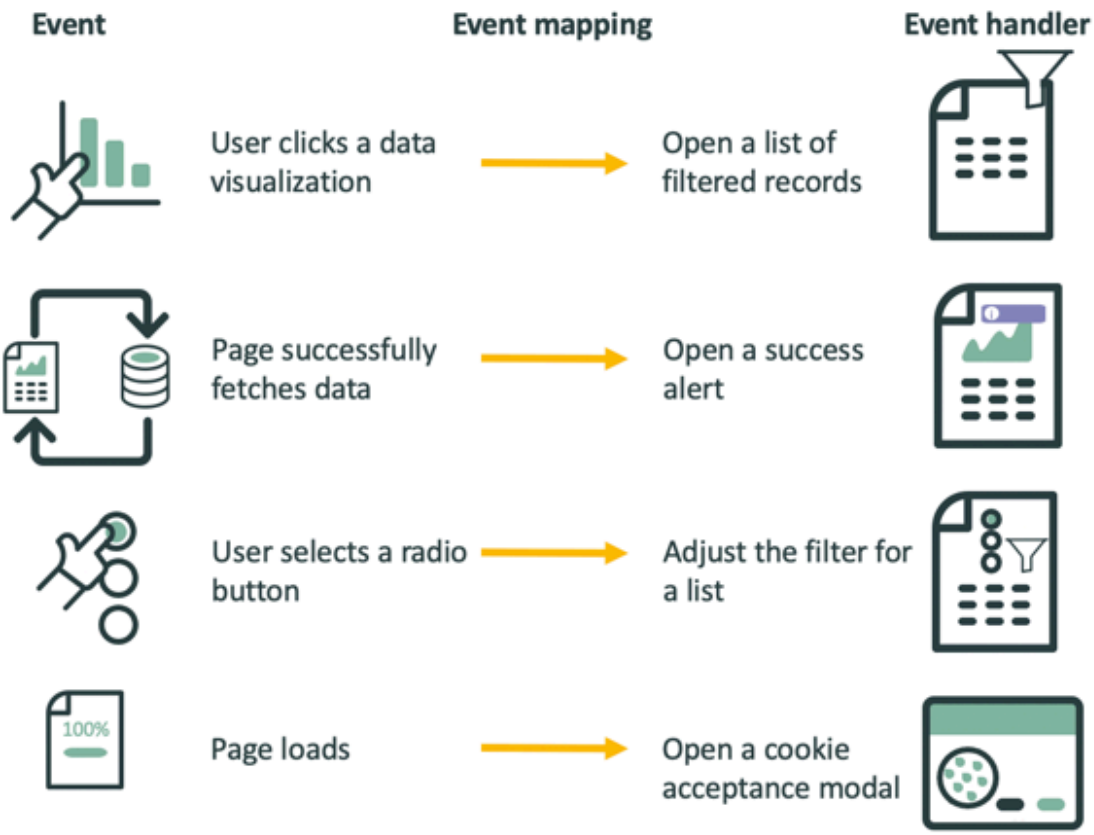
UI actions tell UI Builder what to do when an event is triggered. An event is an action a user takes or occurrence that happens on a page. Use UI actions to create interactive, user-friendly interfaces that help your users complete tasks. Each component has its own events associated with it. Events include:

- User clicks a data visualization
- Page successfully fetches data
- User selects a radio button
- Page loads

Events in UI Builder

Use an event to add actions to your components, pages, and data resources.

- A component event is an action that you set up for a component. You set up an event handler to configure that component action. For example, you can add a button component to your UI Builder page. Then, you can add an event handler to apply an action for that button, such as going to a web page.
- Page events perform actions for the entire page. You can configure the following page events:
  - Page event mappings. Add, remove, or clear alert notifications on your page.
  - Variant event mappings. Add, remove, or clear alert notifications on your page variant.
  - Dispatched events. Create dispatched events for your page to create relayed event mappings that model events after a parent event handler. Select a target parent event handler to model the payload fields after it.
  - Handled events. A handled event is an event that is exposed and available for use by other users. After you create a handled event, it is available under *`Page event mappings`* for other users to use. You can also set up payload fields that you create manually or choose a template for your handled event, such as an open or close a modal dialog.
- Data resources events map data resources to notify information about when data is fetched.
- Events for a page or component do nothing until the event is mapped to one or more event handlers.



Event mapping in UI Builder

Map actions to events such as clicking a button or filling in a field. An event mapping is the process that enables you to map an event's payload or contextual values to the object or handler that acts on that event.

For more information about event mapping, see Define map events.

Event handlers in UI Builder

An event handler is an action performed when an event occurs. By mapping an event handler to an event, you are specifying which action or actions to take when the event occurs. Use an event handler to configure an action for your UI Builder page or the components on the page. For example:

- Clicking a data visualization opens a list of records represented in the visualization
- Fetching data successfully for a list opens an alert that indicates the data fetch was successful
- Selecting a radio button adjusts the filter for a list on the page
- Loading a page opens a modal to confirm acceptance of cookies before proceeding

When you add an event handler to a UI Builder page or component, you can choose different types of event handlers. For example, a Button component can have the following types of event handlers:

- Inherited event handlers. An inherited event handler is exposed from the page that you are working in. If you are in the parent UI Builder page, an inherited event handler could be exposed from the app shell. The following table lists the different types of inherited event handlers that you can use and what you can do with them.

Inherited event handlers

Event handler	Description
Breadcrumb URL changed	
Link to destination	Navigate to a destination. ○ App routes: Link to another page within an app, like a home screen. ○ External URL: Link to a website or any external URL. Sample script `return { route: null, /* Page route, e.g. 'record' */ fields: null, /* Required params, e.g. {"table":"incident","sysId":"X"} */ params: null, /* Optional params, e.g. {"selectedIndex" : 1} */ ##redirect: null, /* ??? True/false? */ ##passiveNavigation: null, /* Load in background, e.g. 'false' */ title: null, multiInstField: null, ##targetRoute: null, /* ??? */ ##external: null /* ??? True/false? */ };`
Add parameters to URL	Add additional parameters to a URL. Sample script `{ “selectedTabIndex” : 0 }`
Open or close modal dialog	After you create a modal, use *Open or close modal dialog* to trigger the modal.

- Page-level event handlers. This type of event handler is common to all pages, and you would use this handler type when you want to add or clear page-level alert notifications. The following table lists the different types of page-level event handlers that you can use and what you can do with them.

Page-level event handlers

Event handler	Description
Add alert notifications	Add a code snippet to send an alert notification. For example: `return { items: [{"type" : "info", "message" : "Info message", "id" : "optionalID"}] /* Types: info, warning, error */ };`
Remove alert notification	Add code to call alert notification IDs that you want to dismiss. For example, click a button to remove a page load alert notification.
Clear alert notification	Add code to call all alert notification IDs that you want to dismiss. For example, click a button to remove all alert notifications.
Set loading state	Toggle loading on or off. For example, you can toggle loading on to load the page when you click a button or toggle loading off to not load the page when a button is clicked.
Update client state parameter	Declaratively set the client state parameter. Let's say that you have a client state parameter that you set up with a value. You can configure the *`Update client state parameter`* event handler to update the client state parameter with a new value. For example, you have a client state parameter that is called **Greeting** that is set up with `Hello` as the initial value. You can add an *`Update client state parameter`* event handler, select the **Greeting** client state parameter, and then enter a new value like `Goodbye`. When you click the button, **Goodbye** replaces **Hello** on the page.
UXF macroponent viewport load requested	Add to a component, such as a button component, to open a viewport. For more information, see Add a viewport component to your page.

- Data resource handlers. This type of event handler triggers the fetching or writing of data to the server.

  You can refresh the app shell data source data on your UI Builder page by clicking a button. For example, with a data resource handler, you can do the following actions:

  - Bind data to the description of an incident record.
  - Change the value of the incident description.

- Add a button component to your page.
- Label the button as `Refresh incident`.
- Add a *`Look Up Record`* event handler for the button.
- Save your page.
- If the description of the incident record changes, click **Refresh** to update the description on your page.

- Client scripts. Scripts that execute when an event is triggered on a component. You create these scripts in the Client scripts section in UI Builder. For more information, see Define and bind client scripts to components.

Binding events to components in UI Builder

Bind event handlers to the events on a component. When you add components to your UI Builder page, these components are not configured to perform any action on your page. For example, a button component is static and does not do anything until you bind an event action to it, such as deleting a record. Some components have several events where event handlers can be assigned. For example, on the list component, you can assign a navigation handler to the *`Row clicked`* event. You can also assign an open modal to the *`Data fetch failed`* event. For more information, see Bind an event to a component.

Binding events to UI Builder pages

Bind a page-level event to execute event handlers on the page. For example, use page-level events for page notifications, page load, or when a page property changes. The assignment of the event handler to the page-level event is similar to assigning handlers to events from components.

You can bind event mappings using the following methods:

- Page event mappings. Add, remove, or clear alert notifications on your page.
- Variant event mappings. Add, remove, or clear alert notifications on your page variant.
- Dispatched events. Create dispatched events for your page to create relayed event mappings that model events after a parent event handler. Select a target parent event handler to model the payload fields after it.
- Handled events. Add a handled event for an event that is exposed and available for use by other users.

For more information, see Bind an event to a page.

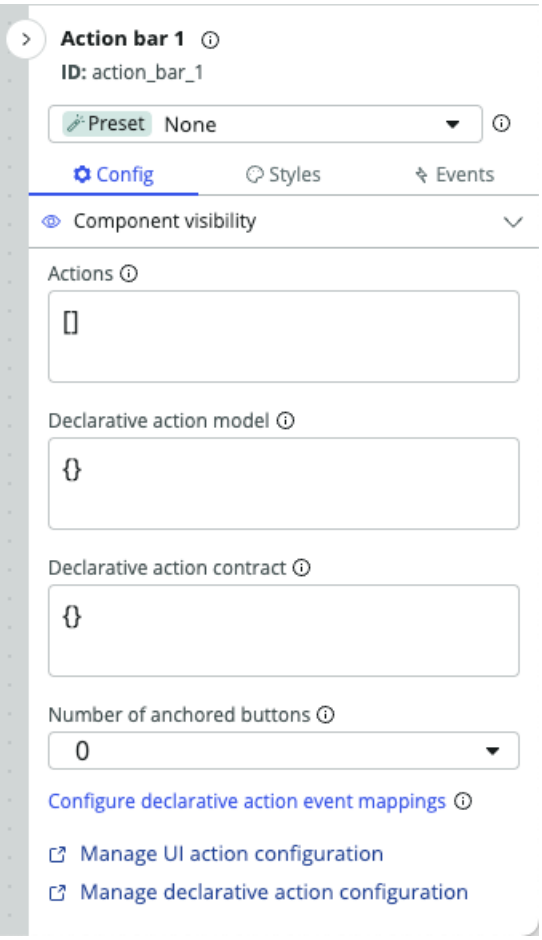
Binding events to data resources in UI Builder

Bind event handlers to individual data resources on your UI Builder page. For example, when a data resource successfully fetches new data, it executes an event handler, like navigation, to take a user to the next step in a flow. When a data resource successfully adds a record to a table, it shows a success modal that uses the show modal event handler. For more information, see Bind an event to a data resource.

Binding events to declarative actions in UI Builder

Bind data elements to add event actions to a declarative action definition in **Actions & Components** in the ServiceNow AI Platform®. For example, you could bind a data element to add an event action to complete work on a table.

If you add a component to your UI Builder page that has a declarative action, you must bind it to a handled event. The handled event creates an action that is performed when a user selects the component. By selecting **Configure declarative action event mapping**, you add a new event handler to define what the declarative action does on the page.



For more information, see Bind an event to a declarative action.

Define map events

An event mapping in UI Builder is the process that enables you to map an event's payload or contextual values to the object or handler that acts on that event. The four event types are: component, page, data resource, and declarative action.

Event mapping is an important process within UI Builder. When you build pages with components, you need those components to perform actions for users. For example, if you add a button component to the page, a button-clicked event must be mapped to an event handler. The event handler performs a button-clicked action when it is selected by a user. An example is when you add a data resource, such as a form, and have an event handler notify the user when the form successfully loads.

Event types

The event types that are available are based on the component. For example, declarative action events are available for specific components, such as the Action bar and List components.

You choose a type of event based on what action you want to perform on your page. For example, if you want to bind an action to a component, such as a button loading a web page, you would use a component event. If you want an event to apply to your whole page, such as adding

an alert notification to a page, you use a page event. The following table describes each event type that is available in UI Builder and provides some examples on how you can use the events.

Event types and descriptions

Event type	Description
Component events	Action that you set up for a component. You set up an event handler to configure that component action. For example, add an event handler to apply an action for a button, such as going to a web page. For more information on binding events to components, see Bind an event to a component.
Page events	Page event that performs an action for the entire page. You can configure the following page events: • Page event mappings. ○ These event mappings are saved on the page definition record, which can be found in the [sys_ux_macroponent] table. ○ The source events for these event mappings are Page ready and Page property. They are defined for your page. ○ The available handlers for these event mappings are: ▪ User session events ▪ Page-level events ▪ UXR App Shell Data Source ▪ Client scripts that are defined on the page ▪ Operations from local and inherited data resources • Variant event mappings. ○ These event mappings are saved on the variant record, which you can find in the [sys_ux_screen] table. ○ The source events for these event mappings are any dispatched events that are defined for your page. ○ The available handlers for these event mappings are canvas-level events, the UXR App Shell Data Source, and operations from the inherited data resources. ○ Variant event mappings are used as relays so that the events that are dispatched from components on your page can be relayed up to user session event handlers.

Event types and descriptions (continued)

Event type	Description
	○ Mappings are created automatically on a page save when you have mapped a component's dispatched event to a user session handler. For example, by mapping a **Button clicked** event to the canvas-level **Link to destination** event, the event creates a dispatched relay event and a variant event mapping when the page is saved. • Dispatched events. ○ These events are saved in the [sys_ux_event] table. The page definition record contains references to the [sys_ux_event] record. ○ These events serve as source events for variant event mappings. ○ You can select **+Add** to create new dispatched events for your page. Configure the event label to auto-populate the event name and payload fields for your new `sys_ux_event`. ○ These events are used to create relay event mappings. You can select a **Target parent event handler** to model the payload fields after the selected event. You can also manually create payload fields for your dispatched event. • Handled events. ○ These events are saved in the [sys_ux_event] table. The page definition record contains references to the [sys_ux_event] record. ○ These events serve as source events for page event mappings. ○ You can select **+Add** to create new dispatched events for your page. Handled events are not modeled after parent event handlers. Payload fields for handled events are created manually. To use an

Event types and descriptions (continued)

Event type	Description
	existing handler's payload fields as a template, select a template and edit the fields as necessary.  For more information on binding an event to a page, see Bind an event to a page.

Event types and descriptions (continued)

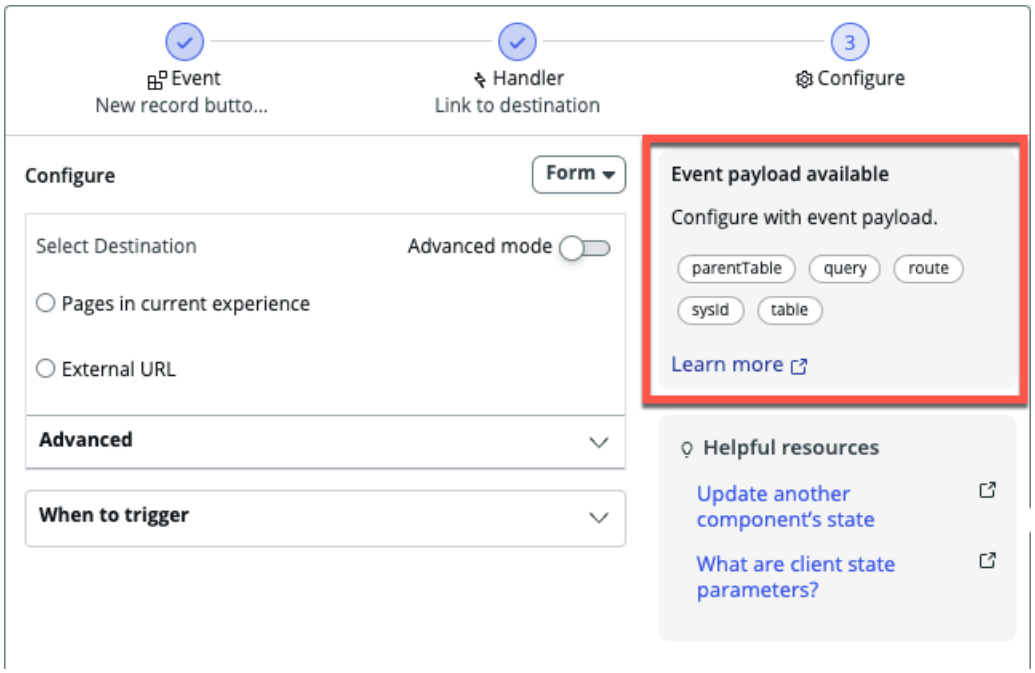
Event type	Description
Data resource events	Events that are mapped to data resources to provide notifications about when data is fetched. • Data Fetch Initiated. When a data resource event is triggered, the event handler executes the data fetch process. • Data Fetch Succeeded. When a data resource event is triggered, the event handler executes the process to notify a user when the data fetch completed successfully. • Data Fetch Failed. When a data resource event is triggered, the event handler executes the process to notify a user if the data fetch was unsuccessful.  For more information on binding an event to a data resource, see Bind an event to a data resource.
Declarative action events	Bind data elements within UI Builder to add event actions to a declarative action. You configure a declarative action event mapping in the ServiceNow AI Platform® declarative action assignment table. For an example, navigate to **Filter navigator** > **sys_declarative_action_assignment.list** and then search for and open an existing declarative action. In UI Builder, you bind an event to the declarative action. For more information on how to use declarative action events, see Bind an event to a declarative action.

Event payloads in UI Builder

Use event payloads to link additional data to an action.

Event payloads are pieces of data sent by a component when a selected event is triggered. The data sent by an event can include the type of event, timestamps, user actions, or resource data such as a SysID.

You can use this payload data when configuring an event handler so that the resulting interaction can be linked to the emitted data. For example, a SysID can be passed to other components on a page to display information related to a specified record.



Each component and event has a unique set of payload options. Event payloads may not be properly defined for each component. If that is the case, define a client script so that the console logs payloads such as `console.log(event.payload)`.

Configure an event handler

Add an event handler to a page, component, data resource, or declarative action within UI Builder so that your user can trigger an action.

Before you begin

Role required: ui_builder_admin

About this task

An event handler lets you configure an action, components, data resource, or declarative action on your page. For example, you can map an event to your page to add an alert notification when the page successfully loads or you can add an event handler for a button component to perform an action when a user clicks it. The event handler could also be a modal on your page that asks a user to verify that the user wants to delete the record. For more information, see Manage actions in UI Builder pages.

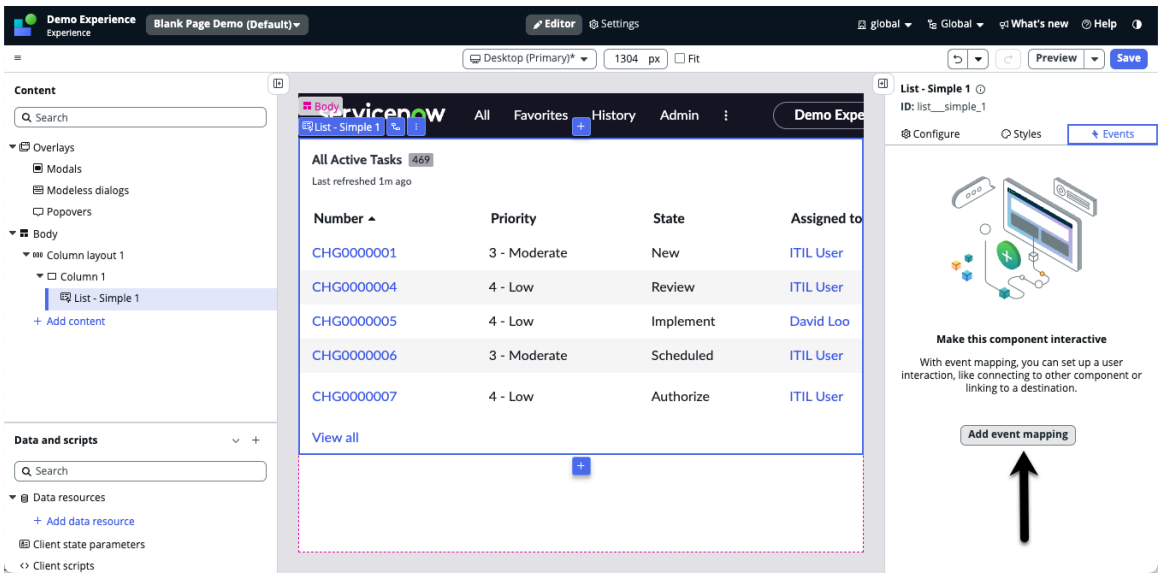
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   For more information, see Configure how users interact with your applications in UI Builder.
3. Open or create a page.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Add a component to your page, such as a button.

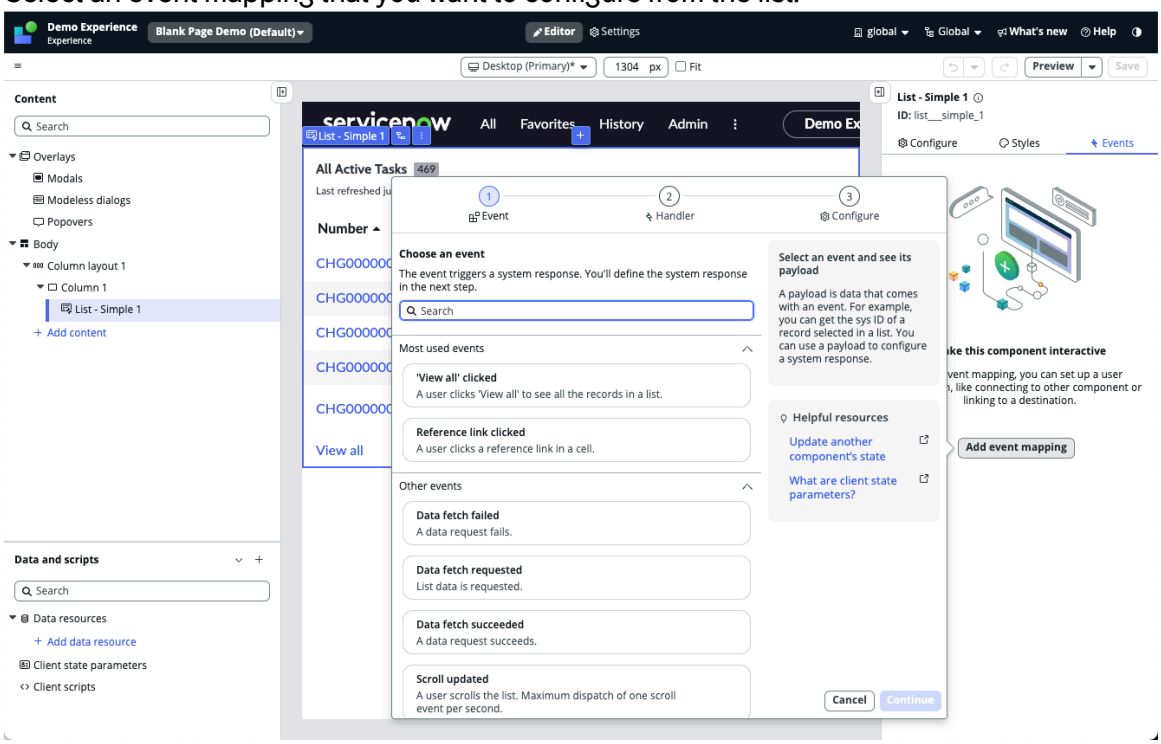
For more information about adding components to a page, see Add and configure components.

5. To add an event handler to your component's event, go to the configuration panel and select **Events**.
   An event handler lets you assign an event to a component. For example, if you add a button component to your page, you want it to perform an action when a user clicks it.
6. To start the process of assigning an event to a component select **Add event mapping**.

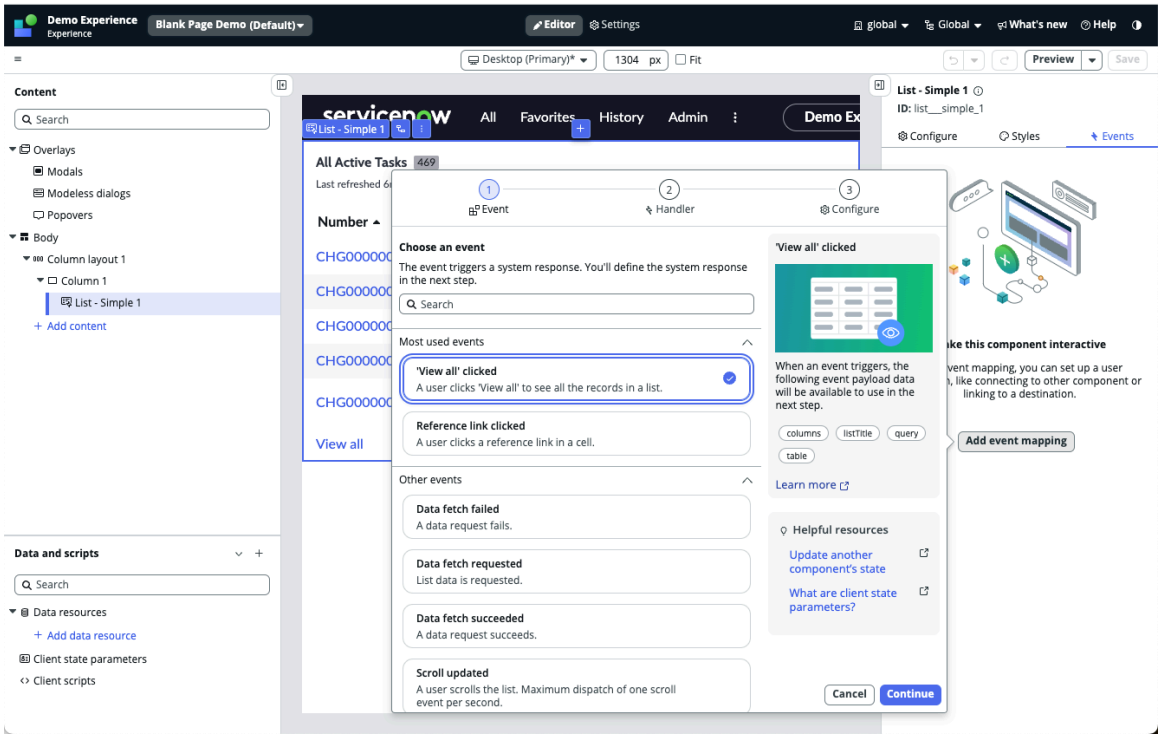
   Some components, such as the button component, only have one event mapping. Other components can have many events.



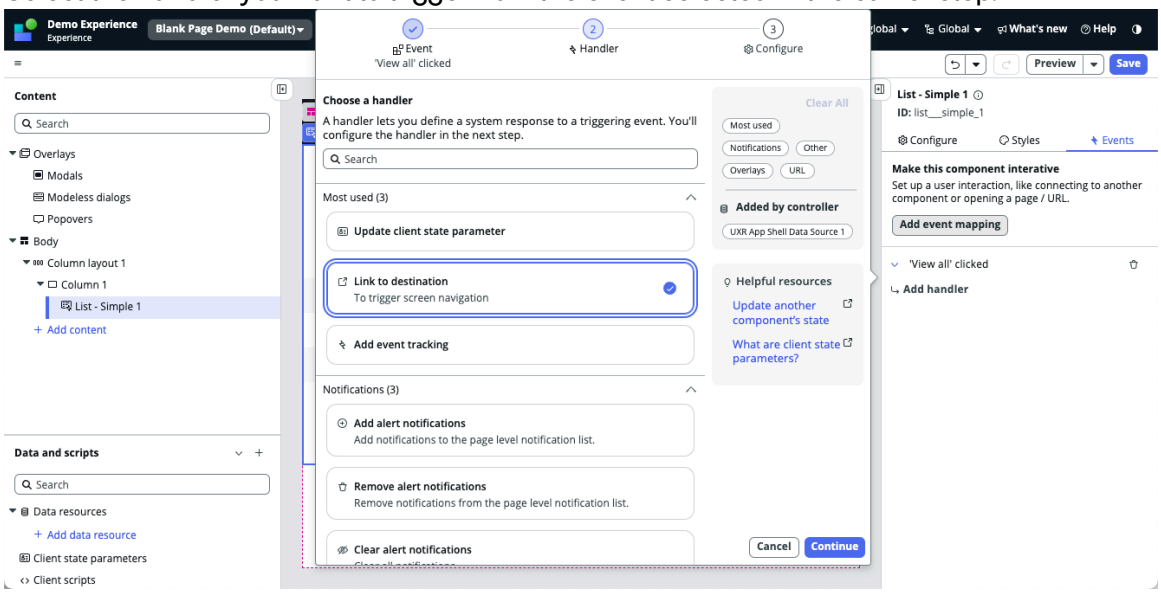
7. Select an event mapping that you want to configure from the list.



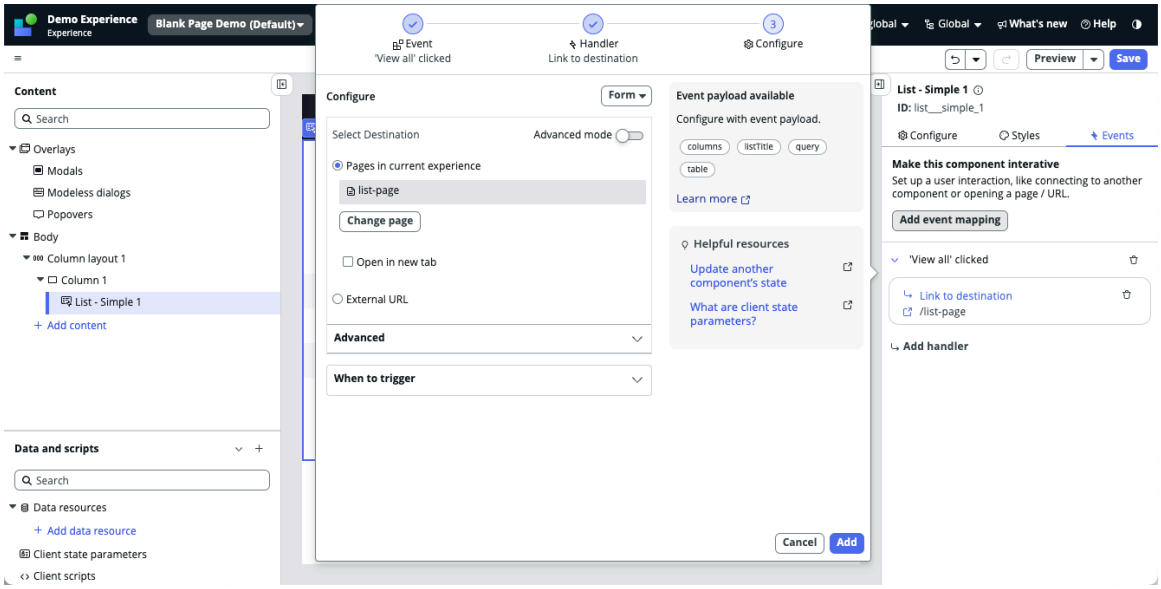
8. From the Event handler preview screen, select an action that you want assigned to the component.



9. Select **Continue**.
10. Select the handler you want to trigger from the event selected in the earlier step.



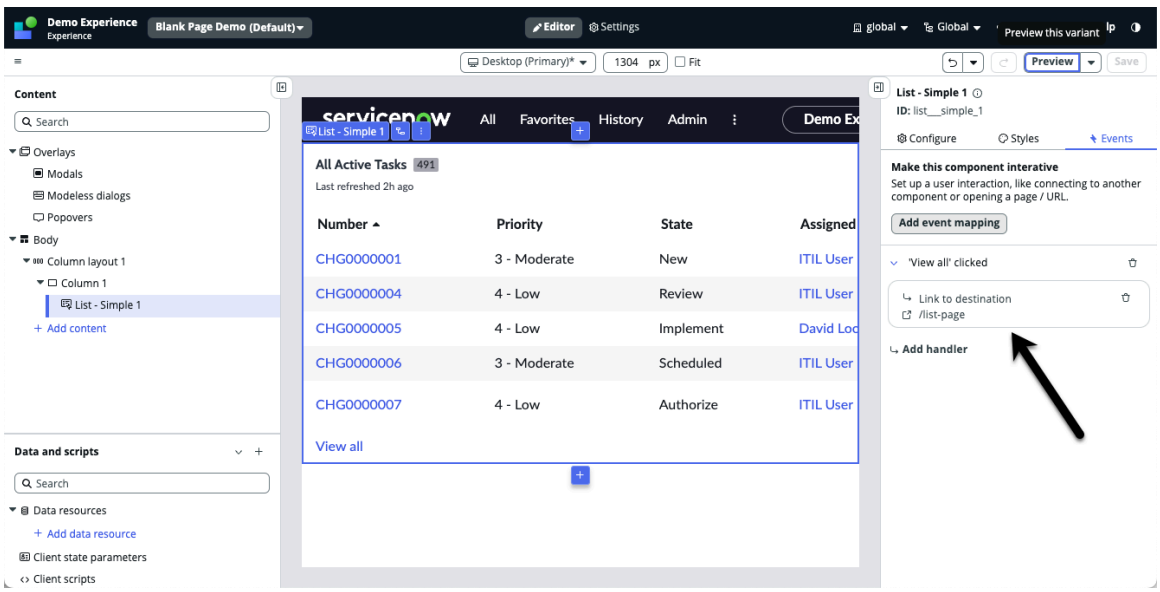
11. Select **Continue**.
12. Configure the payload for the event.



13. Select **Add**.
14. Select **Save**.
15. Test the event by selecting **Preview** in the header and trigger the action.

Result

The configured event handler displays in the events tab of the configuration panel.



Bind events to add actions

After you have created events, you can bind them to actions on your components, pages, data resources, and declarative actions.

Bind an event to a component

Bind data elements within UI Builder so that you can add event actions to your components.

Before you begin

Role required: ui_builder_admin

About this task

Each component has specific events that it binds to. For example, a button component has only a button-clicked event, while other components can have multiple events that are associated with them.

Some components do not have an event action that is applied to them. An example is the heading component. Many components require that you map an event to your component to make it perform an action, such as loading data.

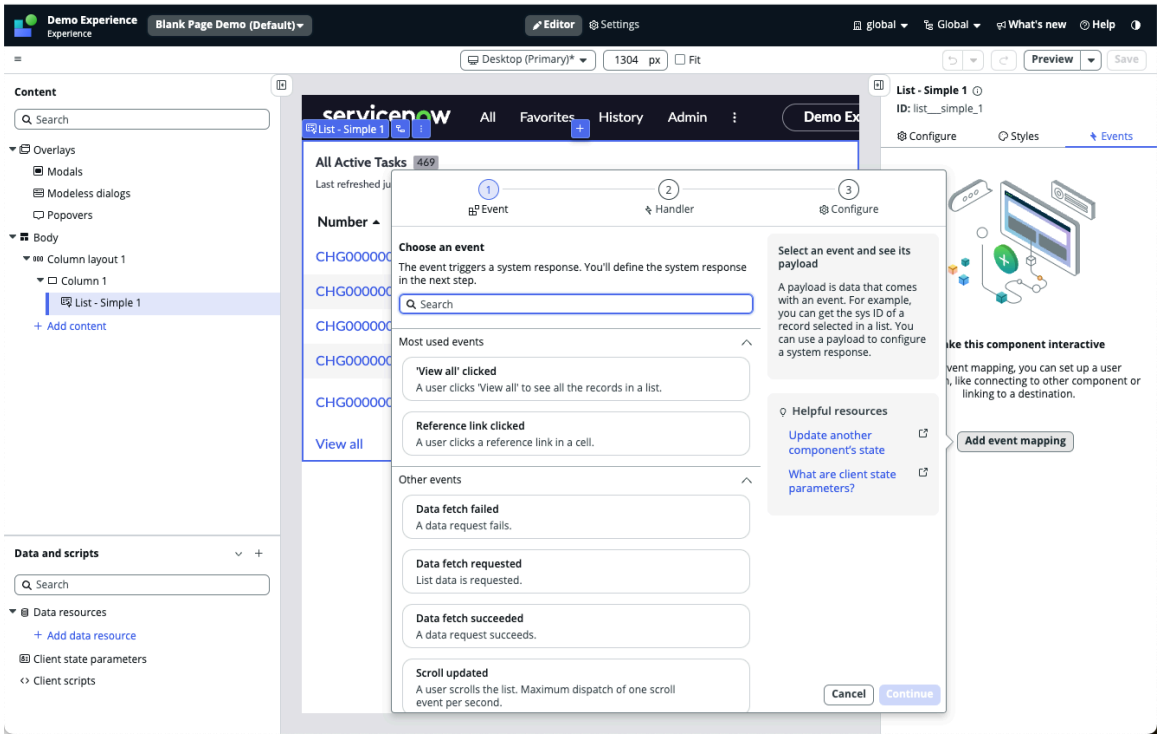
To add actions to components, pages, and data resources on your page, you can add an event handler. A button component that you add to a page is static. By binding an event action to the button, you can link it to a web page.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   For more information, see Configure how users interact with your applications in UI Builder.
3. Create or open a page.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Add a component that has events to which it can bind to your page, such as a button.
   For more information about adding components to a page, see Add and configure components.
5. To add an event handler to your component, select the **Events** tab.
   For more information on how to add event handlers to your component, see Manage actions in UI Builder pages.

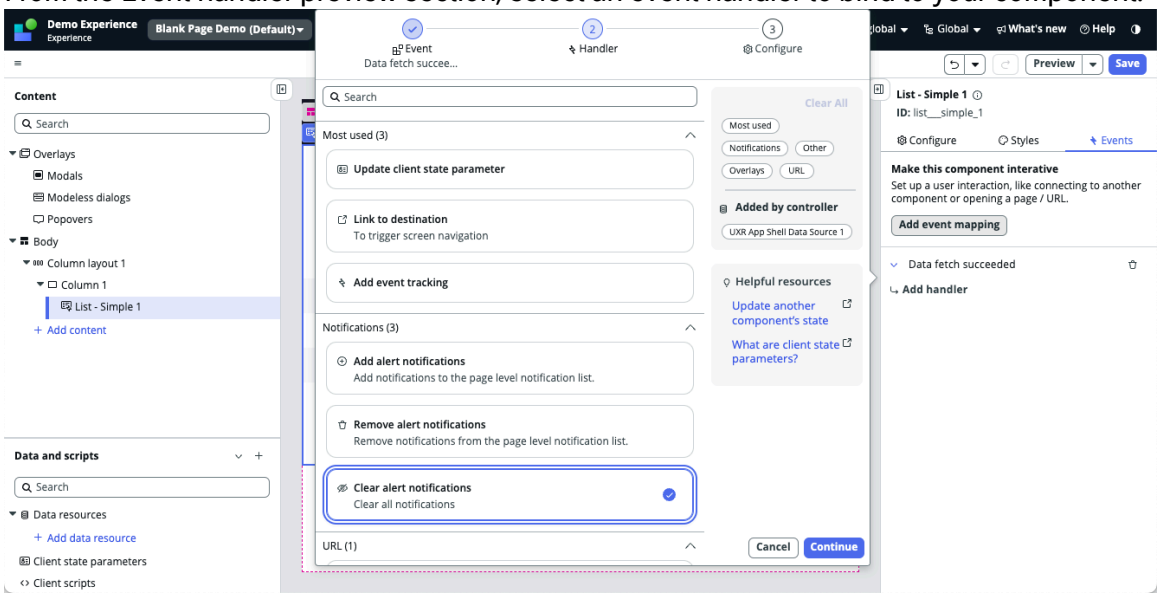
   a. To start the process of setting up an event handler for your component, click **Add event mapping**.

   b. Select the event mapping that you want to configure from the list.



c. Select **Continue**.

d. From the Event handler preview section, select an event handler to bind to your component.



e. Select **Continue**.

f. Configure the payload for the event.
You configure each event handler differently, depending on the action of the event. For example, if you add an event handler for a button component, you can choose what that button action performs.

g. Select **Add**.

6. **Optional:** If you want a modal to pop up for your event, add the modal to the page before you bind your event to the component.
   A modal is a confirmation pop-up that appears when you click the component. For example, if you add a button component that deletes a record, you add a modal to ask the user to confirm that the user wants to delete the record. For more information, see Add modal to component.

   a. Select the **+** icon in the content tree next to **Modals**.

   b. Choose a modal type such as **Confirm**.

   c. Configure the modal.
   You can change the text in the modal, the names of the buttons in the modal, and the size of the modal screen. You can also set actions for the modal. When you finish configuring the modal, close it. Notice that the modal you created sits above the body of your page structure in the content tree.

7. Bind an event to a button component.
   You bind an event to the button to trigger an action. Select the button component to highlight it again, either in the content tree, or on the page.

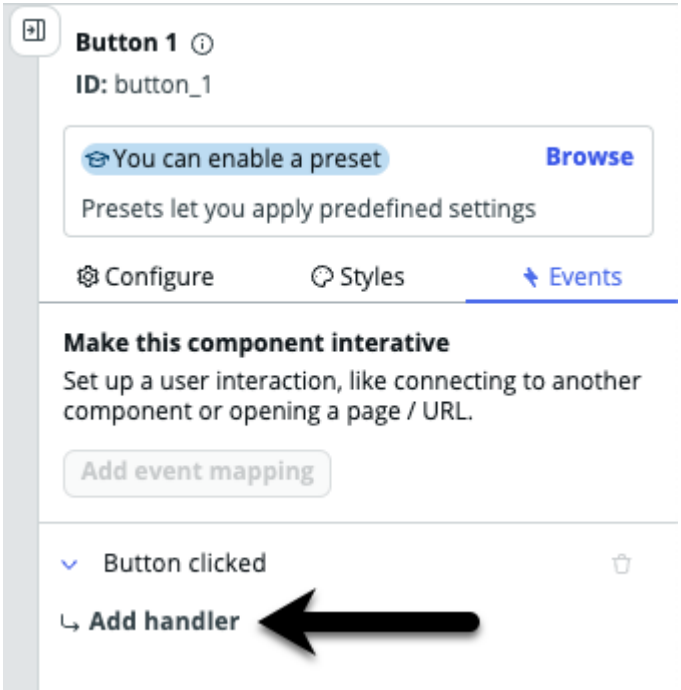
a. Select **+ Add content** in the content tree.

b. Select the **Button** component in the toolbox.

c. Select **None** when asked to choose a preset.

d. In the Configuration pane, click **Events**.

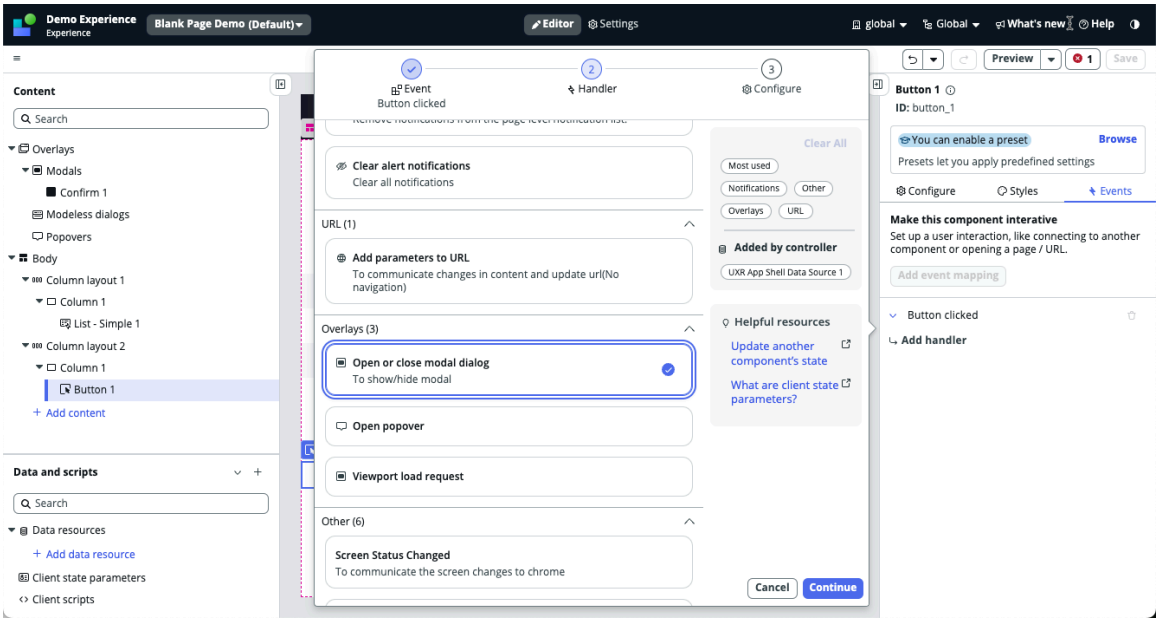
e. Select **Add handler**.



The button component only has the button-clicked event associated with it. Other components can have more than one event.

f. Select an handler that you want assigned to the button.

For example, to add an event handler for the button component, you could link it to another destination and add alert notifications. In this example, you can choose **Open or close modal dialog** to make the button open the modal that you created earlier. In this button scenario, select the Confirm and destroy modal dialog event handler that you created earlier.



g. Select **Continue**.

h. Select a modal from the drop-down.

i. Select **Add** to add the modal event handler to your button component.

8. Click **Save**.
9. Test the modal by selecting **Preview**.
10. To trigger the modal that you created, click the button on the page.

Bind an event to a page

Use page event mappings to bind data elements within UI Builder so that you can add event actions to your page.

Before you begin

Role required: ui_builder_admin

About this task

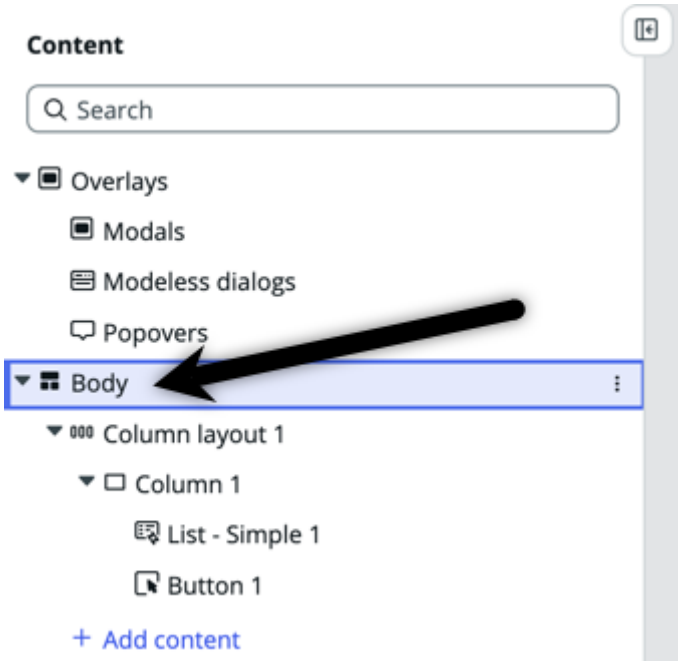
You can bind an event to a page by using the following types of events:

- Page event mappings. Add, remove, or clear alert notifications on your page.
- Variant event mappings. Add, remove, or clear alert notifications on your page variant.
- Dispatched events. Create dispatched events for your page to create relayed event mappings that model events after a parent event handler. Select a target parent event handler to model the payload fields after it.
- Handled events. A handled event is an event that is exposed and available for use by other users. After you create a handled event, it is available under *`Page event mappings`* for other users to use. You can also set up payload fields that you create manually or choose a template for your handled event, such as an open or close a modal dialog.

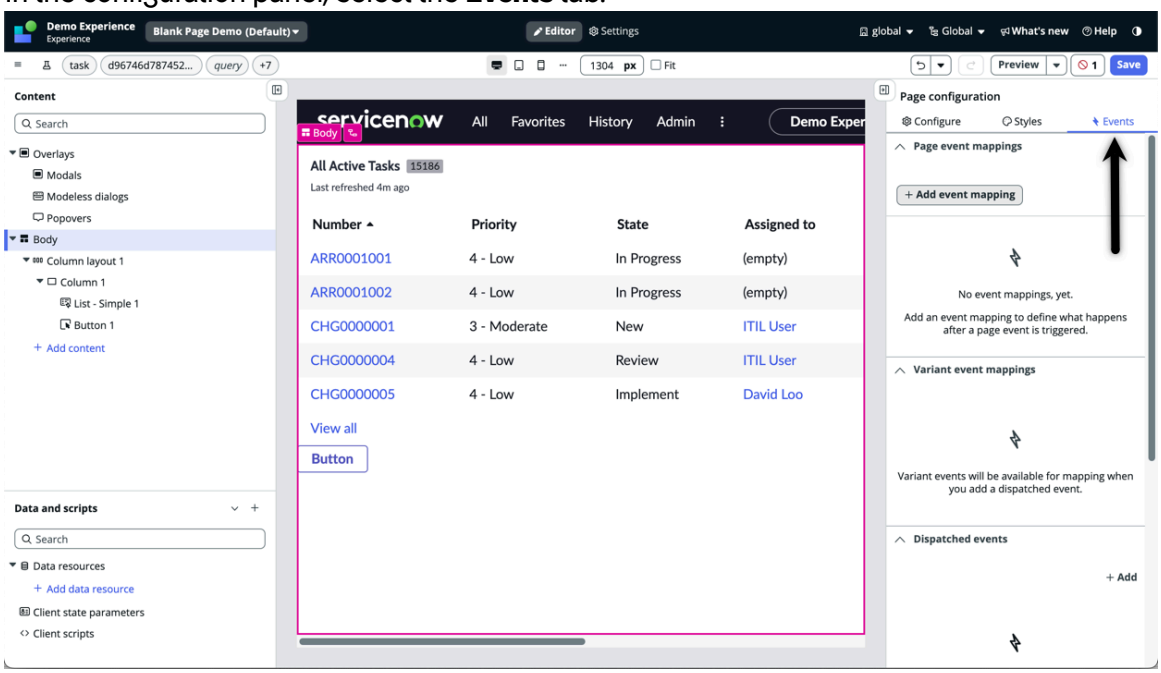
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information.
3. Open or create a page.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Highlight the page body in the content tree.

   The body is the top-level line of the content tree. When you highlight the whole page, you can add page-level events.



5. In the configuration panel, select the **Events** tab.



6. Add an event handler in one of the following ways.

7. Select **Save**.
8. To preview your page and test the data resource event that you set up, select Preview.

Bind an event to a data resource

Assign event handlers within UI Builder to individual data resources on your page. When a data resource successfully fetches new data, it executes an event handler to take a user to the next step in a flow.

Before you begin

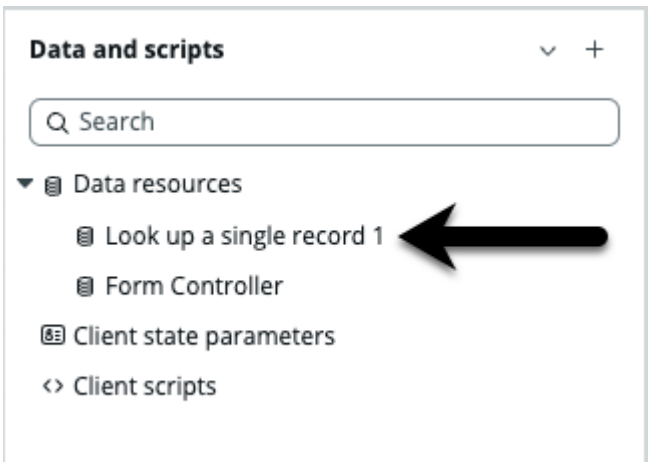
Role required: ui_builder_admin

About this task

Bind an event to a data resource, to perform data-related actions on your page. For example, you can add a button to reload data to a page if it doesn't load the first time. You can also set up a data resource event to reload data behind the scenes of your page.

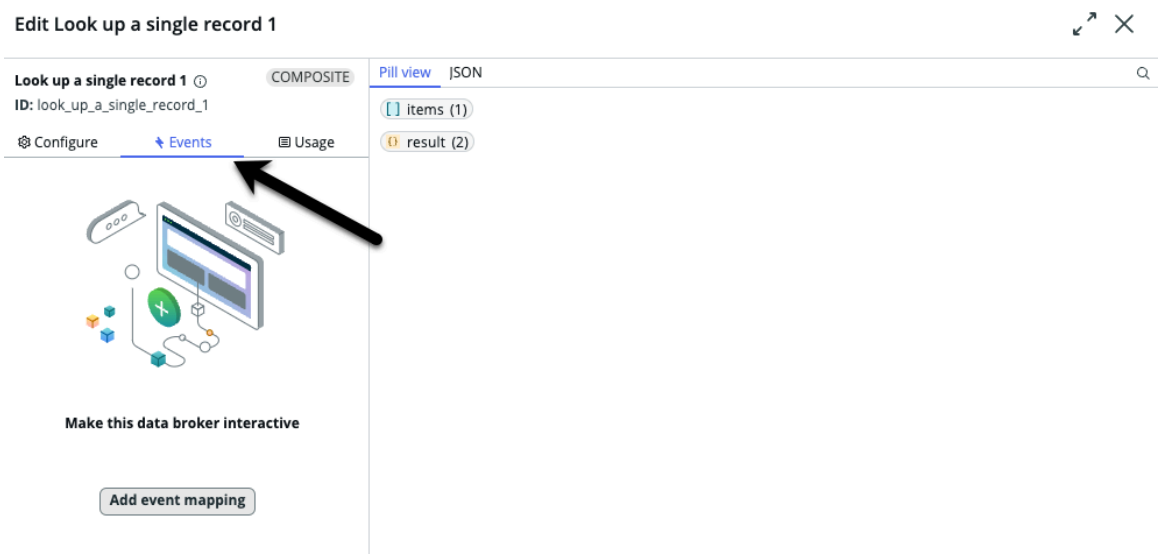
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   For more information, see Configure how users interact with your applications in UI Builder.
3. Create or open a page.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. **Optional:** If you do not have any components on your page, add one to your page.
   For more information, see Add and configure components.
5. Add a data resource to your page.
   For more information, see Add and configure data resources to a page.
6. Select a data resource instance.

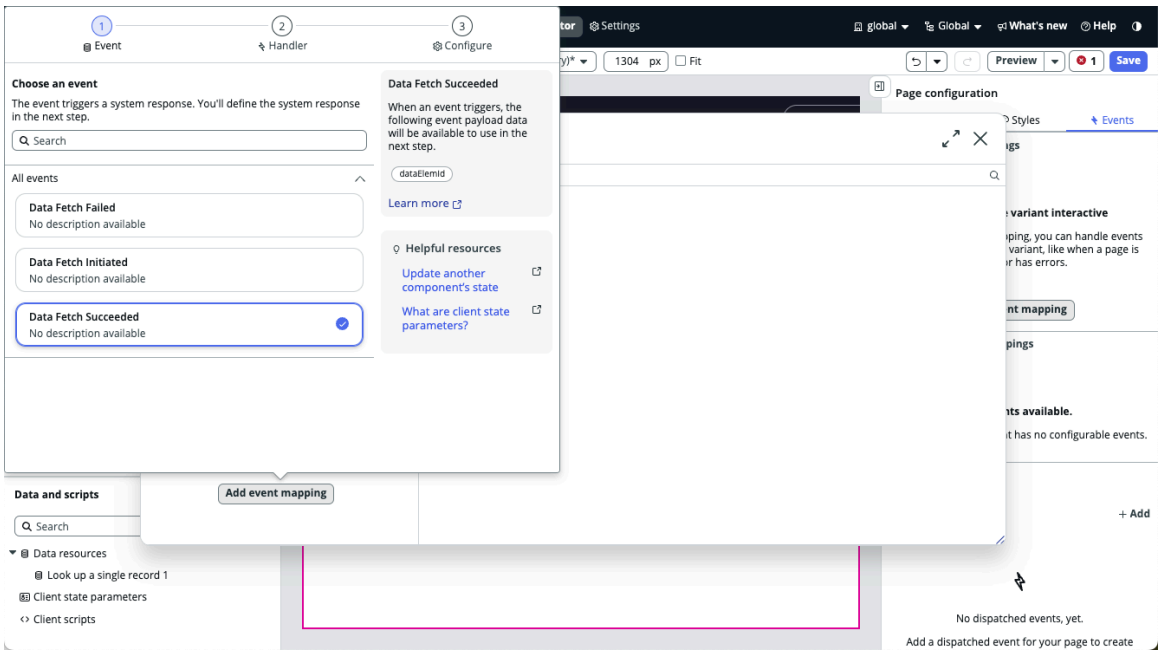


7. To add an event handler to your data resource, select the **Events** tab in the configuration panel of the data resource.

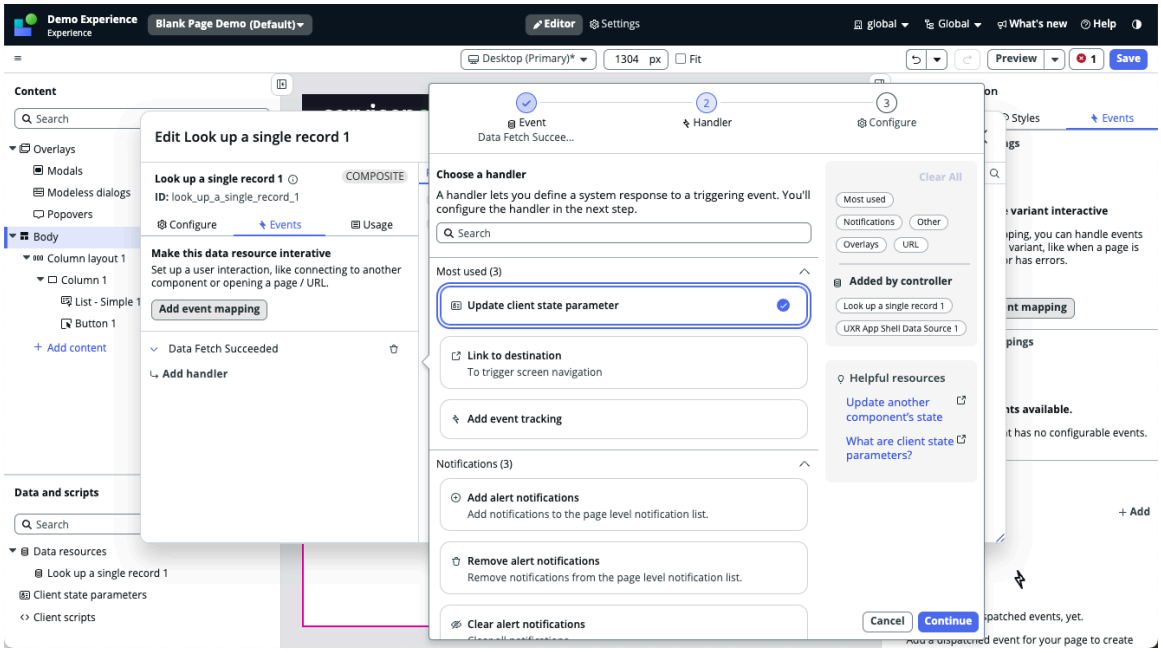
   You can add event handlers to your data resource to handle actions for Operation Initiated, Operation Succeeded, and Operation Failed.



8. Select **Add event mapping**.
9. Select an event from the list.



10. Select **Continue**.
11. Select an event handler from the list.



12. Select **Continue**.
13. Fill in the required information for the event handler.
    The configuration varies depending on which event handler is selected.
14. Select **Add**.
15. Select **Save**.
16. To preview your page and test the data resource event that you set up, select Preview in the UI Builder header.

Link an event to another page

Add a link to the destination event handler within UI Builder so that an event action can open another page. You can also configure the event handler to follow the App Route to the desired page.

Before you begin

You must have a workspace page that contains a component that is intended to open another page when a user clicks it. The dashboard overview is an example of such a component. Components such as **Link to Destination** do not support the link to destination event handle. The component link property takes priority over the link to destination event handler.

Role required: ui_builder_admin

About this task

To configure an event action to open another page, you must know what page you want to open, what the required and optional parameters are for that page, and what payload values to set on the event handler to pass the required parameters to the destination page.

Tip:

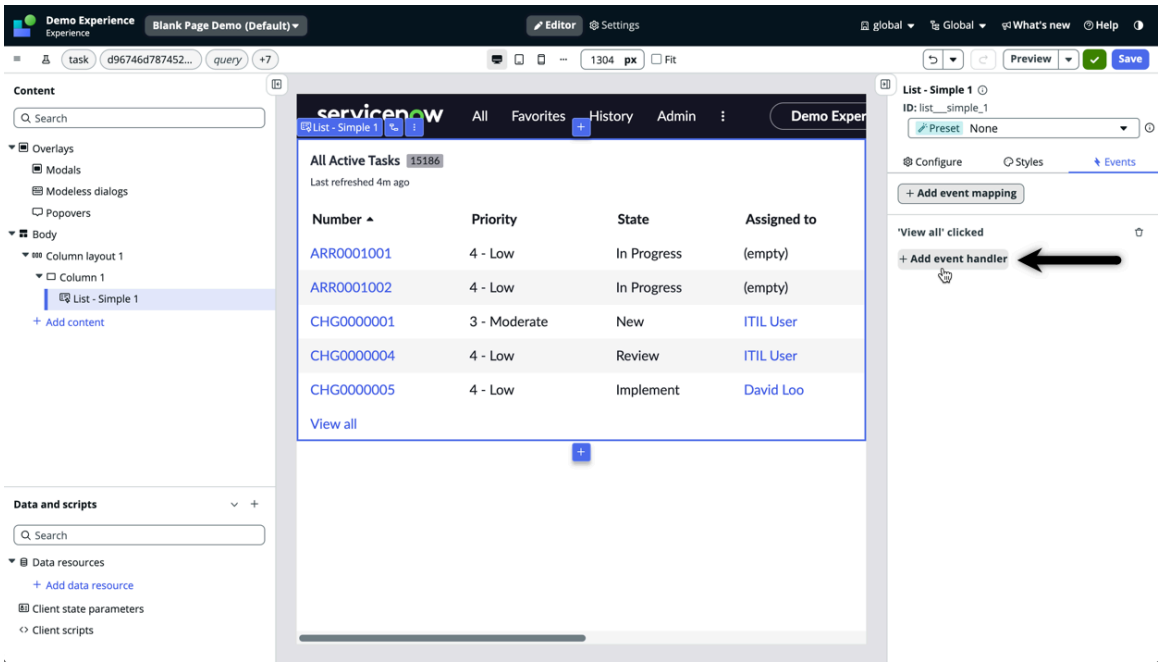
You may be able to find examples of both the components that you want to link from and the destination pages that you want to link to in the Base Agent Workspace Experience. This Next Experience is provided in the base system. If you create a page from a page template, you should only copy the contents of the template. Do not reference it. For more information about the difference between copying and referencing a page template, see Create a page from a template.

Procedure

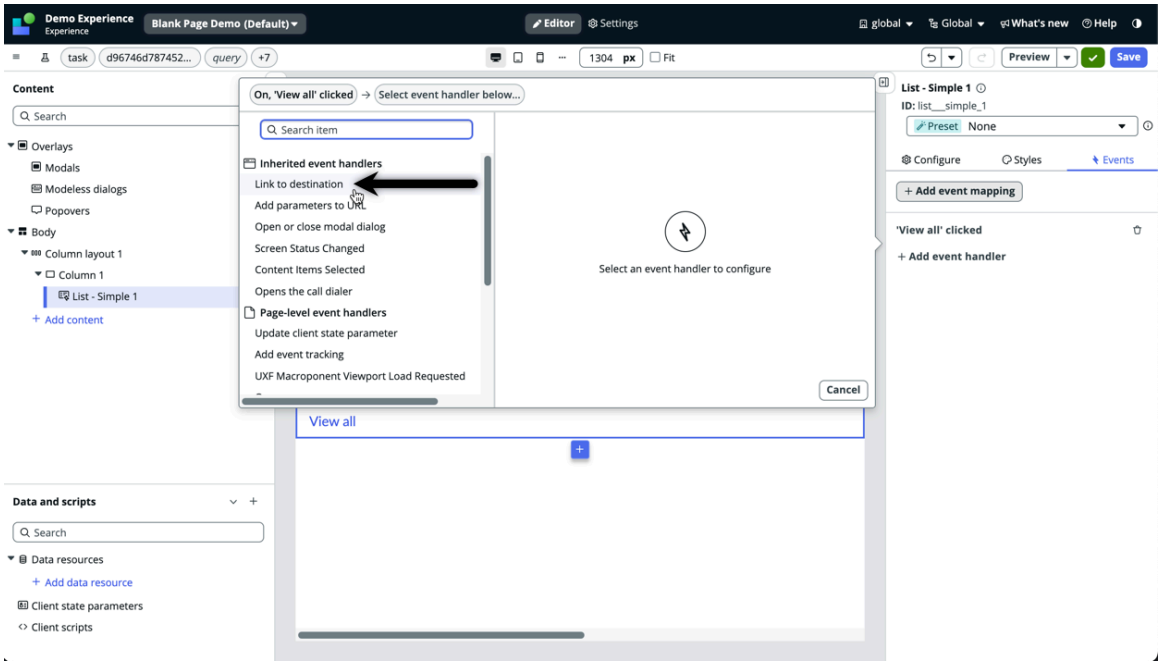
1. Open your experience in UI Builder.
2. **Optional:** If the destination page doesn't exist in your experience, create one.
   For information about creating pages, see Create a page in UI Builder. Make sure that you set the required and optional parameters for the page so that you can use it as a destination. If a particular component in the page is a destination, you must include that component. You also must configure the properties on the component to consume the page parameters with `@context.props.<parameter-name>` values.

   You might consider creating the page from a page template. The Base Agent Workspace Experience has several page templates that are already configured to be destinations for other components. If you create a destination page from a template, the components are already configured with the correct properties. Any necessary state parameters or client scripts are also copied over. You have to add the page parameters. You can copy these parameters from the UX App Routes related list on the Agent app config [sys_ux_app_config] record of the experience that contains the page templates.

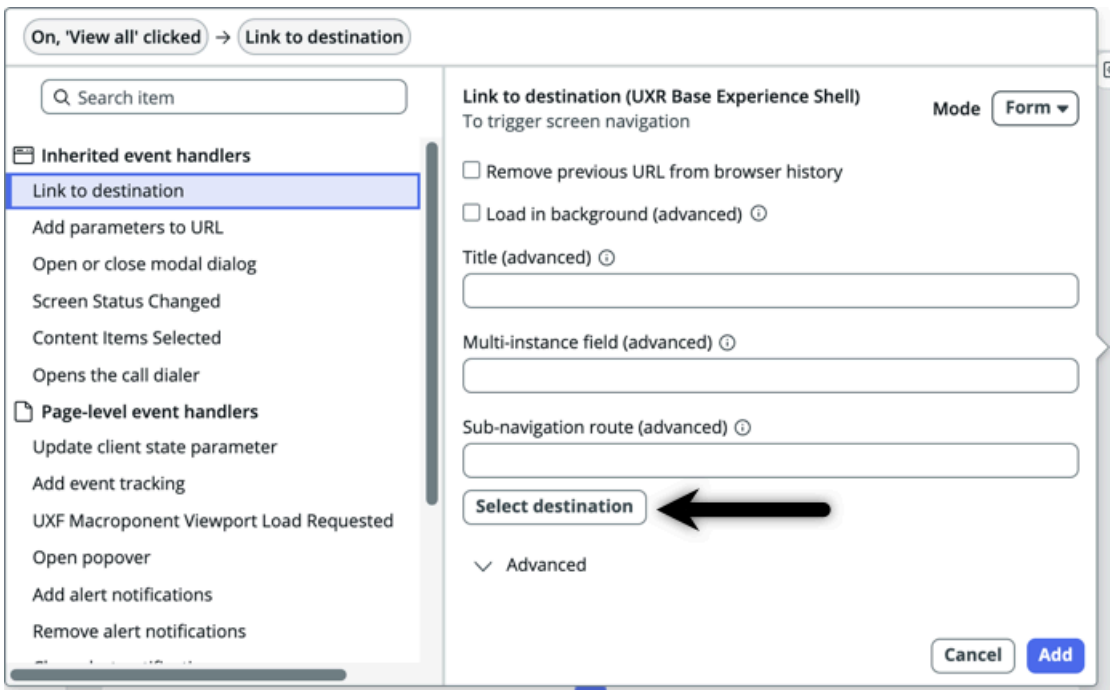
   To make sure that the pages that you are creating work reliably as destinations in your experience, your experience must have the same app shell UI as the experience with the page templates.
3. Switch to the page that you want to link to the destination page.
4. Navigate to the relevant component and select it.
5. Select the **Events** tab.
6. Select **+ Add event mapping**.
7. Select the event you want to use.
8. Select **+ Add event handler**.



9. In the Inherited event handlers section, select **Link to destination**.

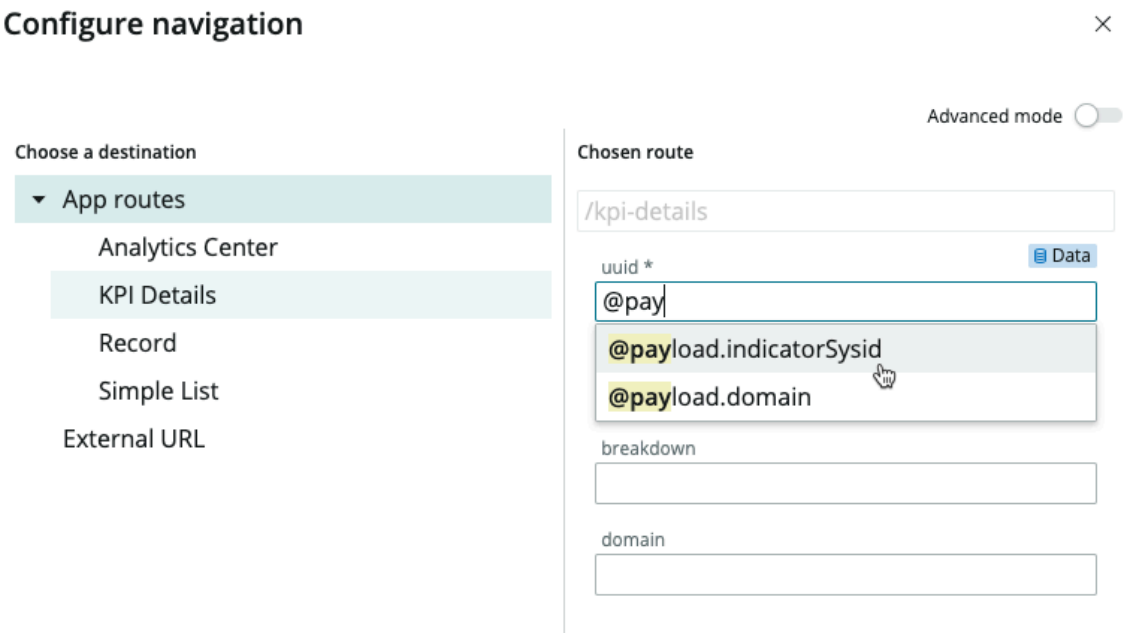


10. Click **Select destination**.



11. Expand **Pages** and select the page in the experience that you want to link to.
    Fields appear for each of the parameters on the destination page that the route leads to.
    Required parameters are marked with an asterisk (*).

12. Complete each required parameter field and the applicable parameter fields with an appropriate `@payload.*` value.
    If the developers of your component included default payload values in your event, you can select one through autocompletion. As shown in the following example, the payload value may not match the parameter name.



Note:
You have the option to link to an External URL instead of specifying an **App route**.

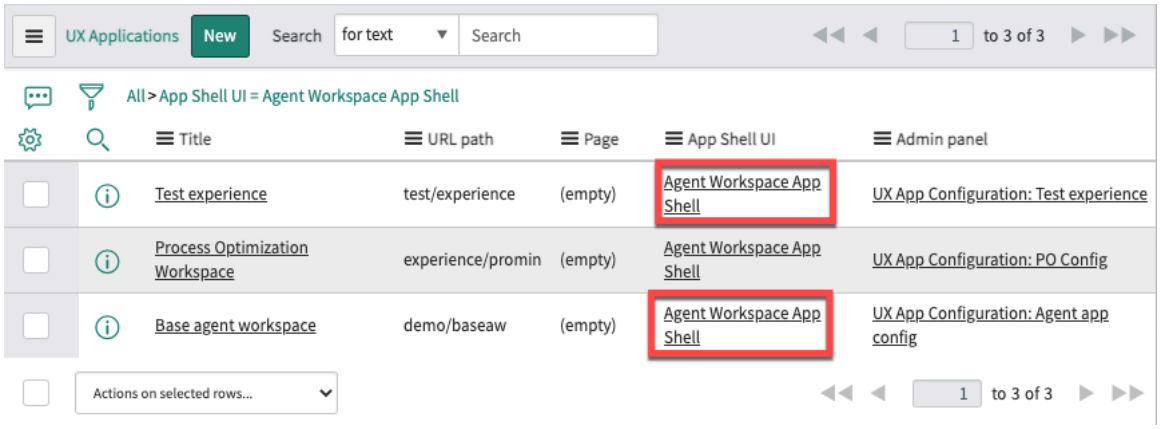
If no default values are provided, or you can't determine which values are correct for some fields, refer to the configuration and API documentation for the component in the ServiceNow® *Developer Site*. If you still can't find the necessary `@payload.*` values, contact Customer Service and Support.

Tip:
If you create your linking component by creating a page from a Base Agent Workspace page template, the component contains Link to destination Relay event handlers. These event handlers do not work. However, they contain the applicable `@payload.*` values for the parameters.

Example: Configuring the event handlers for an Analytics Q&A component

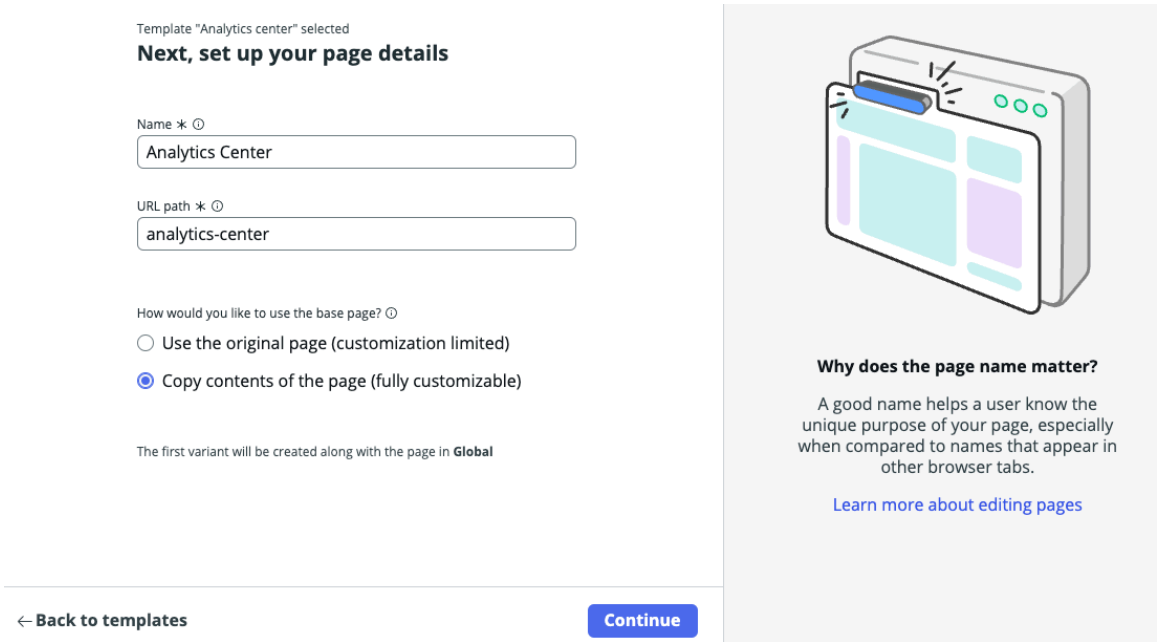
Let's say that you want to take a new Next Experience and add a page with an Analytics Q&A component. First, you create the page from the Analytics Center page template that is provided in the Base Agent Workspace experience. Next, you create a target page for the first of the three events in Analytics Q&A and then you configure an event handler for that event.

By navigating to **Now Experiences Framework** > **Experiences**, you see the Test experience UX application. Because it uses the same Agent Workspace App Shell UI as the Base Agent Workspace, you can use the page templates from the Base Agent Workspace.



You next select the Test workspace admin panel, find an UX App Configuration record with no UX app routes or pages, and then click **Open**.

As the example shows, in the UI Builder, you have created a page named Analytics Center that is based on the Analytics Center page template from the Base Agent Workspace. Next, you select the option to copy only the contents of the page template.



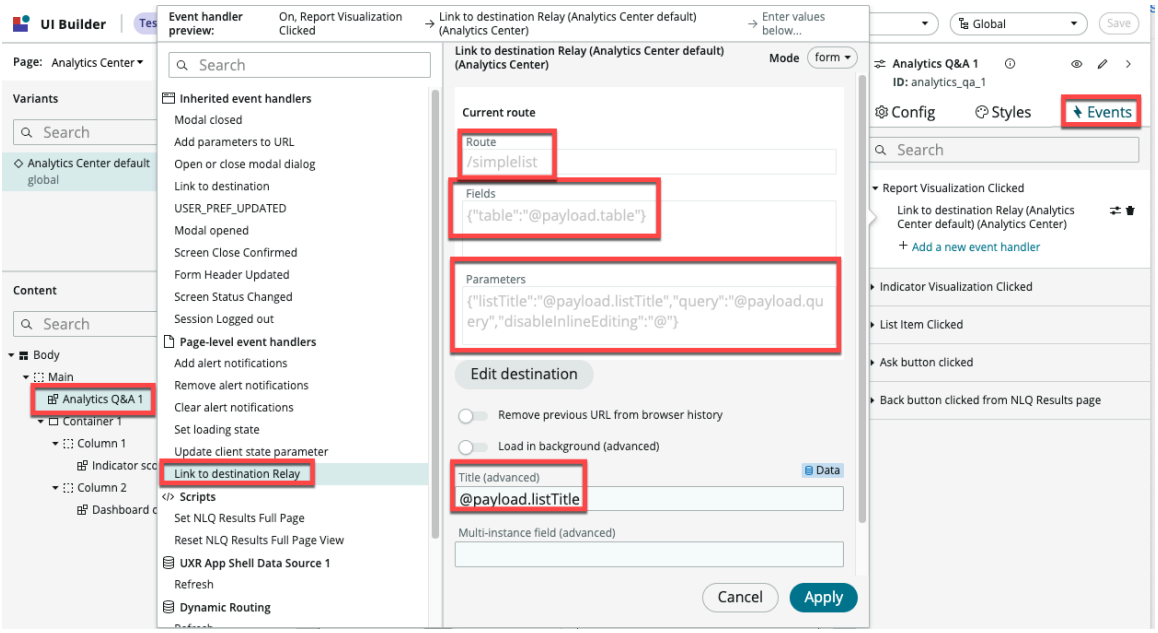
You select the Analytics Q&A 1 component and open the **Events** tab. From here, you can open the**Link to destination Relay** event handler for the **Report Visualization Clicked** event. When a question in Analytics Q&A returns a report, you can trigger this event by clicking a value in the report. When you click a value, you also see a list of the records that contribute to this value. In the **Route** field, you see that the destination is expected to be a page that is based on the Simple List page template. You also see the parameters of the page that the `@payload.*` values correspond to, and that the **Title** field can be populated with `@payload.listTitle`.

Parameters of suggested Simple List destination page and corresponding payloads

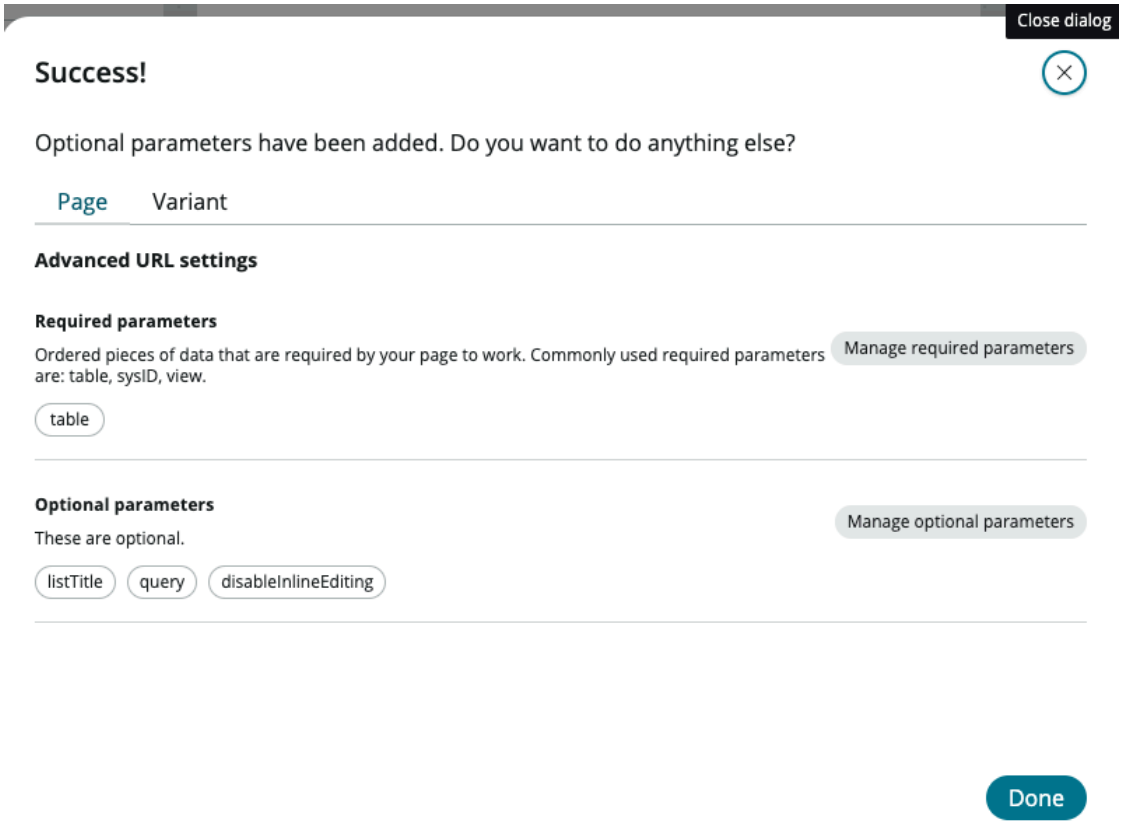
Parameter	@payload.* value
table (required)	@payload.table
listTitle	@payload.listTitle

Parameters of suggested Simple List destination page and corresponding payloads (continued)

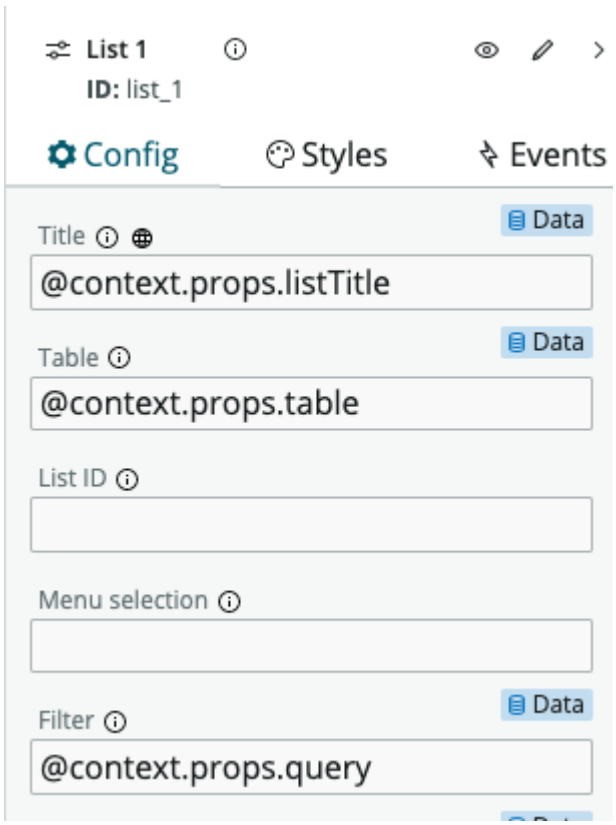
Parameter	@payload.* value
query	@payload.query
disableInlineEditing	none



Next, you navigate to **Menu** > **Create page** and create a page that is based on the Simple List template. Let's say that you name the page as Record list. You then follow a similar process as when you created the Analytics Center page. This time, in the last steps of the process, you would add `table` as a required parameter and `listTitle`, `query`, and `disableInlineEditing` as optional parameters.

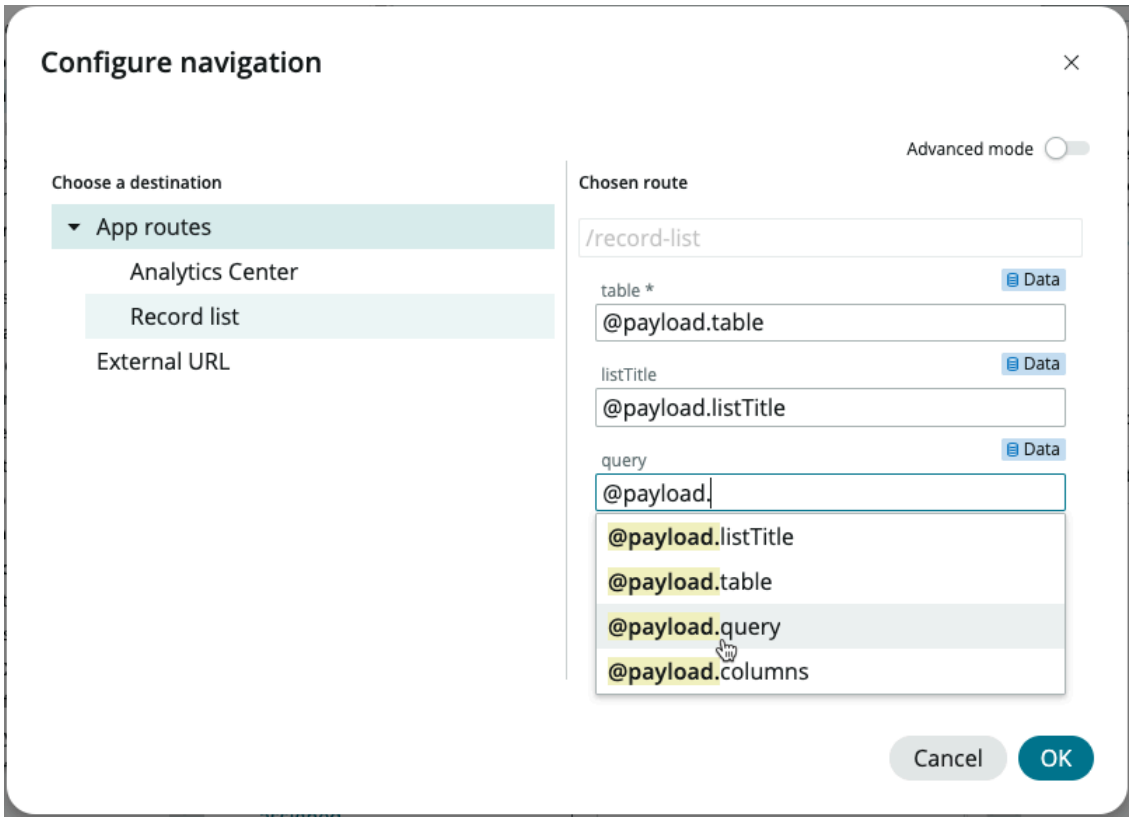


Because this page already contains a List component, when you open the **Config** tab for this component, you see that the parameters are already passed in the `@context.props.*` values.



Now, you return to the Analytics Center page. In the **Report Visualization Clicked** event, you add a new event handler. Next, you select the Record list page that you created and add the

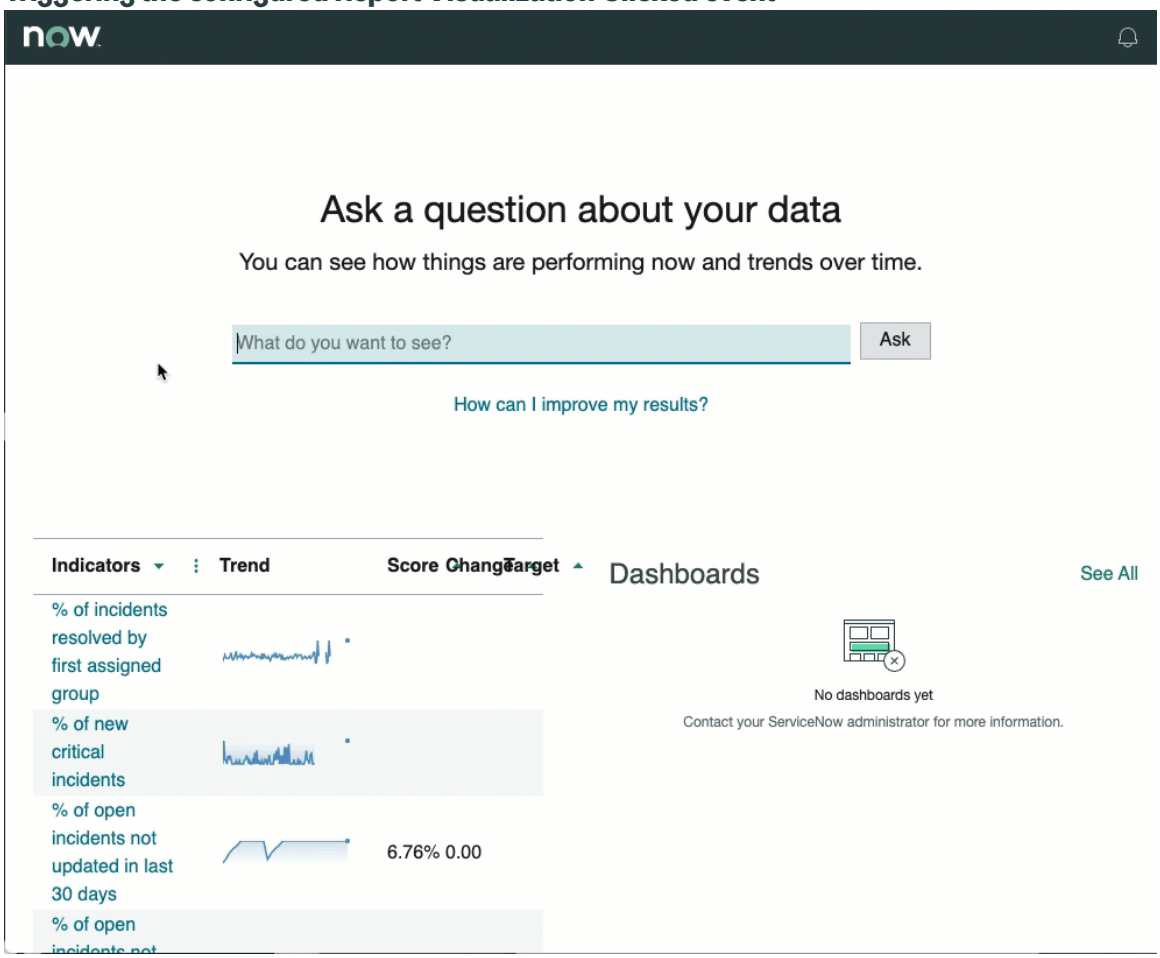
`@payload.*` values in the **table**, **listTitle**, and **query** fields, following the information that you got from the **Link to destination Relay** event handler. Predictive typing helps you to fill in these fields.



After you click **OK** and add `@payload.listTitle` as the **Title**, the event handler is done. You can now delete the**Link to destination Relay** event handler for this event.

The following example shows an Analytics Center page. On this page, you can enter a query for Incidents by Priority and get a report as a result. Also, by clicking a column, you trigger a **Report Visualization Clicked** event. The event handler enables you to see a simple list of the incidents in the report.

Triggering the configured Report Visualization Clicked event



Bind an event to a declarative action

Bind data elements within UI Builder so that you can add event actions to a declarative action.

Before you begin

Role required: ui_builder_admin

About this task

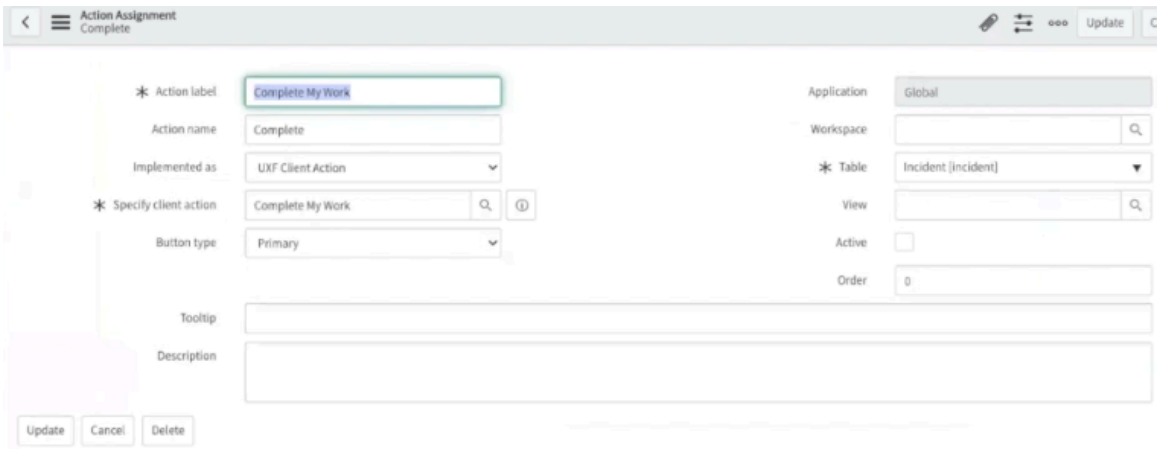
Bind a handled event to a component so that an action is performed when a user selects the component.

Procedure

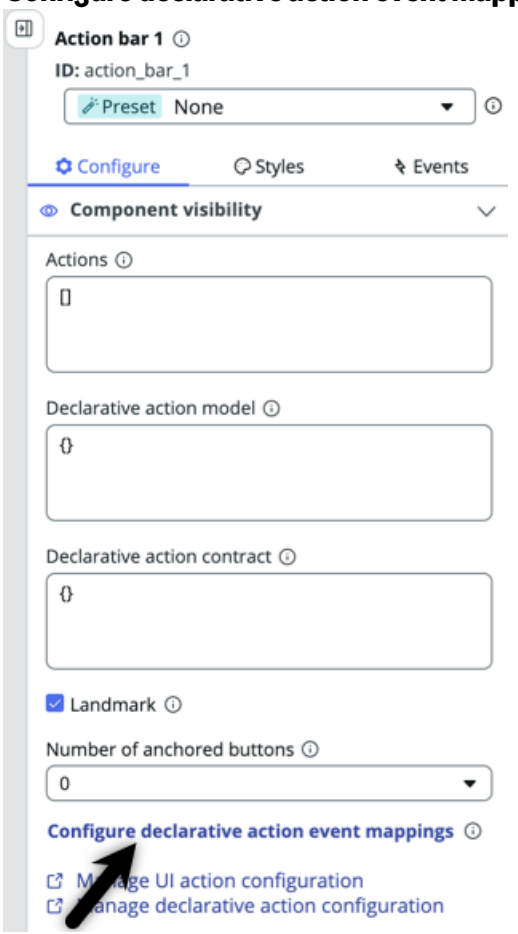
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   For more information, see Configure how users interact with your applications in UI Builder.
3. Open or create a page.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Add a component to your page that can have a declarative action, such as an action bar or related list.
   For more information, see Add and configure components.
5. To create a declarative action definition in a table in the ServiceNow AI Platform®, navigate to **Workspace Experience** > **Actions & Components** > **List actions**.

Choose a table where you want the declarative action to be available in. For example, you could create a Complete my work action in an incident table or you could use an existing declarative action definition record.

Platform declarative action definition record



6. Select the **Active** check box, and then save or update the record.
7. Return to the UI Builder.
8. To invoke a handled event for the declarative action, go to the Configure panel and click **Configure declarative action event mapping**.



9. Choose the declarative action that you created earlier.
   To continue with the example in step 5, the declarative action could be something like **Complete my work**.

10. To define what the declarative action does on your page, click **+ Add event handler**.

    a. Give the event handler a name.
    The name should describe what action you want the event handler to perform.

    b. **Optional:** Provide a description of the event handler.

    c. Choose the handled event that you want to invoke.

    d. **Optional:** Add payload values for your event handler.

    e. Select **Save**.

11. Select **Done**.

12. Select **Save**, and then select Preview.

13. Test the declarative action on your page by clicking **Complete my work** to see if it works.

Disable component preset event mappings

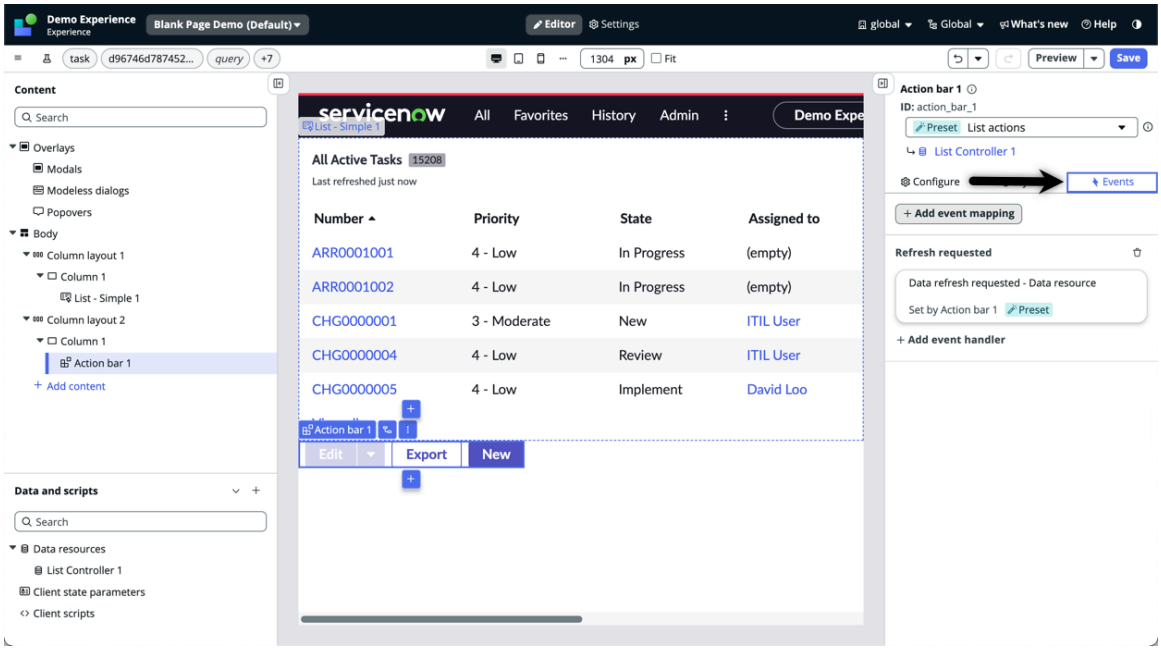
You can disable event mappings that are automatically created by a component preset.

Before you begin

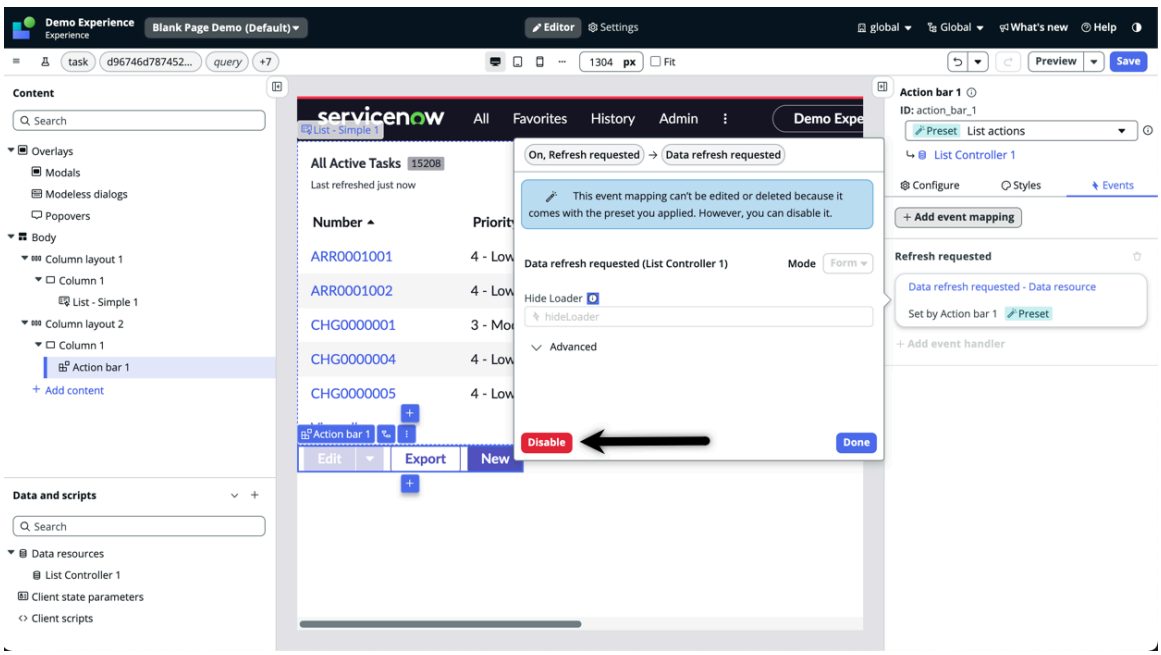
Role required: admin

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   For more information, see Configure how users interact with your applications in UI Builder.
3. Open or create a page.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Select a component with a component preset configured.
5. Select the **Events** tab in the configuration panel.



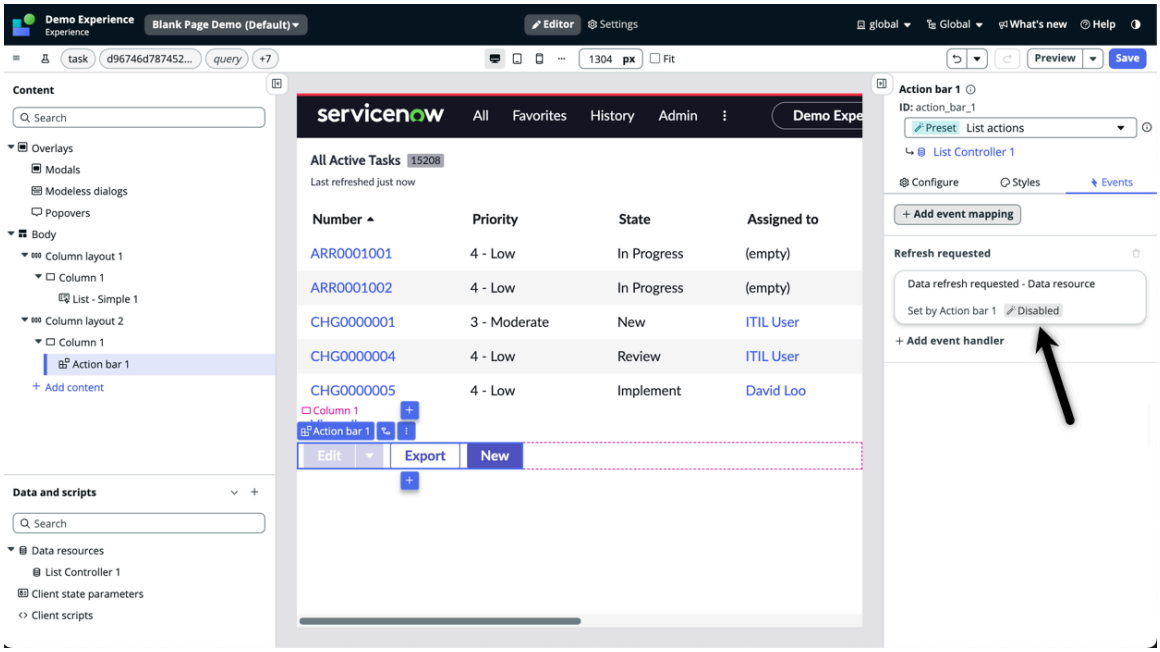
6. Select the event that you want to disable.
7. Select **Disable**.



8. Select **Done**.

Result

The component preset event shows **Disabled** in the **Events** tab of the configuration panel.



Delete an event handler

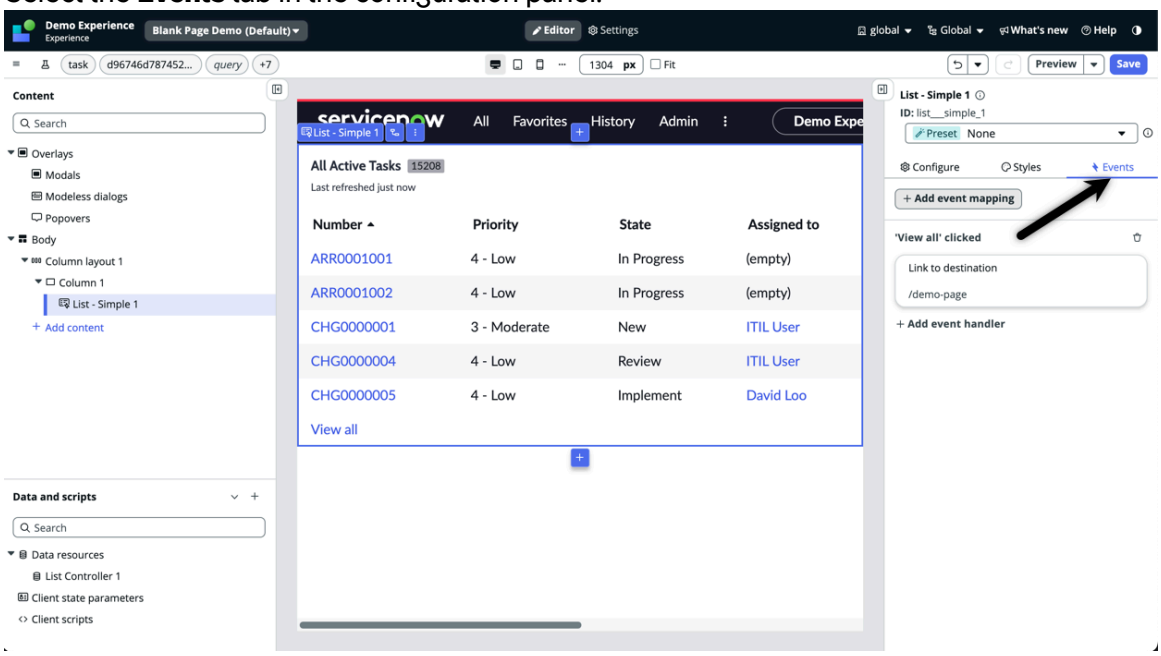
Delete an event handler that you no longer need in UI Builder.

Before you begin

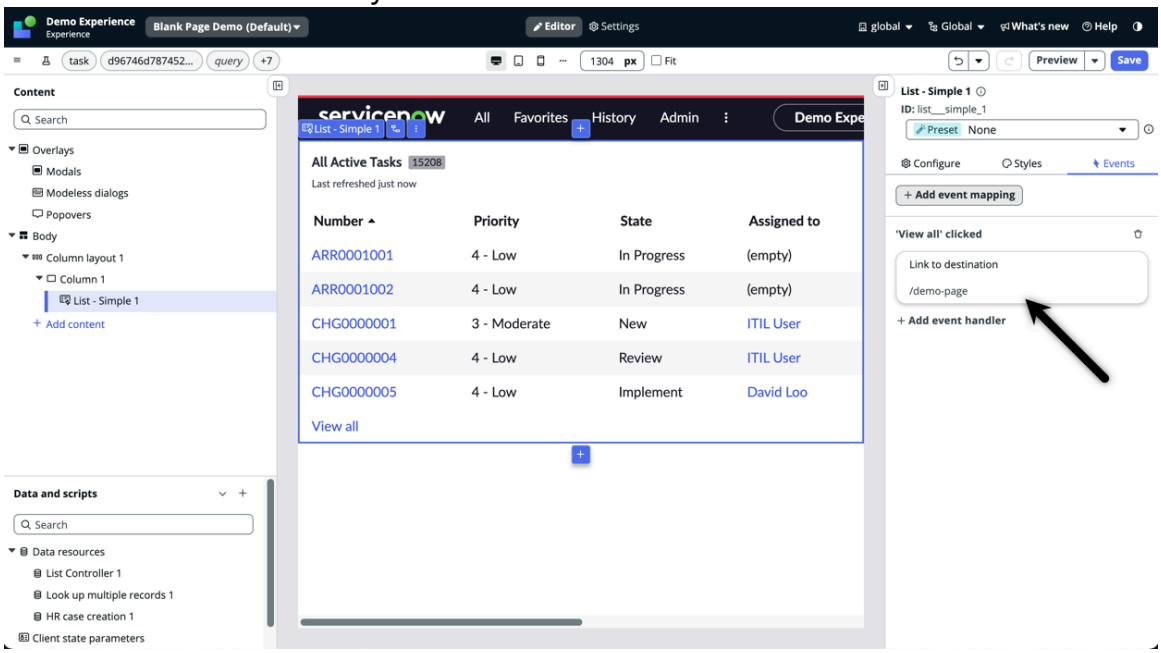
Role required: admin

Procedure

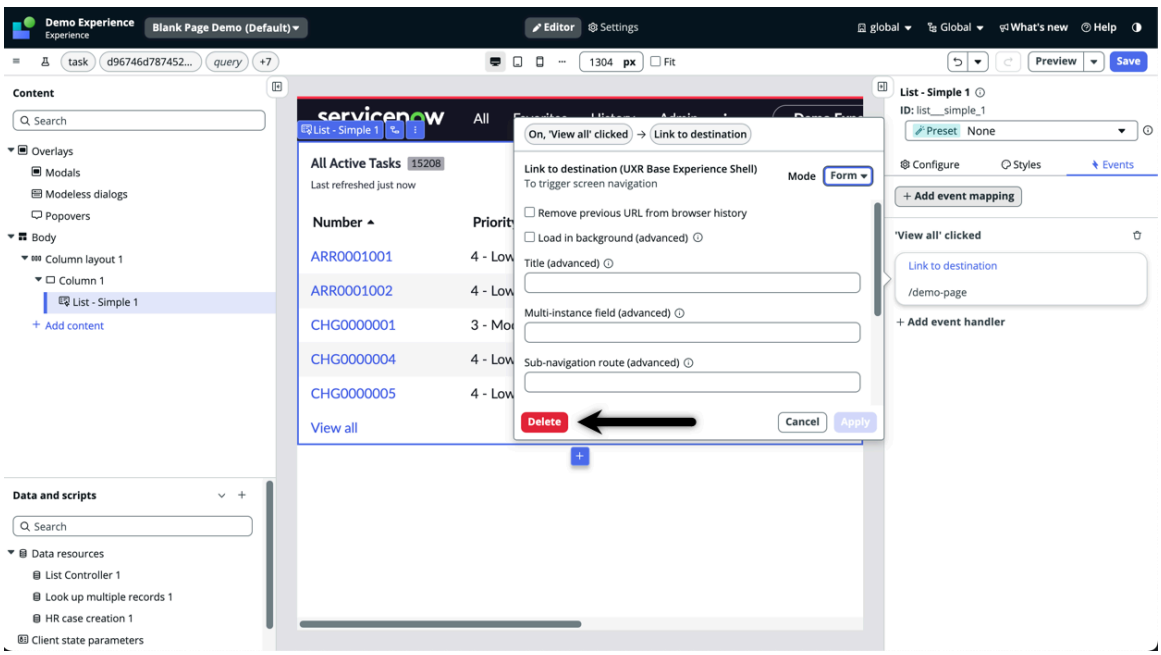
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   For more information, see Configure how users interact with your applications in UI Builder.
3. Open or create a page.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Select a component with a preset configured.
5. Select the **Events** tab in the configuration panel.



6. Select the event handler that you want to delete.



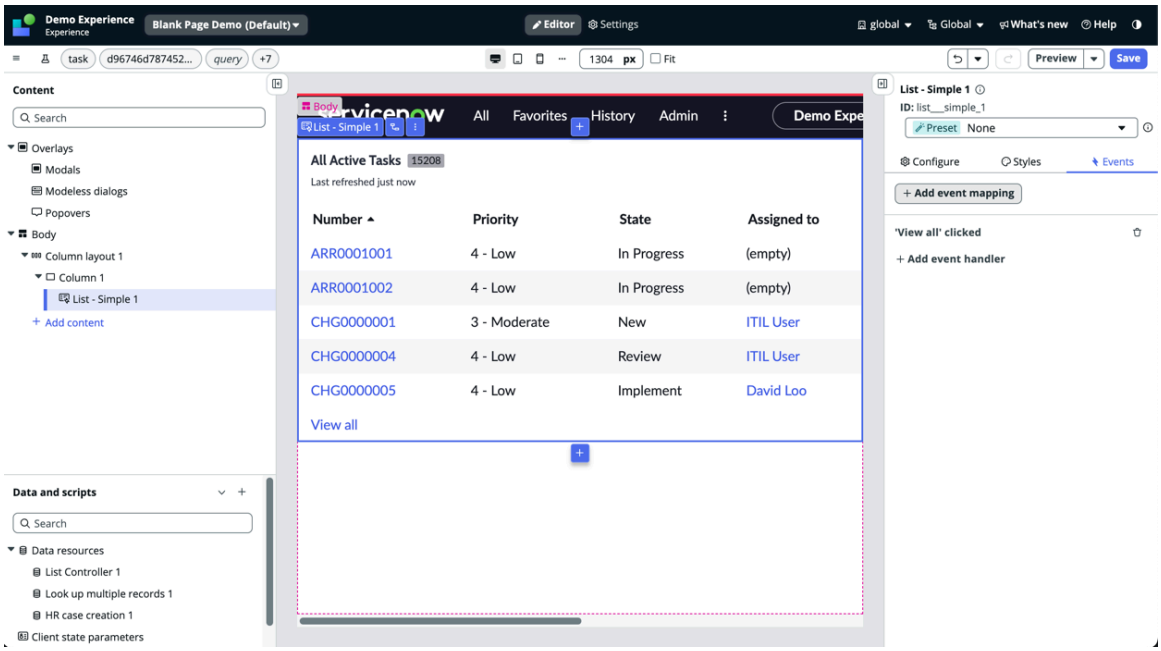
7. Select **Delete**.



8. Select **Delete** in the confirmation modal.

9. The event handler is removed from the associated event mapping.

If you would like to delete the event mapping, see Delete an event mapping.



Delete an event mapping

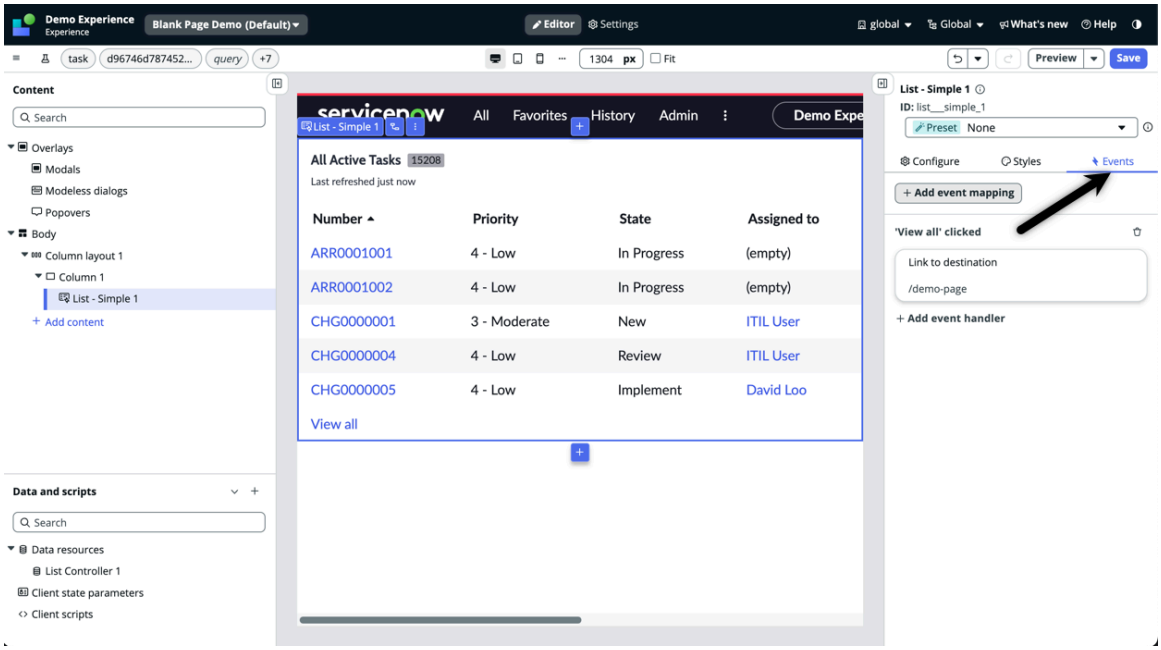
Delete an event mapping that you no longer need in UI Builder.

Before you begin

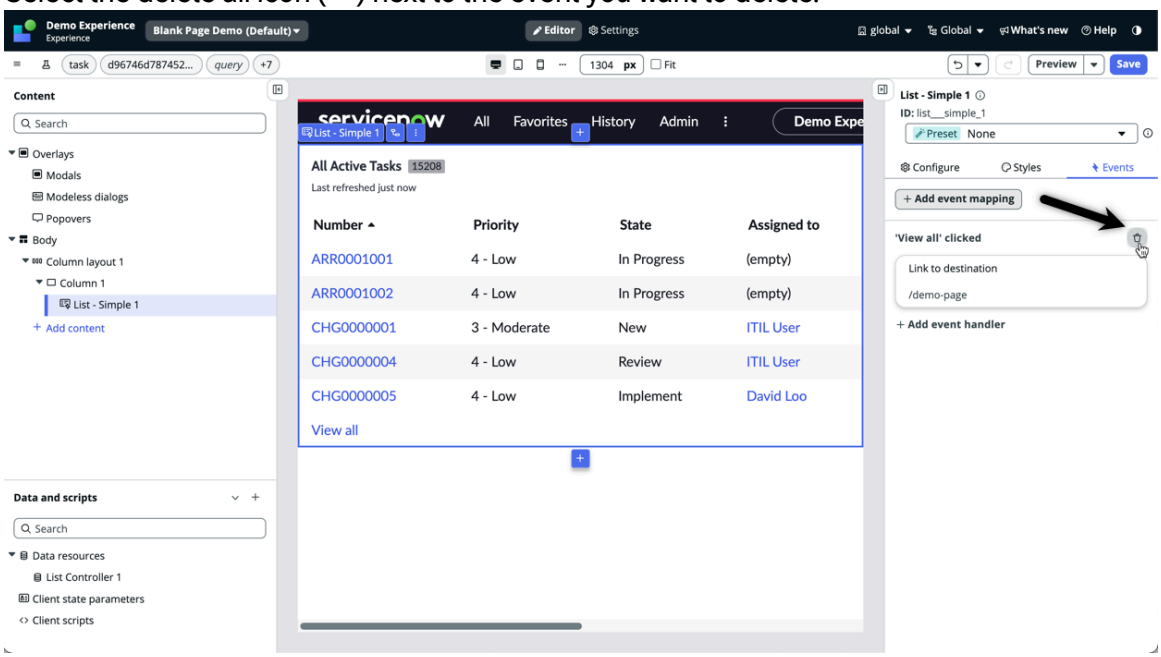
Role required: admin

Procedure

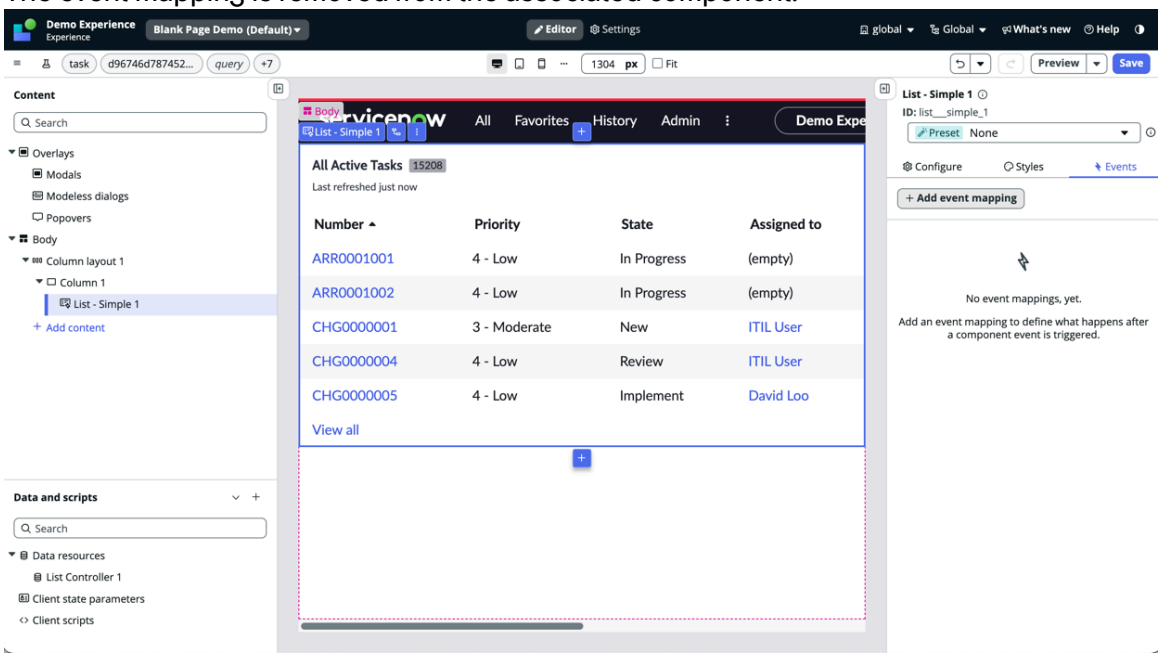
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   For more information, see Configure how users interact with your applications in UI Builder.
3. Open or create a page.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Select a component with a preset configured.
5. Select the **Events** tab in the configuration panel.



6. Select the delete all icon ( ) next to the event you want to delete.



7. The event mapping is removed from the associated component.



Manage the visual style of UI Builder experiences

Themes enable you to change the visual style of your UI Builder experiences so that they express the look and feel of your brand

Getting started with themes

By default, the Polaris theme is applied to UI Builder experiences. For more information, see Working with themes in Next Experience.

Create a new theme with Theme Builder

Theme Builder enables you to create, edit, manage, and apply Next Experience themes using a friendly visual interface. For more information, see Configuring Next Experience with Theme Builder.

Create a custom theme

If you are an admin user comfortable working in style records and JSON code, you can create a custom theme to override the default Polaris style. This option gives you the most control over typefaces, colors, and images (including the banner and logo) in a theme. For more information, see Configuring Next Experience themes and preferences.

Working with dark theme

If you are interested in dark theme, see Working with the dark theme.

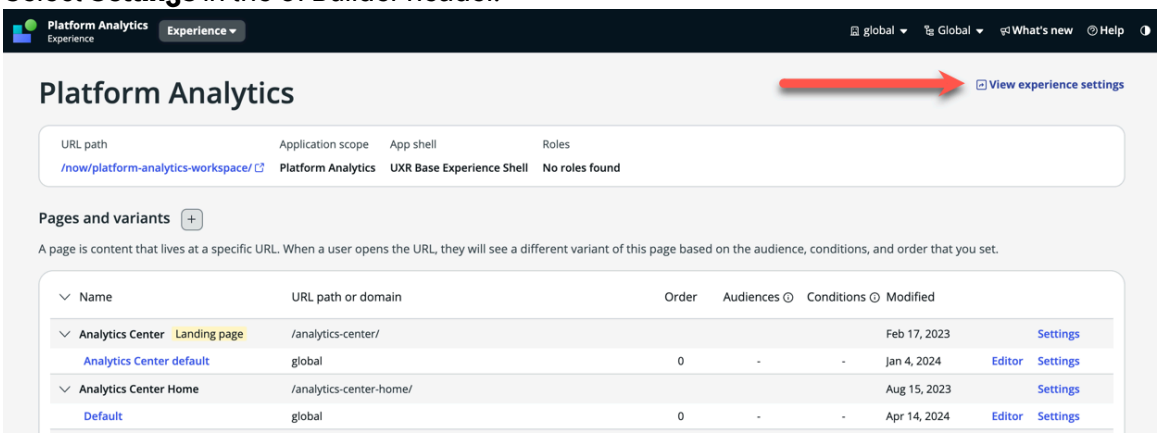
View experience theme

View the theme applied to your experience. The theme sets the visual style of the experience and provides a consistent look and feel across all pages.

Before you begin
Role required: ui_builder_admin

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Select **Settings** in the UI Builder header.



4. Scroll to the **Branding and theming** section and note what is listed in **Themes**. By default, the Polaris theme is applied to UI Builder experiences.

What to do next

If you want to customize the theme, there are two options:

- **Theme Builder** enables you to create, edit, manage, and apply Next Experience themes using a friendly visual interface. For more information, see Configuring Next Experience with Theme Builder.
- If you are an admin user comfortable working in style records and JSON code, you can create a custom theme to override the default Polaris style. This option gives you the most control over typefaces, colors, and images (including the banner and logo) in a theme. For more information, see Configuring Next Experience themes and preferences.

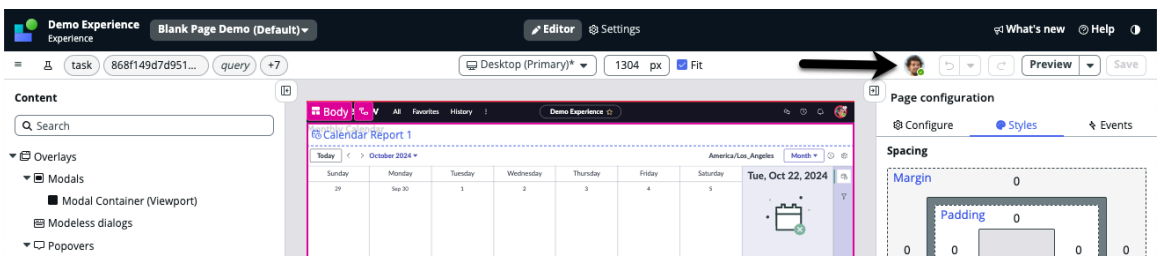
Collaborate with other UI Builder developers

UI Builder provides real-time collaboration tools and user presence indicators for more efficient and intuitive UI development.

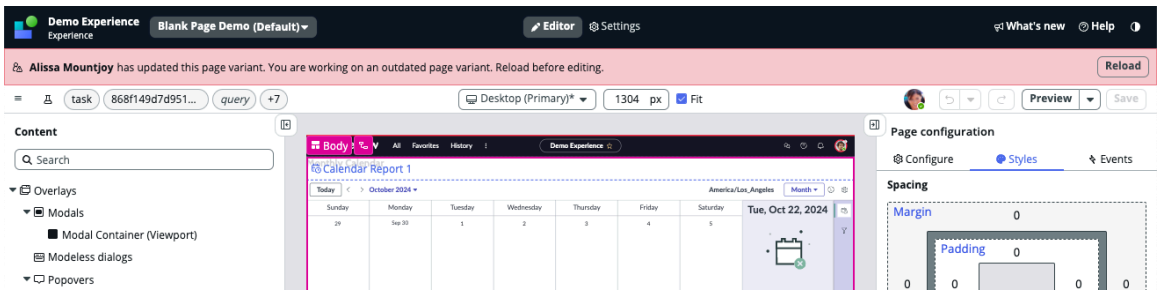
UI Builder lets you see who is online and working on the same page in an experience.

The avatars of other developers appear in the UI Builder header next to the undo button. A dot on the avatar of the user represents online status.

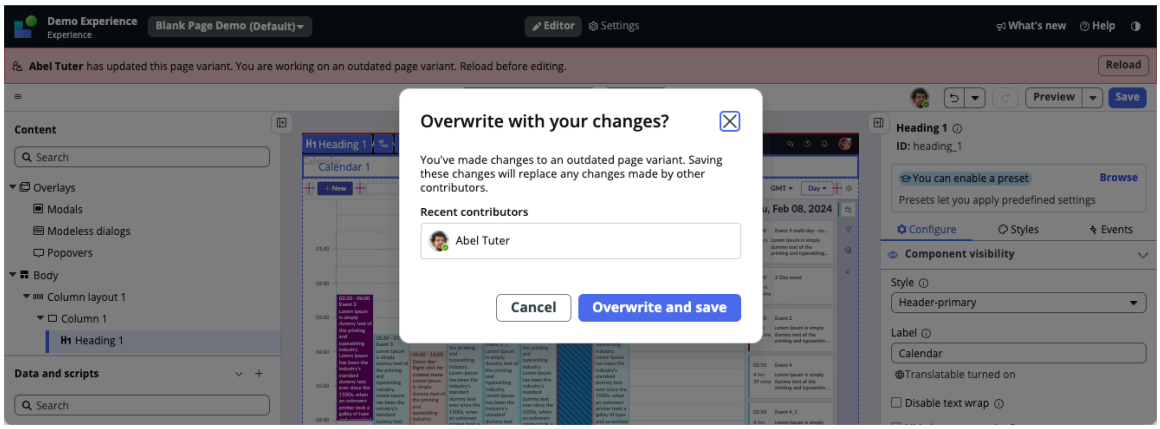
- Green dot if the user is currently working on the page
- No dot if the user is not logged in



A banner will appear asking you to reload the page to view the latest version if changes are made by other users while you are editing a page.



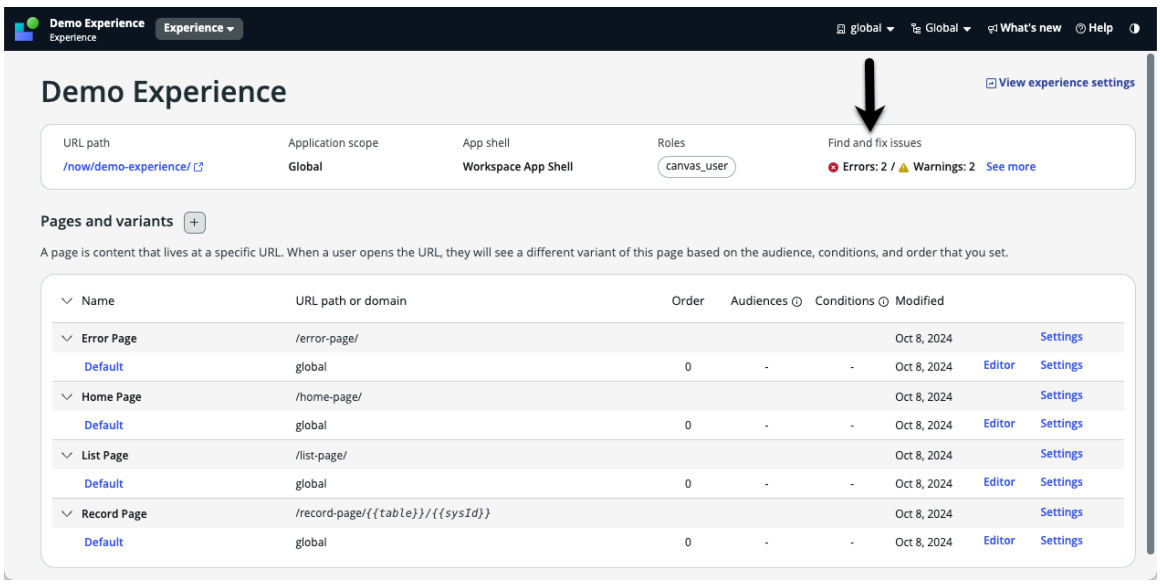
If you have made changes at the same time as another user you will be prompted to **Overwrite and save** your changes to proceed with previewing the page.



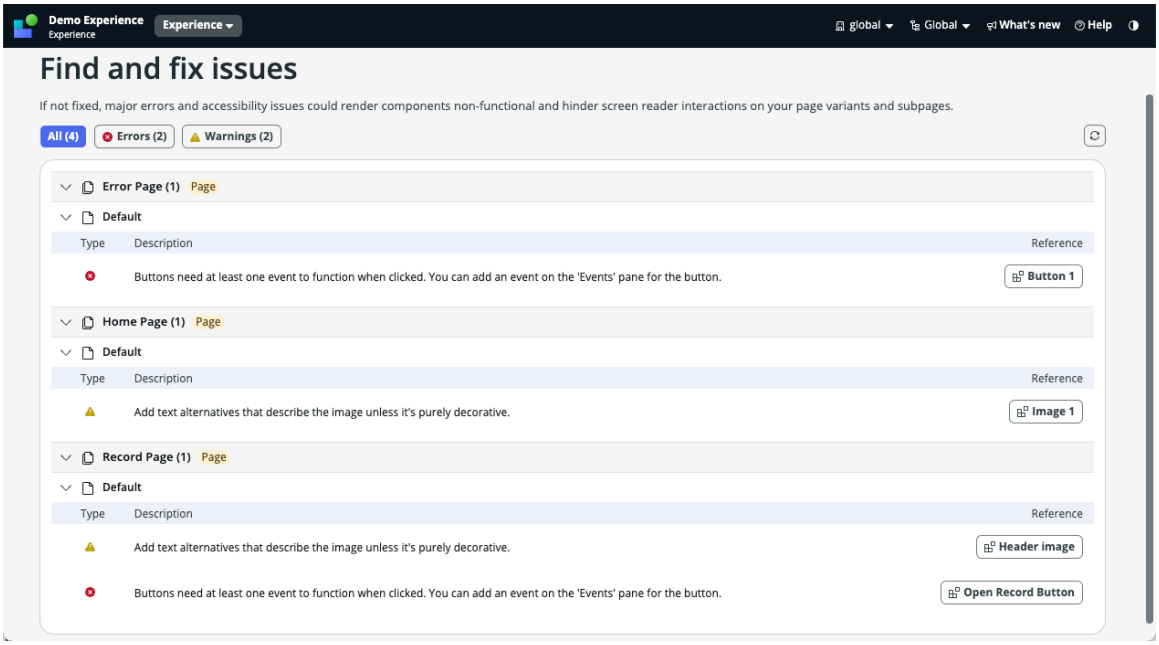
Find and fix issues in UI Builder

UI Builder can help identify common configuration issues and guidance on how to fix them.

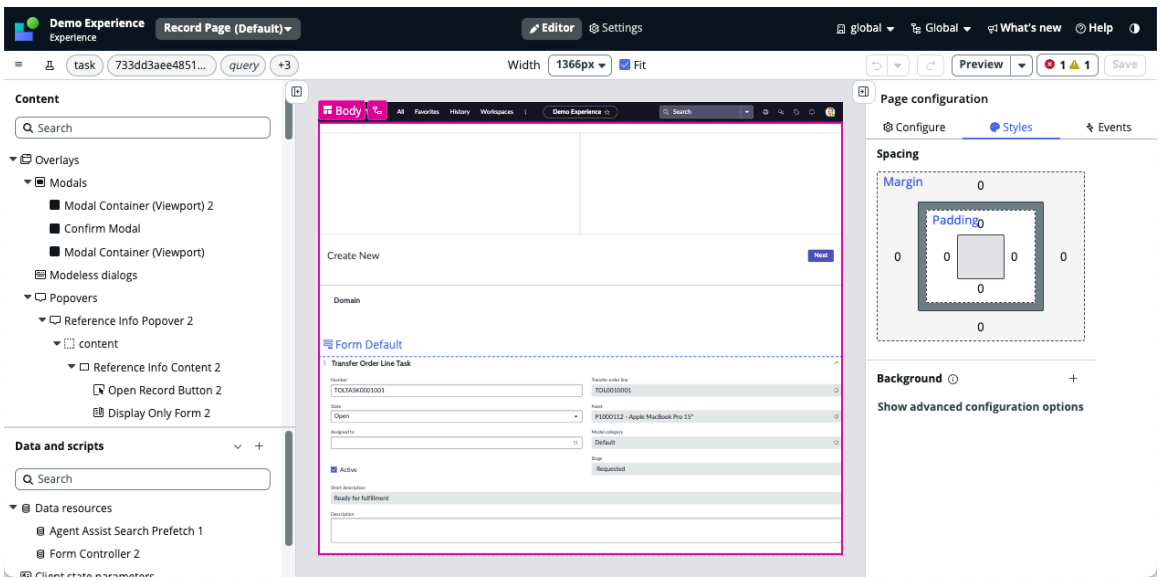
UI Builder can help you find and fix issues by checking your experience for missing configurations, errors, and accessibility standards. The list of issues can be found within the experience view of UI Builder under the **Find and fix issues** section.



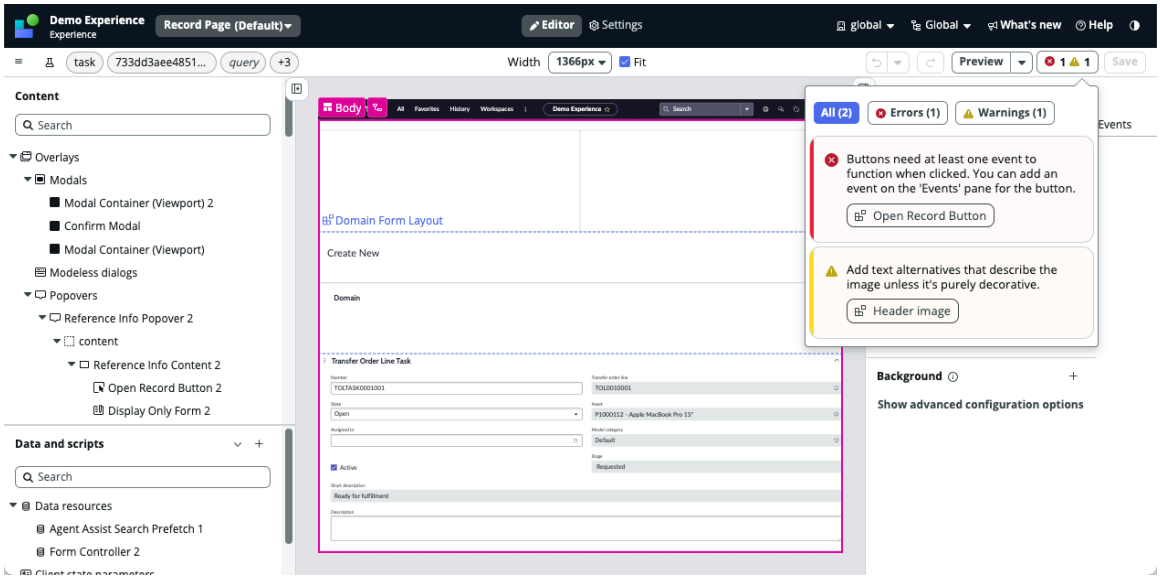
Find and fix issues list



You can also find UI Builder issues in the header of the page builder next to the **Save** button. The button auto updates as it finds errors and recommendations for the content on your page.



To find more information, select the builder icon to view the list of recommendations made by UI Builder. Each error and warning will list the component name that contains the issue.



Find and fix issues in UI Builder

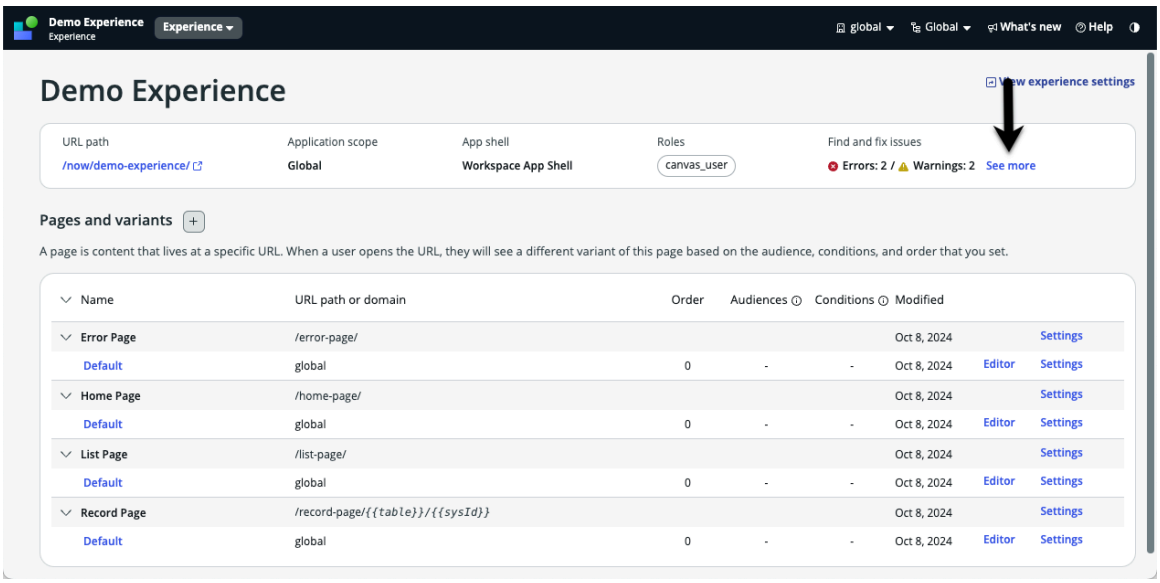
Find and fix issues found in your UI Builder experience.

Before you begin

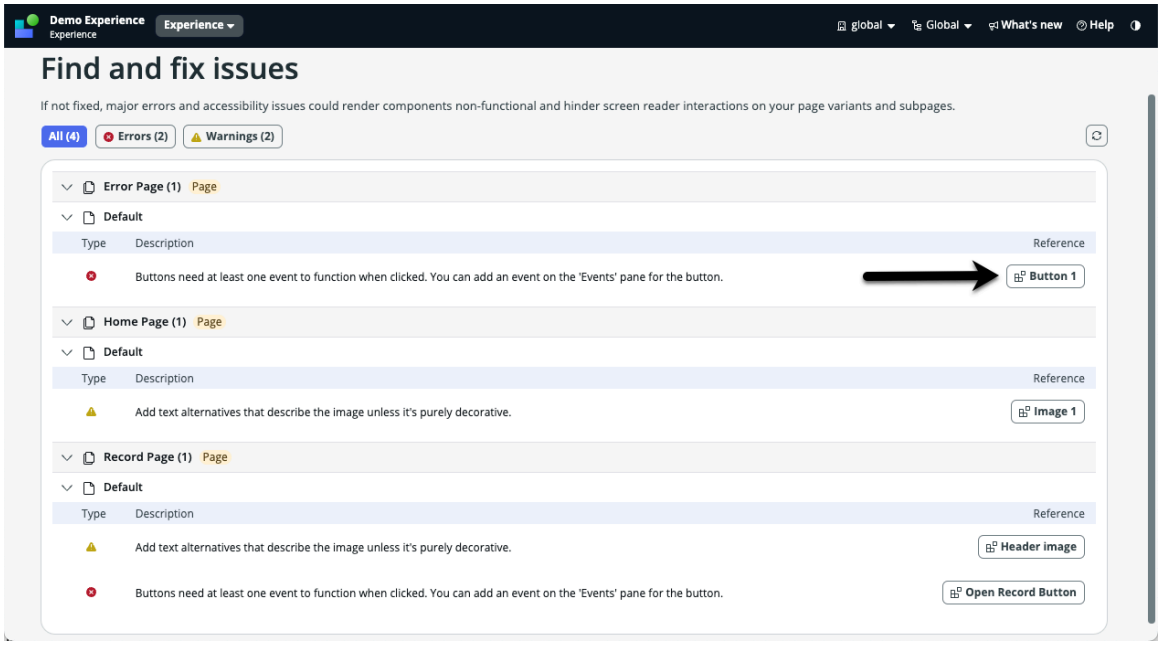
Role required: ui_builder_admin

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open the experience you want to check for issues by selecting **Experiences**.
3. Select **See more** under the **Find and fix issues** section.

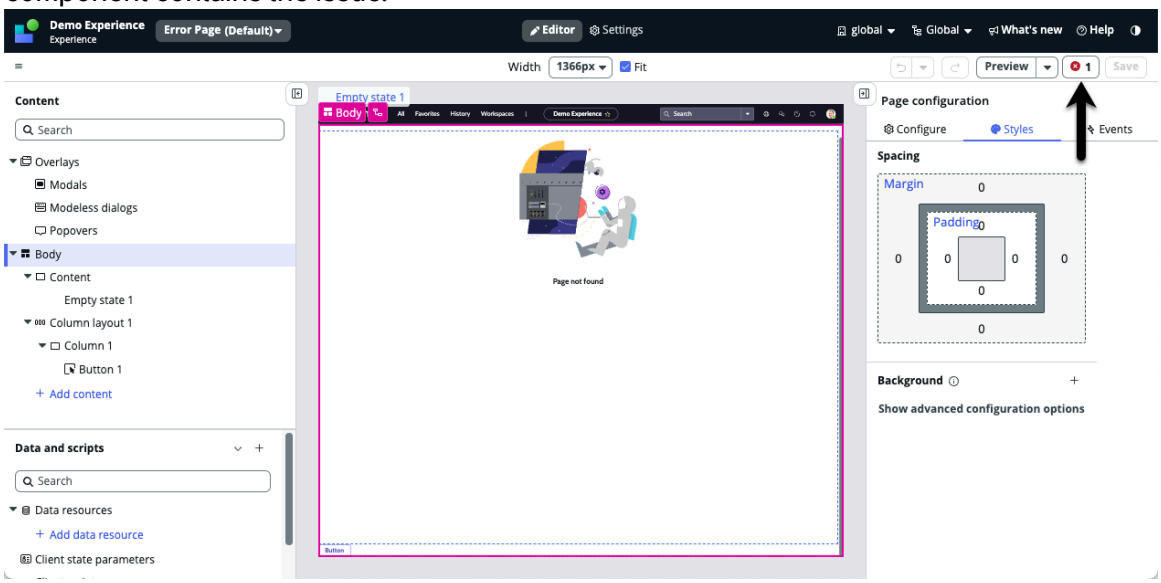


4. Fix the issues found in your experience by selecting button under the **Reference** section.

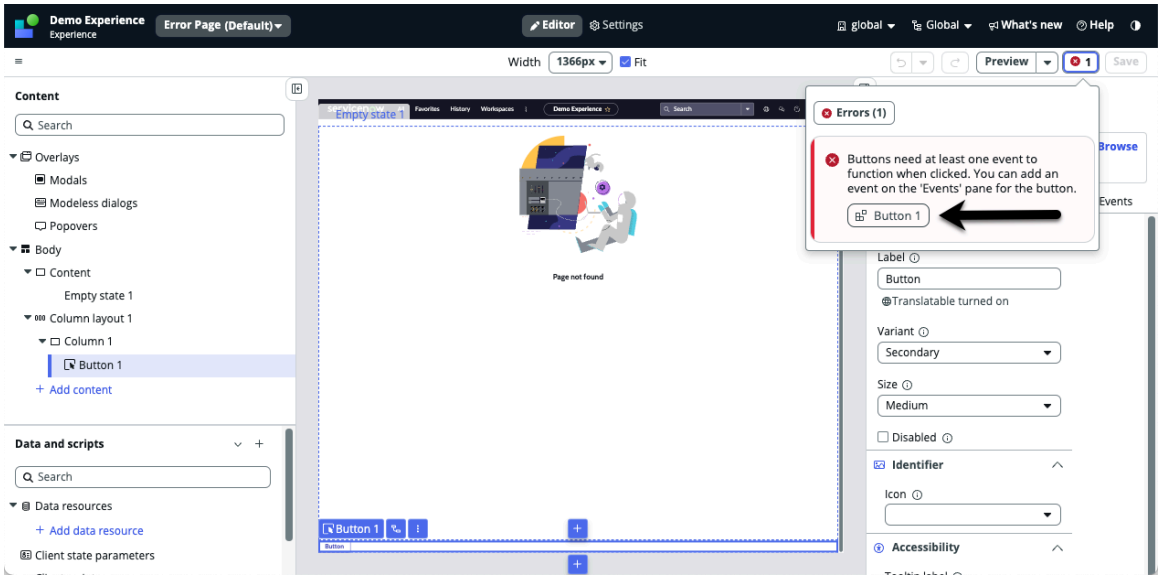


A new tab will open to the page with the issue.

5. Select the error button in the header to get a brief description of the issue and which component contains the issue.



The component name will be listed in the error or warning.



6. Select the component with the issue and follow the instructions listed in the warning or error text.
7. Select **Save**.

Advanced UI Builder

UI Builder can be used by application developers with a variety of skill levels. We recommend developers with a high level of experience, sometimes referred to as pro-coders, perform the procedures in this section.

Configure components and repeaters (advanced feature)

You can add and configure components as you build pages in UI Builder. You can also use repeaters to repeat components or multiple components with results from a data resource.

Add and configure components

Learn how to add components to your page in UI Builder. A page is built by adding components.

Before you begin

Role required: ui_builder_admin

About this task

Components are the building blocks used to create custom pages in UI Builder. Learn how to add a component to a page. After you add a component to a page, you must configure the component. For more information about configuring components, see Component documentation on the ServiceNow Developer Site.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Open or create a page.
   If you open an existing page, make sure you are in the same scope as the original page. If not, change the scope before you start editing the page. Application scoping protects applications by identifying and restricting access to application files and data. Administrators set the scope to specify what parts of an application are accessible to other applications. Application scope

protects data and application files. See Learn about security and roles for more information about application scope.

4. Select an existing container or create a column layout.
   See Organize components in UI Builder pages for more information.
5. Add components to your page.
   UI Builder comes with a library of components to choose from. You add components as the building blocks of your page. For example, you can add a heading, data visualizations, and so on. The following table shows you the different ways you can add a component to a page.
6. Now configure the properties of the components that you just added.
   Configuring components means to customize them to your needs. For more information about configuring components, see Next Experience Components.

   a. Select the component that you want to configure.

   b. Select the **Configure** tab from the configuration panel in UI Builder.

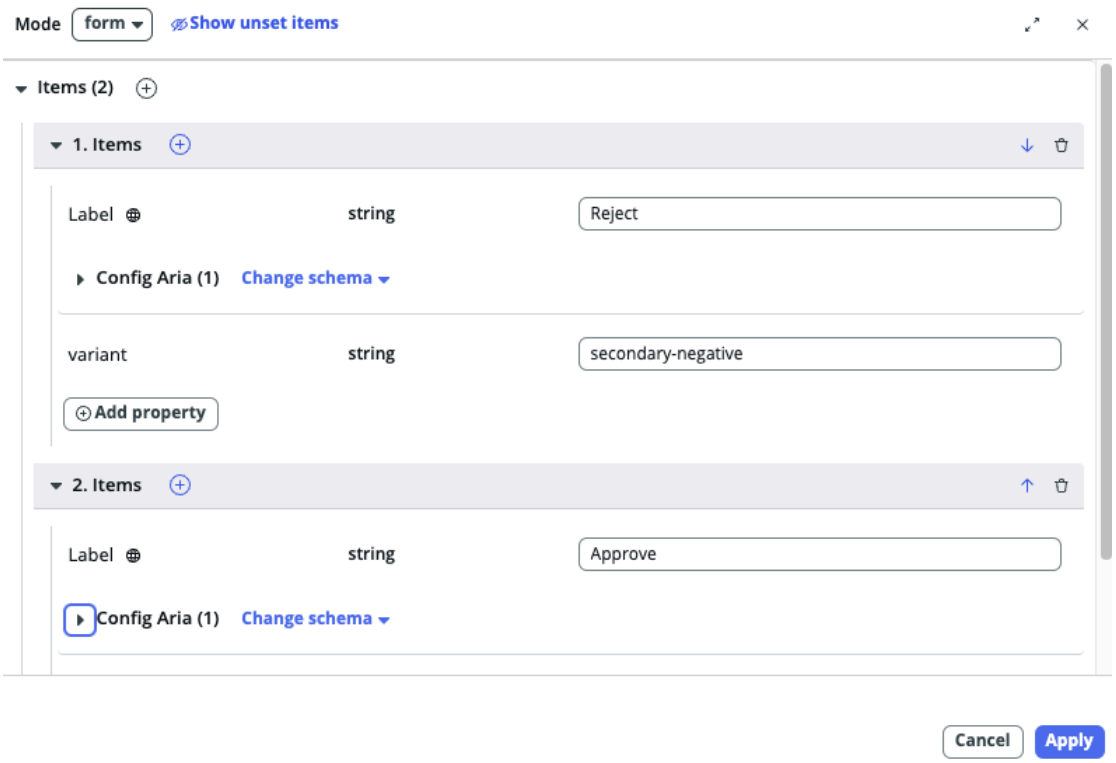
   c. Customize the component properties for the component.
   For example, you could add a name for a button component. Some components, like data visualizations, require a data source before you can configure the properties. Each component has different configuration properties based on the requirements and options for each component. For example, the **Button** component configuration is simple, while a **List** component requires more configuration.

   d. For components with configurable JSON properties, you can use UI Builder's low-code JSON editor to edit component properties without needing to edit JSON code.

   The JSON editor UI displays all available properties, even properties not defined in the dummy data or defined values. You can update properties or add your own custom properties within the JSON editor. For more information about configuring components, see Edit code with the Now Code Editor (advanced feature).

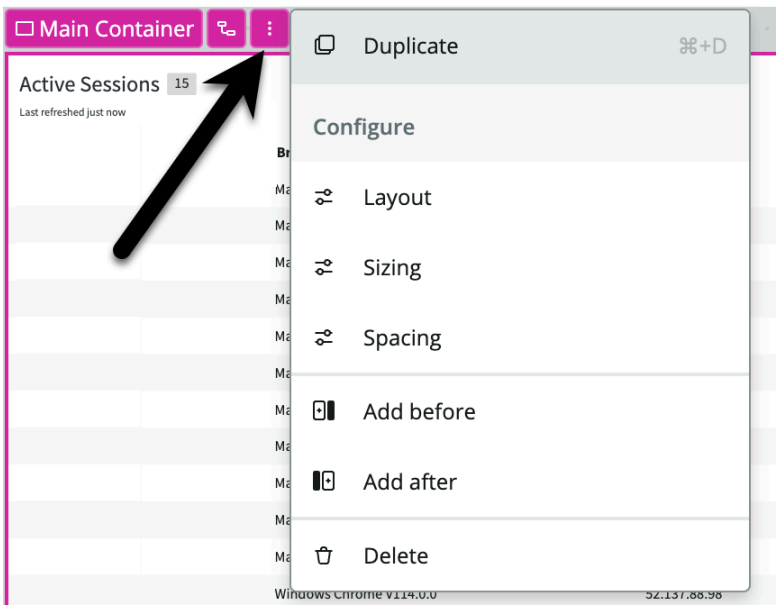
   Note:
   The low-code JSON editor is only available to properties that have a schema and whose JSON input matches said schema.

   The low-code JSON editor supports simple objects, simple array properties, complex arrays, arrays of objects, and partially supports complex objects. For complex arrays, you can add, delete, or move the position of array items. You can also select **Hide unset items** to hide objects with empty or null values for a simplified editing experience.

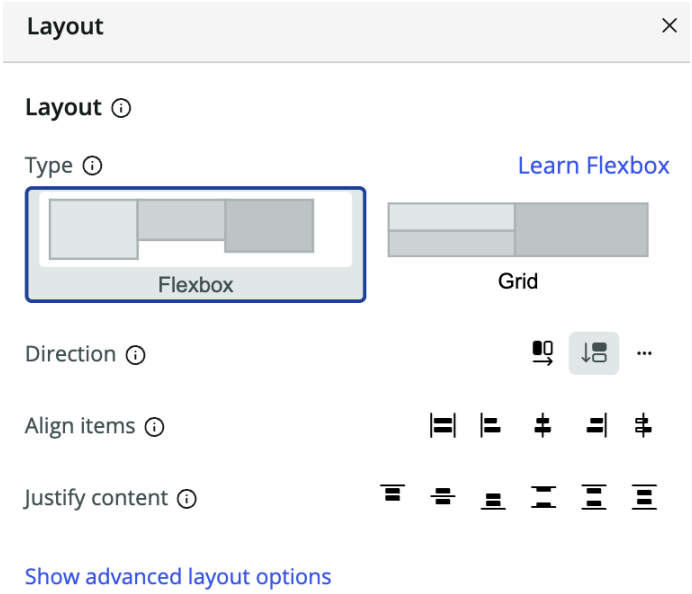


e. When working with a container component, you can edit some styles by using the floating panels.

Select the **Menu** icon to view a menu.



Select the **Layout**, **Sizing**, or **Spacing** option to open a floating panel with the most common options displayed. Drag the floating panel to another location as needed. Only one floating panel can be open at a time.



For more information about configuring components, see Next Experience Components.

7. **Optional:** Select the **Events** tab to add an event handler to your component.
   Add an event handler to add actions to the components on your page. For example, a button component is static and doesn't do anything until you bind an event action to it, such as saving a record. Some components don't have an event action applied to them, such as a heading component. But many components require you to map an event to your component to actually make it perform an action. See Bind an event to a component for more information on how to add event handlers to your component.
8. **Optional:** You can override any styles for a component by adding CSS styling under the **Styles** tab.
   For more information, see Change the default appearance of components.

   Note:
   Style changes only affect a single component at a time. To change the visual style of all the components in your experience, you must apply a theme to your experience. For more information, see Manage the visual style of UI Builder experiences.

9. **Optional:** Add additional containers to your page to display your components in an organized way.
   For example, one container could have a heading component. Another container below it could include a list component, a button component, and so on.
   a. Select the **+** at the top of your container to add a container component before the existing component and select the **+** at the bottom of a component to insert a container component after it.
   b. Drag a container component from the Components list to your existing container on the page; Hold over the top line of the container to insert the new container before the existing container or over the bottom line of the existing container to add it after.
10. **Optional:** Add more components to your page by selecting the **+** on the top or bottom of the components on the page (the **+** changes to **+ Add**).

a. Select the **+** at the top of your component to add a component before the existing component or select the **+** at the bottom of a component to insert a component after it.

b. Drag a component from the component list to insert the component before or after an existing component.

11. **Optional:** To make a modal appear when you select a component such as a button, you must add the modal to the component first.
A modal is a confirmation pop-up that appears when you select the component. For example, if you add a button component that deletes a record, you add a modal to ask the user to confirm they want to delete the record. See Create modals in UI Builder for more information.

12. Select **Save** often on your page as you work.

13. View and test your page by selecting the **Preview** button.

What to do next

You have added and configured components on your page. See Dynamically expose data in UI Builder pages (advanced feature) for more information. A data resource in UI Builder is the data that a page fetches to display content in components. Components use data resources as a way to reuse data and configurations across different experiences, and make the components dynamic on a page.

Supported functions in the UI Builder component formula editor

Learn about the various functions supported in the UI Builder component formula editor.

The following table lists the functions you can use in the UI Builder component formula editor. For more information about the component formula editor, see Customize UI Builder pages using components.

Operators available for condition builders

Operator label	Example condition	Equivalent query operator	Example query	Example output
All empty	[Short description] [ALL_EMPTY]	ALL_EMPTY	short_descriptionALL_EMPTY	All records in which there is no value in the **Short description** field.
All equal	[Short description] [ALL_EQ] [Network storage unavailable]	ALL_EQ	short_description=Network storage unavailable	All records in which the value for the **Short description** field is equal to "Network storage is unavailable."
All greater than	[Impact][ALL_GT] [2 - Medium]	>	impact>2	All records in which the **Impact**

Operators available for condition builders (continued)

Operator label	Example condition	Equivalent query operator	Example query	Example output
				field has a value of **3 - Low**
All greater than or equal	[Impact][ALL_GTE][2 - Medium]	>=	impact>=2	All records in which the **Impact** field has a value of **2 - Medium** or **3 - Low**.
All less than	[Reassignment count][ALL_LT][2]	<	reassignment_count<2	All records in which the value in the **Reassignment count** field is any number less than (but not equal to) **2**.
All less than or equal	[Reassignment count][ALL_LTE][2]	<=	reassignment_count<=2	All records in which the value in the **Reassignment count** field is one of the following: • a number less than 2 • 2
All not equal to	[Impact][ALL_NEQ][1 - High]	!=	impact!=1	All records in which the value in the **Impact** field is anything but **1 - High**.
All not empty	[Impact][ALL_NOTEMPTY]	ALL_NOTEMPTY	impactALL_NOTEMPTY	All records in which the **Impact** field has any value.
All not one of	[Impact][ALL_NOTONEOF][1 - High, 2 - Medium]	ALL_NOTONEOF	impactALL_NOTONEOF1,2	All records in which the **Impact** field is populated by anything except the following values: • **1 - High** • **2 - Medium**

Operators available for condition builders (continued)

Operator label	Example condition	Equivalent query operator	Example query	Example output
All one of	[Impact] [ALL_ONEOF][1 - High, 2 - Medium]	ALL_ONEOF	impactALL_ONEOF1,2	All records in which the **Impact** field is populated by one of the following values: • **1 - High** • **2 - Medium**
Any empty	[Short description] [ANY_EMPTY]	ANY_EMPTY	short_descriptionANY_EMPTY	Any record in which there is no value in the **Short description** field.
Any equal	[Short description] [ANY_EQ] [Network storage unavailable]	ANY_EQ	short_description=Network storage unavailable	Any record in which the value for the **Short description** field is equal to "Network storage is unavailable."
Any greater than	[Impact][ANY_GT] [2 - Medium]	ANY_GT	impactANY_GT2	Any records in which the **Impact** field has a value of **3 - Low**
Any greater than or equal	[Impact] [ANY_GTE][2 - Medium]	ANY_GTE	impactANY_GTE2	Any record in which the **Impact** field has a value of **2 - Medium** or **3 - Low**.

Add repeaters to components

In UI Builder, use repeaters to repeat one or more components with results from a data resource.

Before you begin

Role required: ui_builder_admin

About this task

The repeater component acts as a basic loop that repeats the data you provide in multiple components within UI Builder. Repeaters use an array or an array of objects. For example, the array `[{"task": "A"},{"task": "B"}]` repeats the content inside it two times. Repeaters enable you to bind values to a data array property. `@item.value.{property_name}` binds the values to the component inside the repeaters. If you want to bind a task, you can bind it as `@item.value.task`, and the repeater displays the correct value.

Components inside a repeater repeat the number of items in the data source, regardless of whether the component output is made dynamic or not. For example, say that you place a Header component inside a repeater with three data elements but don't change the Label field. Then you see three instances of the Header with the same output Label.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Open the editor for the page where you want to add the repeater.
   If you haven't created a page for your experience, see Create a page in UI Builder for more information on how to create a page.
4. Connect a data resource to your page.

   For example, add the **Look up multiple records** data resource to your page. See Add and configure data resources to a page for more information on connecting a data resource.

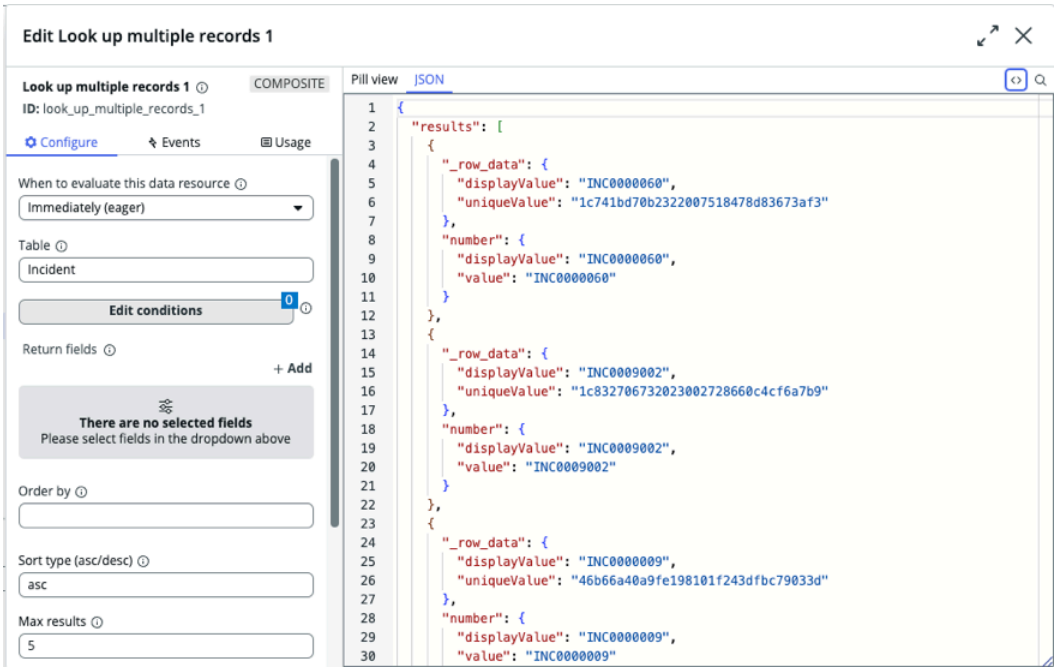
   a. In the data resource drawer, select **+ Add data resource**.

   b. In the modal, search for the **Look up multiple records** data resource and select **Add**.

   c. In the **Table** field, enter `Incident`.

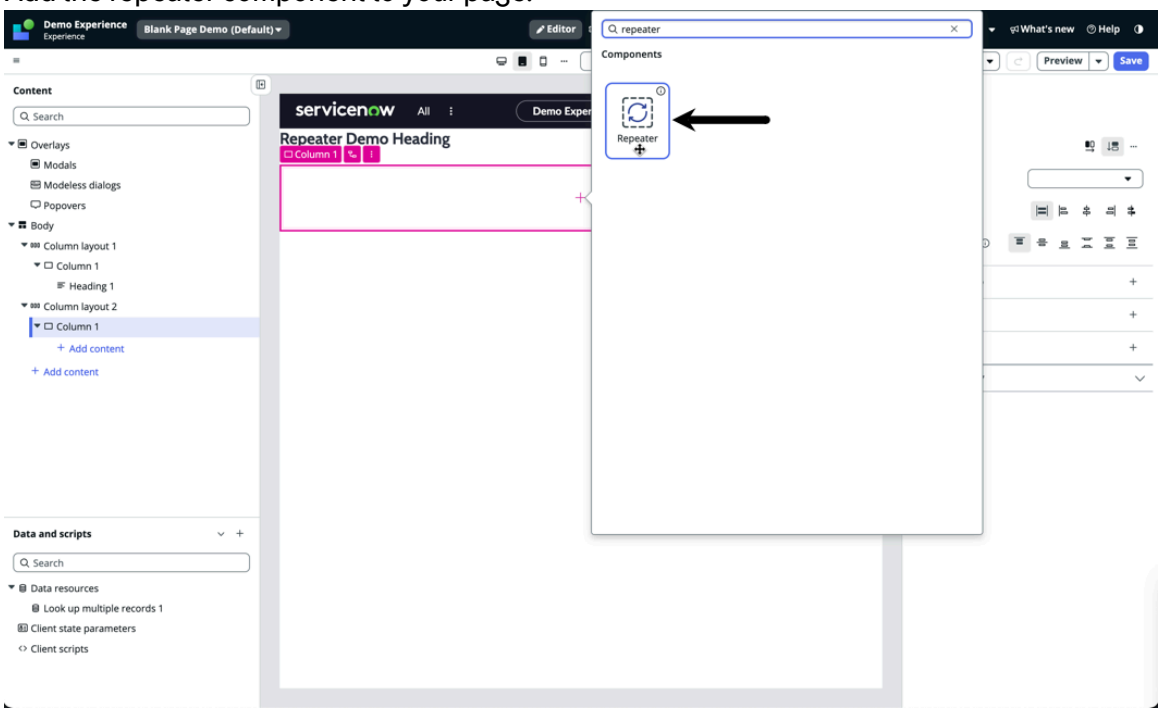
   d. In the **Max results** field, enter `5`.

   The **Look up multiple records** data resource is configured.



e. Close the modal.

5. Select an existing container or create a column layout.
   See Organize components in UI Builder pages for more information.
6. Add the repeater component to your page.



For information about adding components, see Add and configure components.

7. In the **Configure** tab, select **None - Configure the component manually**.
8. In the **Configure** tab, add an array that defines the data for repeated components.

a. Point to **Data array** and select the Bind data icon ( ).

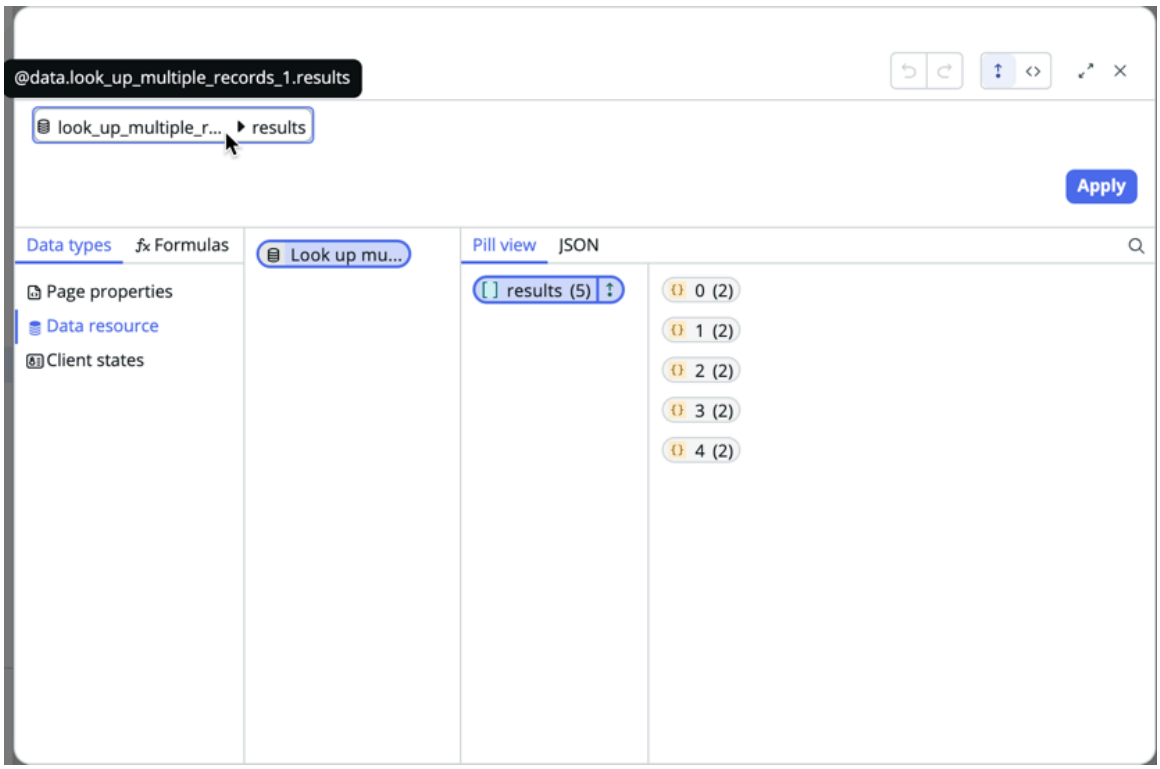
b. Under **Data types**, select **Data resource**.

c. In the next column, select the **Look up multiple records 1** pill.

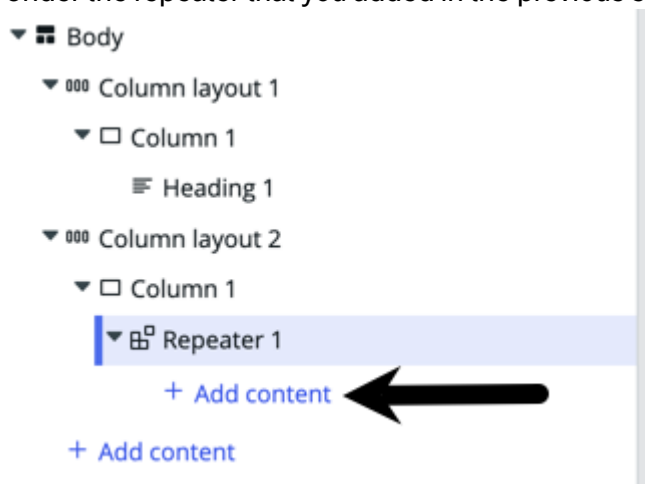
d. Under **Pill view**, double-click or drag **results** to add the **@data.look_up_multiple_records_1.results** output.

e. Select **Apply**.

The results from the data resource are bound to the repeater component. Within the repeater, one component represents each result.



9. Under the repeater that you added in the previous step, select **+ Add content**.



10. Add a **Heading** component.
11. In the **Configure** tab, select **None - Configure the component manually**.
12. Configure the component you nested in the repeater.

    For example, bind the **displayValue** to the component. See Connect data to your components for more information.

    a. Move your cursor to the **Label** field and select the Bind data icon ( ).

    b. Under **Data types**, select **Repeater**.

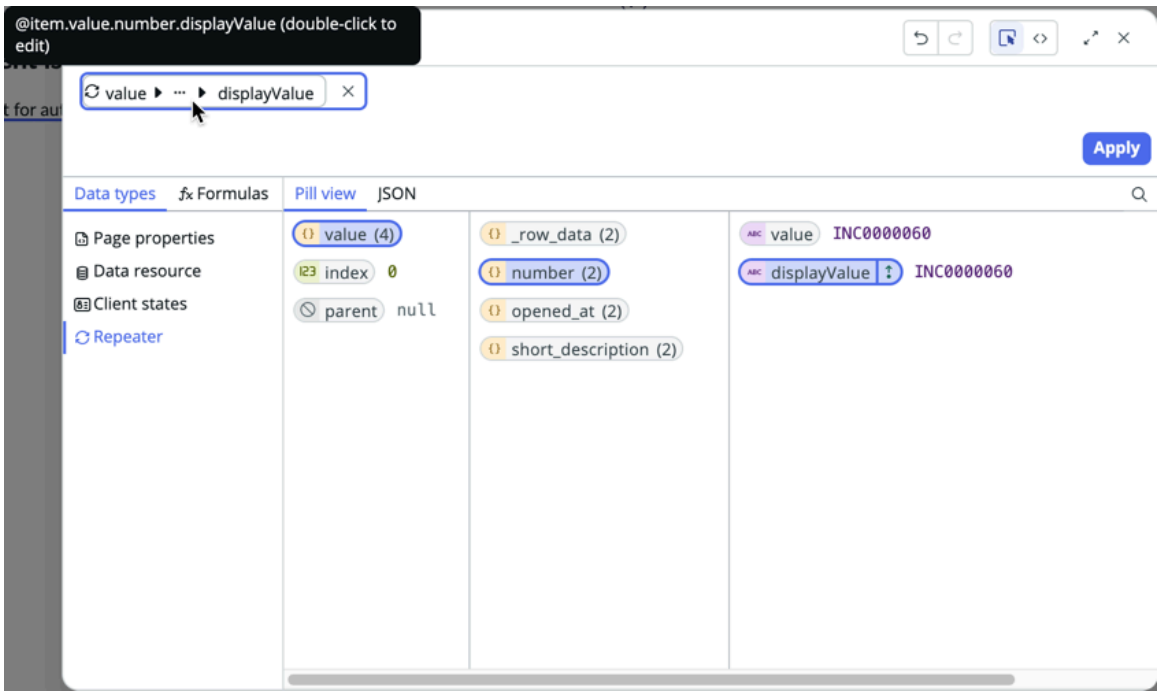
    c. Under **Pill view**, select the **value** pill.

    d. In the next column, select the **number** pill.

    e. In the next column, double-click or drag **displayValue** to add the **@item.value.number.displayValue** output.

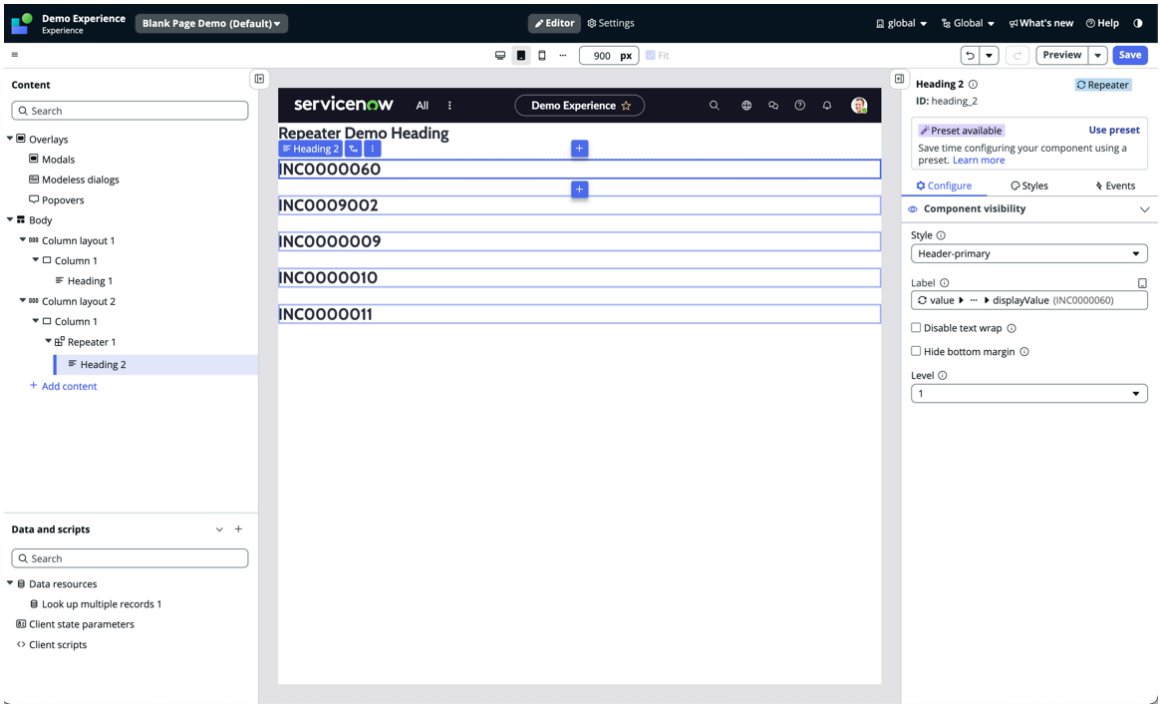
    f. Select **Apply**.

    The **displayValue** is bound to the Heading component.

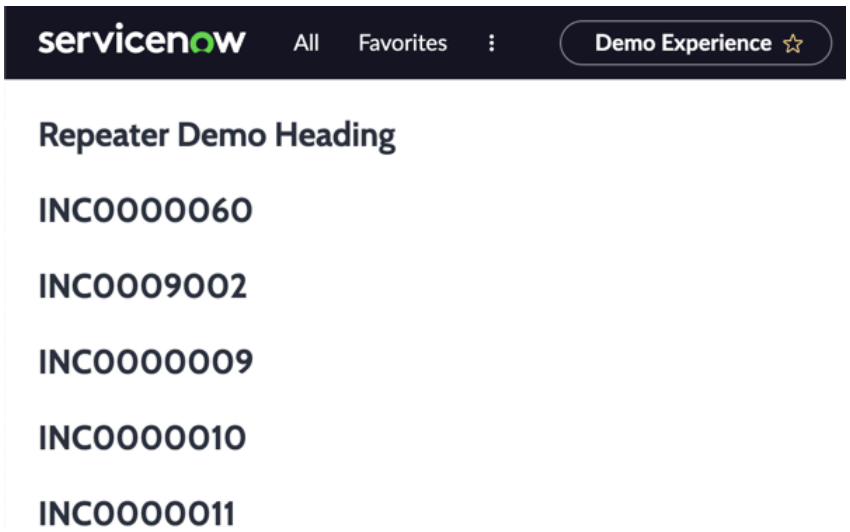


13. Select **Save**.

    The component you bound to the data resource appears on the stage and is repeated five times, once for each result returned from the Incident table.



14. View and test your page by selecting the **Preview** button.
A tab opens to display the page preview with repeated data.



Dynamically expose data in UI Builder pages (advanced feature)

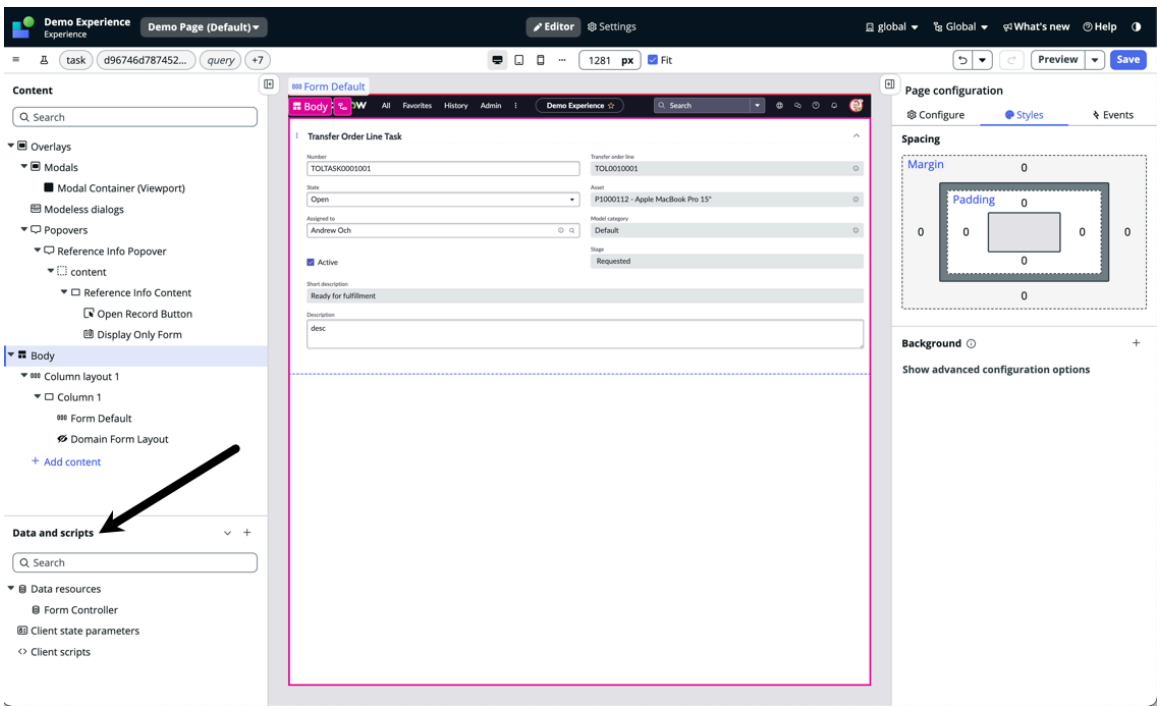
Sync data between ServiceNow tables and data with the pages you build with UI Builder. Pages display synced data in real time and update data/tables when a user inputs information.

Learning about data resources in UI Builder

UI Builder syncs ServiceNow tables/data using data resources. A data resource fetches the data that UI Builder uses to display information in a component. UI Builder components use data resources to sync data across different experiences. Data resources make the data in components dynamic, which means that you don't have to recreate data for every page.

Data resources are found in the data resource drawer. The data resource drawer is where you can add and configure a data resource for your page. After you configure the data resource, you can sync the data between components on your page and ServiceNow tables/data.

Data Resource Drawer



The data resource drawer contains three sections:

- Data resources: The data resources that are part of the experience
- Configuration/Events: Configured data resources and events for the experience
- Preview: JSON for the information returned by the data resource

You can bind the configuration properties for components, other data resources, client scripts, client state, and events to these data resources.

Set conditions for a filter in your data resource. For more information, see Connect data to your components.

How data resources work in UI Builder

Data resources fetch data from Glide, GraphQL, and REST APIs, then transform it for use in a component on a UI Builder page.

Components use both inherited and local data resource instances. Inherited data resources are automatically loaded into a UI Builder page, and local data resource instances can be added and configured. Data resources are evaluated based on specified input values to make sure the right data is retrieved. For more information about inherited and local data resources, see Inherited versus local data resources in UI Builder.

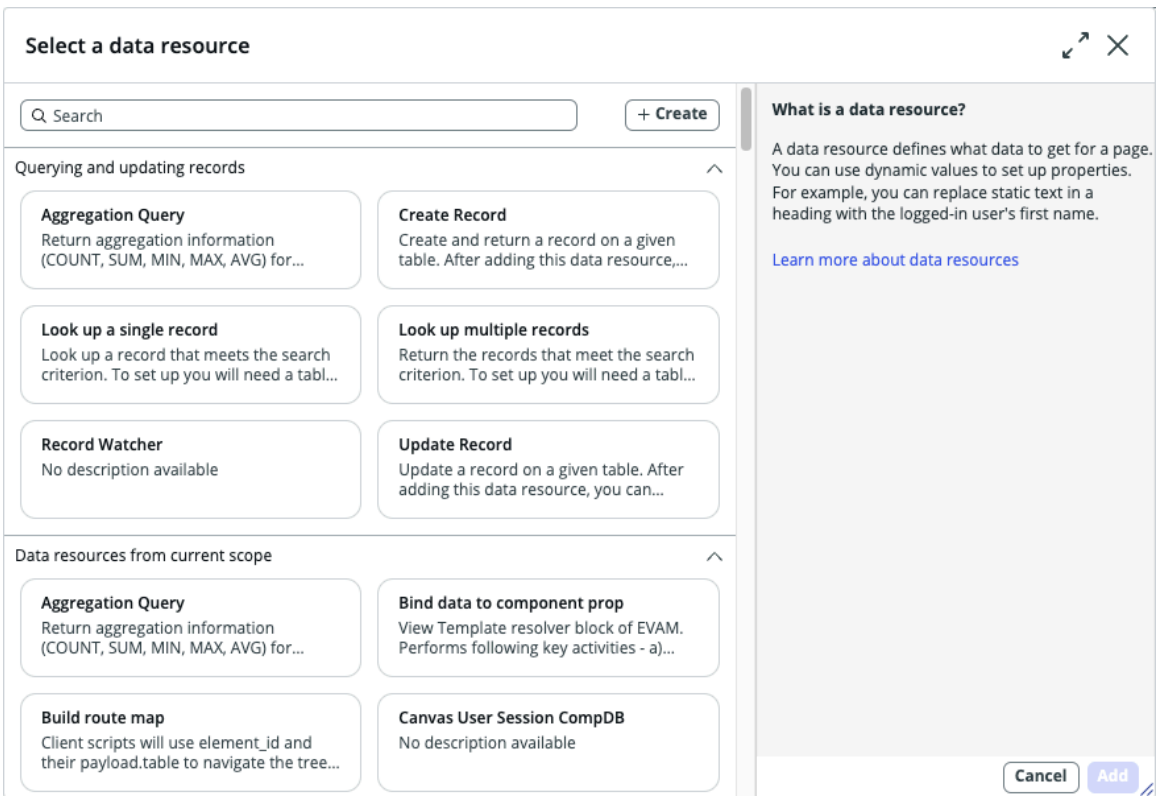
Local data resources in UI Builder

You can select local data resources, such as server data, operations, transforms, or client data, like the gForm API, to bring data to the UI Builder page.

Note:
Only one GlideForm is supported per page in UI Builder. For more information about GlideForm, see the ServiceNow Developer site.

Data resources are organized by application in the data resource drawer. They are then further categorized by the data resource type like Server data or Transform. For example, the Global application has several data resources, but the Customer Service Management (CSM) Workspace application has only a few data resources.

Data resources



You see different data resources depending on the application that you are in. If you select the Global application, you will see different data resources under Server data than if you select the CSM Configurable Workspace application.

Using data binding in UI Builder

Data binding enables you to create dynamic pages by syncing pages and components to data resources. You can bind data to a component to retrieve data from the back end, and use field parameters to get properties from the URL. Changing the URL parameters enables you to create dynamic pages that show different data depending on the parameters.

You can bind data to a component in the following ways:

Context binding

Use URL parameters to connect parts of the URL with your page's properties. For example, you can link the table name from the URL to your component by using the @context syntax, like this: `@context.props.table`.

Imagine you have a UI Builder page with a required field named `table`. The URL for your page might look like /demo/page/<table-name>. The <table-name> could be something like `incident`. The data can also come from parent data resources or be local properties specific to the page.

To link your component properties, other data resource properties, or event details to the page property, you use a `@context.props.table` binding. Be sure to either provide a test value in the URL or set a fixed value for that property in your page's configuration if you are using context binding.

Data resource binding

Use data resources to fetch data from the back end of your instance, such as Client state, GraphQL, or a REST API. These data sources have properties that can be linked to elements on a UI Builder page.

For instance, if you are using the Lookup Record data resource, you can utilize it in a button component. You might use a data expression in the "label" property like this: `@data.lookup_record_1.result.number.displayValue`.

Component binding

Use component binding to connect one component to another. Let's say that you have a List Menu component on the UI Builder page. The List Menu reveals the currently chosen list to other components on the same page. These other components can access the data by linking to it using an expression such as `@elements.list_menu_1.selectedListId`.

Client state parameter binding

Use client state parameter binding to connect and synchronize data between a client-side application and UI Builder components. Parameter binding allows the client state to automatically update data in components, and vice versa. Use `@state` syntax to bind a state property to a client state parameter.

Types of data sources available in UI Builder

You can use the following data resource types that are shown in the table.

Data resource types

Data resource type	Description
Controller	Encapsulates data and event logic and enables presets for components.

Data resource types (continued)

Data resource type	Description
GraphQL	GraphQL queries and mutations that are executed.
Transform	Script that transforms the input data into another format.
Client state	Client-side data resources that include the client information, domain-specific states or logic, user preferences, and so on.
Composite	Single reusable data resource that contains multiple data resources.
REST	Data resources that are made through REST API requests.

Inherited versus local data resources in UI Builder

Inherited data resources share information from the surrounding parts of a UI Builder page such as an application. Imagine your page is in a large frame, and it gets some information from the frame or other parts around it. You can use this info by connecting it to your page's properties, kind of like linking puzzle pieces together. If you get this information from the frame, you don't have to get it again yourself.

Local data resources are items you add to a UI Builder page yourself. Imagine you're making a page for travel requests. You can sync employee data to a list component so employees can request trips linked to their own info.

To use these data resources, either bring them in from an app or create them in the ServiceNow platform. Then, in UI Builder, make these resources available for your components. Next, tie the data to your component, so it can work with it. For instance, you could have a set of records, expose it in UI Builder, and link it to a component. From there, configure the component to do things with the data, like saving new records.

Once your page is syncing data, you connect it to the part of the page that needs it such as a component. It's like making sure the right puzzle piece fits in the right spot. Then you can tell that part of the page what to do with the data. For example, you might use it to add new travel plans for employees.

UI Builder Data resource properties

When you add a data resource in UI Builder, it's like adding a tool that knows where to get information from. Data resource properties are the instructions that tell a data resource how to bring data into UI Builder pages. These properties tell a data resource which data to get, how to organize it, and what conditions to follow. For instance, you can use these properties to specify

which tables to look in, how to sort the data, and more. These properties are what make the data resource work correctly and give you the data you need.

UI Builder Data resource scripts

Data resource scripts are special instructions you give UI Builder to return specific pieces of data. For example, if you're dealing with a list of products, a script could tell a data resource to show only products that are available in stock or to arrange them in a particular order. Data resource scripts enable you to customize how UI Builder treats the information, such as adding extra rules or actions.

Add and configure data resources to a page

Add data resources to dynamically expose data from tables, records, or other elements on your page in UI Builder.

Before you begin

Role required: ui_builder_admin

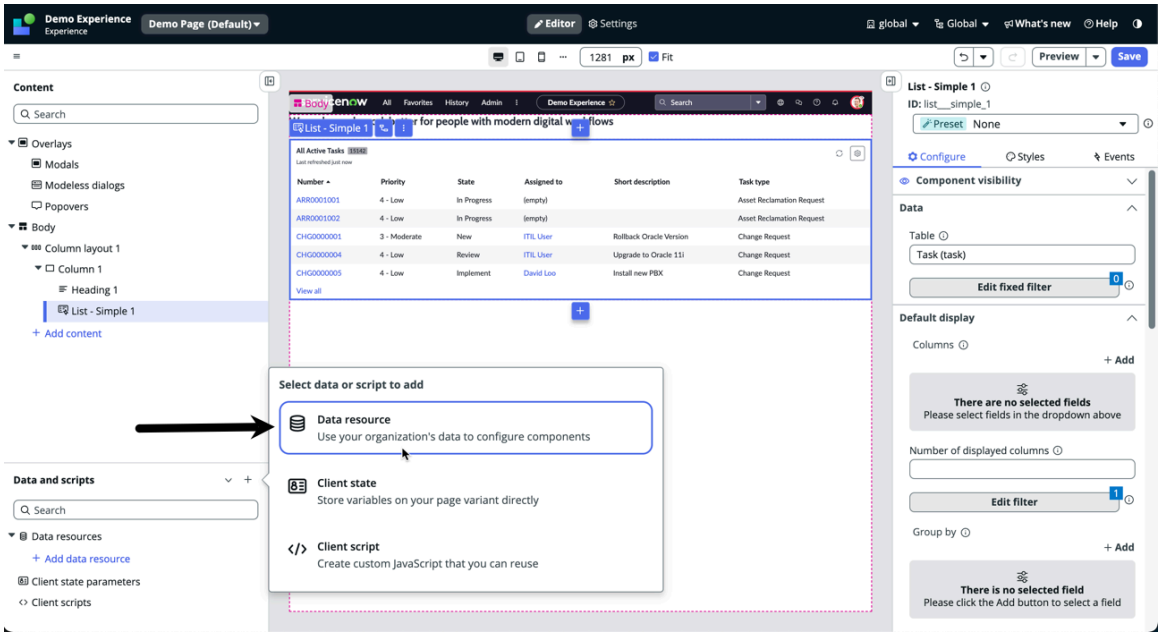
Choose the application containing your data resource. The Global application contains the most common data resources. The data resources relate to Server data, Operations, and Transform. You can add a data resource such as Look Up Records, Table route map, GlideRecord Query, and so on.

About this task

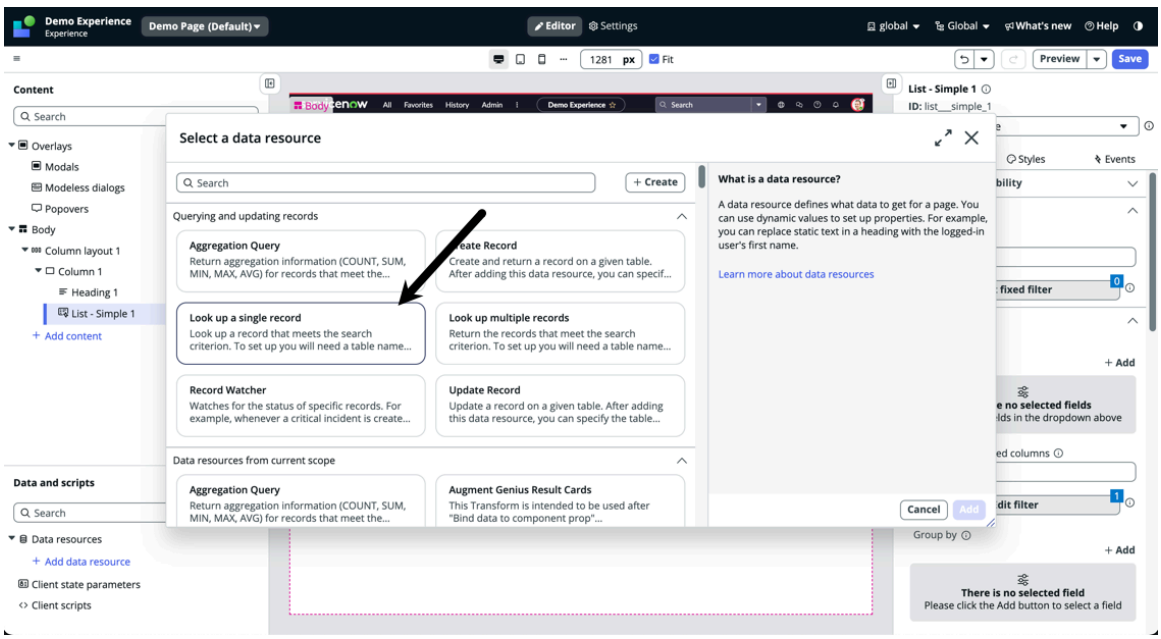
In the data resource section of UI Builder, you can add and configure local data resource instances for your page. Local data resource instances dynamically expose data to components. If you have any inherited data resources, they are listed in the inherited data resource pane and are read-only. You don’t configure inherited data in UI Builder. Data resources from any application can be added to any page unless restricted by security permissions. You can add multiple local instances of the same data resource, if you need different configurations of the same data resource on your page.

Procedure

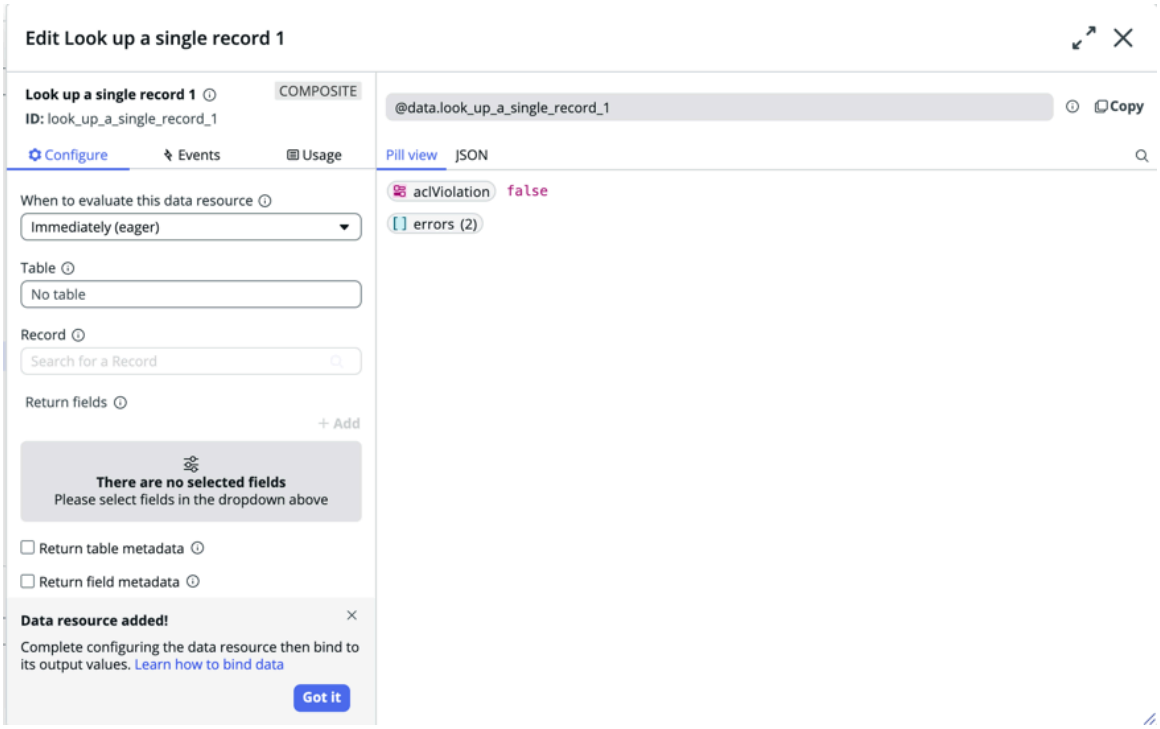
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page.
4. Add a component to your page.
   You need a component on your page before you can bind a data resource to it.
5. Select the **+** icon in the data resource drawer.
6. Select **Data resource**.



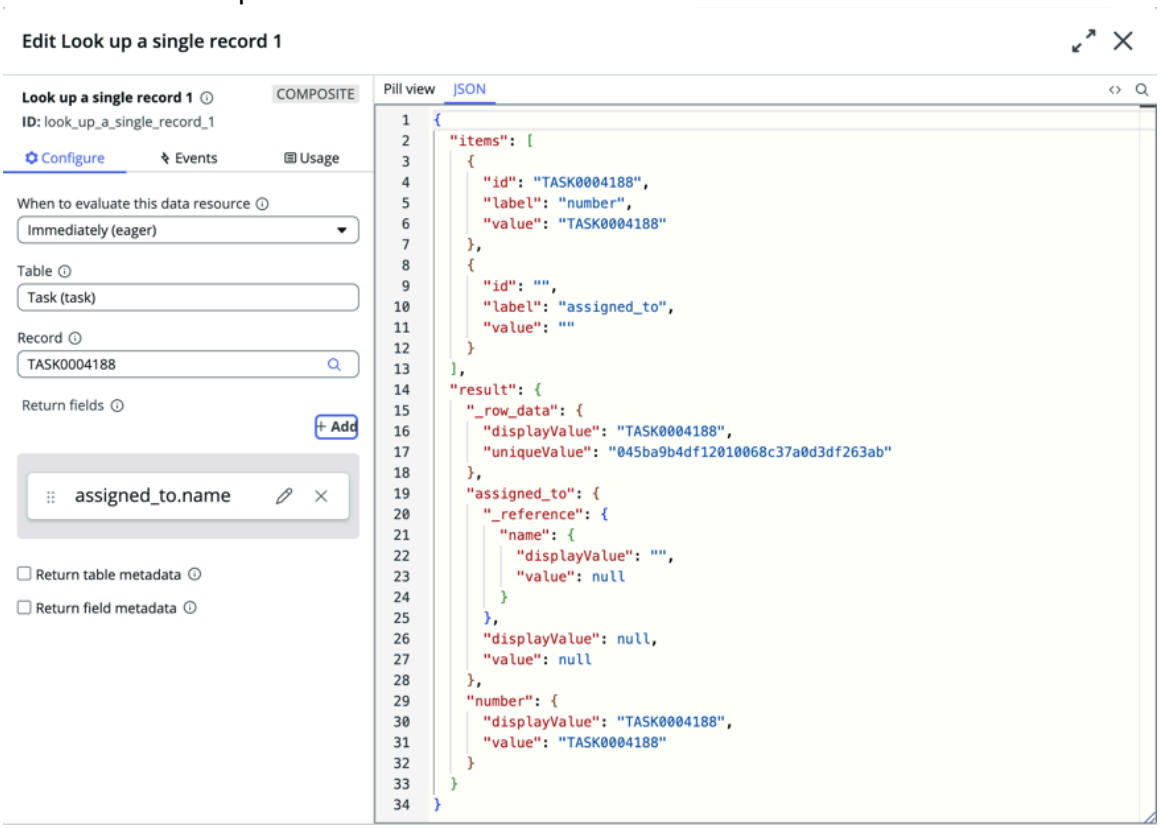
7. Select a data resource to add to your page.
For example, you could select **Look up a single record**.



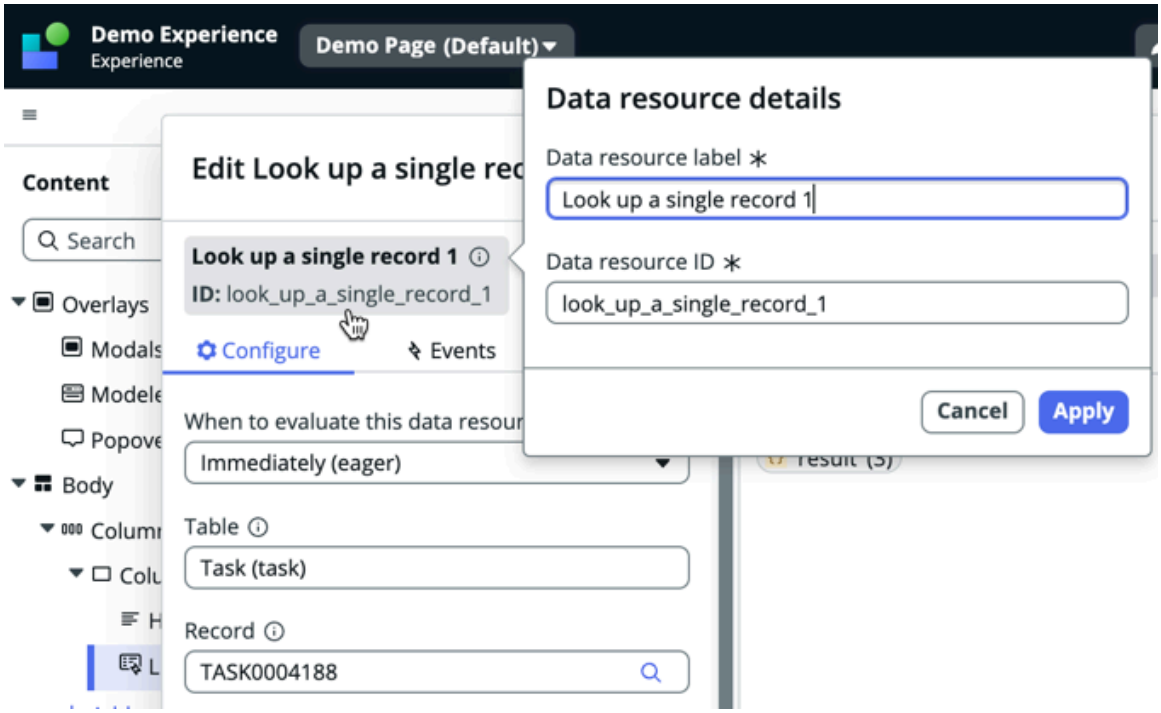
8. Select **Add** to add the data resource to your page.
The Data Resource configuration modal appears.



9. Fill in the required information for the data resource in the **Configure** tab to expose the data you want.
The configuration fields vary depending on which Data Resource instance is selected. The **Configure** panel and preview window may display errors when a Data Resource is added to a page. UI Builder attempts to evaluate Data Resources when they're added to a page. The errors remain until the required Data Resource fields have been filled.



10. Select the default label to provide a custom label and ID value.



The data resource appears in the data and scripts drawer.

11. Select **Save** in the UI Builder header.

What to do next

Now that you have a data resource connected to your page, you can bind the data to a component or bind an event to the data resource. For more information, see Connect data to your components and Bind an event to a data resource.

Bind data to UI Builder pages using controllers (advanced feature)

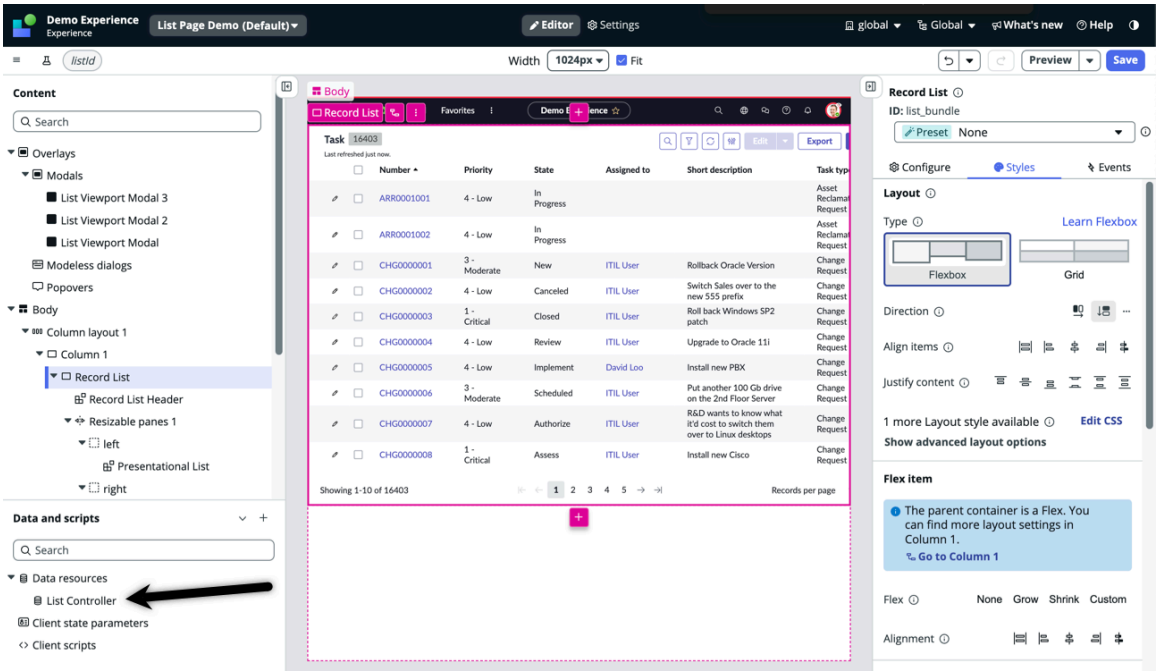
Controllers simplify the linking of data and event logic to enable component presets in UI Builder.

Controllers enable page builders to easily connect data and scripts to their pages in UI Builder. A controller is a type of data resource that component presets use to bind data to components. Controllers differ from other data resources in that they contain data and event logic that enables presets for components. A controller brings data from the server to a component, and it brings updated data back to the server based on interactions with the component. For more information about component presets, see Automatically configure components using presets.

Note:
Creating controllers is not supported in Xanadu.

Controllers are added by default when you use a UI Builder page template. You can add controllers to UI Builder pages without a controller within the data resources drawer or by selecting a component preset after adding a component to a page. You can view which controllers are configured on your page by opening the data resources drawer.

Controller in the Data resource drawer



Types of data controllers in UI Builder

Data controllers

Data controllers decide what information should be displayed on UI Builder pages. Data controllers use data resources to sync information in real time and update data/tables when a user inputs information. You can manually add data controllers to a page.

UI controllers

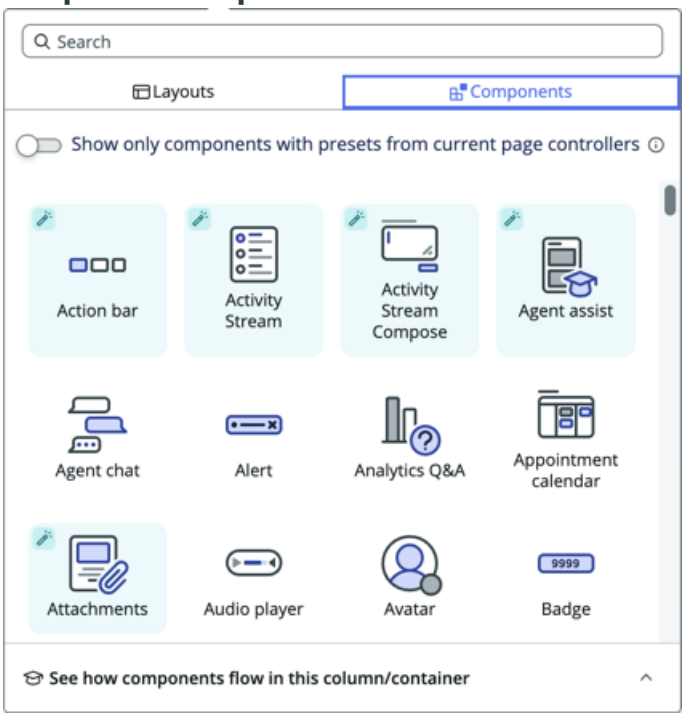
UI controllers are added to pages when using UI Builder page templates and cannot be added manually.

Using controllers with presets in UI Builder

You can add multiple controllers to a UI Builder page, but you can't use the same one twice. If you try to use a component preset that needs a controller, UI Builder prompts you to add it.

Not all components work with controllers, but you can easily see which ones do in the component library. If you have a controller configured on your UI Builder page, you can open the component library to view which components have presets. Components with presets available are highlighted in the component library.

Components with presets



Add a controller

Add a data controller to your page to use component presets.

Before you begin

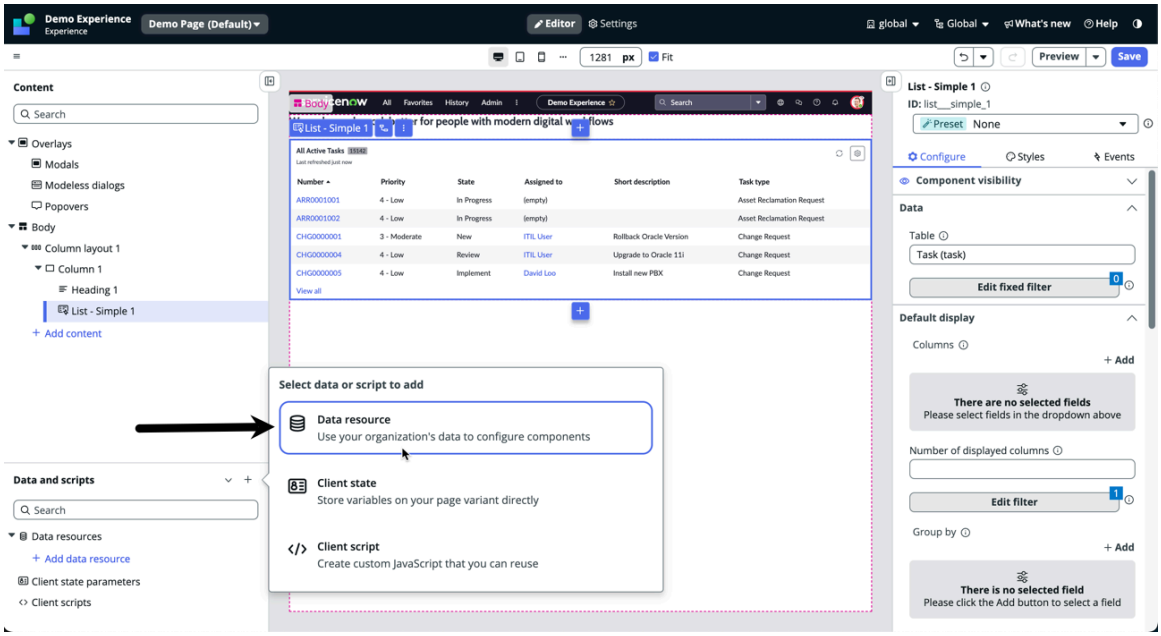
Role required: admin

About this task

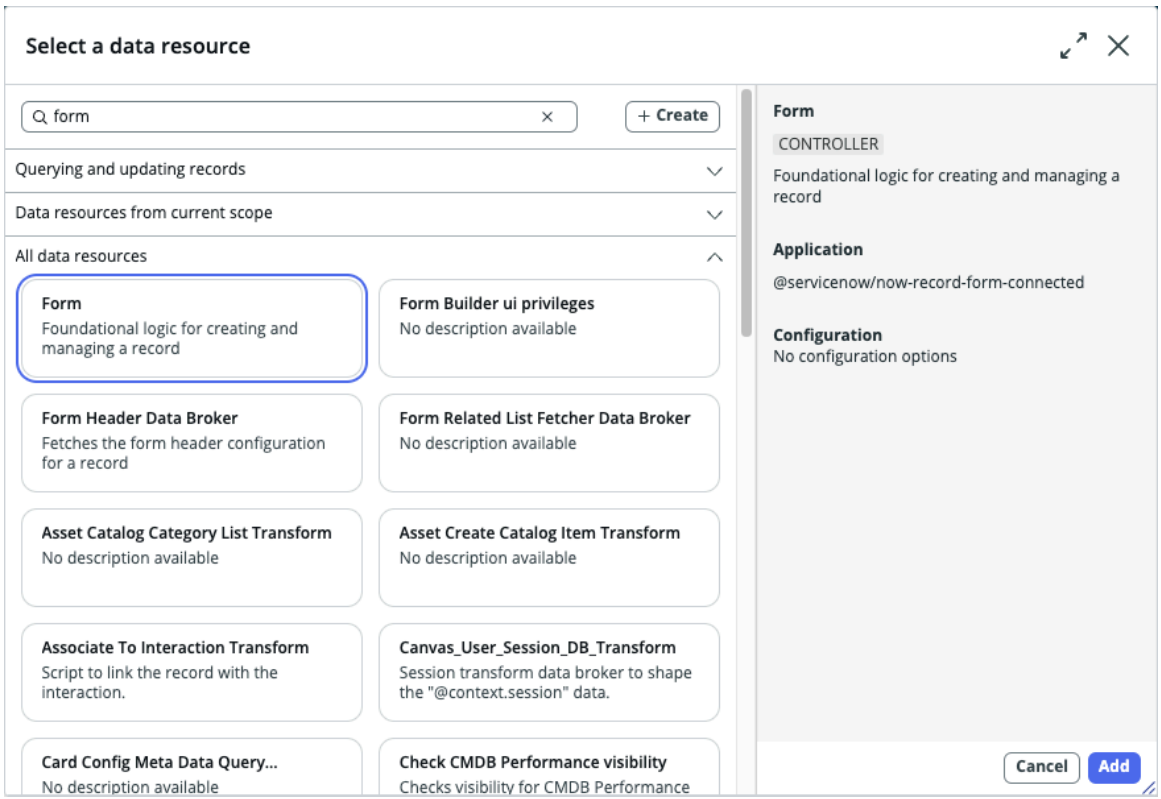
The record controller is the only controller that you can add to a page in Xanadu.

Procedure

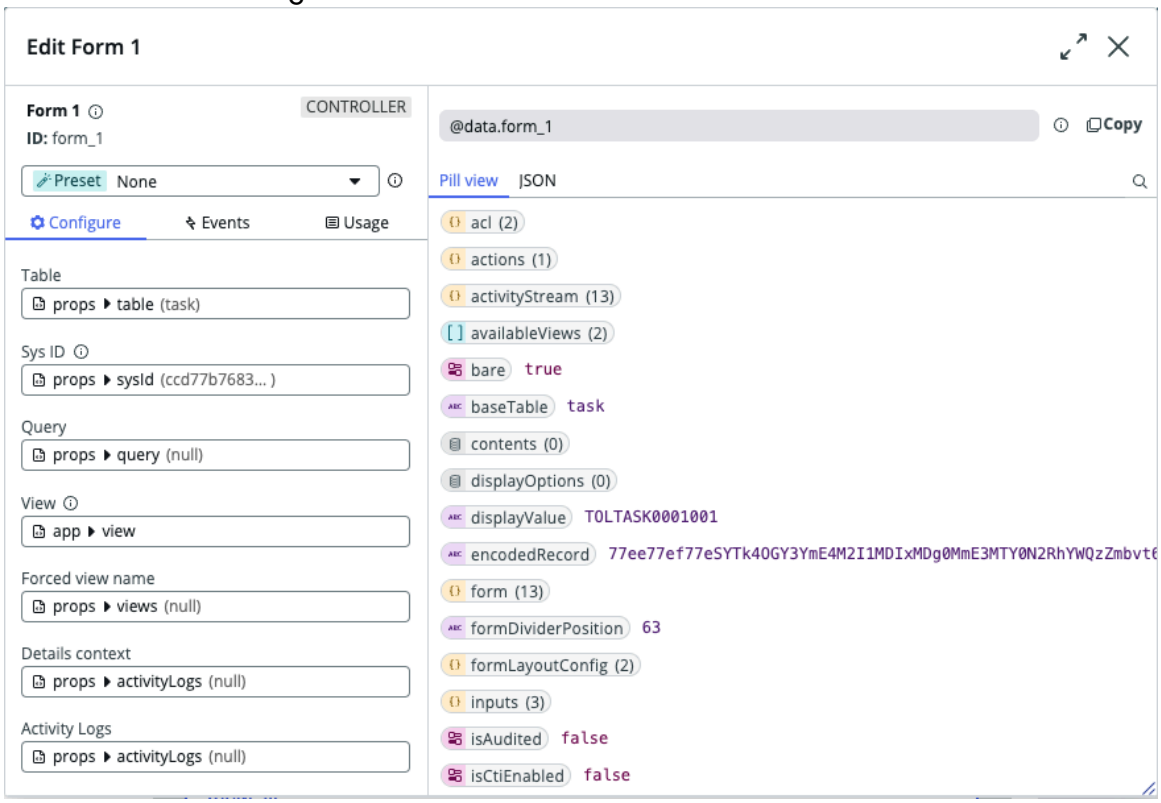
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   For more information, see Configure how users interact with your applications in UI Builder.
3. Create or open a page or page variant.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Select the **+** icon in the data resource drawer.
5. Select **Data resource**.



6. Enter `form` in the search field.
7. Select the controller you would like to add to your page.
8. Select **Add**.

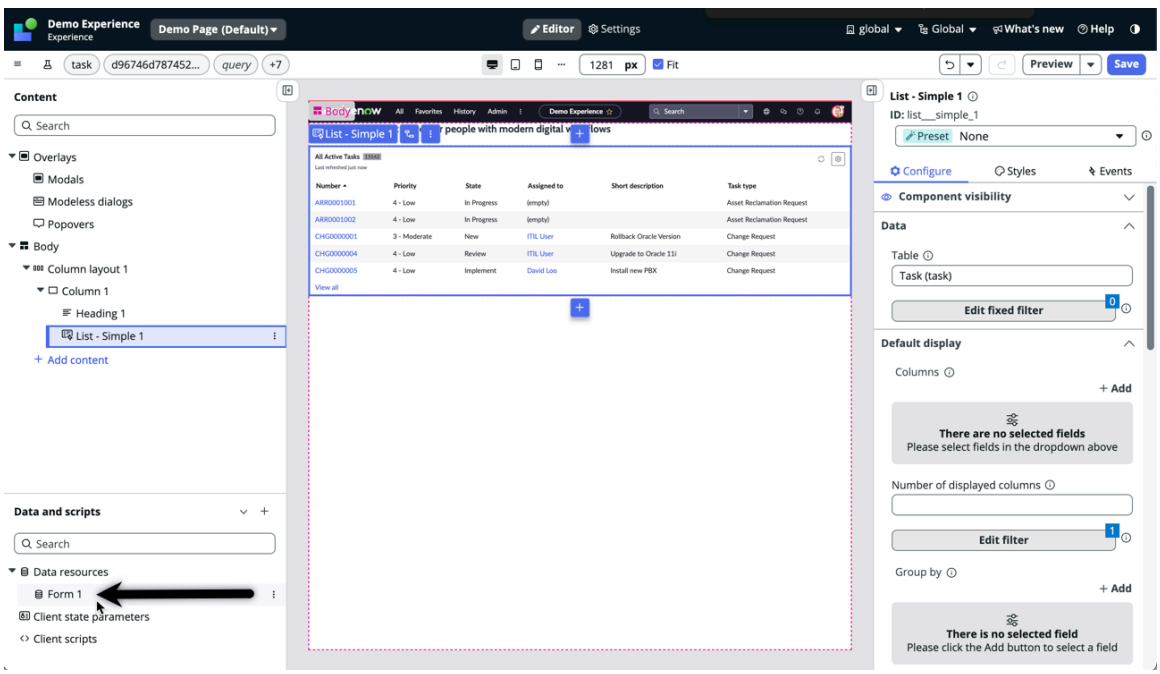


9. Fill in the fields to configure the controller.



Result

The form controller displays in the **Data resources** section.



Edit a controller

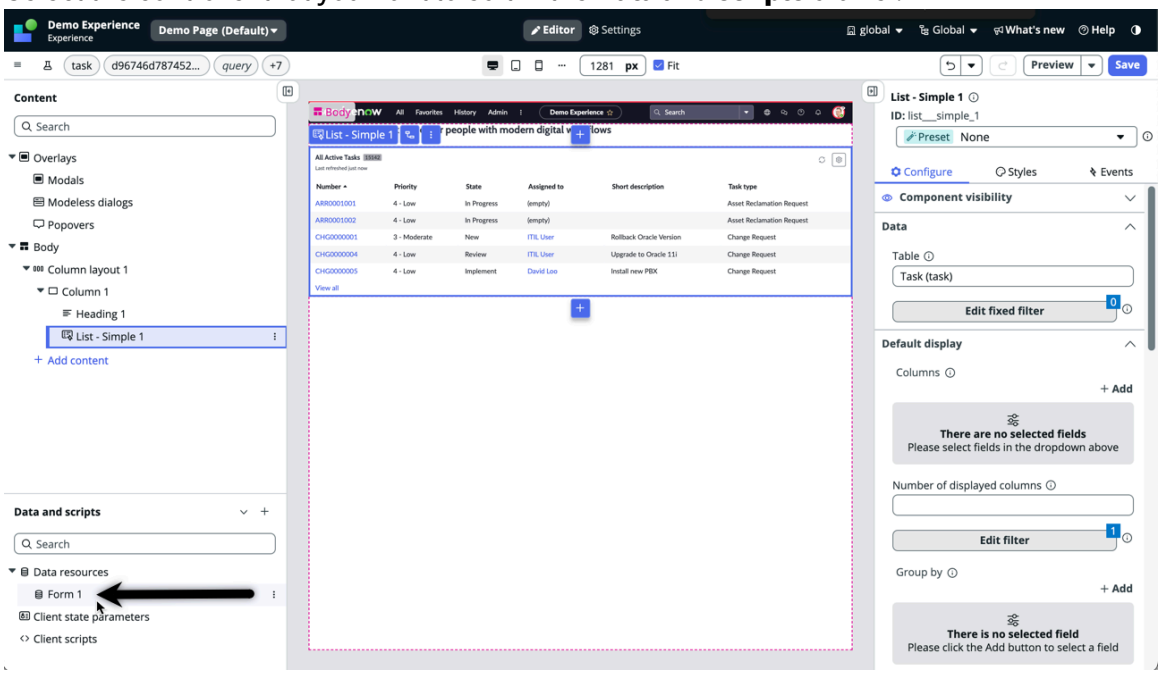
Configure a controller to pull data from a table.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   For more information, see Configure how users interact with your applications in UI Builder.
3. Create or open a page.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. Select the controller that you want to edit in the **Data and scripts** drawer.



5. On the form, fill in the fields.

Form controller form

Field	Description
Type	Controller is predefined as the type for all controllers.
Table	Add a table that you want the controller to pull data from.
Sys ID	Enter the unique identifier for a record, provide a value, or use -1 to generate a new value.

6. Close the edit controller modal.
7. Select **Save**.

Delete a controller

Delete a controller that you no longer need in UI Builder.

Before you begin

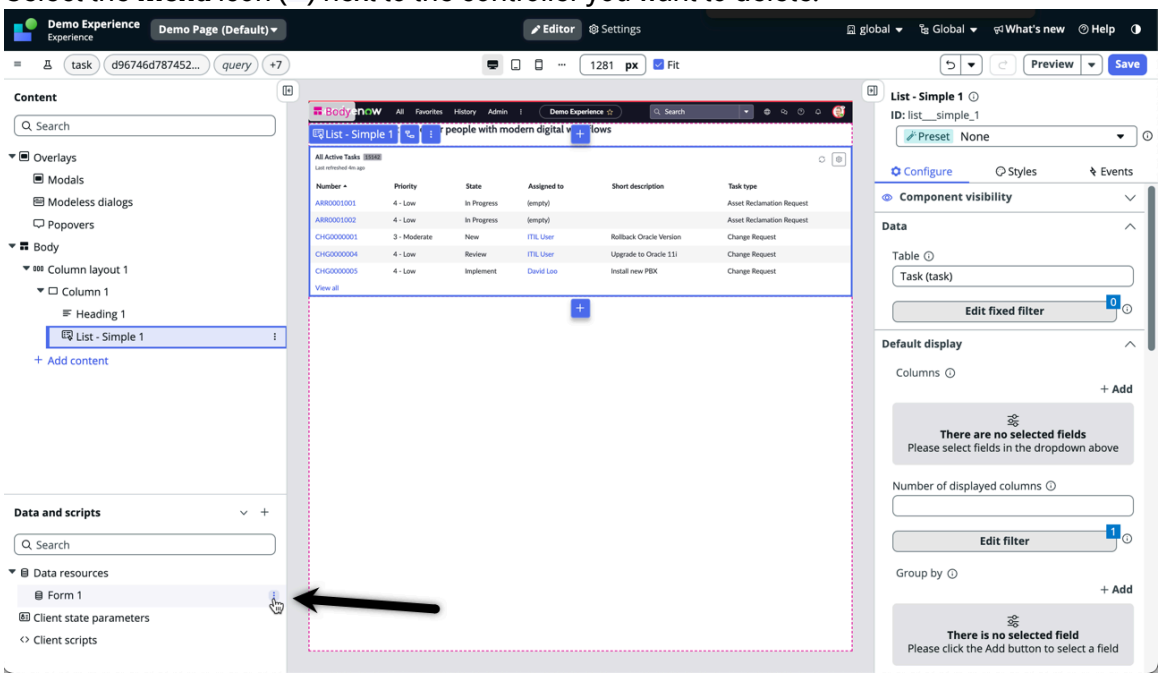
Role required: admin

About this task

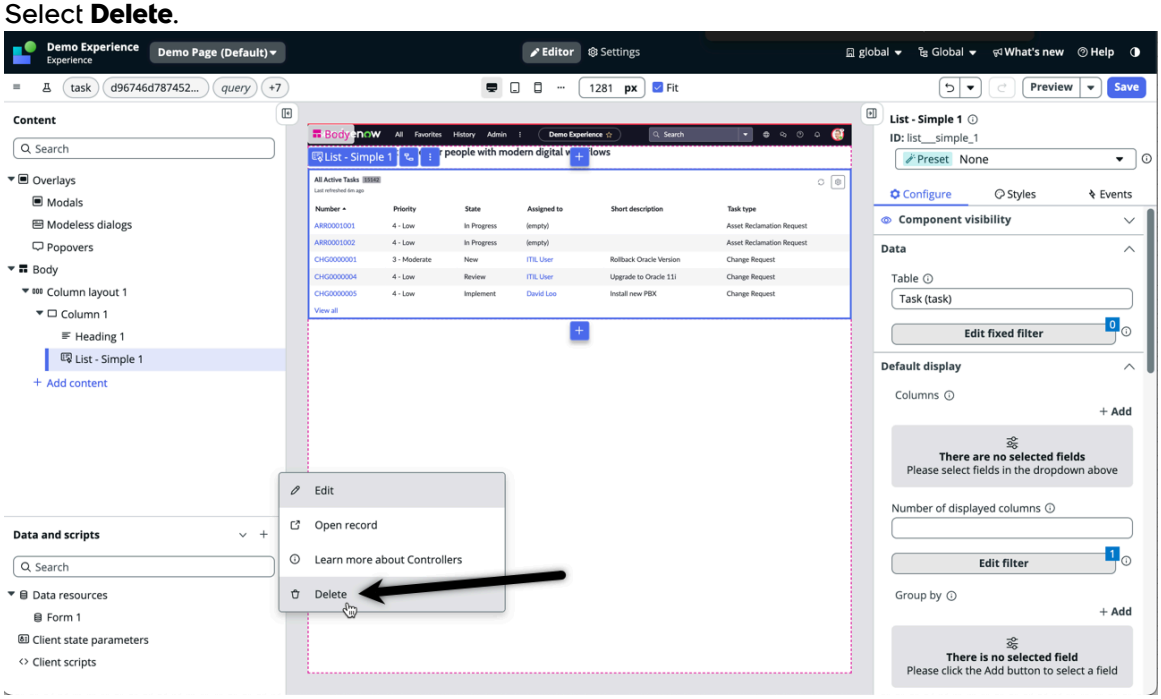
Controllers cannot be deleted from pages created with a page template.

Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. For more information, see Configure how users interact with your applications in UI Builder.
3. Open the page with the controller you want to delete.
4. Select the **Menu** icon (⋮) next to the controller you want to delete.



5. Select **Delete**.



The controller is removed from the local data resource instances.

View properties and events in the Controller API

The controller public API defines the output data that a controller provides to a preset. This includes the property values and handled events used by a component when a preset is selected. Property and event information is available to view in UI Builder.

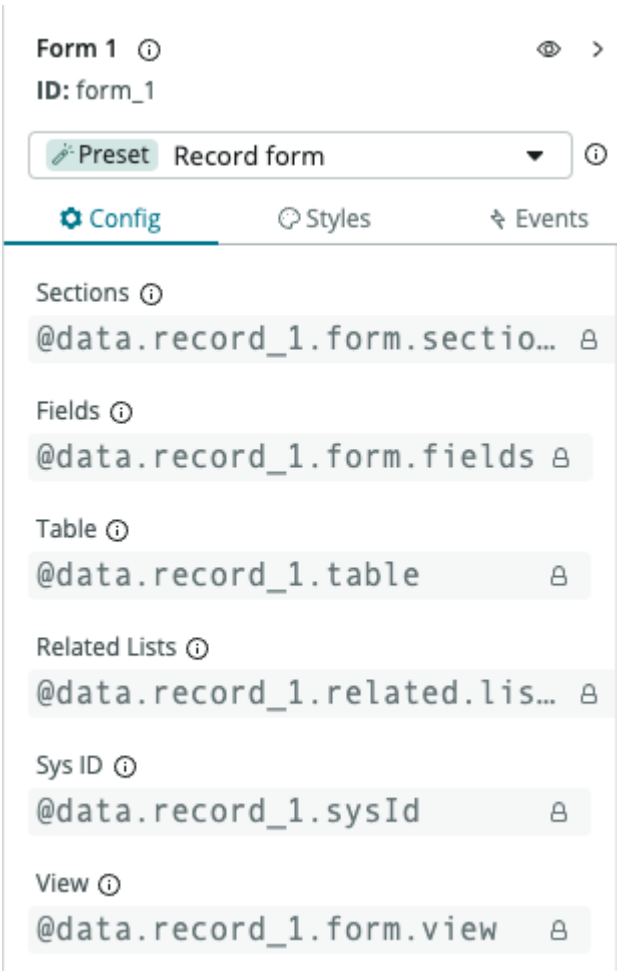
The component property values in a preset can be static values or paths to controller output data. You can use the data resource inspector in UI Builder to display the values from the controller data structure used by a preset. To view the payload carried by an event in the preset, you can look in the event handler picker for that event.

Viewing properties in the Controller API

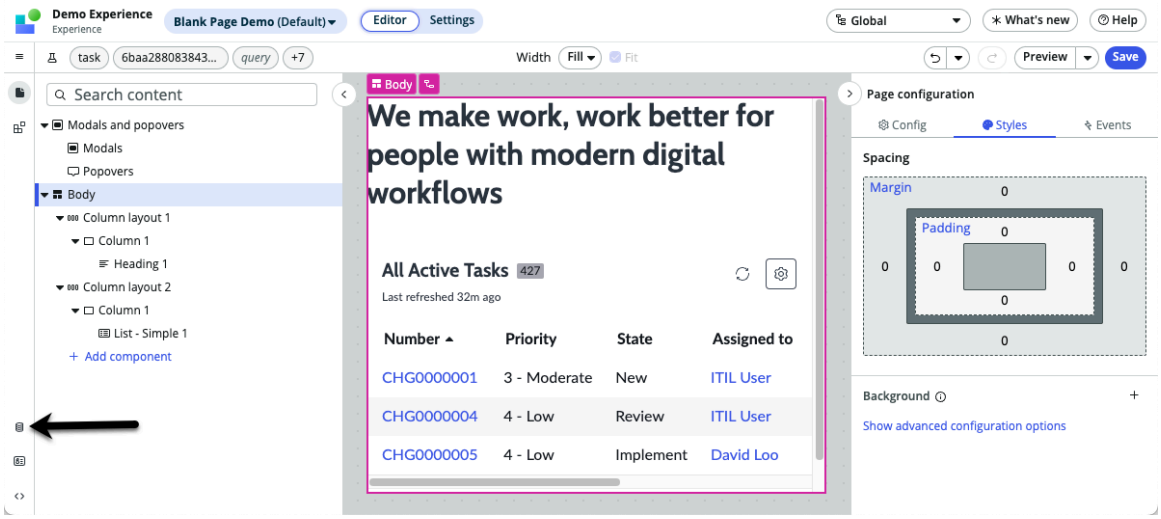
You can view preset properties in the UIB data inspector. Knowing the available values helps you understand how a component will behave in your design and helps you identify any properties in the preset you might want to override.

This procedure assumes that you have placed a component with a preset on the page and have configured a controller. For instructions, see Add a controller.

The configuration tab displays preset property values as a path to the controller output. The base data path is expressed as `@data.<controller_name>`. The remainder of the path is built using the contents of the categories within the controller data hierarchy. You can use this path to view the current values for the record for which the controller has been configured.



1. To view the data resources for a component, select the data icon in the lower left sidebar.

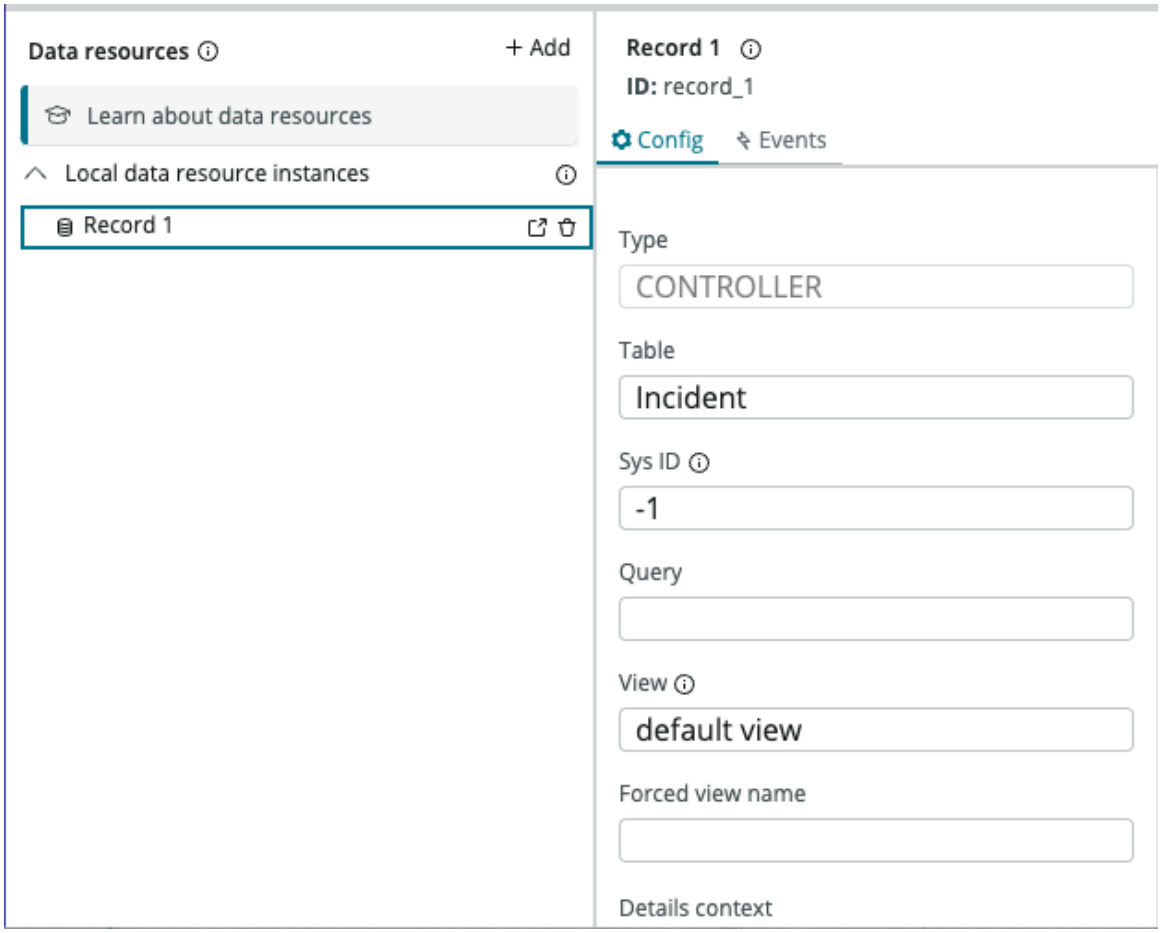


The three column UIB data inspector appears.

2. In the first column where the data resources are listed, select the controller whose output you want to view.

   The configuration data for the selected controller appears in the Config tab of the second column. These are the input properties you entered when you configured the controller for the first component with a preset you placed on the page. You can edit these connection values here if you want.

   Note:
   Configuring **-1** for the value in the **Sys ID** field configures the controller for a new record. The controller then generates a full GUID that you can use to store data against the record before it's saved. This allows you to perform actions in a newly created record such as saving attachments.

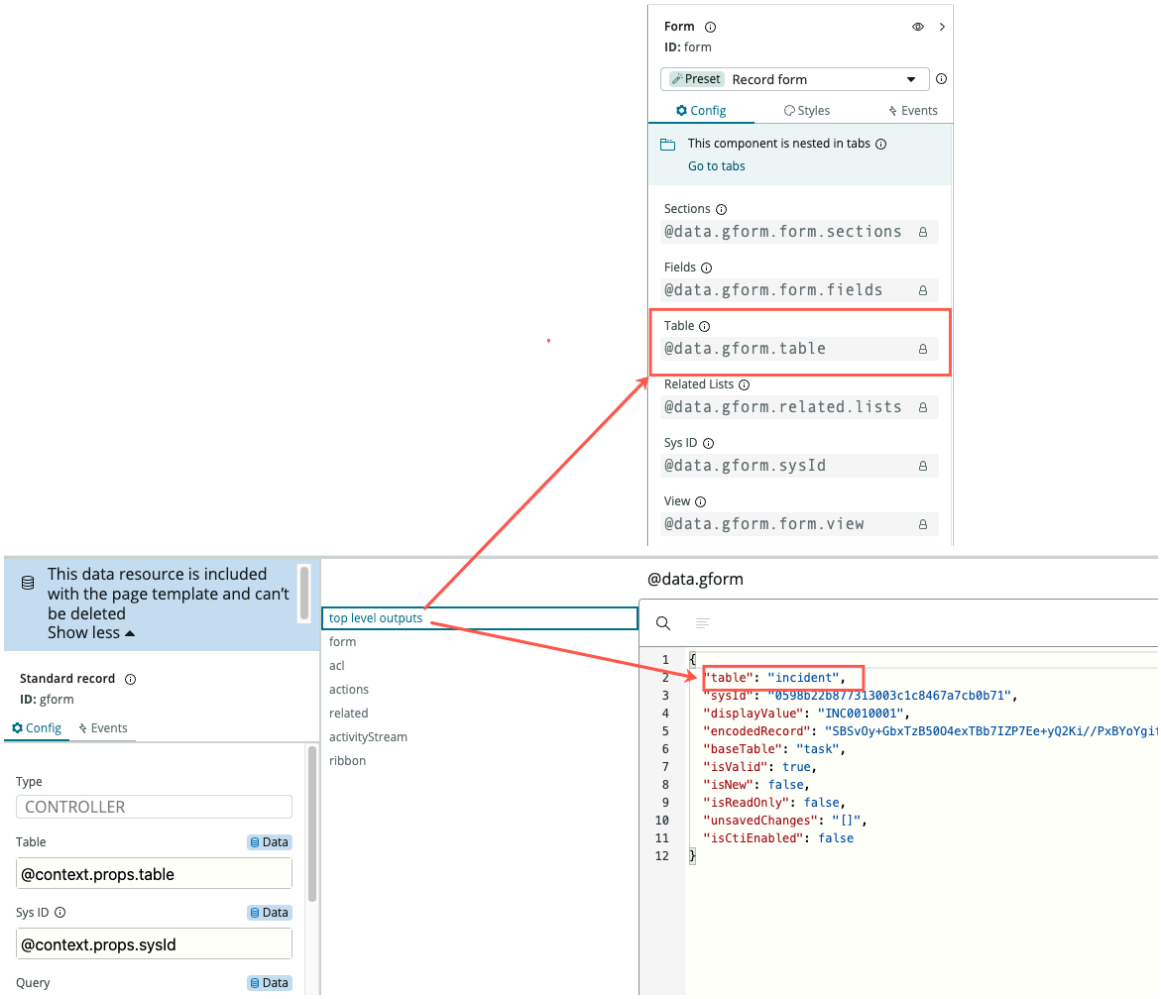


3. Select **top level outputs** in the third column.

   This is the parent level of the controller data hierarchy, indicated with the prefix `@data.`, followed by the controller ID. This combination forms the root path to the data. The data contained in the top level outputs are displayed in the adjacent code field and are available for presets and scripts to use. Other properties at that level are some common properties that apply to all records.

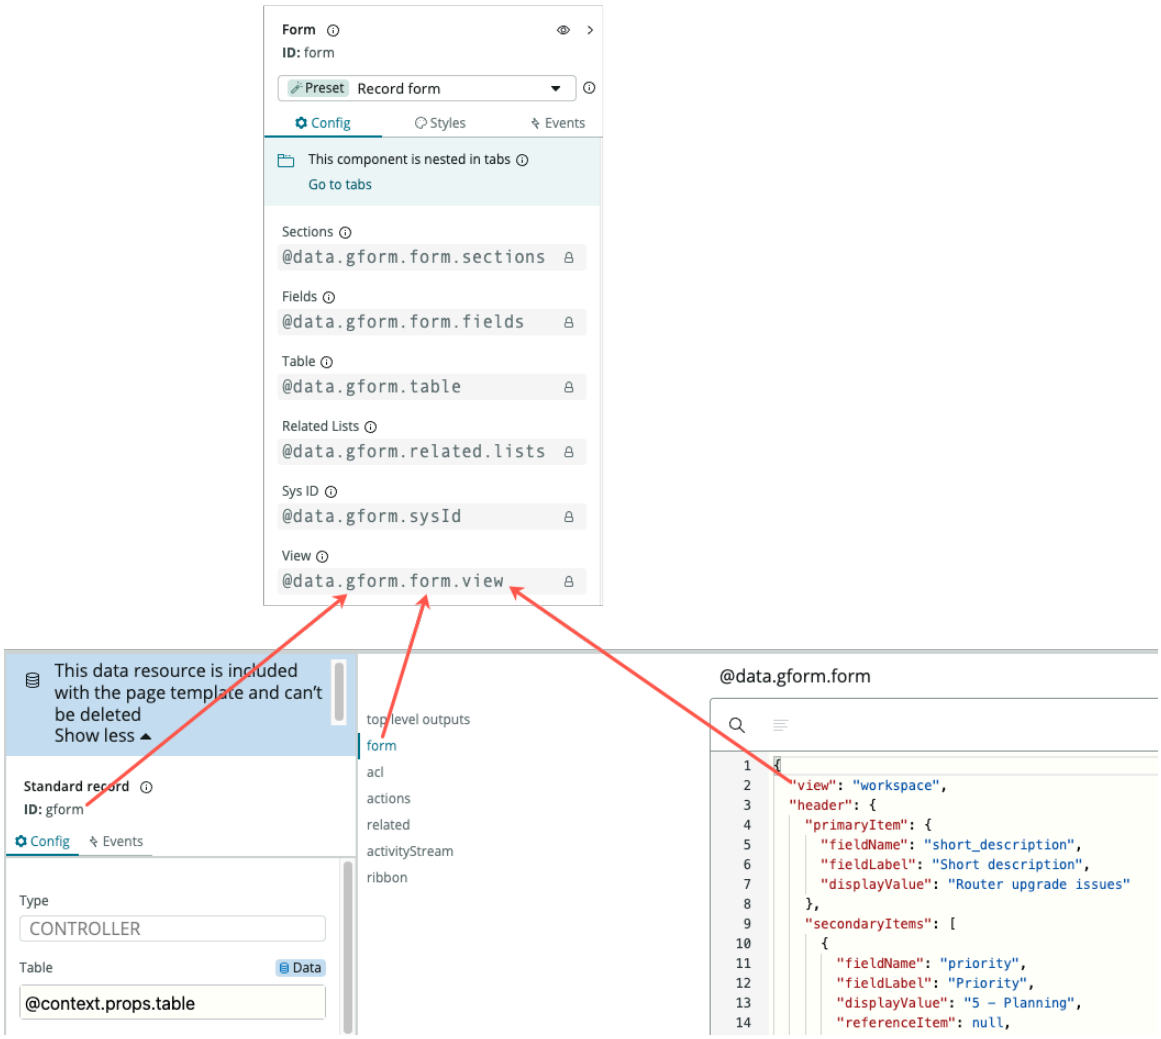
   When the preset maps a component property to controller output, the path to the output is shown instead of the value. Paths are denoted as **@data.<controller id>.<path from top level to output property>** and can be used as the values or as part of formula expressions.

   In this example, the mapping in the preset results in a path to `@data.gform.table`.

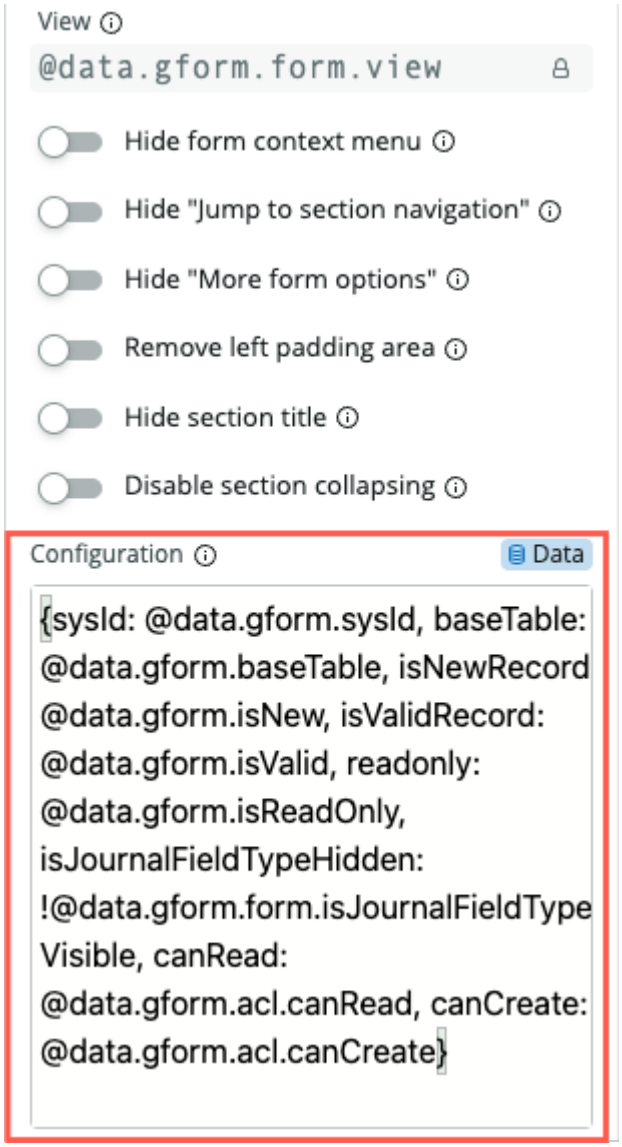


4. To view data below the top level, select the child category indicated by the path in the preset property value.

   The name of the child category appears in the path as `@data.<controller ID>.<category>`. The data from that category is then appended to that path. The root path above the code field indicates the child category being used. In this example, the path to the **View** property in the `form` category is expressed as `@data.gform.form.view`. That preset value displays forms in the **workspace** view.

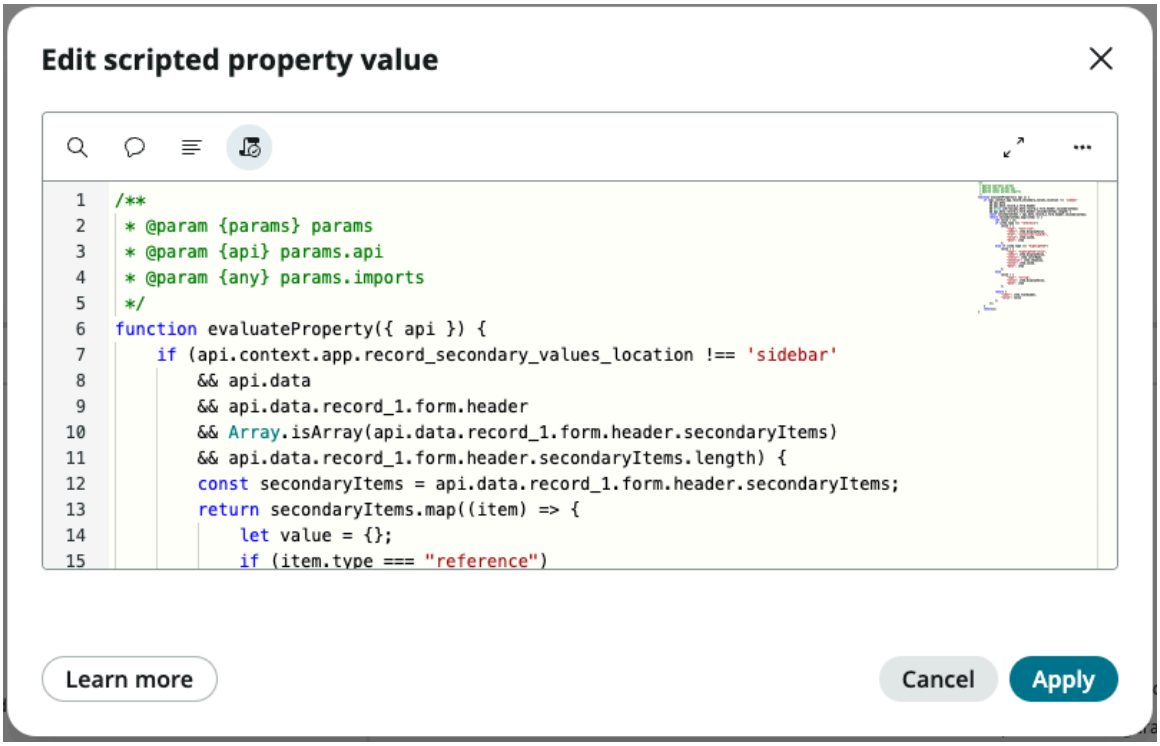


In this example, multiple controller output properties are used in a formula expression to build an object.



5. To view a scripted property value, select the lock icon next to the property.

This puts the property into edit mode and opens a modal for editing the script.



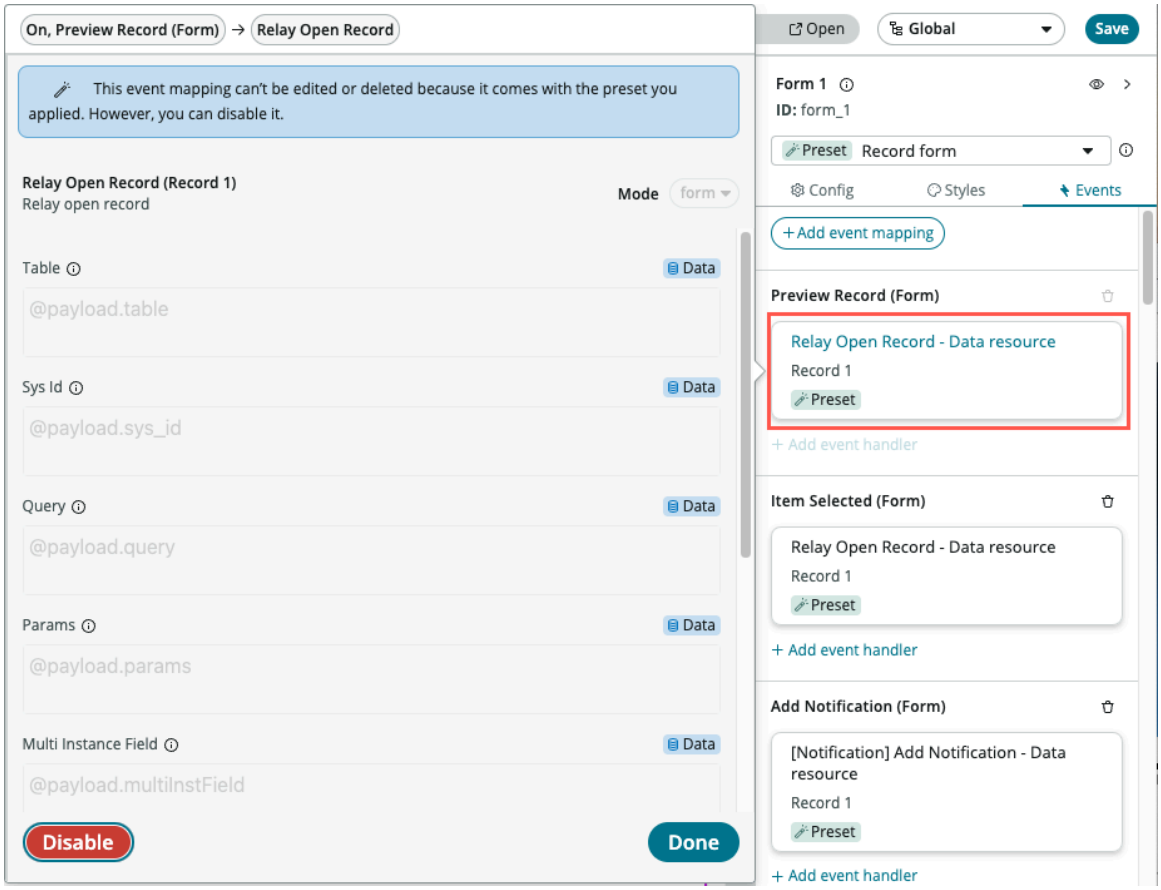
Viewing events in the Controller API

You can view handled events mapped to a component by a preset and their payloads in the Events tab in the UI Builder configuration panel. If the data mapping for an event isn't appropriate for your use case, you can add additional data handlers.

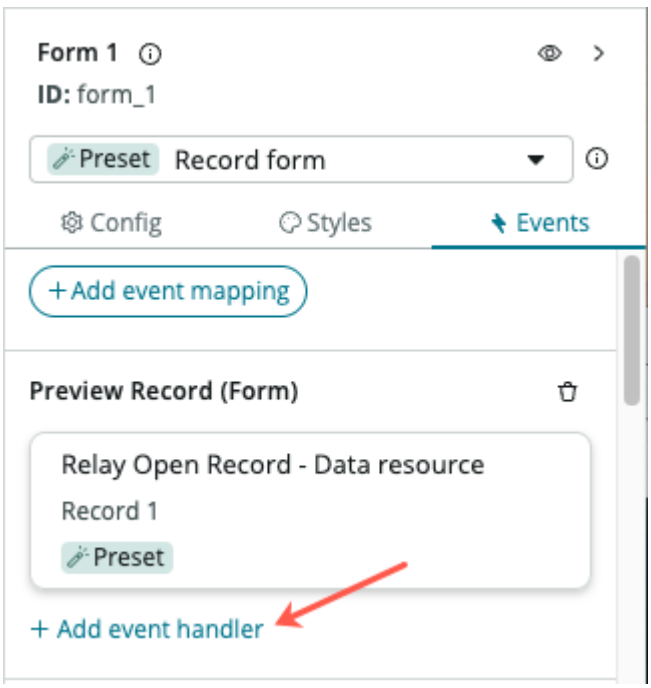
Note:
Data handler mappings provided with the preset are not editable.

1. Select the Events tab in UI Builder.
2. To view the mapping for a preset event, select the event tile.

   A modal appears showing the payload properties for the preset event. You can **Disable** the event in this modal.



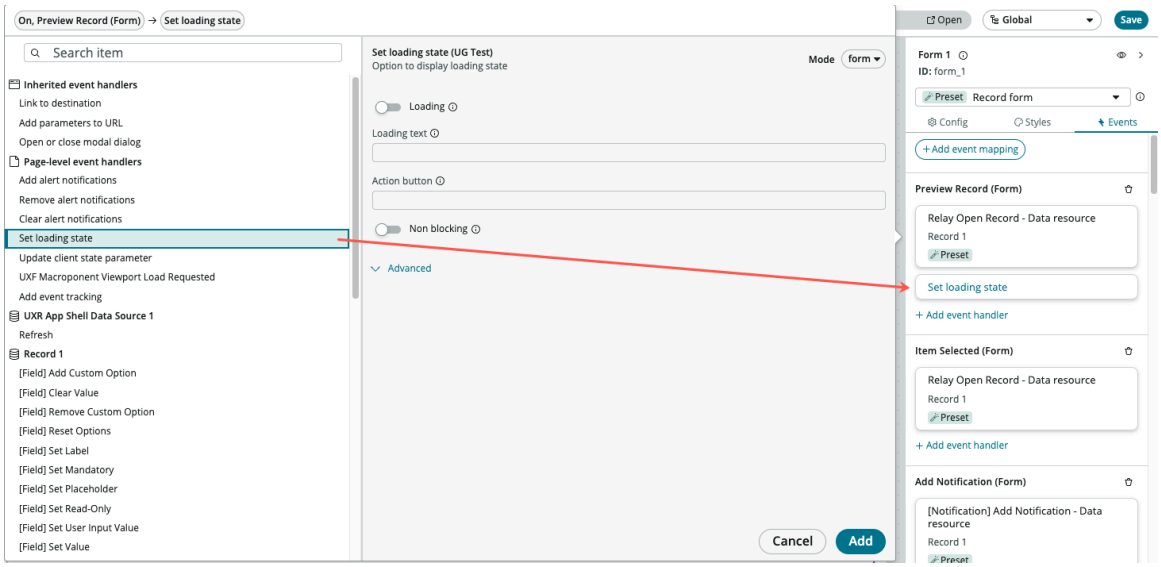
3. To add an event handler to the event, select **+ Add event handler** under the event tile.



A modal appears, showing a list of available, handled events. You can select any action from the list, including an event handler from one of the controllers listed.

4. Select an event handler from the list and select **Add**.

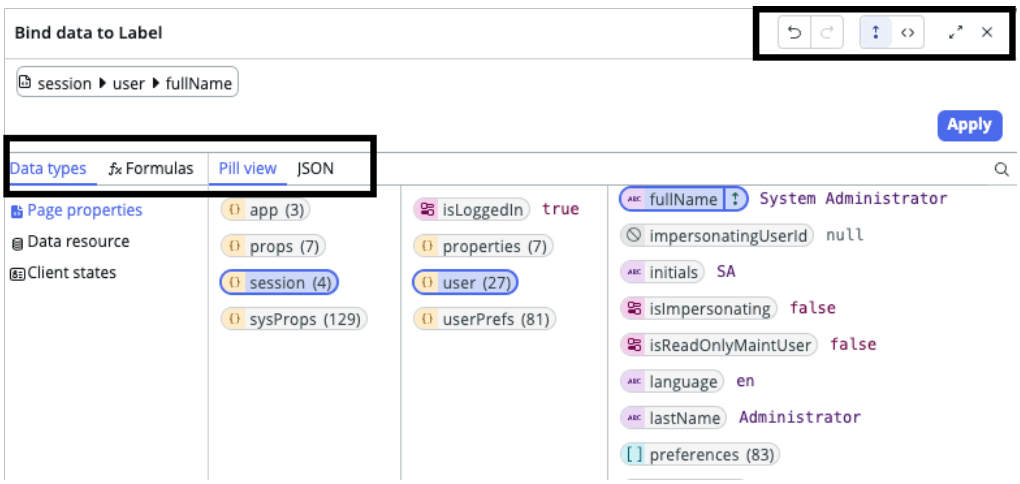
The new handler is listed under the event tile.



Connect data components

Use the data binding modal to associate data exposed by local data resources to components on your UI Builder page.

Data binding modal



Data binding modal options

Option	Description
Undo	Undo the previous change.
Redo	Redo a change that has been undone.
Bind data using drag and drop	Show Pill view.
Use script	Show JSON view.
Toggle full screen	Expand the data binding modal to full screen size. Select again to reduce the data binding modal to smaller size.

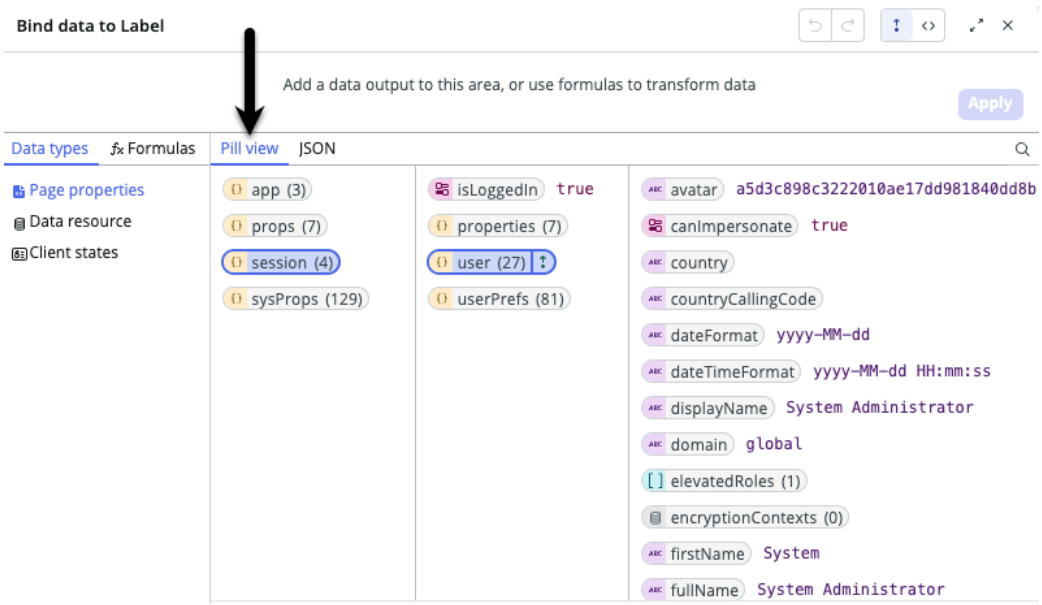
Data binding modal options (continued)

Option	Description
Close	Close the data binding modal. If you have unsaved changes, you are given the option to save.
Data types	Lists page properties, data resources, and client states.
Formulas	Lists formulas that can be used. A search field is available.
Pill view	When **Data types** is selected, pill view enables you to specify a property value or display value. You may have to select several pills to get to a specific value.
JSON	When **Data types** is selected, the JSON option enables you to edit the raw JSON code.

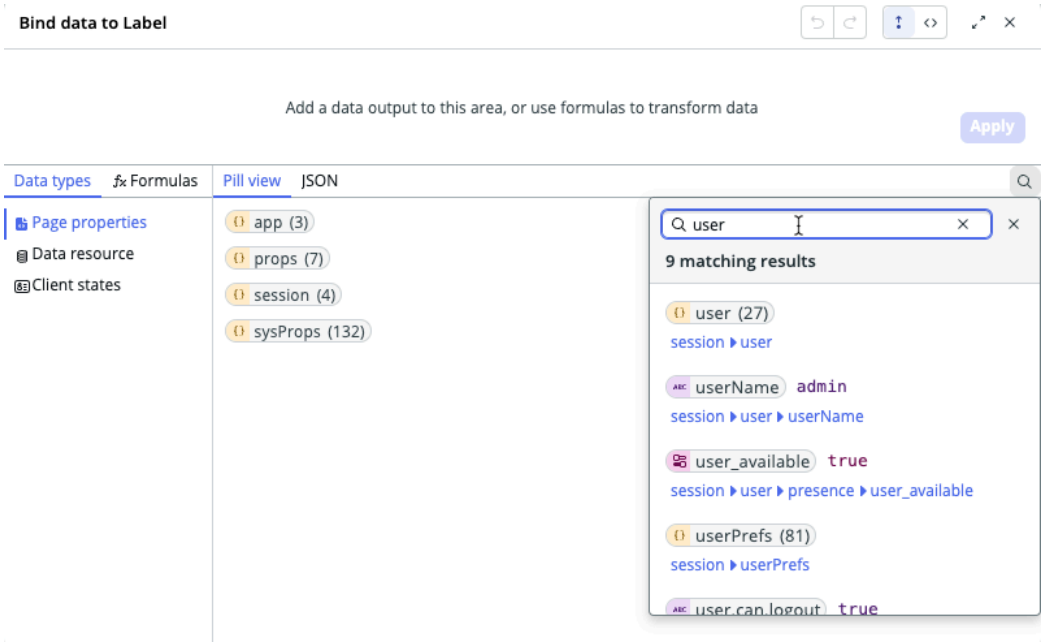
There are two methods you can use for binding data: drag and drop, and editing JSON.

Binding data with drag and drop

Use this method if you want to use a visual process.

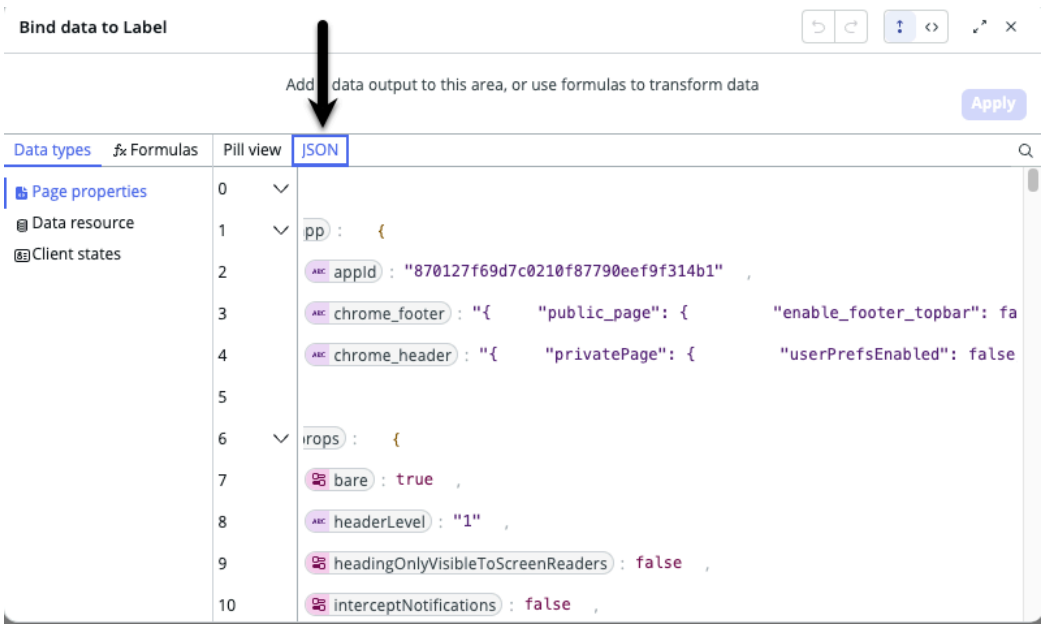


Use the search bar to find the data you would like to bind to your component.



Binding data by editing JSON

Use this method if you are comfortable working in and editing JSON code.



Connect data to your components

Bind data exposed by local data resources to components on your UI Builder page.

Before you begin

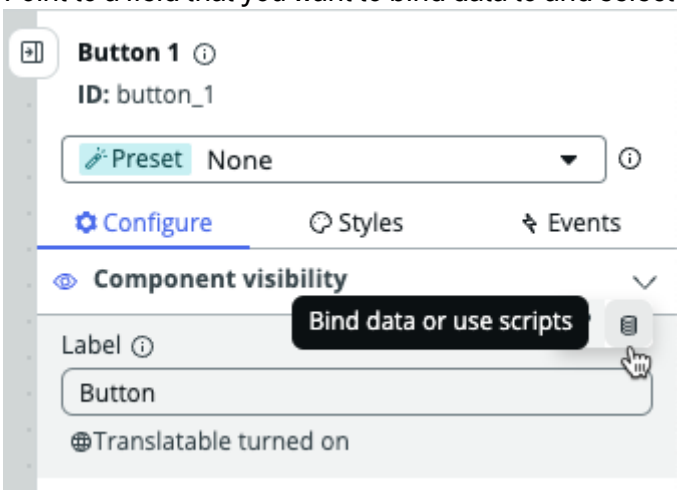
Role required: ui_builder_admin

About this task

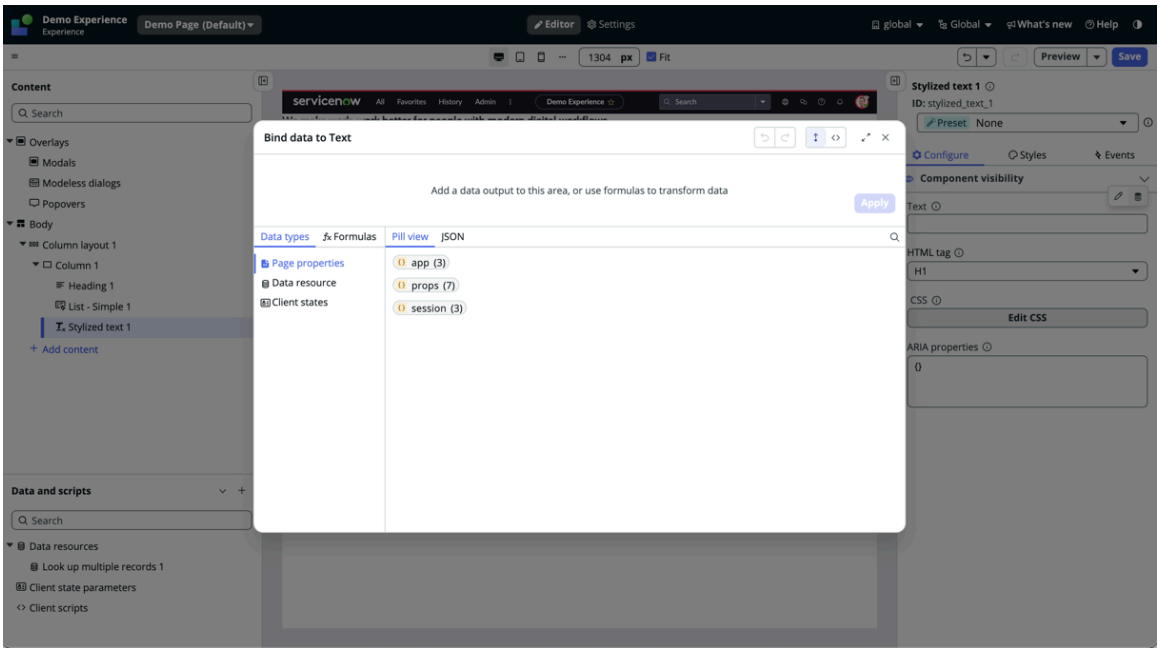
Data binding is the process of associating data with a UI element that displays the information. Before binding data to components you must add a data resource to your UI Builder page, see Add and configure data resources to a page for more information.

Procedure

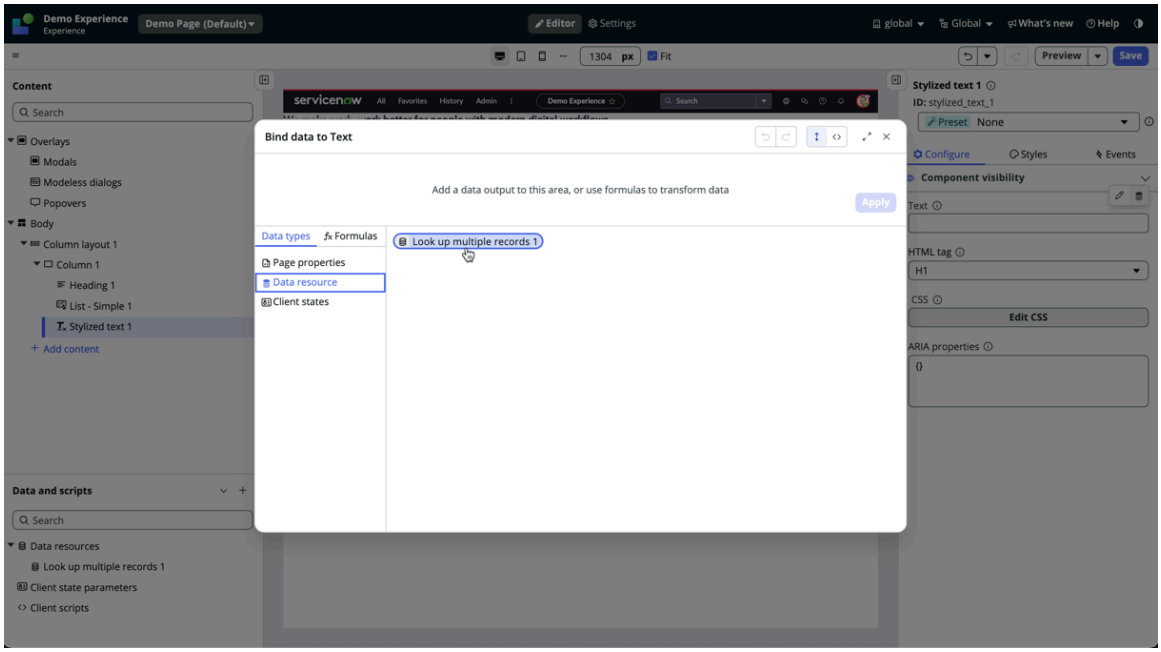
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page.
4. Add a data resource to your page.
   For more information, see Add and configure data resources to a page.
5. Add a component to your page.
   You need a component on your page before you can bind a data resource to it. For more information, see Customize UI Builder pages using components.
6. Select the **Configure** tab from the configuration panel in UI Builder.
7. Point to a field that you want to bind data to and select the dynamic data binding icon ( ).



The data binding modal appears.

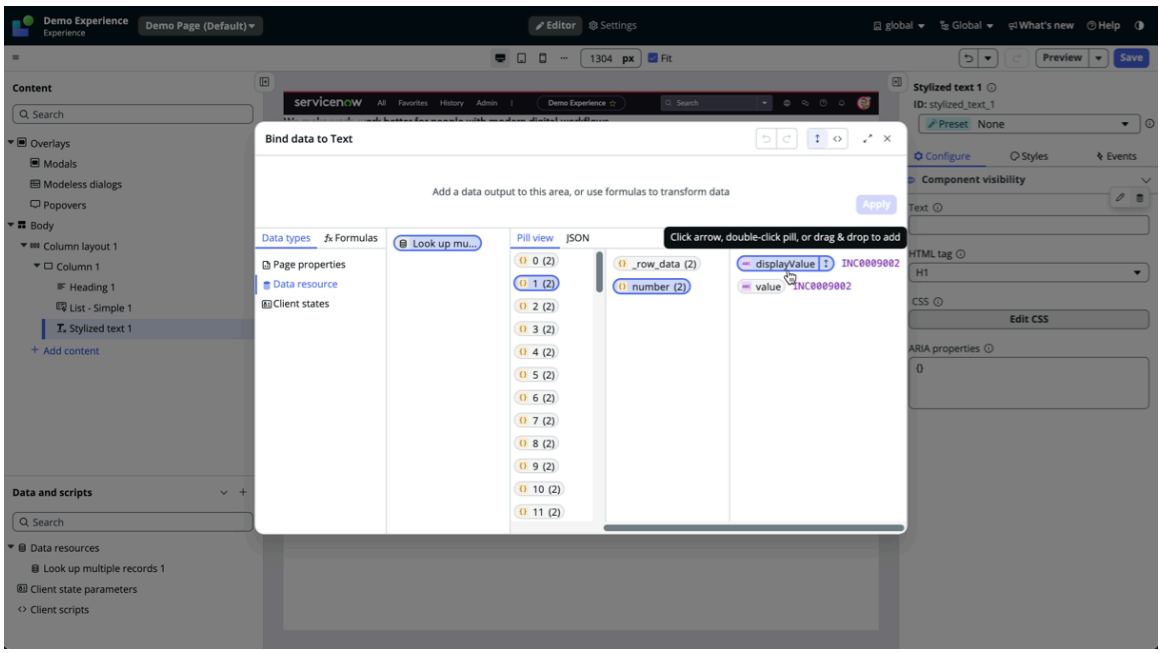


8. Select **Data resource** in the **Data types** tab.
9. Select the data resource that you want to bind to the component.



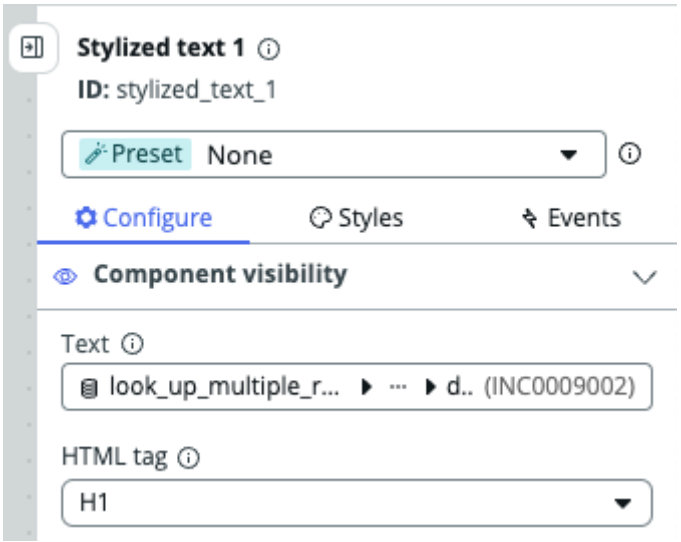
10. Select and drag the data you want to bind to the component into the field above.

You may have to select several pills to get to a specific property value or display value.



11. Select **Apply**.

The component displays the property value or display value that you've selected.



12. Select **Save** in the UI Builder header.

Connect data to your components with formulas

Bind data exposed by local data resources to components with formulas on your UI Builder page.

Before you begin

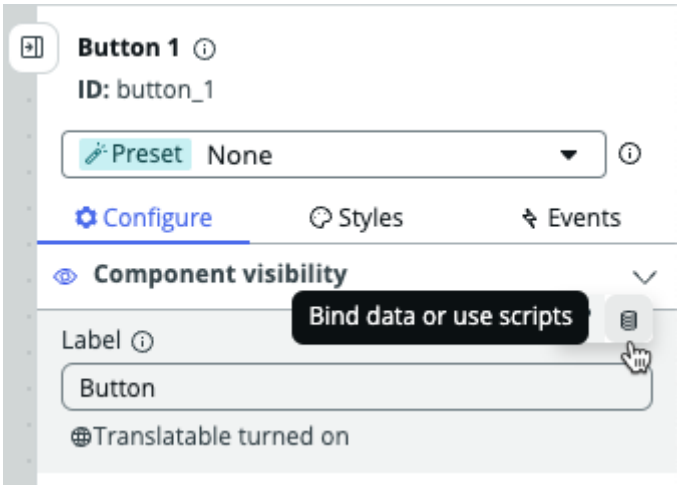
Role required: ui_builder_admin

About this task

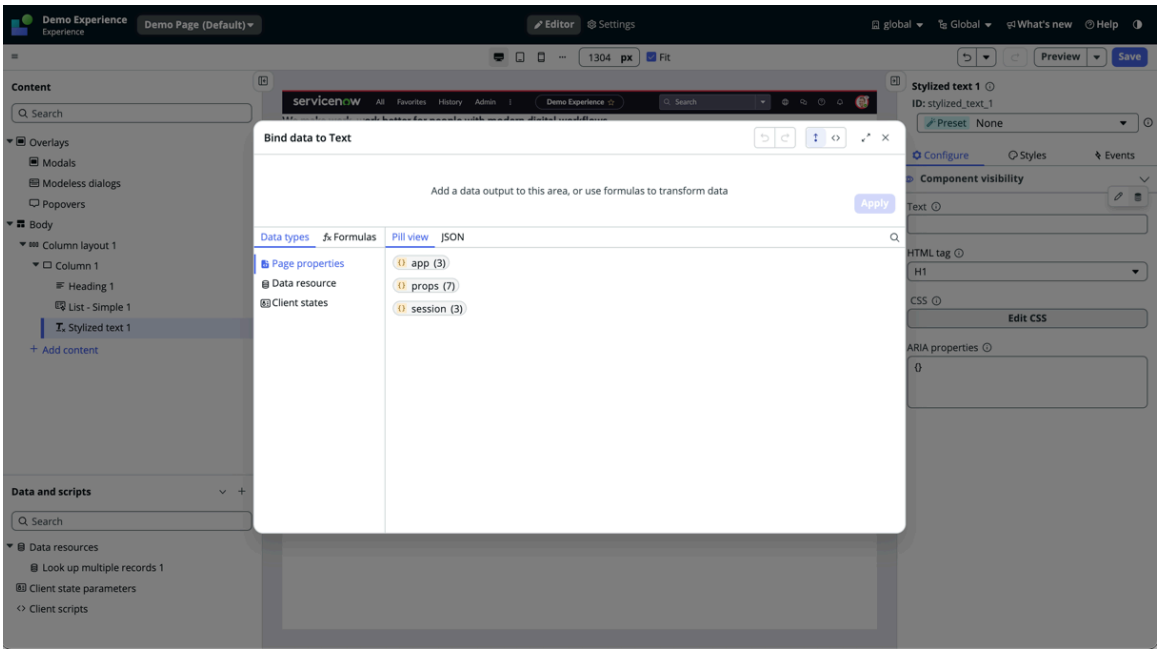
Data binding is the process of associating data with a UI element that displays the information. Before binding data to components you must add a data resource to your UI Builder page, see Add and configure data resources to a page for more information.

Procedure

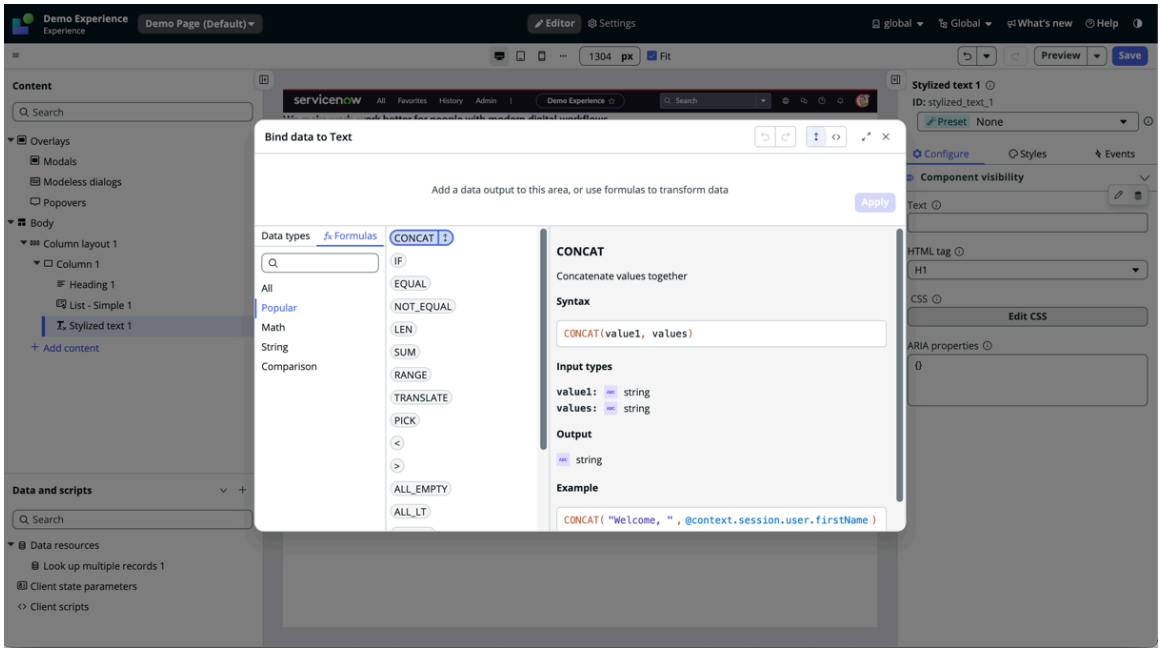
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page.
4. Add a data resource to your page.
   For more information, see Add and configure data resources to a page.
5. Add a component to your page.
   You need a component on your page before you can bind a data resource to it. For more information, see Customize UI Builder pages using components.
6. Select the **Configure** tab from the configuration panel in UI Builder.
7. Point to a field that you want to bind data to and select the dynamic data binding icon ( ).



The data binding modal appears.

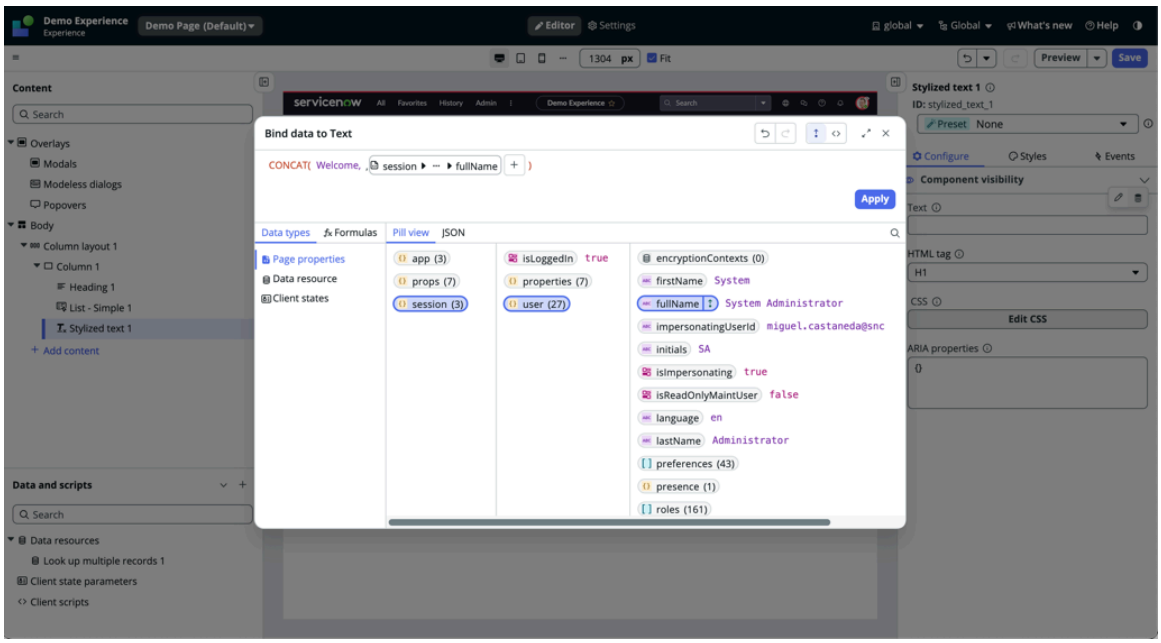


8. Select the **Formulas** tab.
9. Select and drag the formula you want to bind to the component into the field above.



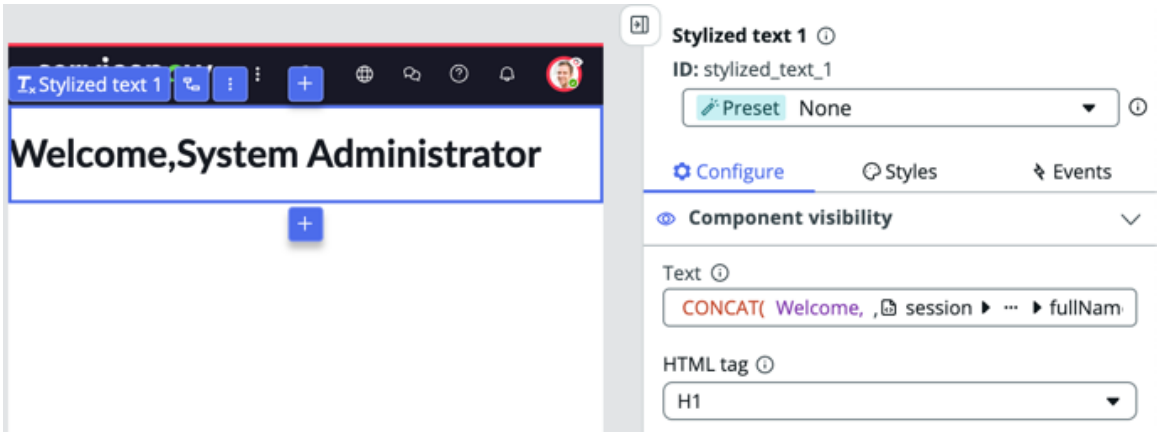
For more information about formulas, see Supported functions in the UI Builder component formula editor.

10. Fill in the fields of the formula.



11. Select **Apply**.

The component displays the property value or display value that you've selected.



12. Select **Save** in the UI Builder header.

Client state parameters

Use client state parameters to bind values to component configurations. When the client state parameter's value changes, the component updates to use the new value.

What is a client-side interaction

In web-based applications, anything that happens in the browser is client-side. Client-side interactions occur when users interact with experience components by clicking. Examples of client-side interactions include:

- Clicking a button
- Applying a filter
- Sorting a list
- Refreshing a list
- Providing inline search results
- Alerting a user to incomplete or incorrect data

Users sometimes interact with pages in order to navigate to other pages. In other cases, users want to make updates to a page's content, appearance, or data. Rather than refreshing the entire page, client-side interactions update only the affected parts of a page.

For example, a user can sort a list by clicking a column header. Sorting redraws only the list and not the entire page.

Creating client-side interactions in UI Builder involves:

- Client state parameters
- Events
- Client scripts

What are client state parameters

Client state parameters are page variables. Define and configure a client state parameter and use the value to configure components. Client state parameters centralize management of configuration values for page components. UI Builder uses client state parameters to enhance user experience and provide personalized content and services.

Example of client state parameters

In the example, a page has a client state parameter called color. Two of the three components are configured to use the color client state parameter. If color is set to orange, the components are orange. If color is set to purple, the components are purple. If color is set to green, the components are green. The client state parameter is a single place to manage a common value for the page. Without the client state parameter, each component that uses a value would need to be updated individually if that value changed.

For example, a web experience stores the primary color used by components in the color client state parameter. When the components are configured to use the client state parameter, changing the value of the client state parameter updates the components to the new value.

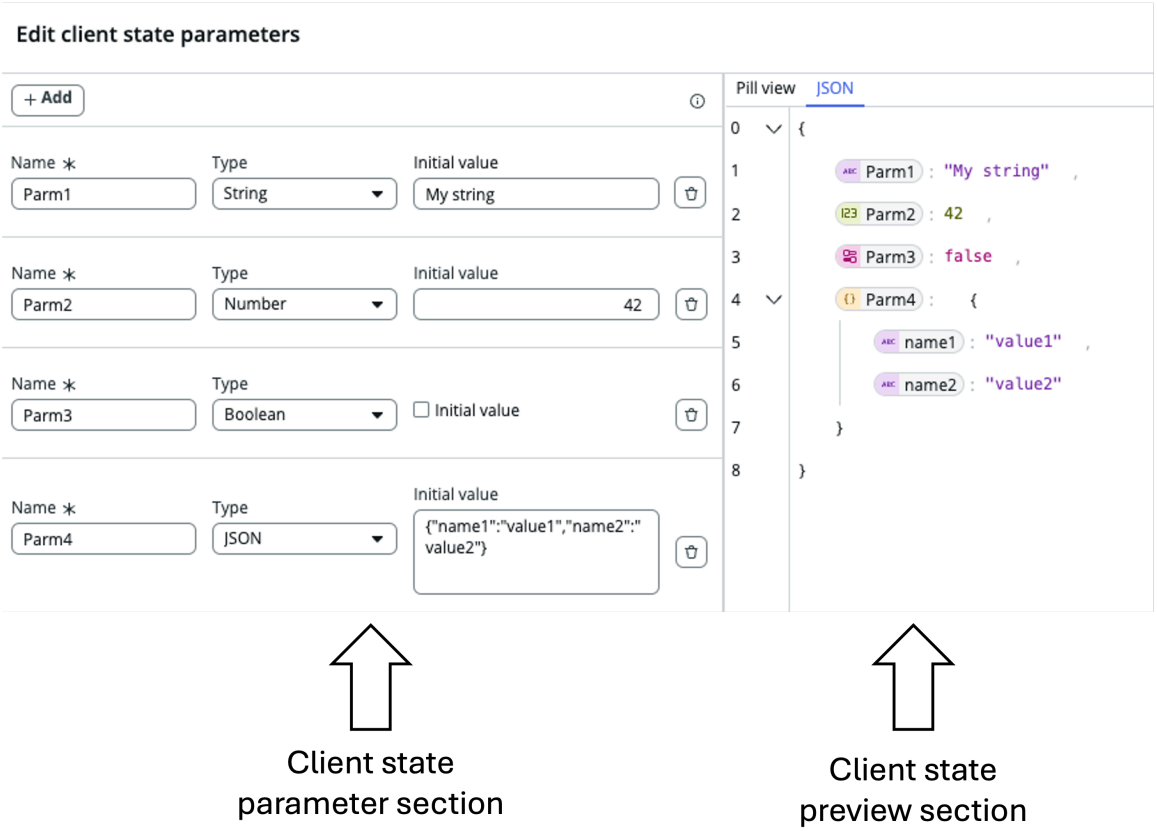
Buttons can be added to the experience to allow users to select a color for the page components. With a single click, a user can simultaneously change the color of all components on a page. Store the user's color choice in a client state parameter, then use the client state parameter to configure the page's components. When a user interaction causes the client state parameter value to change, the page's components are updated in real time.

The client state panel

The client state panel is collapsed by default. Click the client state icon in the left navigation bar to open the client state panel.

The client state panel contains two sections:

- Client state parameters: The client state parameters for the page
- Client state preview: The JSON for the page's client state parameters

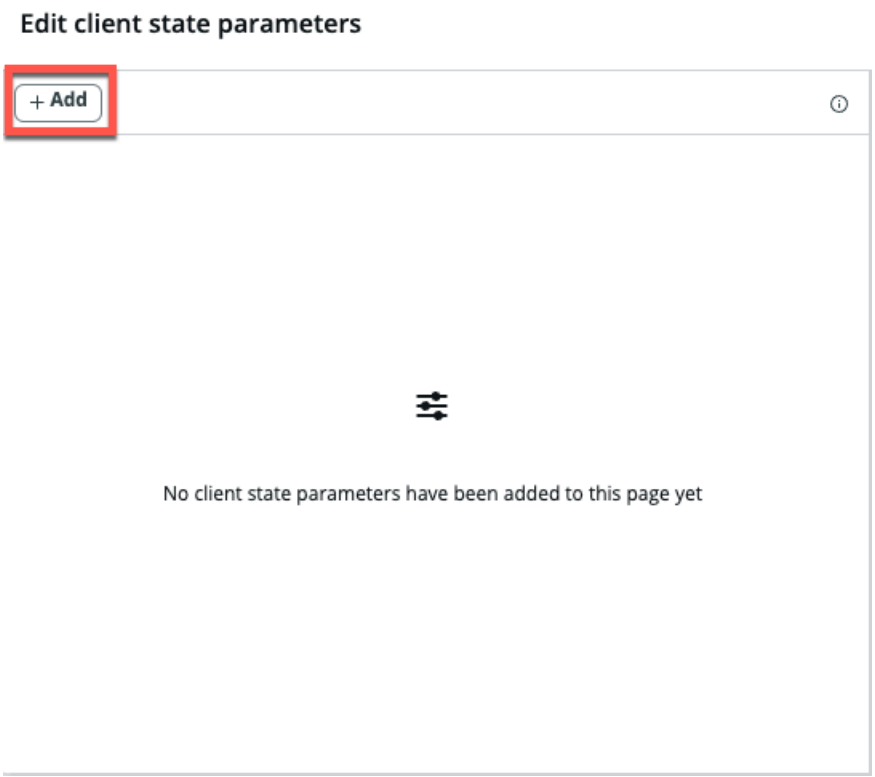


Client state parameter section

Client state preview section

Creating client state parameters

To add a client state parameter to a page, click the **+ Add** button in the client state parameters section.

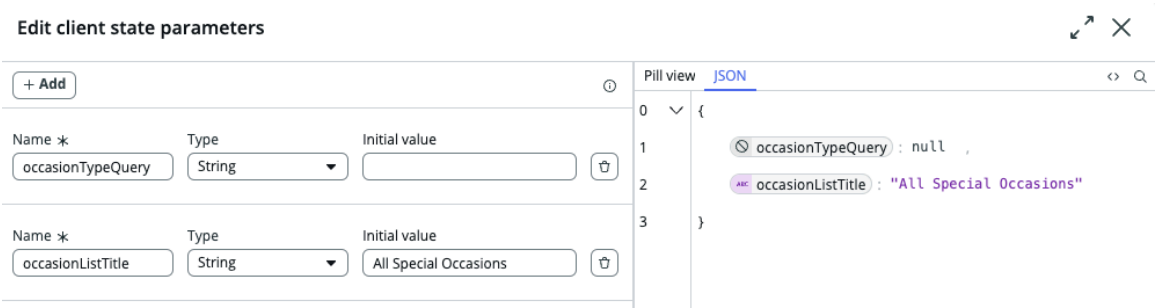


Client state parameters have three configuration fields.

- Name: The name of the parameter. Names should not include spaces
- Type: The parameter's type
  - String
  - Number
  - Boolean
  - JSON
- Initial value: The default value for the parameter

In the example, the client state panel has two client state parameters.

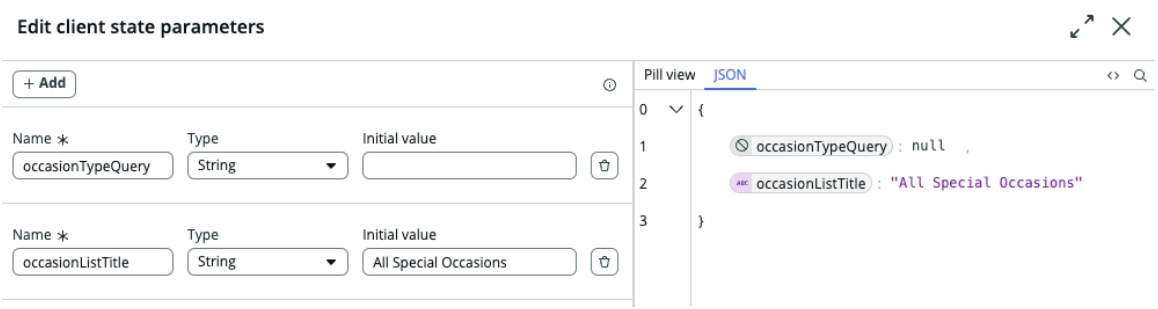
- `occasionTypeQuery` is a string with no default value
- `occasionListTitle` is a string with a default value of `All Special Occasions`



Working with client state parameters

Once you have a client state parameter, what can you do with it? To work with client state parameters, first bind the value of the client state parameter to component configurations. When the client state parameter's value changes, the component updates to use the new value. One way to change a client state parameter's value is with event handlers.

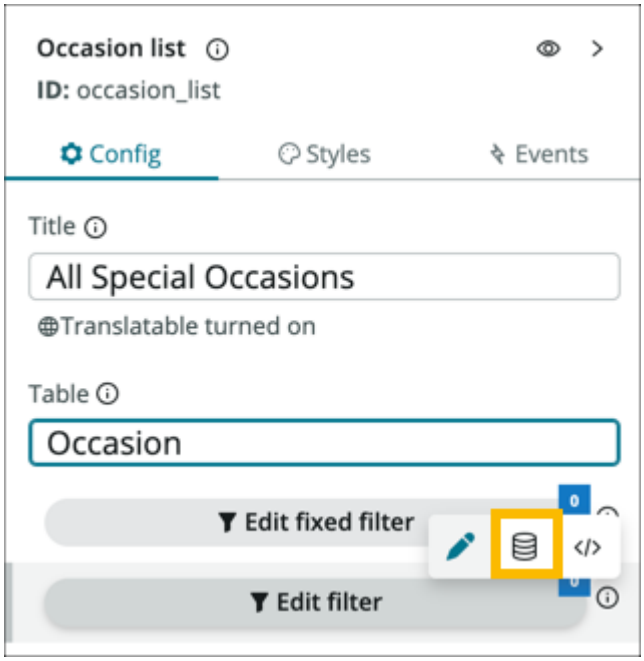
In the creating client state parameters page example, two client state parameters were added to the special occasions application: `occasionTypeQuery` and `occasionListTitle`. The `occasionTypeQuery` parameter has no value by default and `occasionListTitle` has the default value `All Special Occasions`. These client state parameters will be applied to the Occasion List component to set the list's title and filter. A button will be used to update the values of these client state parameters to dynamically update the list.



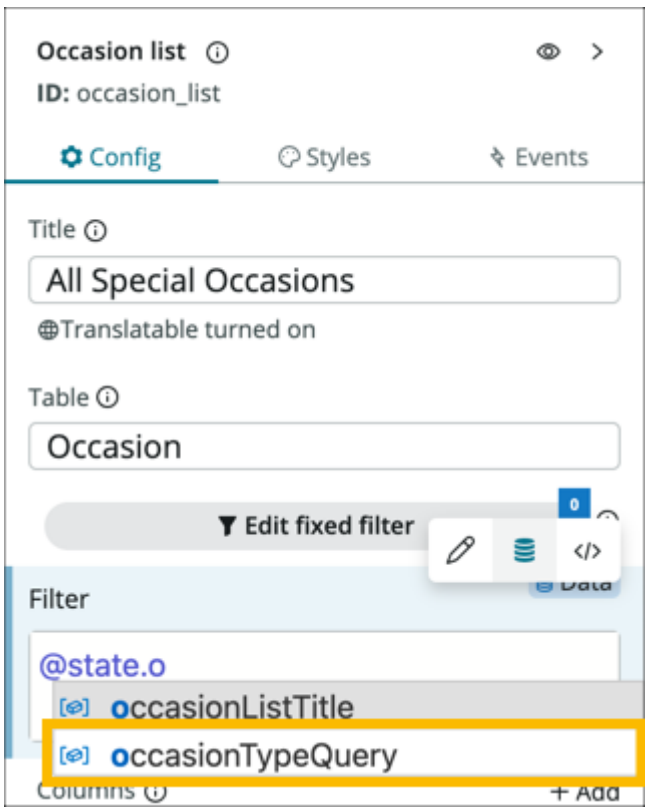
Binding client state parameters

Client state parameter values can be bound to component configuration fields the same way page context, payload, and data resources are. When configuring components, hover over a field, then select the **Dynamic data binding** button ( ) to bind a client state parameter to the

field value. In the example, the **Dynamic data binding** button is highlighted for the Occasion List component's filter field.

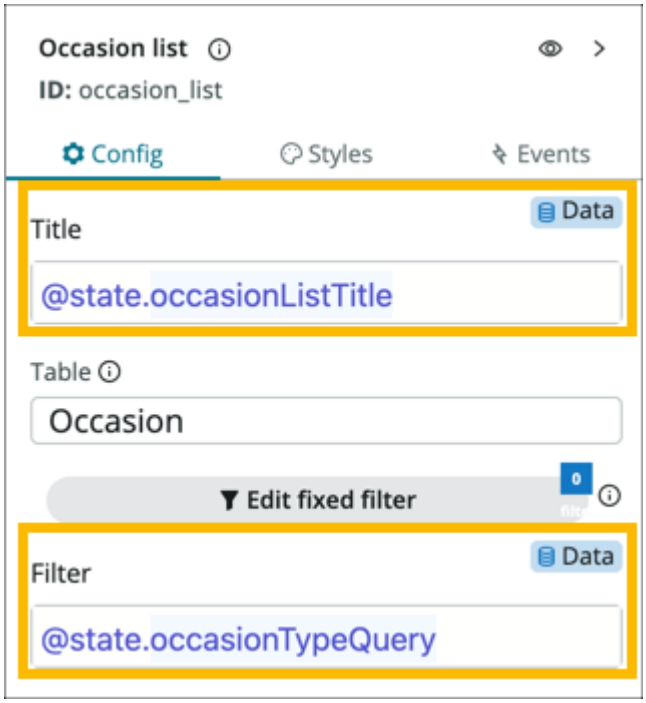


The character @ indicates data binding and the state object contains the client state parameters. Select a client state parameter from the choice list. The example shows selecting the `occasionTypeQuery` client state parameter. The default value for the `occasionTypeQuery` client state parameter is empty, so no filter will be applied by default.

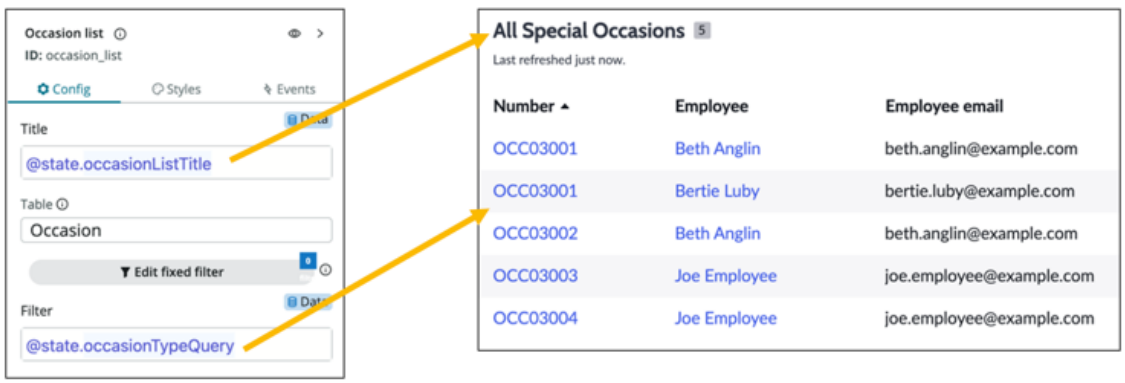


The Title for the component is set in a similar manner: select the **Dynamic data binding** button for the Title field or type @, then select the **state.occasionListTitle** client state parameter from the choice list. The default value for the `occasionListTitle` client state parameter is `All`

`Special Occansions`. The example shows both Title and Filter configured to use client state parameters.



With both client state parameters applied, no filter is applied to the list and the title is `All Special Occasions`.



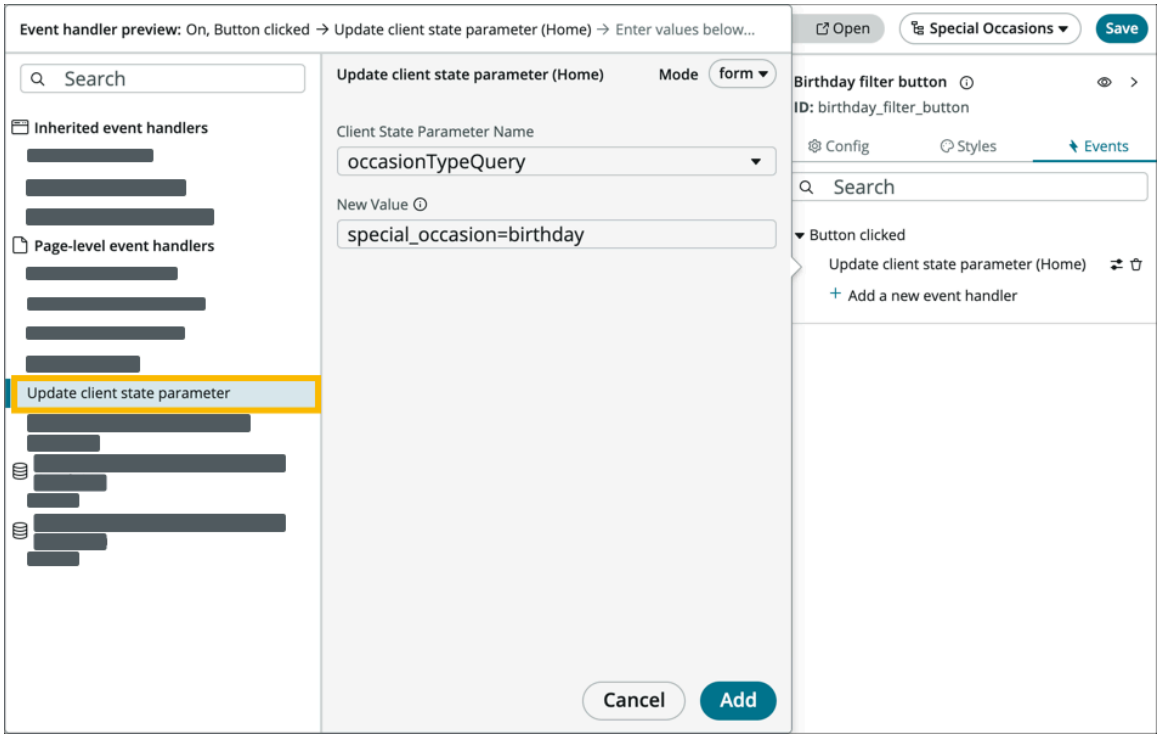
The `occasionTypeQuery` and `occasionListTitle` client state parameter values remain unchanged until a user interacts with a component that changes the value of the client state parameter.

Change client state parameter values

User the **Update client state parameter** event handler to change the value of a client state parameter in runtime. The **Update client state parameter** event handler has two properties: client state parameter to update and the new value to use for the client state parameter.

As an example, a `Birthdays` button is added above the `Occasion List` component in the `Special Occasions` application. The objective of this button is to change the `Title` of the list to `All Birthdays` and to adjust the filter of the list to only show birthdays. To achieve this objective, two event handlers are mapped to the **Button clicked** event for the button, one to change the `occasionTypeQuery` client state parameter and another to change the `occasionListTitle` client state parameter. The image shows the **Update client state**

parameter event handler configured to set the `occasionTypeQuery` client state parameter to `special_occasion=birthday`, which will filter the list to only show birthdays.



When the **Button clicked** event is mapped to event handlers to update both the `occasionTypeQuery` and `occasionListTitle` client state parameters, clicking the button updates the client state parameters, which automatically updates the `Occasion List` component with the new values.

Using client state parameters in UI Builder

Create a simple counter by adding the stylized text component and two buttons to an experience page. Use a client state parameter to implement the functionality so that when the buttons are selected the count increases or decreases.

Before you begin

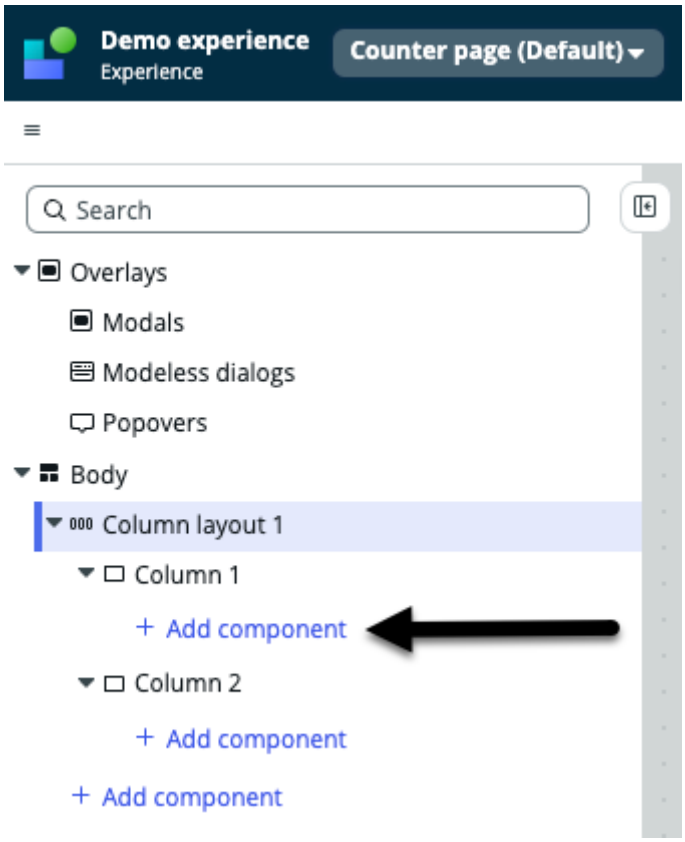
Role required: ui_builder_admin

Three minute video showing how to add a stylized text component and two button iconic components to create a simple counter application.

Procedure

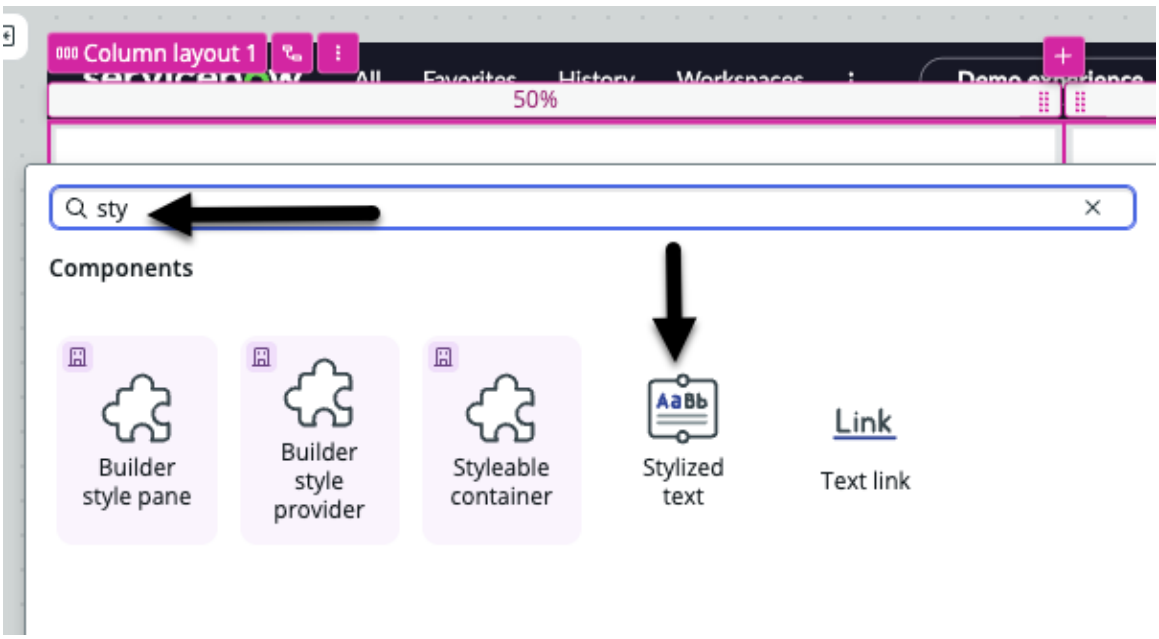
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create > Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.

3. Create a page in UI Builder or open a page.
4. Add a column layout by selecting **+ Add content** in the content tree under **Body**.
5. On the **Layouts** tab, select **Two columns**.
6. Add the first component by selecting **+ Add content** in the content tree under **Column 1**.

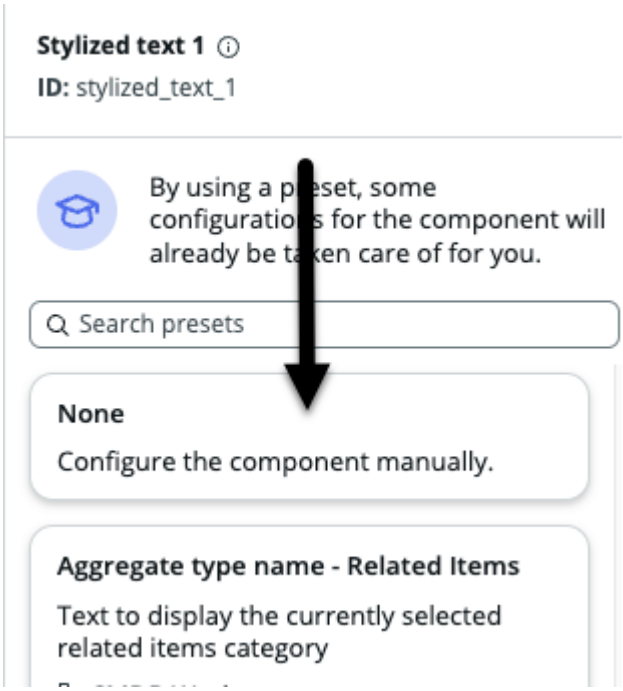


a. In **Search**, type `sty`.

b. Select the **Stylized text** component.



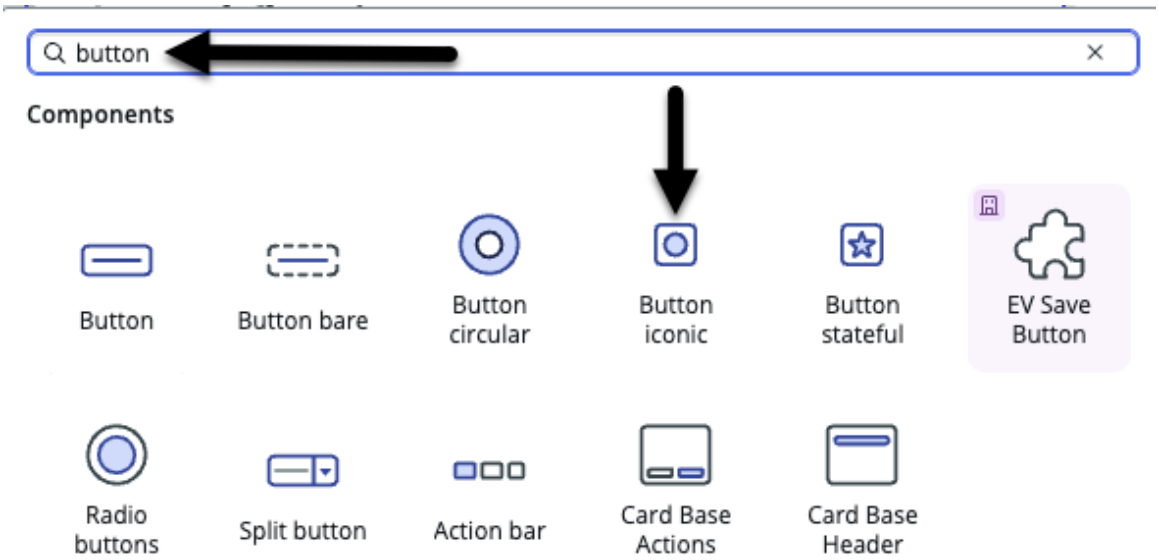
c. In the configuration panel, select **None - Configure the component manually**.



7. Add the second component by selecting **+ Add content** in the content tree under **Column 2**.

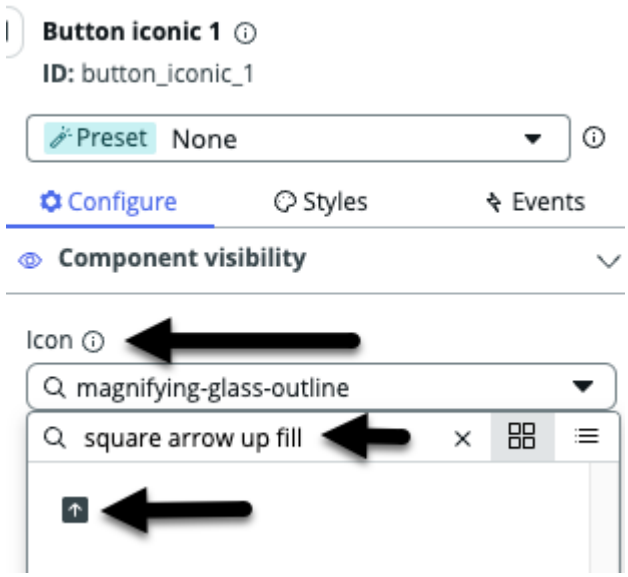
a. In **Search**, type `button`.

b. Select **Button Iconic**.

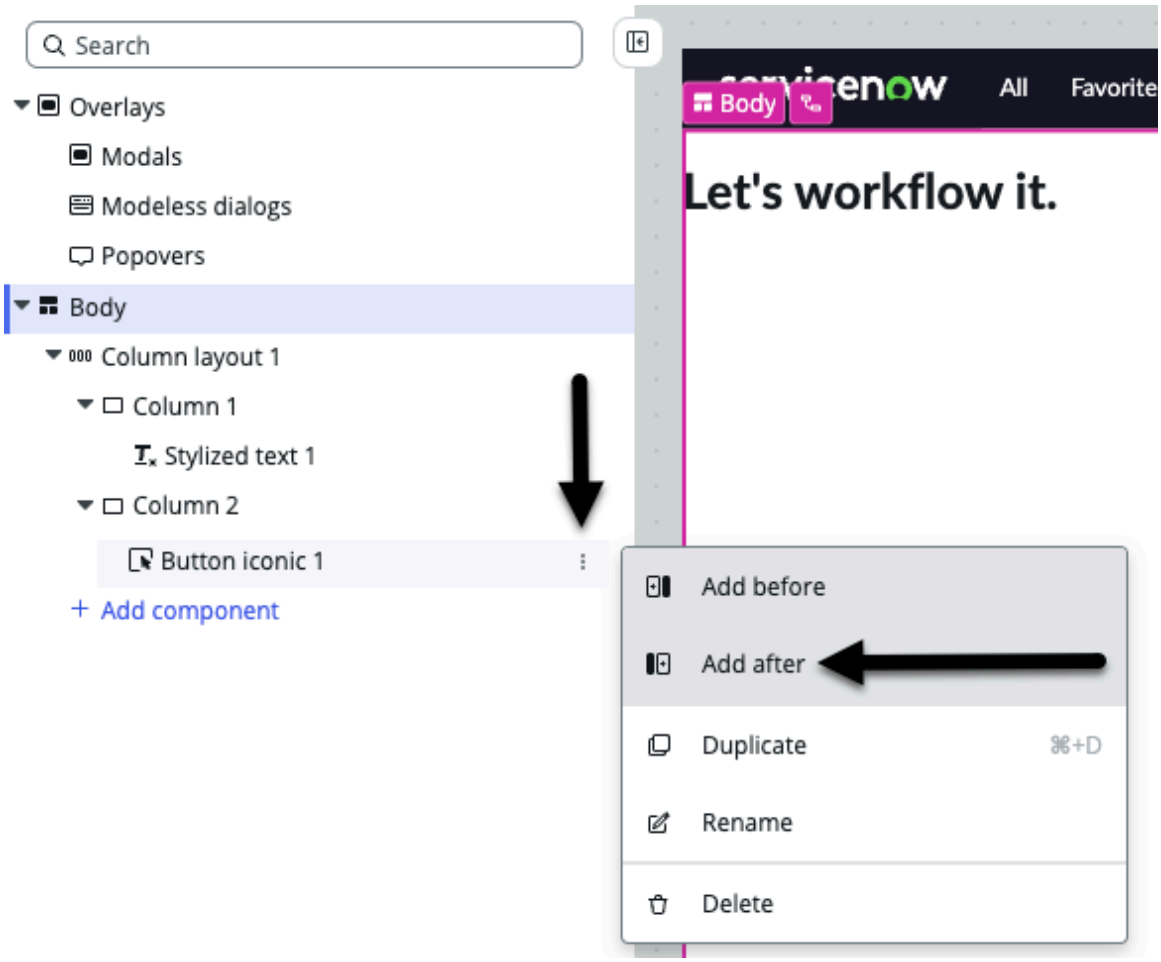


c. In the configuration panel, select **None - Configure the component manually**.

d. In **Icon**, select **Square Arrow Up Fill**.



8. Add the third component by pointing to **Button iconic 1** in the content tree, selecting the **Menu** icon, and selecting **Add after**.

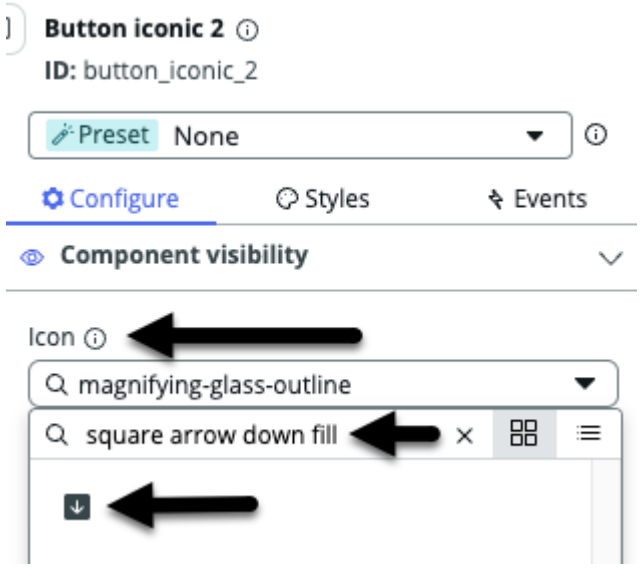


a. In **Search**, type `button` as you did in the previous step.

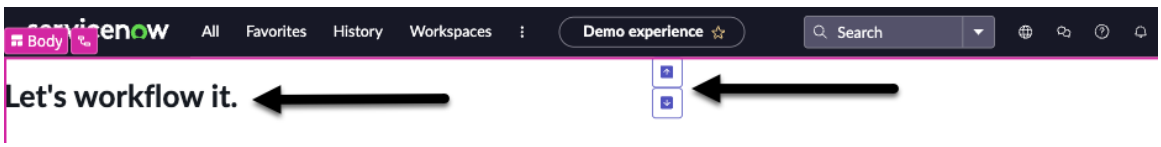
b. Select **Button Iconic** as you did in the previous step.

c. In the configuration panel, select **None - Configure the component manually** as you did in the previous step.

d. In **Icon**, select a different icon this time, the one named **Square Arrow Down Fill**.



9. Select **Save**.
The stylized text component and the two button iconic components are saved and appear on the stage.



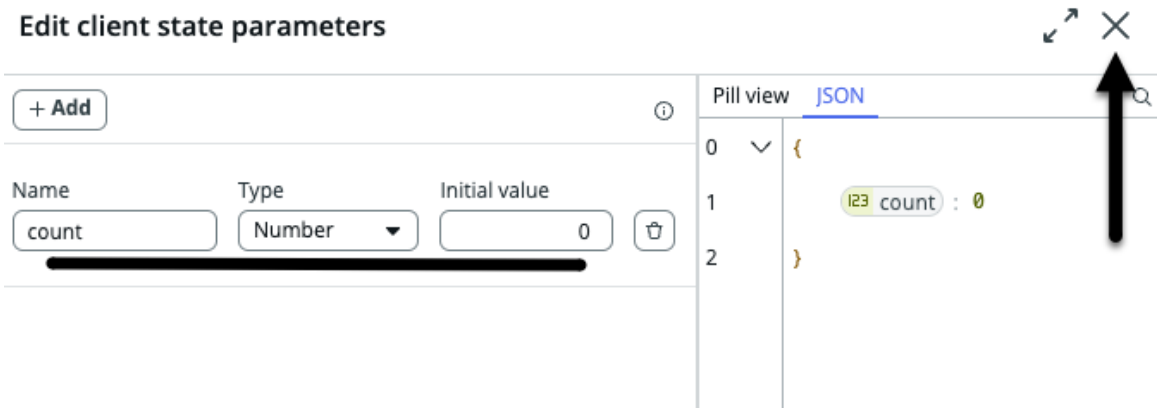
10. Add a client state parameter by going to **Data and scripts**, pointing to **Client state parameters**, and selecting the **Add new (plus)** icon.

a. Change the **Name** by entering `count`.

b. Change the **Type** to **Number**.

c. Set the **Initial value** by entering the number `0`.

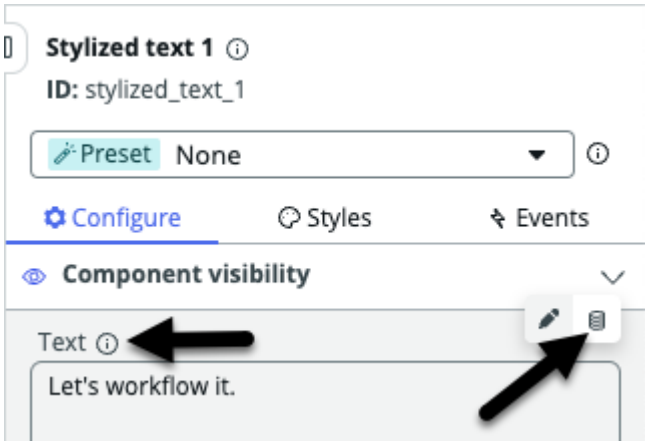
d. Select the **X** to close the window.



11. Bind the stylized text component to the client state parameter.

a. Select the stylized text component on the stage.

b. In the configuration panel, point to the **Text** field and select the **Bind data or use scripts** icon.



c. On the **Data types** tab, select **Client states**.

d. Double-click on the **count** pill.

e. Select **Apply**.

The **Text** field changes to **count**.

12. Now configure the buttons to increase or decrease the number.

a. Select the top button on the stage.

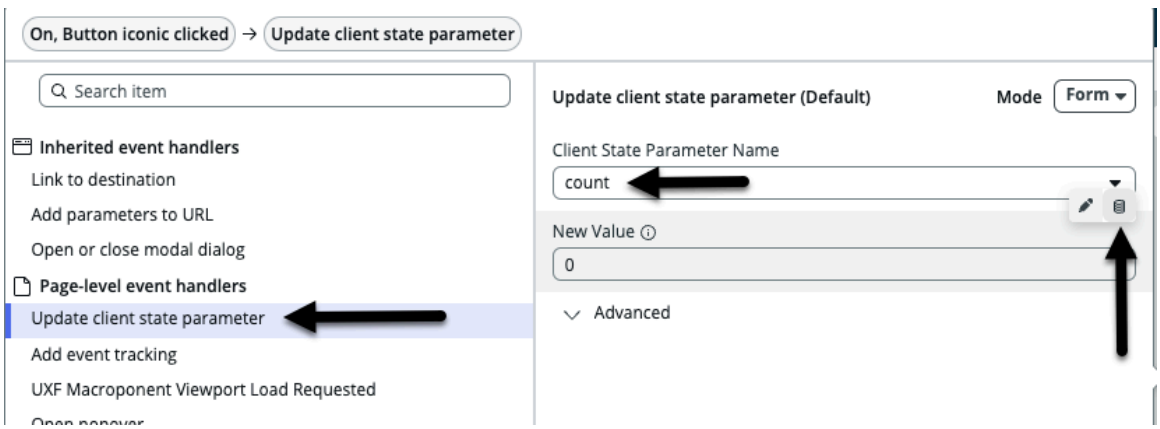
b. In the configuration panel, select the **Events** tab.

c. Select **+ Add event handler**.

d. Under **Page-level event handlers**, select **Update client state parameter**.

e. In **Client State Parameter Name**, select **count**.

f. Point to the **New Value** field and select the **Bind data or use scripts** icon.



g. On the **Data types** tab, select **Client states**.

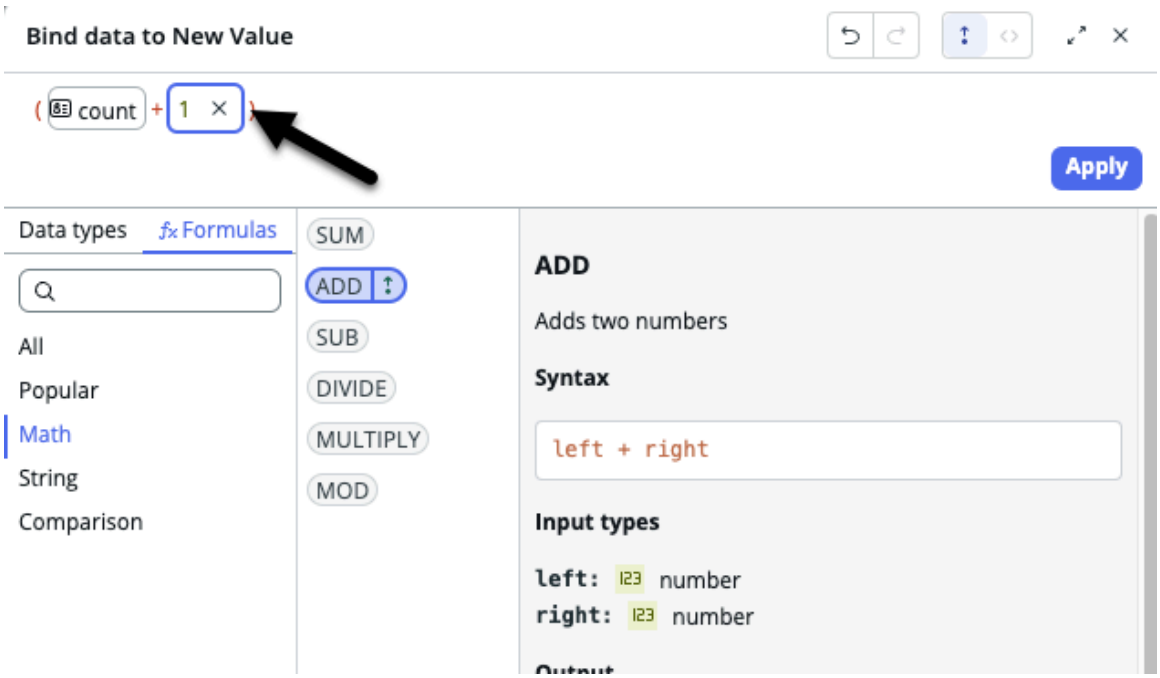
h. Double-click on the **count** pill.

i. Select the **Formulas** tab.

j. In the list, select **Math**.

k. Double-click on the **ADD** pill.

l. In the **right** pill at the top, remove the text and enter `1`.

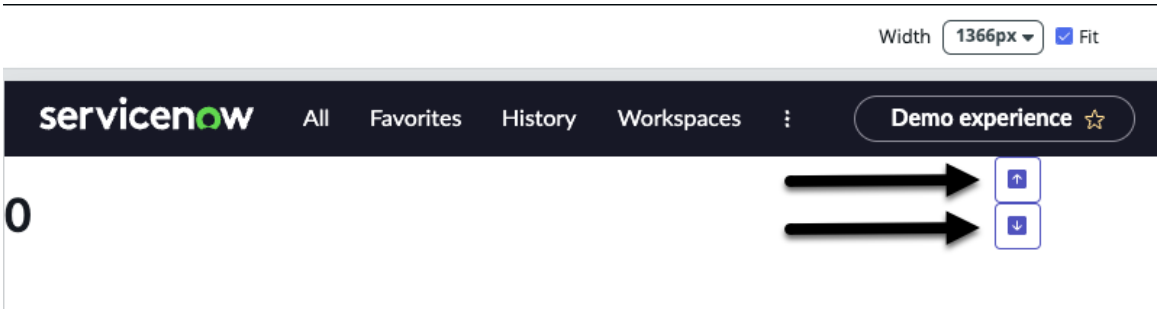


m. Select **Apply**.

n. Select **Add**.

13. Now configure the second button by following the same process that you used for the first button, but select the SUB pill instead of the ADD pill.
    a. Select the bottom button on the stage.
    b. In the configuration panel, select the **Events** tab.
    c. Select **+ Add event handler**.
    d. Under **Page-level event handlers**, select **Update client state parameter**.
    e. In **Client State Parameter Name**, select **count**.
    f. Point to the **New Value** field and select the **Bind data or use scripts** icon.
    g. On the **Data types** tab, select **Client states**.
    h. Double-click on the **count** pill.
    i. Select the **Formulas** tab.
    j. In the list, select **Math**.
    k. Double-click on the **SUB** pill.
    l. In the **right** pill at the top, remove the text and type `1`.
    m. Select **Apply**.
    n. Select **Add**.
14. Test the counter by selecting **Preview**.

15. Select the up arrow button to increase the count and the down arrow button to decrease the count.



Result

You added a button component to increase the count by one and another button component to decrease the count by one. You added the stylized text component to show the count as it increased and decreased.

For detailed, technical information about the button component, see Button Overview & API.

For detailed, technical information about the stylized text component, see Stylized Text Overview.

Update a component's state using client state parameters

Create and bind a client state parameter value to a component in UI Builder. By adding custom values to your components, these components can then be automatically updated through a script.

Before you begin

Role required: ui_builder_admin

About this task

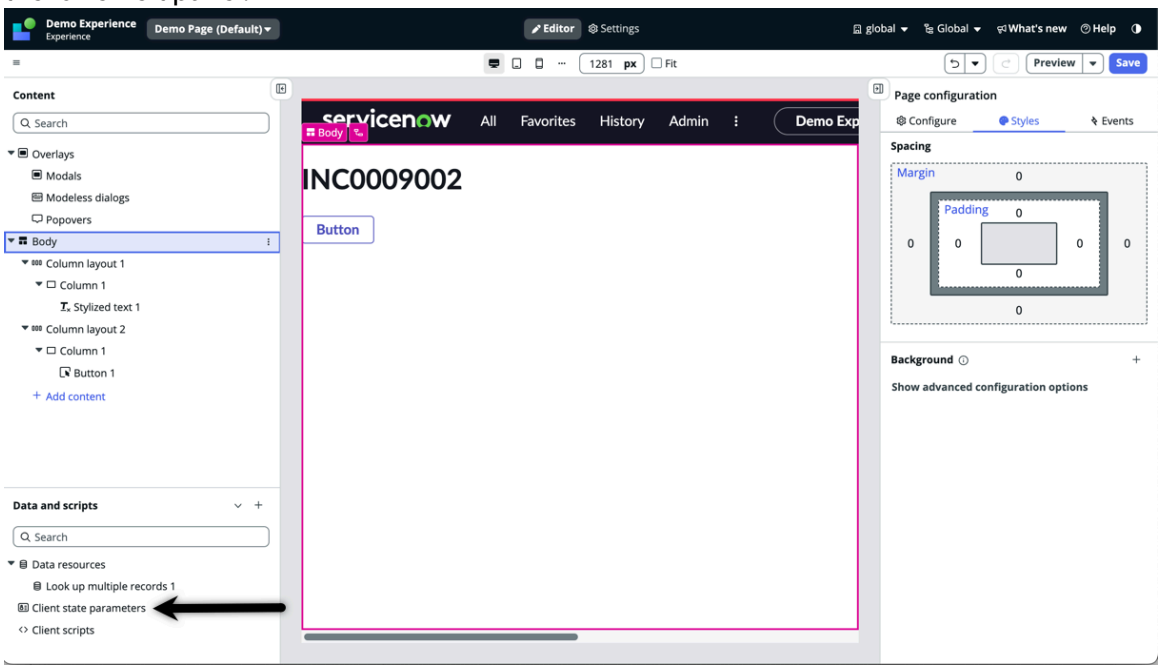
You can add two components to a page and then connect them by using client state parameters and scripts. Start by creating a client state parameter and then binding the client state parameter to one of the components, such as a label. Next, you create a client script and bind it to a second component, such as a button, using an event handler. When you create the event handler, bind the client state parameter value to it to connect the two components. If you click one component, it changes the state of the other component. Client states are useful because you can add custom values to your components that can be automatically updated through a script. Think of a client state as a bucket for storing information that is specific to the page.

For example, you can add a button and label component to your page. The button changes the value of the label, such as changing the text color.

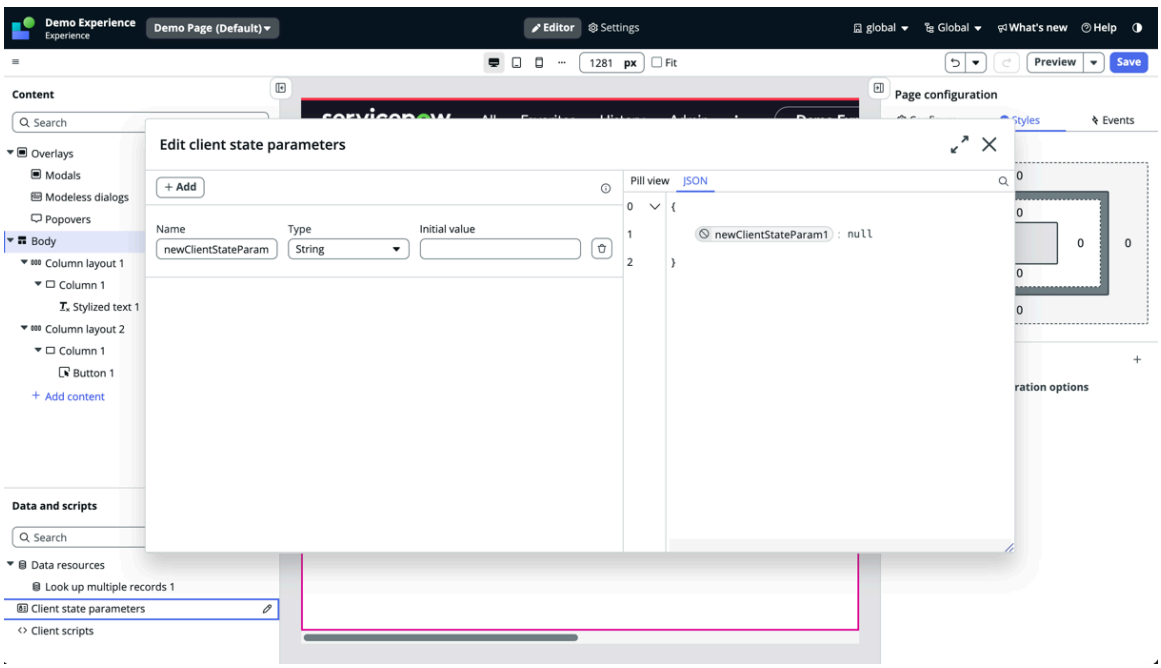
Procedure

1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create or open a page.
   For more information, see Manage UI Builder pages and page variants.
4. Add two components to your page.
   For more information, see Add and configure components.

5. To define a client state parameter with an associated value, select Client state parameters in the lower-left panel.

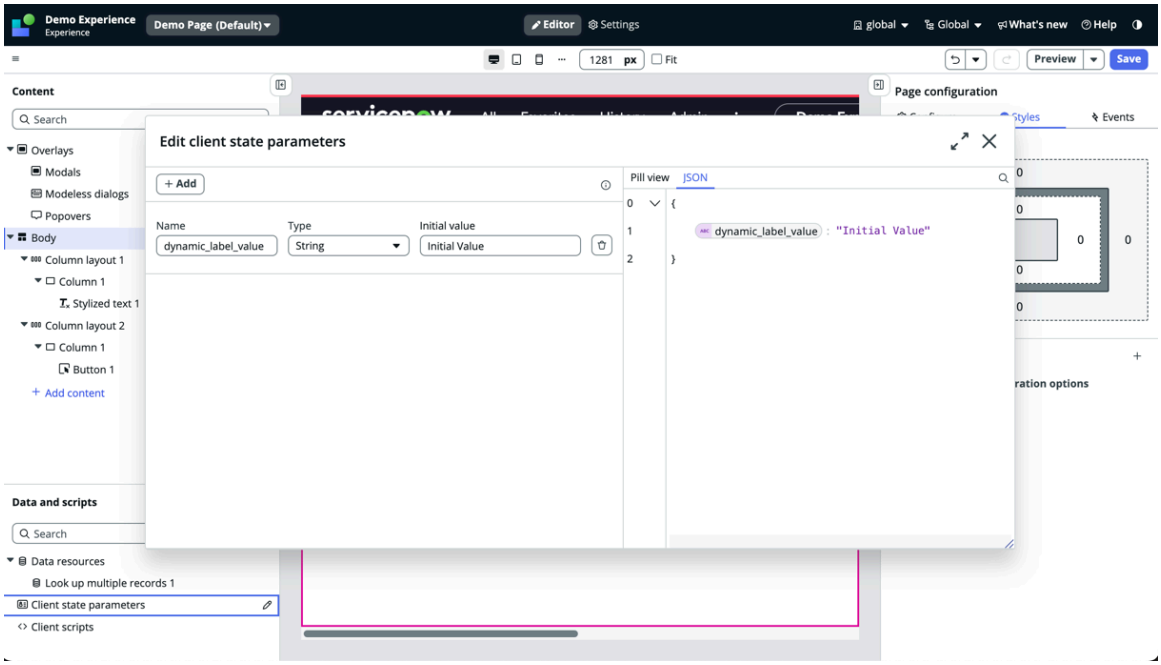


6. Select **+ Add**.



7. Enter a name for the client state name, type, and initial value.

   The client state supports Strings, Numbers, Boolean, and JSON. For example, you could enter the name as `dynamic_label_value`, the type as `String`, and the initial value as `Initial Value`.



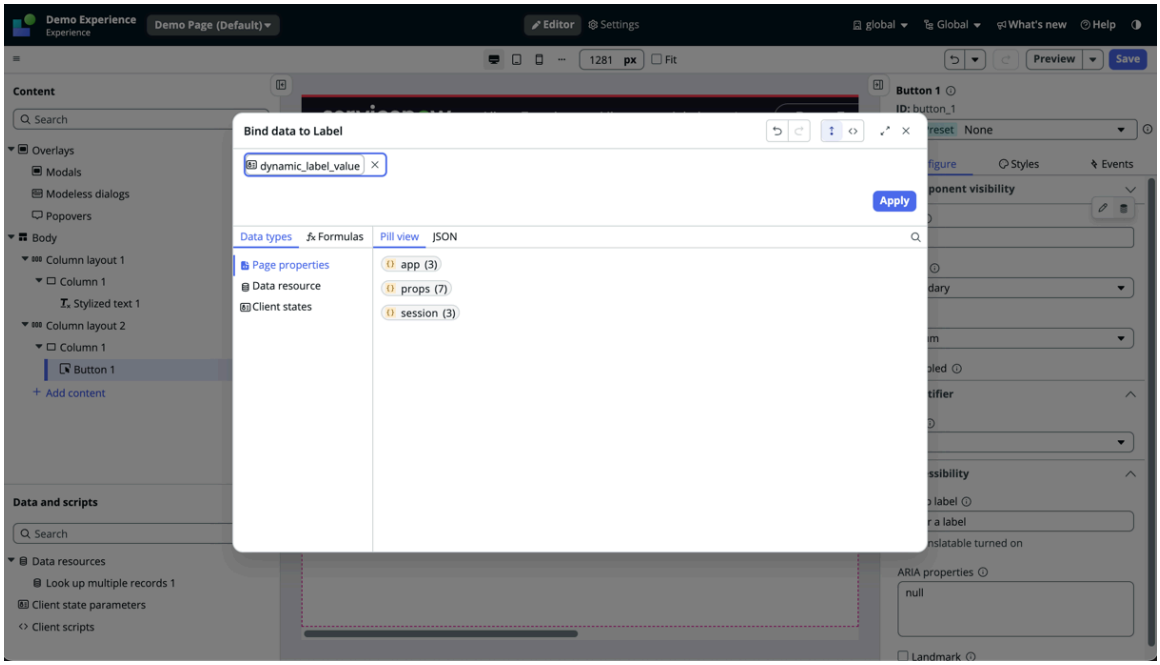
8. Bind the value of the client state parameter to your component.

   a. Select the component that you want to bind the client state parameter to.

   b. Open the configuration panel and select the **Configure** tab.

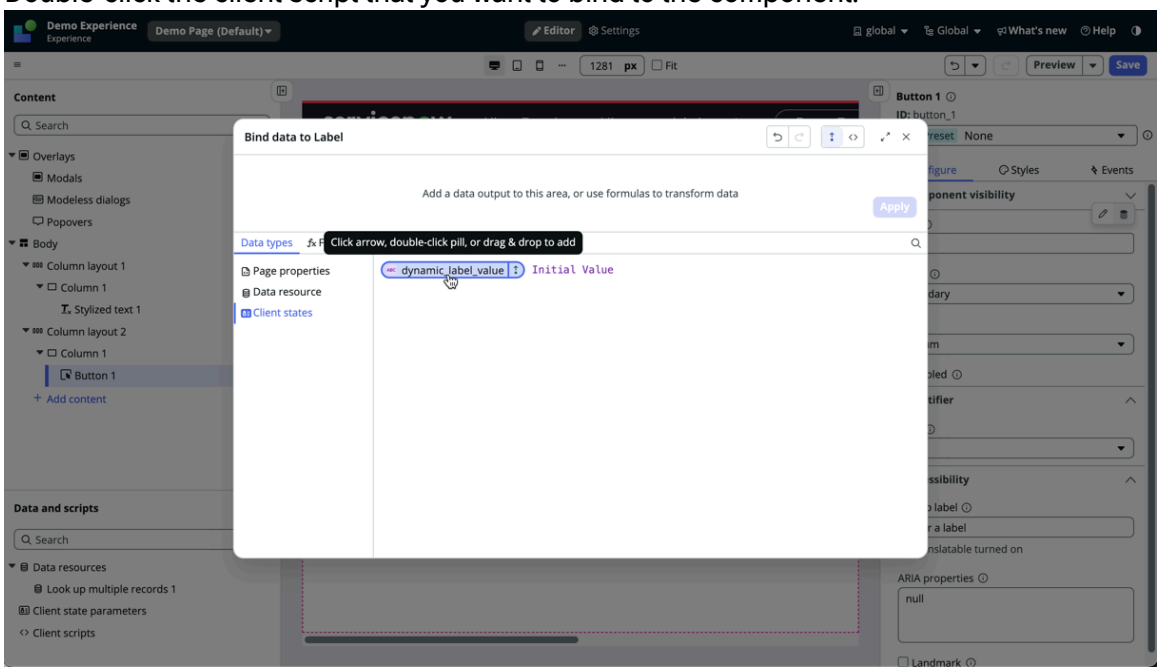
   c. Point to the field that you want to bind data to and select the dynamic data binding icon ( ).

   The data binding modal appears.

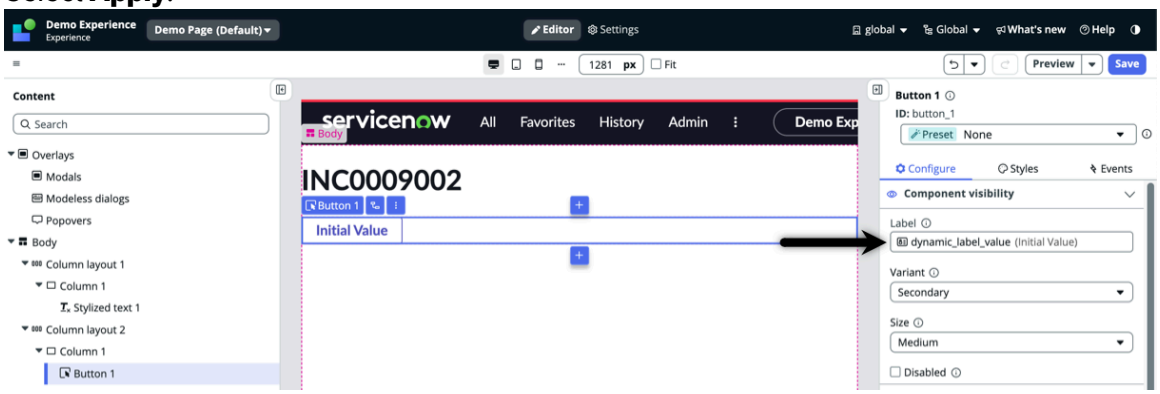


d. Select **Client states** in the **Data types** tab.

e. Double-click the client script that you want to bind to the component.



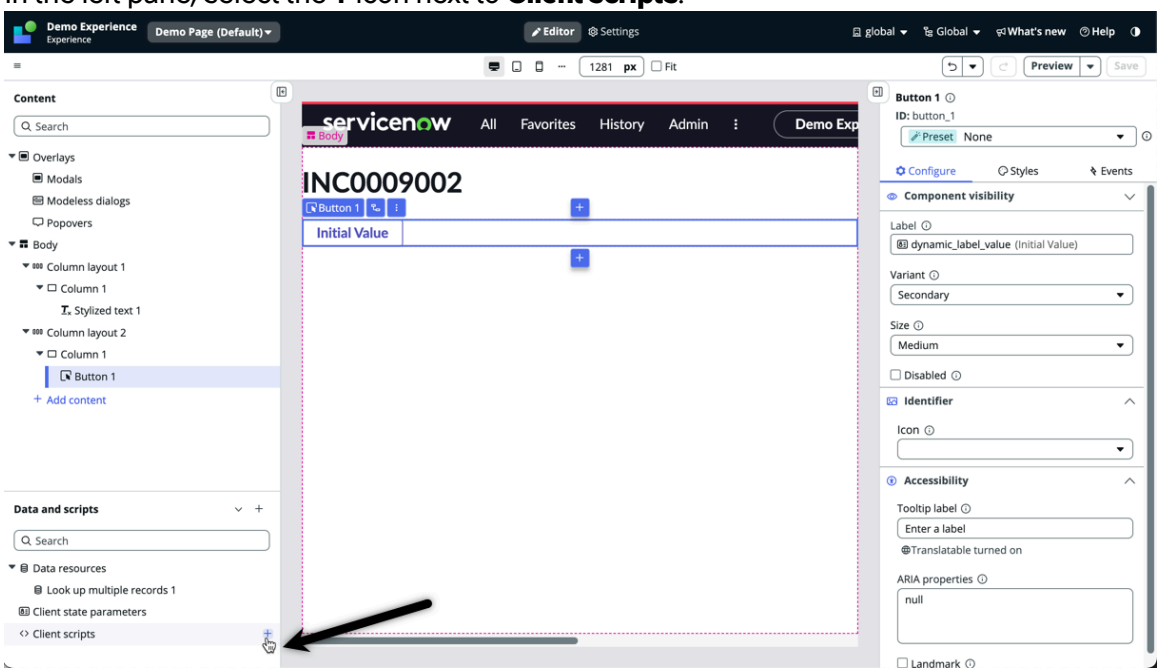
f. Select **Apply**.



9. Select **Save**.

10. Bind the client state value to one component and create a script to connect the second component to the first.

a. In the left pane, select the **+** icon next to **Client scripts**.

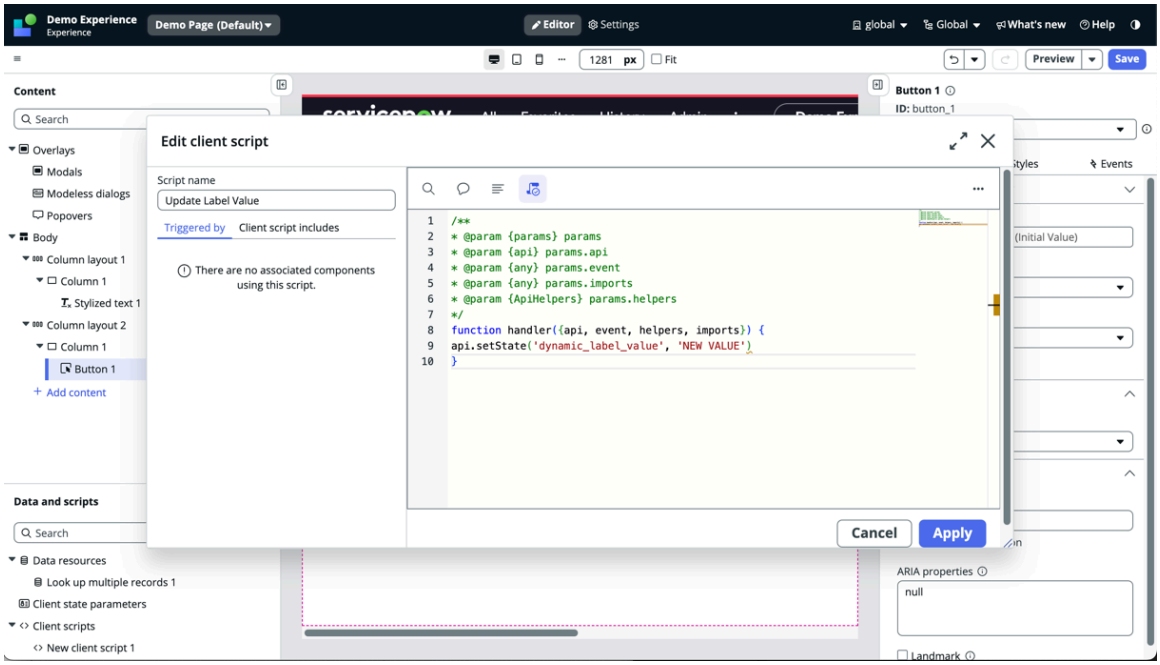


b. Enter a script name that describes the task.
For example, you could enter `Update Label Value` because that is what you want the script to do.

c. In the Now Code Editor, add your script.

Let's say that you choose an API to call, and the parameters for the API, such as a state and a value. For example, you could call the `api.setState`, and include the

`dynamic_label_value` as the first parameter, and a `NEW VALUE` as the second parameter.



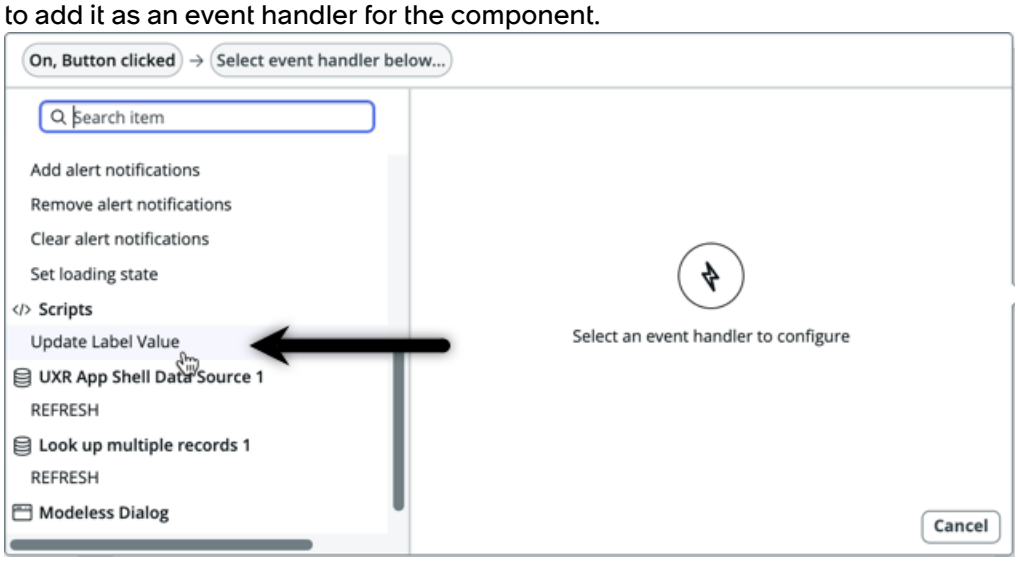
11. Add an event handler to your second component to call the new client script that you created.

a. Select the component on your page that you want to bind the script to.

b. Select the **Events** tab.

c. Select **+ Add a new event handler**.

d. Under the Scripts section of event handlers, select the script that you created, and select **+** to add it as an event handler for the component.



12. Select **Save**.

13. To preview your page and test the components to ensure they're connected, select **Preview**. When you select one component, it should change the state of the second component. For example, select the **Button** component to change the **Label value** component text from **Initial Value** to **NEW VALUE**.

Result

What you did in this procedure:

- Added two components to your page.
- Defined a client state parameter that had an initial value.
- Bound the client state parameter to the first component.
- Created a client script that updates a value that is defined by the client state parameter.
- Created an event handler for the second component to call the new client script that you just created
- Selected the second component so that it changed the state of the first component.

Define and bind client scripts to components

Add and edit client scripts in UI Builder so that you can update the client state through events. You can bind these scripts to any component by using an event handler.

Before you begin

Role required: ui_builder_admin

About this task

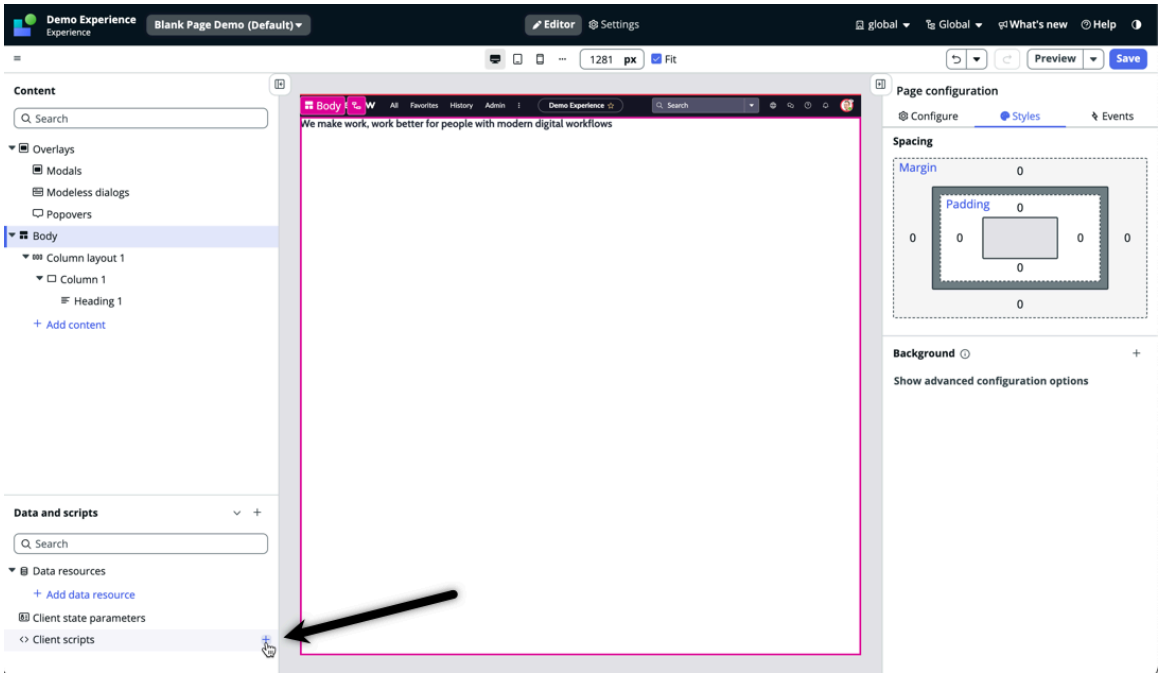
You can create JavaScript client scripts in UI Builder by using the Now Code editor. Then, you can add the client script as an event handler to update the client state, emit a handled event of your page, or execute a data resource operation. For example, you could write a script to increment a date or counter, and bind the script to a component event, like a button click. For more information about the Now Code Editor, see Edit code with the Now Code Editor (advanced feature).

With these scripts, you can do the following actions:

- Get available data, manipulate the data, and store it in the client state.
- Access data resource results.
- Execute data resource operations.
- Dispatch events.

Procedure

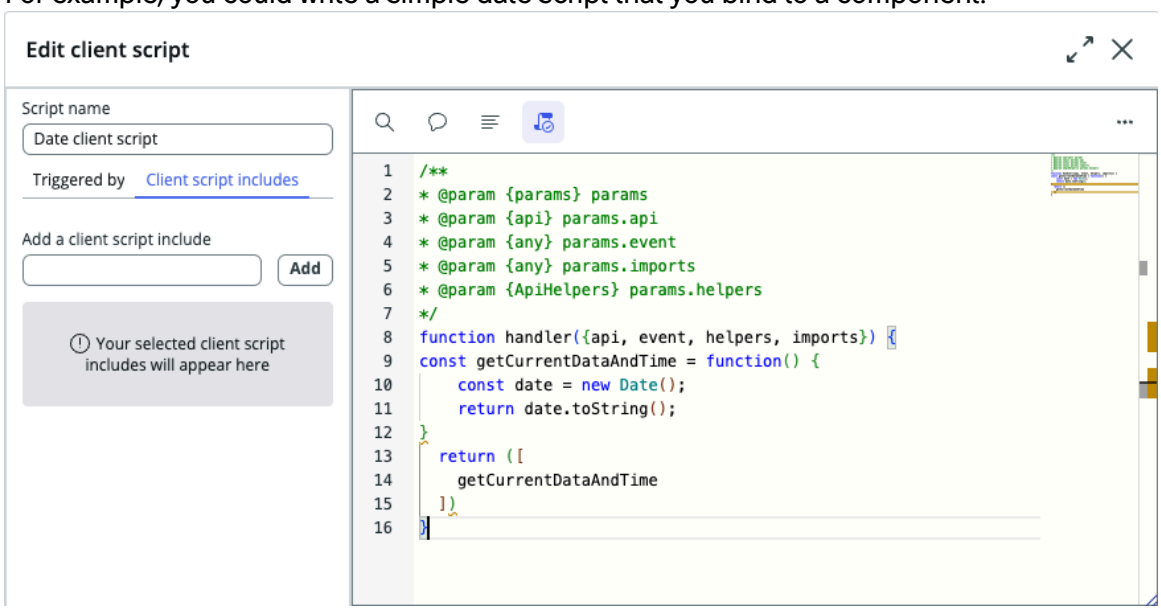
1. Navigate to **All** > **Now experience framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**.
   For more information, see Configure how users interact with your applications in UI Builder.
3. Open or create a page.
   For more information about how to create a page in UI Builder, see Create a page in UI Builder.
4. **Optional:** If you do not have any components on your page, add a component to your page.
   For example, you can add a Heading component. For more information, see Add and configure components.
5. Select **+** next to **Client scripts**.



6. Name your script.

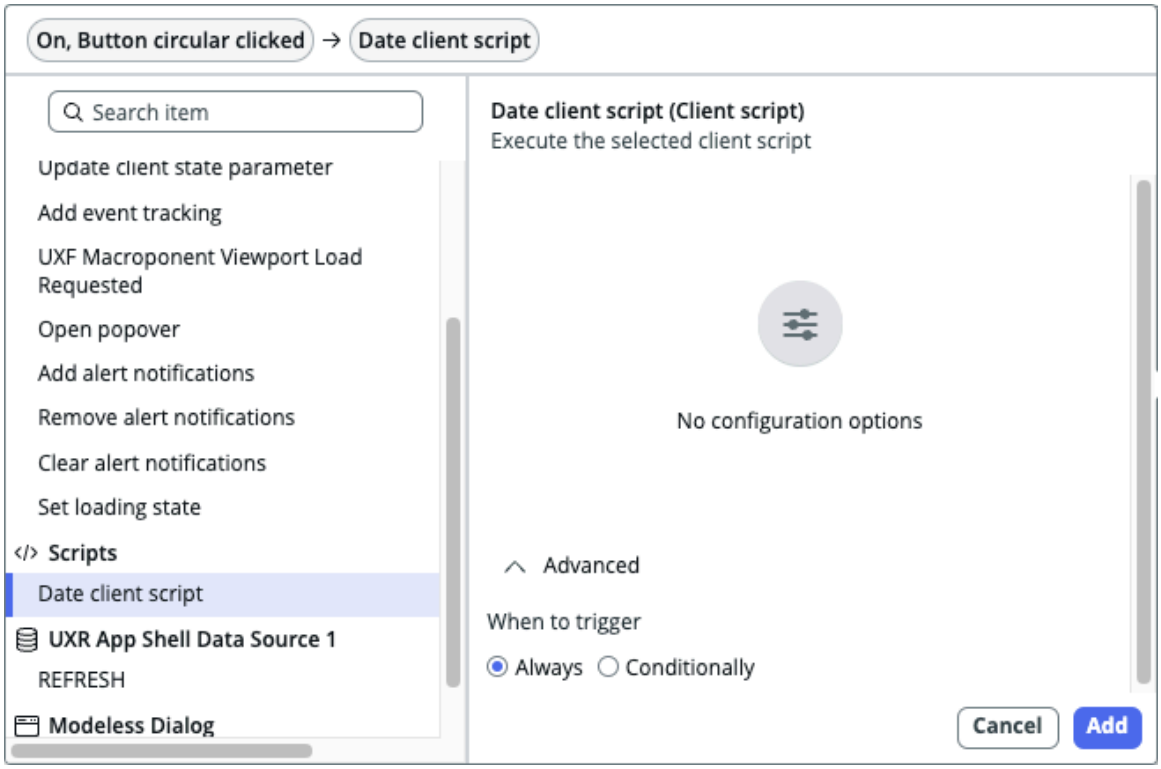
   A descriptive name helps you know what the script does. It also makes it easier to find the script later when you add it to an event handler. The following example shows a simple date client script.

7. Write your script to perform an action.
   For example, you could write a simple date script that you bind to a component.



8. **Optional:** Add a **Script include** or **Associated components**, which shows up in the `imports` parameter of your client script function.
9. Select the component on your page that you want to bind the script to and then select **Events**.
10. Select **+Add a new event handler**, select the script that you created under **Scripts**, and then select **Add**.

    The following example shows a date client script.



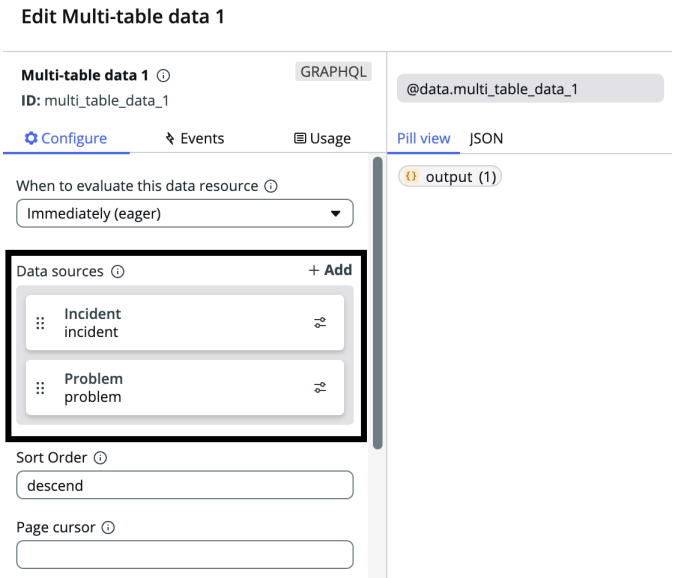
11. Select **Save**.
12. To preview your scripted component, select **Preview**.

Multi-table data configuration

Present data from multiple tables using components and control the layout and styling.

A data resource fetches the data that UI Builder uses to display information in a component. Most often, a component is mapped to data contained in one table. However, there are numerous use cases where there's a need to map a single component to information in multiple tables, for example:

- Place the card component in a repeater and use multi-table data configuration to pull data from different sources to display on the cards.
- Create a portal page that displays a list of tasks pulled from different locations.



Note:
You can configure more than one multi-table data resource on a single page to display different sets of data.

Multi-table data configuration and Entity View Action Mapper

The Entity View Action Mapper (EVAM) can also be used to configure cards and lists using different data sources. The EVAM is an option for users who understand and are comfortable working with JSON. The multi-table data configuration option gives you greater control over the presentation of data, makes it easier to configure the data, and enables you to remain in UI Builder. Use the option that you prefer. For more information about EVAM, see Work with the Entity View Action Mapper for UI Builder.

Fetch data from multiple sources

Learn how to obtain data from different sources to use in a single component.

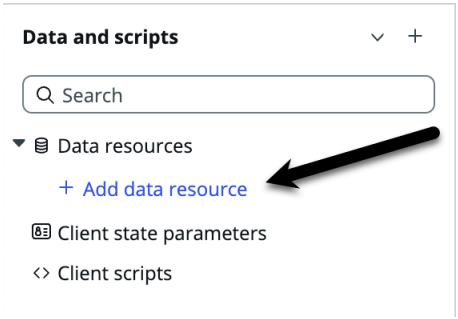
Before you begin
Role required: ui_builder_admin

About this task
Place the card base container component in a repeater and use multi-table data configuration to present all active incidents and problems created in the last two years.

Procedure

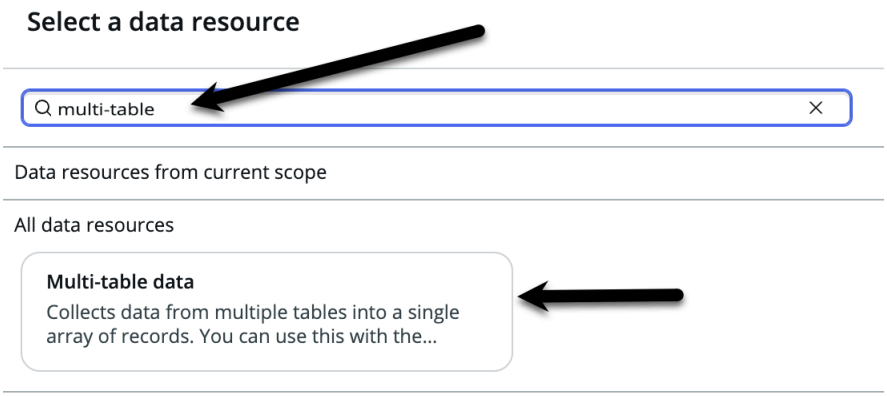
1. Navigate to **All** > **Now Experience Framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create > Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Create a page from scratch.
   For more information about how to create a page, see Create a page in UI Builder.
4. Add a multi-table data resource.

a. In the data shelf, select **+ Add data resource**.



b. In **Search**, enter `multi-table`.

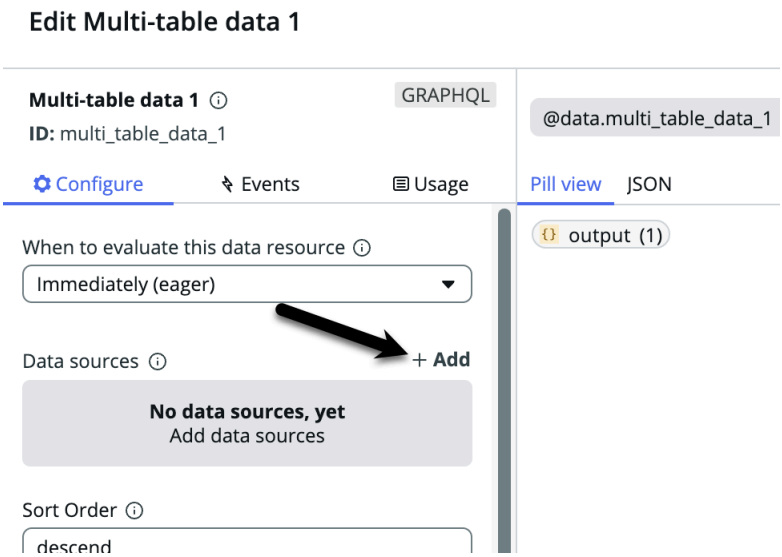
c. Select **Multi-table data**.



d. Select **Add**.

5. Configure the first data source.

a. In **Data sources**, select **+ Add**.

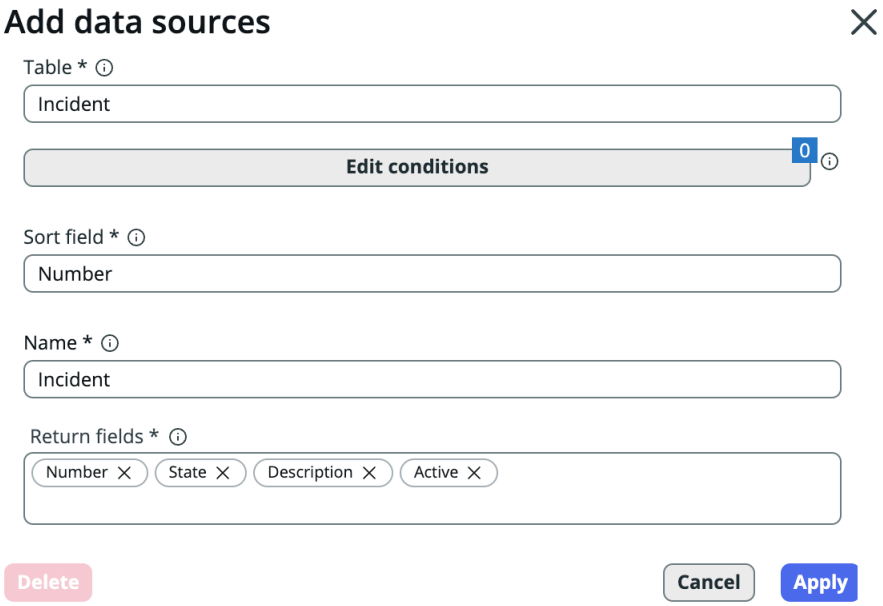


b. In **Table**, enter `incident` and select the **Incident** table.

c. In **Sort field**, enter `number` and select **Number**.

d. In **Name**, enter `Incident`.

e. In **Return fields**, add **Number**, **State**, **Description**, and **Active**.

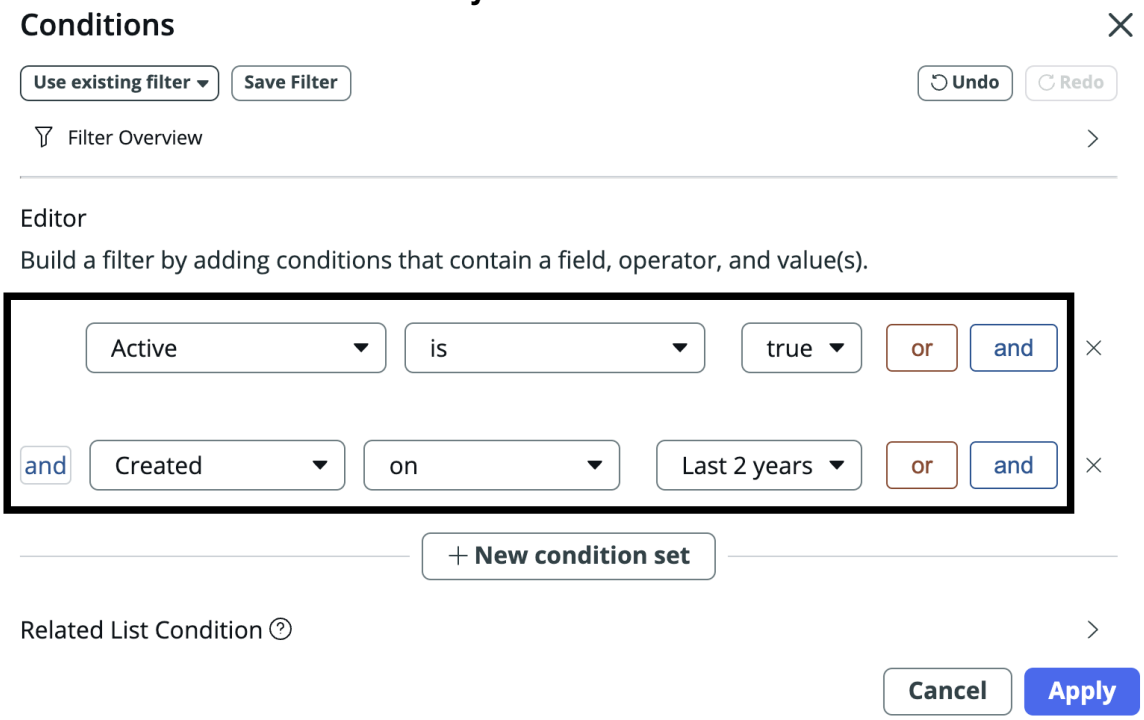


f. Select **Edit conditions**.

g. Build the condition **Active is true**.

h. Select **and**.

i. Build the condition **Created on Last 2 years**.



j. Select **Apply**.

k. Select **Apply**.

6. Configure the second data source.

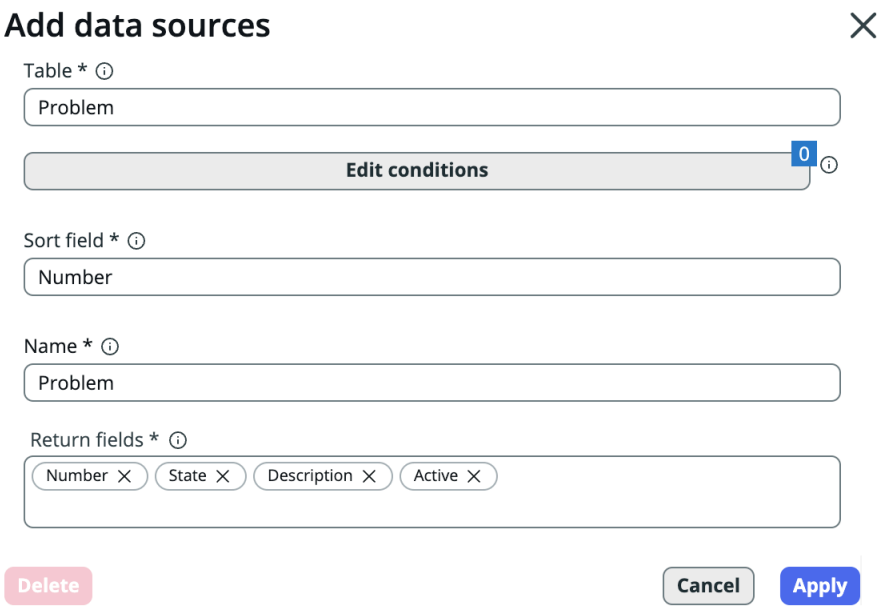
a. In **Data sources**, select **+ Add**.

b. In **Table**, enter `problem` and select the **Problem** table.

c. In **Sort field**, enter `number` and select **Number**.

d. In **Name**, enter `Problem`.

e. In **Return fields**, add **Number**, **State**, **Description**, and **Active**.
When creating a multi-table data resource, each data source should have the same return fields specified and in the same order. This helps ensure that the data displayed on the page is consistent and accurate.



f. Select **Edit conditions**.

g. Build the condition **Active is true**.

h. Select **and**.

i. Build the condition **Created on Last 2 years**.

j. Select **Apply**.

k. Select **Apply**.

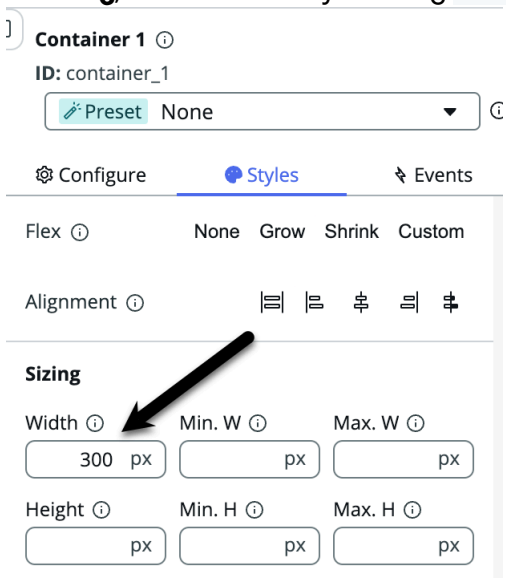
l. Select the **X** to close the **Edit Multi-table data** pop-up.

7. Select **Save**.
8. Add the heading component.
   a. In the content tree, select **+ Add content** under **Body**.
   b. In **Search** enter `heading`.
   c. Select the **Heading** component.
   d. In the configuration panel, on the **Configure** tab, select **None - Configure the component manually**.
   e. In **Label**, delete the default text and enter `Active incidents and problems created in last two years`.

   f. Select **Save**.
9. Add a container.
   a. In the content tree, select **+ Add content** under **Heading 1**.
   b. On the **Layouts** tab, in the **Advanced** section, select **Flexbox**.

   c. In the configuration panel, on the **Configure** tab, select **None - Configure the component manually**.

d. In **Sizing**, set the **Width** by entering `300`.



e. Select **Save**.

10. Add the repeater component.

a. In the content tree, select **+ Add content** under **Container 1**.

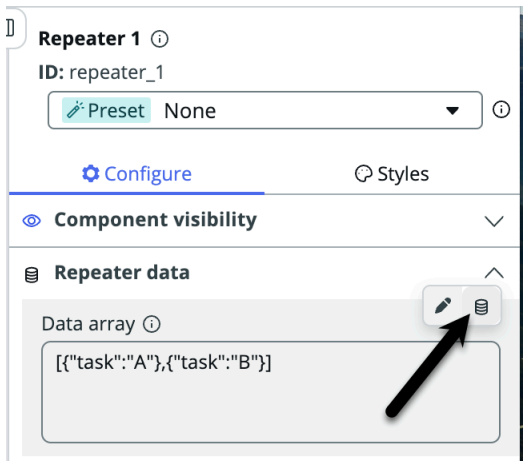
b. In **Search** enter `repeater`.

c. Select the **Repeater** component.

d. In the configuration panel, on the **Configure** tab, select **None - Configure the component manually**.

e. Select **Save**.

f. In the configuration panel, on the **Configure** tab, hover over the **Data array** field and select the bind data icon.

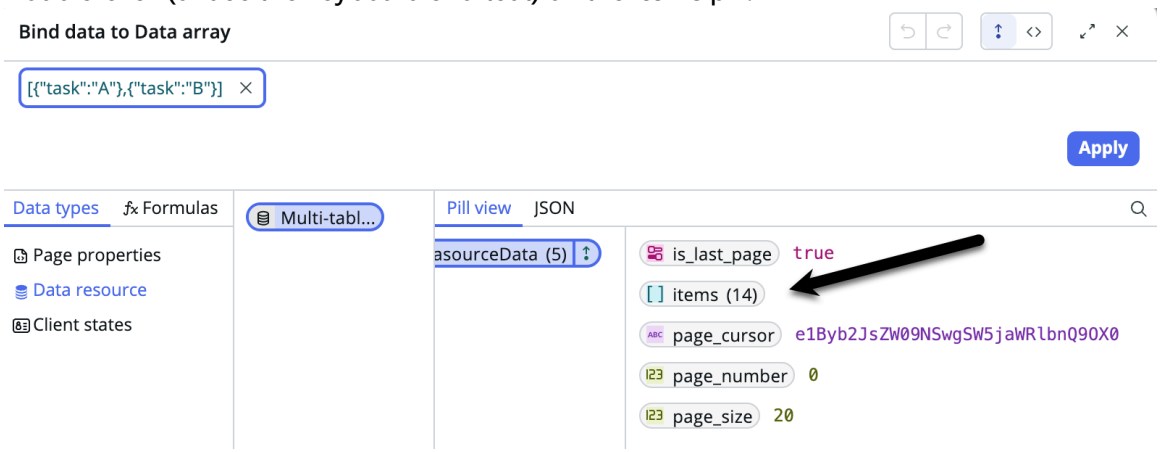


g. Under **Data types** select **Data resource**.

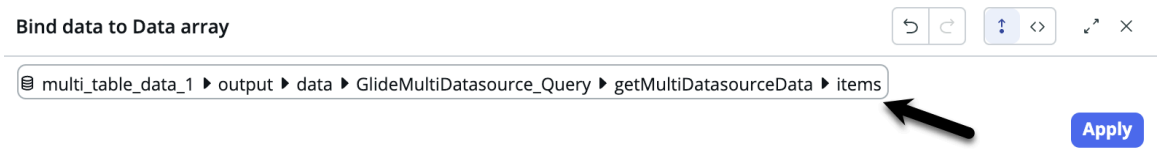
h. Select **Multi-table data 1**.

i. Select **output** > **data** > **GlideMultiDatasource_Query** > **getMultiDatasourceData**.

j. Double-click (or use the keyboard shortcut) on the **items** pill.



Check that the top section is accurate.



k. Select **Apply**.

l. Select **Save**.

11. Add the card base container component within the repeater.

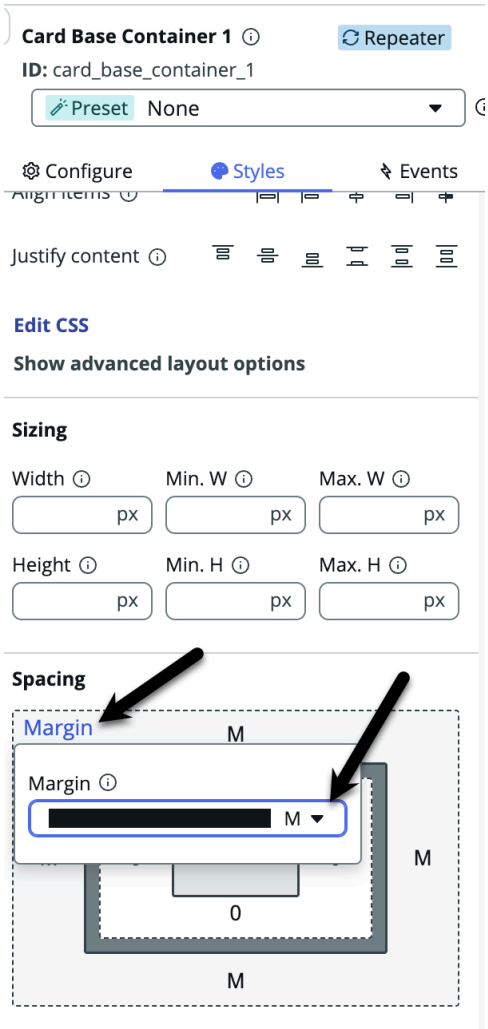
a. In the content tree, select **+ Add content** under **Repeater 1**.

b. Locate and select the **Card Base Container** component.

c. In the configuration panel, on the **Configure** tab, select **None - Configure the component manually**.

d. Select the **Styles** tab.

e. To add a little space around the cards, go to **Spacing**, select **Margin**, and then select **M** (for medium).



f. Select **Save**.

12. Add the heading component within the card base container.

a. In the content tree, select **+ Add content** under **Card Base Container 1**.

b. Locate and select the **Heading** component.

c. In the configuration panel, on the **Configure** tab, select **None - Configure the component manually**.

d. In the configuration panel, on the **Configure** tab, delete the default text in **Label**.

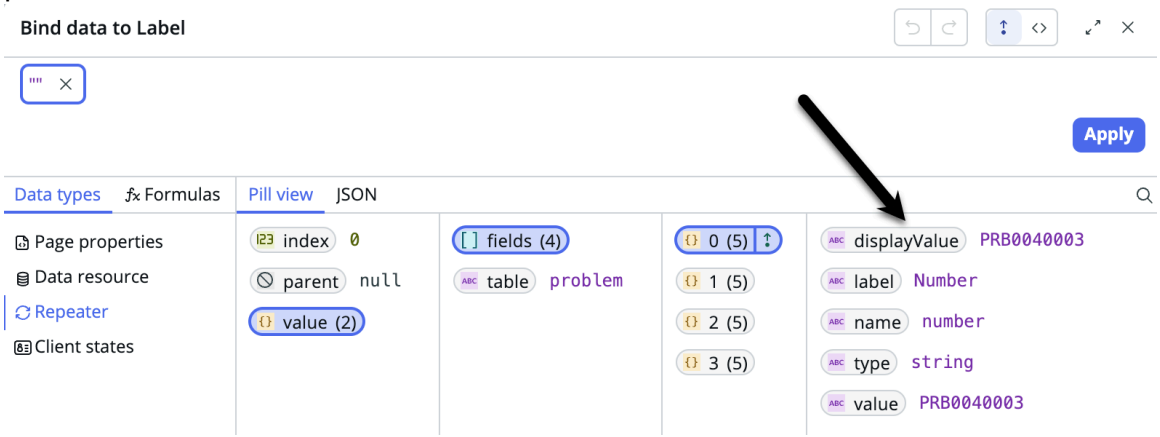
e. Point to the **Label** field and select the bind data icon.

f. Under **Data types** select **Repeater**.

g. Select **value** > **fields**.

h. Select the top pill and in the last column check for **displayValue** with an incident or problem number.

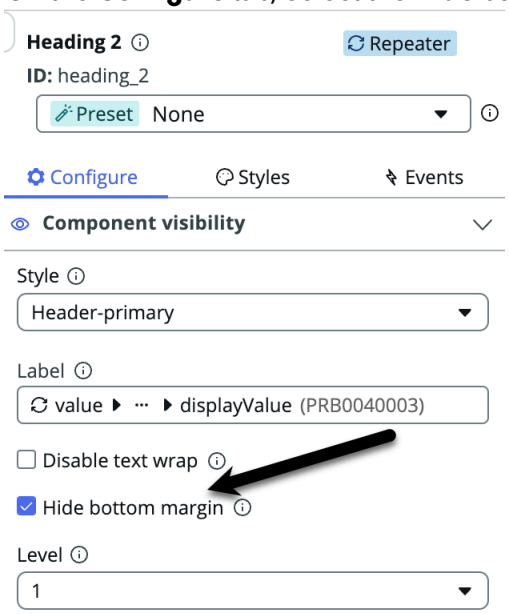
i. Double-click (or use the keyboard shortcut) on the **displayValue** pill with an incident or problem number.



Check that the top section is accurate.

j. Select **Apply**.

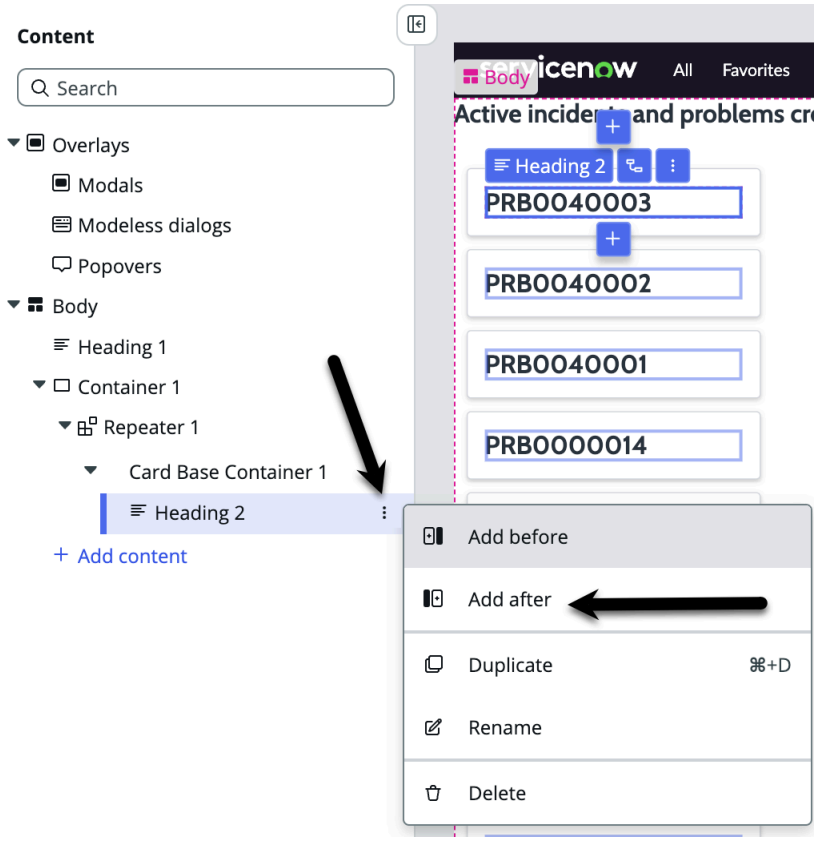
k. On the **Configure** tab, select the **Hide bottom margin** option.



l. Select **Save**.

13. Add the first stylized text component to show the description of the incident or problem.

a. In the content tree, point to **Heading 2**, select the menu (three vertical dots) icon, and select **Add after**.



b. Locate and select the **Stylized text** component.

c. In the configuration panel, on the **Configure** tab, select **None - Configure the component manually**.

d. In the configuration panel, on the **Configure** tab, delete the default text in **Text**.

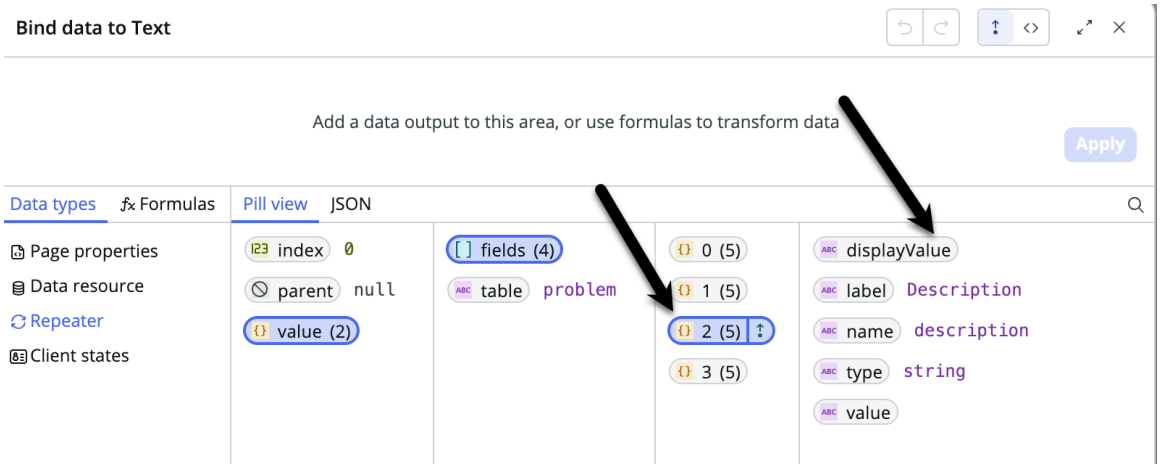
e. Point to the **Text** field and select the bind data icon.

f. Under **Data types** select **Repeater**.

g. Select **value** > **fields**.

h. Select the third pill in the list and in the last column check that the **displayValue** contains no information.

i. Double-click (or use the keyboard shortcut) on the **displayValue** pill with no value.



Check that the top section is accurate.

j. Select **Apply**.

k. To reduce the text size, go to the **Configure** tab and change the **HTML tag** to **Paragraph**.

l. Select **Save**.

14. Add the second stylized text component to show the state of the incident or problem.

a. In the content tree, point to **Stylized text 1**, select the menu (three vertical dots) icon, and select **Add after**.

b. Locate and select the **Stylized text** component.

c. In the configuration panel, on the **Configure** tab, select **None - Configure the component manually**.

d. In the configuration panel, on the **Configure** tab, delete the default text in **Text**.

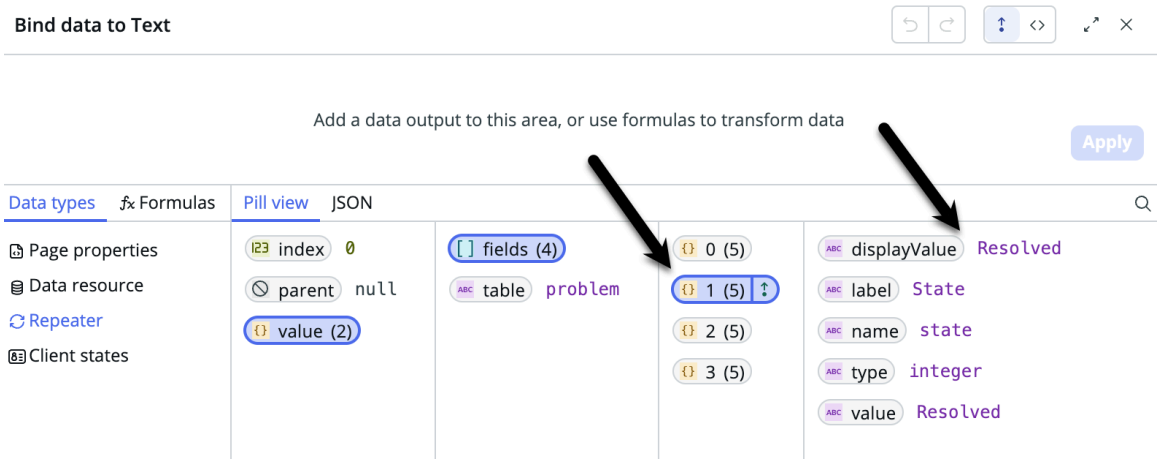
e. Point to the **Text** field and select the bind data icon.

f. Under **Data types** select **Repeater**.

g. Select **value** > **fields**.

h. Select the second pill in the list and in the last column check that the **displayValue** contains a state such as **Resolved** or **In Progress**.

i. Double-click (or use the keyboard shortcut) on the **displayValue** pill with a state value.



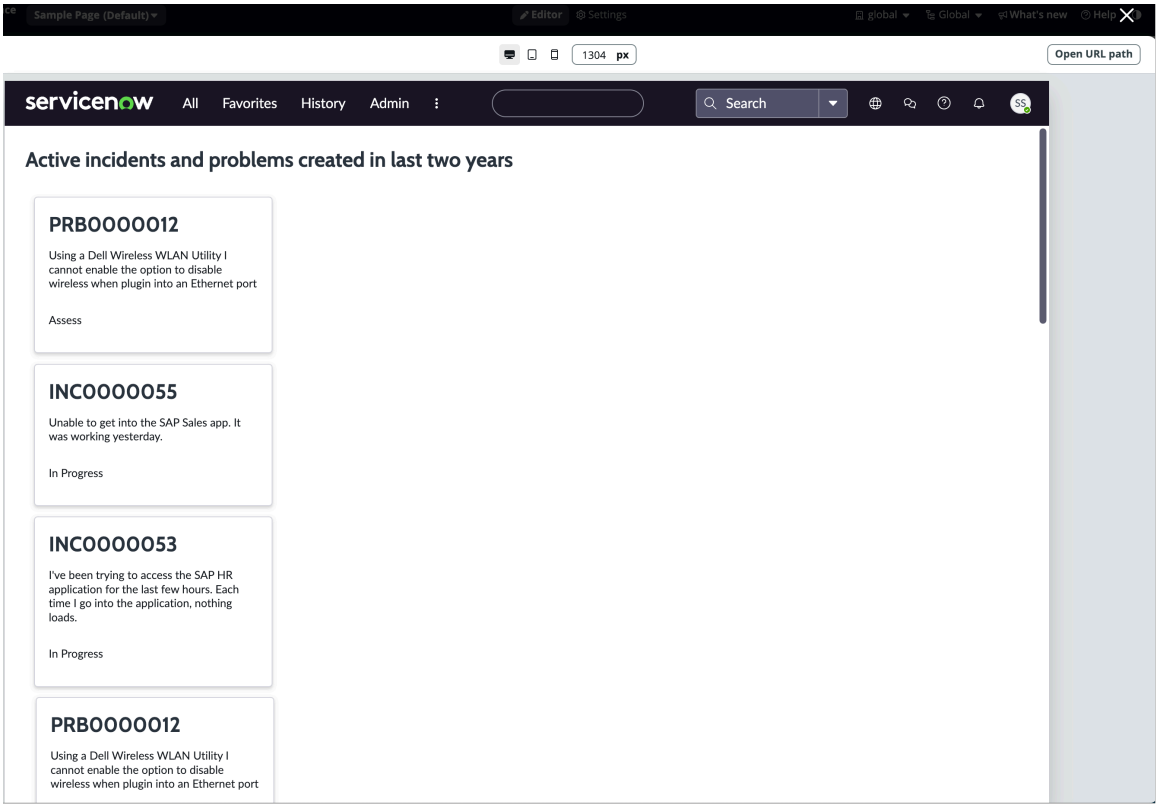
Check that the top section is accurate.

j. Select **Apply**.

k. To reduce the text size, go to the **Configure** tab and change the **HTML tag** to **Paragraph**.

l. Select **Save**.

15. Select **Preview**.
The page heading is at the top. Each card contains a heading with the incident or problem number. The cards also show the description (if one is available) of the incident or problem and the state. Data is being pulled successfully from two sources: the incident table and the problem table.



16. Select the **X** to close the preview overlay.

Work with the Entity View Action Mapper for UI Builder

With UI Builder, you can use the Entity View Action Mapper (EVAM) application to standardize how the data sources in your components are displayed in your cards and lists.

EVAM Overview

Entity View Action Mapper (EVAM) is an application that standardizes how different data sources are displayed in cards and lists. UI Builder uses EVAM data sources to show information in a component as a card grid view or as a list of information. You can add a toggle to your component to let users switch between card grid and list views.

EVAM consists of the following components:

- Entity (data source). Associated data that you intend to display, such as a community post or a user.
- View. How a card displays data and actions.
- Actions. Action that it performs on the card. For example, you can activate a user into your system.
- Map. A process that maps the data source to generic fields that are displayed on the card. You can also associate actions that trigger from the card view.

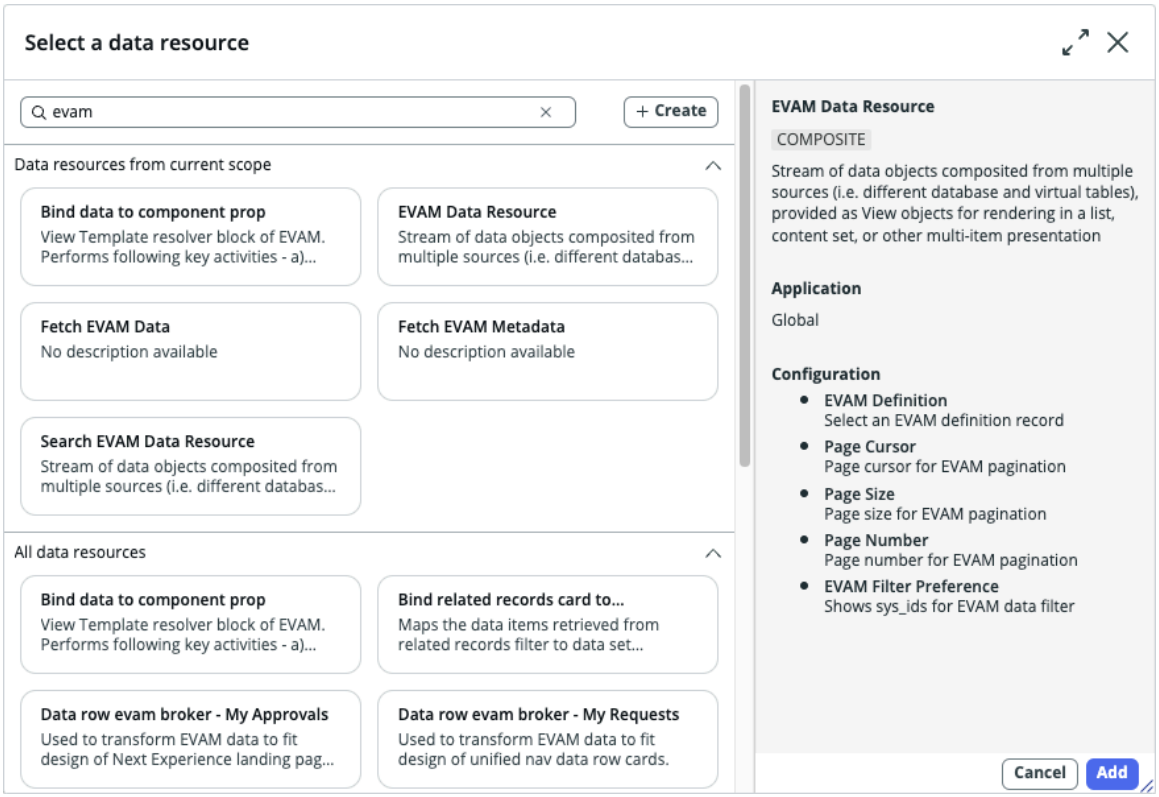
EVAM and Multi-table data configuration

The EVAM is an option for users who understand and are comfortable working with JSON. The multi-table data configuration option is an alternative that gives you greater control over the presentation of data, makes it easier to configure the data, and enables you to remain in UI Builder. Use the option that you prefer. For more information, see Multi-table data configuration.

EVAM data sources

You add EVAM data sources in UI Builder and bind them to a component.

EVAM data resources



EVAM data sources

EVAM data source	Description
EVAM Data Resource	Add an EVAM definition and other information about the data source. • Type: Composite. • When to evaluate: In the **When to evaluate this data resource**, select **Immediately** to have the EVAM data resource instance evaluated on page load or select **Only when invoked** to use an event handler to evaluate the EVAM data resource. • EVAM definition: In the **EVAM Definition** field, add the EVAM definition record that is associated with the data resource. • Page cursor: In the **Page Cursor** field, add a page cursor for the EVAM definition. • Page size: In the **Page Size** field, add a size for the EVAM pagination.

EVAM data sources (continued)

EVAM data source	Description
	• Page number: In the **Page Number** field, add the page number for the EVAM pagination. • EVAM Filter Preference: In the **EVAM Filter Preference** field, enter the sys_ids for the EVAM data filter. To add an event handler for when that data fetch is initiated, succeeded, or failed, select **Events**. In the **Now Code Editor** section, which is next to the Configuration pane, preview the EVAM definition script. **EVAM Data Resource configuration** Fetch EVAM Data	To add an EVAM definition and other information about the data source, select **Configuration**. • Type: GRAPHQL. • When to evaluate: To have the EVAM data resource instance evaluated on a page load, select **Immediately**. To use an event handler to evaluate the EVAM data resource, select **Only when invoked**. • EVAM definition: In the **EVAM Definition** field, enter the EVAM definition record that is associated with the data resource. • Page cursor: In the **Page Cursor** field, enter a page cursor for the EVAM definition. • Page size: In the **Page Size** field, enter a size for the EVAM pagination.

EVAM data sources (continued)

EVAM data source	Description
	• Page number: In the **Page Number** field, enter the page number for the EVAM pagination. • EVAM Filter Preference: In the **EVAM Filter Preference** field, enter the sys_ids for the EVAM data filter. To add an event handler for when that data fetch is initiated, succeeded, or failed, select **Events**. Preview the EVAM definition script in the **Now Code Editor** to the right of the Configuration pane. Fetch EVAM Metadata	To select when to evaluate the EVAM data resource and add an EVAM definition, select **Configuration**. • Type: GRAPHQL. • When to evaluate: To have the EVAM data resource instance evaluated on a page load, select **Immediately**. To use an event handler

EVAM data sources (continued)

EVAM data source	Description
	to evaluate the EVAM data resource, select **Only when invoked**. • EVAM definition: In the **EVAM Definition** field, enter the EVAM definition record that is associated with the data resource. To add an event handler for when that data fetch is initiated, succeeded, or failed, select **Events**. Preview the EVAM definition script in the **Now Code Editor** to the right of the Configuration pane. Search EVAM Data Resource	To add an EVAM definition, and other information about the data source, select **Configuration**. • Type: Composite. • When to evaluate: To have the EVAM data resource instance evaluated on a page load. select **Immediately**. To use an event handler to evaluate the EVAM data resource, select **Only when invoked**. • EVAM Config ID: In the **EVAM Config ID** field, add the **EVAM Config ID** that is associated with the data record. • Search Context Config ID: In the **Search Context Config ID** field, add the **Search Context Config ID** that you are searching for. • Search Term: In the **Search Term** field, add the search terms that you are searching for. • Facet Filters: In the **Facet filters** field, add any facet filters to help define your search. • Search Filters: In the **Search Filters** field, add any search filters to help define your search.

EVAM data sources (continued)

EVAM data source	Description
	• Disable Spell Checking: In the **Disable Spell Checking** field, select if you desire spell checking to be on or off during your search. • Pagination Token: In the **Pagination Token** field, enter a pagination token if needed. To add an event handler for when that data fetch is initiated, succeeded, or failed, select **Events**. Preview the EVAM definition script in the **Now Code Editor** to the right of the Configuration pane. 
Add an Entity View Action Mapper data resource to a page

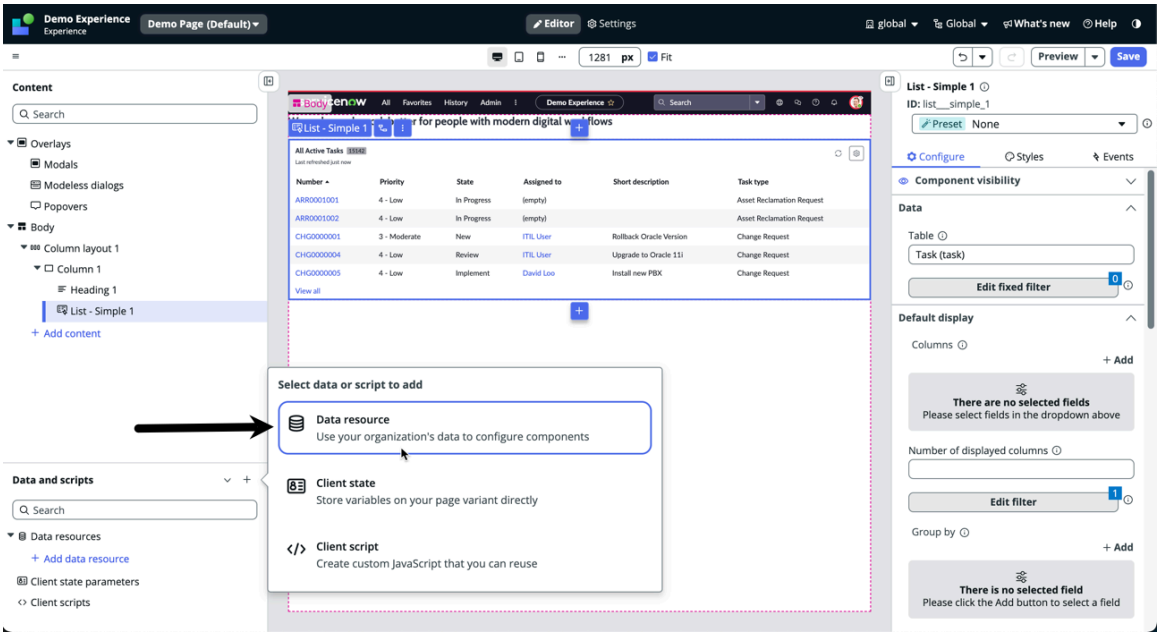
Add an Entity View Action Mapper (EVAM) data resource to your page in UI Builder so that you can standardize how the data sources in your components are displayed in your cards and lists.

Before you begin

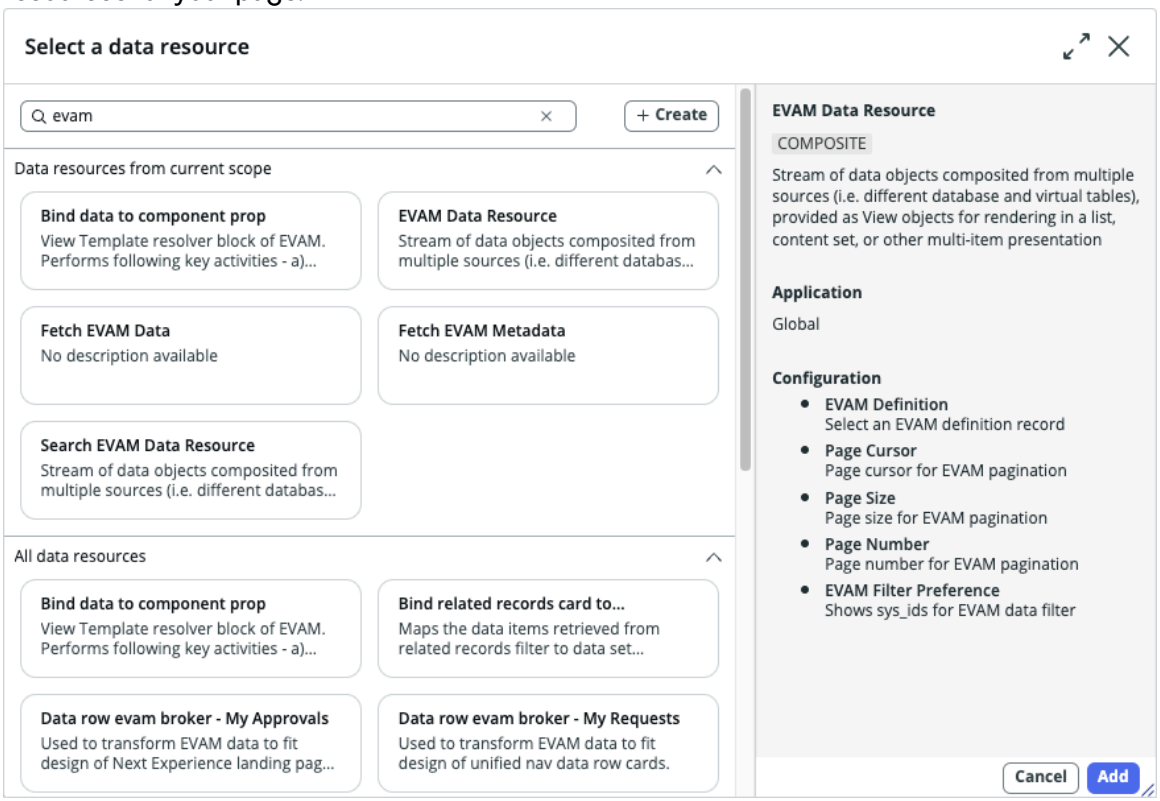
Role required: ui_builder_admin

Procedure

1. Navigate to **All** > **Now experience framework** > **UI Builder**.
2. Open an experience to work in or create an experience by selecting **Create** > **Experience**. See Configure how users interact with your applications in UI Builder for more information on creating experiences.
3. Open or create a page.
   For more information, see Manage UI Builder pages and page variants.
4. **Optional:** If you do not have any components on your page, add a **Data set** component to your page.
   For more information, see Add and configure components.
5. In the **Data and scripts** panel, select the **+** icon and then select **Data resource**.



6. Enter `evam` in the search field.
7. Select the EVAM data resource that you want to add and repeat this step for all the EVAM data resources for your page.



8. Configure each EVAM data resource.

EVAM data sources

EVAM data source	Description
EVAM Data Resource	Add an EVAM definition and other information about the data source.

EVAM data source	Description
	○ Type: Composite. ○ When to evaluate: In the When to evaluate this data resource list, select **Immediately** to have the EVAM data resource instance evaluated on page load or select **Only when invoked** to use an event handler to evaluate the EVAM data resource. ○ EVAM definition: In the **EVAM Definition** field, add the EVAM definition record that is associated with the data resource. ○ Page cursor: In the **Page Cursor** field, add a page cursor for the EVAM definition. ○ Page size: In the **Page Size** field, add a size for the EVAM pagination. ○ Page number: In the **Page Number** field, add the page number for the EVAM pagination. ○ EVAM Filter Preference: In the **EVAM Filter Preference** field, add the sys_ids for the EVAM data filter. Preview the EVAM definition script in the **Now Code Editor** to the right of the Configuration pane. Search EVAM Data Resource	To add an EVAM definition and other information about the data source, select **Configuration**. ○ Type: Composite. ○ When to evaluate: To have the EVAM data resource instance evaluated on a page load, select **Immediately**. To use an event handler to evaluate the EVAM data resource, select **Only when invoked**. ○ EVAM Config ID: In the **EVAM Config ID** field, add the **EVAM Config ID** that is associated with the data record. ○ Search Context Config ID: In the **Search Context Config ID** field, add the Search Context Config ID that you are searching for. ○ Search Term: In the **Search Term** field, add the search terms that you are searching for ○ Facet Filters: In the **Facet filters** field, add any facet filters to help define your search.

EVAM data source	Description
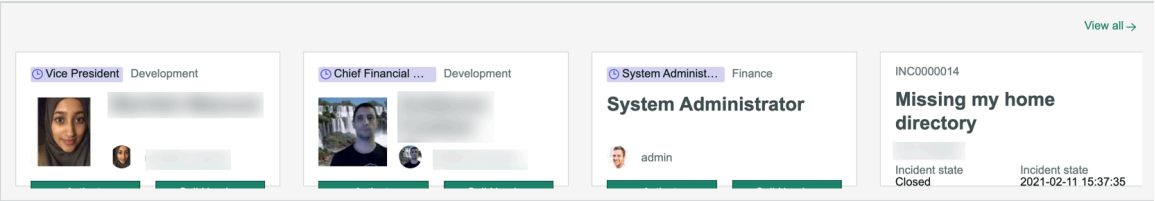
	○ Search Filters: In the **Search Filters** field, add any search filters to help define your search. ○ Disable Spell Checking: In the **Disable Spell Checking** field, select if you desire spell checking to be on or off during your search. ○ Pagination Token: In the **Pagination Token** field, add a pagination token if needed. To add an event handler for when that data fetch is initiated, succeeded, or failed, select **Events**. Preview the EVAM definition script in the **Now Code Editor** to the right of the Configuration pane. 
9. Configure your data set component:
   - Bind an EVAM data resource to your component.
   - Set the **Show grid/list** toggle to on to let users choose between the grid or list view of the EVAM information on the page.
   - Set the other configuration settings for the cards on the page.
10. Select **Save**.

11. View and test your page by selecting the **Preview** button.

Finished state of the EVAM



Edit code with the Now Code Editor (advanced feature)

Now Code Editor is a rich-text editor like interface that supports Cascading Style Sheets (CSS), Hypertext Markup Language (HTML), JavaScript, Extensible Markup Language (XML), and JavaScript Object Notation (JSON). Use Now Code Editor to modify UI configuration, data resource configuration, styles, events, client-side and server-side scripts in Next Experience UI Builder components.

Now Code Editor supports the following features:

- Basic editing
- Debugging
- Command palette
- Code formatting
- Syntax checking and highlighting
- Auto-suggestions
- Script macros for common code

Basic editing

Action	Description
Format code	Applies proper indentation to the script. Keyboard shortcut: • Windows: Shift+Alt+F • Mac: Shift+Option+F
Highlight syntax	Highlights the syntax of the code.
Check syntax	Checks for formatting errors and highlights syntax errors. • Windows: Shift+Alt+C • Mac: Shit+Option+C
Show suggestions	Displays a list of valid elements at the insertion point such as:

Action	Description
	• Class names • Function names • Object names • Variable names Select and click an entry to add it to the script. Keyboard shortcut: • Windows: Control+Space • Mac: Control+Space You can also enable or turn off **Syntax highlighting** from the **Settings** menu.
Toggle comments	Comments one or more lines of code with two consecutive forward-slashes //. Keyboard shortcut: • Windows: Control+/ • Mac: Command+/
Show minimap	Displays the minimap of the code snippet. You can display or hide the minimap option, from the **Settings** menu.
Enable word wrap	Enables word wrap function in the editor area. You can toggle the **Enable word wrap** option from the **Settings** menu.
Show command palette	Displays a list of available commands for the common operations. You can execute editor commands, find and replace text, fold and unfold code blocks, toggle comments and many more tasks using the same interactive window. Keyboard shortcut • Windows: F1 • Mac: F1
Expand editor or collapse editor	Expands or collapses the editor. Keyboard shortcut • Windows: Control+M • Mac: Control+M

Debugging

To launch Script Debugger, click the Script Debugger icon in the toolbar.

Note:
You can add a breakpoint, conditional breakpoint, or logpoint, only when debugging is enabled and selected language is JavaScript.

Task	Do this
Add breakpoint	Right-click beside a line number in the ruler area and select **Add breakpoint**.
Add conditional breakpoint	1. Right-click beside a line number in the ruler area and select **Add conditional breakpoint**. 2. Enter a break condition in the editor.
Add logpoint	Right-click beside a line number in the ruler area and select **Add logpoint**.
Compare text in Diff mode	Use the side-by-side view icon and inline view icon to toggle between views.

Code editor macros

for

- Description: Inserts a standard for loop with an example array.
- Output:

```
for (var i=0; i< myArray.length; i++) {
 //myArray[i];

}
```

method

- Description: Inserts an empty JavaScript function template.
- Output:

```
/*-------------------------------------------------
-------------
   * Description:
   * Parameters:
   * Returns:

 -------------------------------------------------
-----------*/
   : function() {

   },
```

info

- Description: Inserts a *GlideSystem* information message.
- Output:

```
gs.addInfoMessage(gs.getMessage(""));
```

doc

- Description: Inserts a comment block for describing a function or parameters.
- Output:

```
/**

* Description:

* Parameters:

* Returns:
*/
```

vargror

- Description: Inserts a *GlideRecord* query for two values with an OR condition.
- Output:

```
var gr = new GlideRecord('');

var qc = gr.addQuery('field', 'value1');

qc.addOrCondition('field', 'value2');
gr.query();

while (gr.next()) {

}
```

vargr

- Description: Inserts a standard *GlideRecord* query for a single value.
- Output:

```
var gr = new GlideRecord("");
gr.addQuery("name", "value");
gr.query();
if (gr.next()) {

}
```

Testing and debugging applications

Verify the application meets your business requirements. Your testing should cover record operations (such as create, read, update, and delete), user interface elements (such as views and UI policies), runtime operations (such as business rules), and event script actions.

Testing and debugging on Core UI

Automated Test Framework

Create and run automated tests to confirm that your instance works after making a change. Review failed test results to identify the changes that caused the failure and the changes that you should review.

Debugging scripts

Debug scripts using session logs and ServiceNow AI Platform debugging tools, such as a walk-through script debugger and error messages that display in the UI.

Script Debugger and Session Log

The Script Debugger enables users with the script_debugger role to debug server-side JavaScript, while the Session Log enables you to view and download required logs.

Script Tracer and debugging scripts

Use the Script Tracer to filter your debugging search and quickly narrow down script problems. Finding specific lines of scripts, rather than doing a wide search, helps save time and improves productivity.

Related ServiceNow applications and features

Test Management 2.0

The ServiceNow® Test Management 2.0 application streamlines the management of testing processes to help you deliver software products more efficiently and with fewer errors. You can create multiple versions of a test and integrate with Agile Development 2.0.

Impersonate a user

Administrators can impersonate other authenticated users for testing purposes and view impersonation logs. When impersonating another user, the administrator has access to exactly what that user can access in the system, including the same menus and modules.

Test your apps with the ATF

The Automated Test Framework (ATF) enables you to create and run automated tests to confirm that your instance works after making a change. For example, after an upgrade, during application development, or when deploying instance configurations with update sets. Review failed test results to identify the changes that caused the failure and the changes that you should review.

Note:
By default, the system property to run automated tests is disabled to prevent you from accidentally running them on a production system. Run tests only on development, test, and other non-production instances to avoid data corruption and outage.

For developer training, see Using the Automated Test Framework on the ServiceNow Developer Site.

Benefits

Automated Test Framework provides these benefits for change managers and developers.

- Reduce upgrade and development time by replacing manual testing with automated testing.
- Design tests once and reuse them in different contexts and with different test data sets.

- Keep test instances clean by rolling back test data and changes made after each test run.
- Create test suites to organize and run tests in batches.
- Schedule test suite runs.
- Enable non-technical test designers to create tests of standard ServiceNow AI Platform functionality.
- Reduce test design time by copying quick start tests and test suites.
- Create custom test steps to expand test coverage.

Automated Test Framework records and components

The Automated Test Framework consists of these records and components.

Test

A test is a logical grouping of related automated test steps that verify some functionality or feature. Each test is a record in the Test [sys_atf_test] table. Test designers typically create a test to verify one feature or a group of related features. For example, the **CSM: Create Product Case** test validates the creation of Product Case records. Each test has a related list of test steps and test results.

Test suite

A test suite is a collection of tests that run in a specific order. Test designers typically create a test suite to test an application or a group of related features. For example, the **CSM: Case Management** test suite validates the functionality of the Customer Service Management application. Test designers can schedule running test suites and starting any required client test runners.

Quick start test

A quick start test is a test or test suite installed with the demo data of an application. Use quick start tests as templates to build your own tests and test suites. See this quick start test overview video for more information.

Test step

A test step combines a step configuration with the runtime test data necessary to run a step. The test step always specifies the order in which it runs in the test. Test steps have their own related list of step results. Each test step is a record in the Test Step [sys_atf_step] table that specifies a test action, the step configuration, and an execution order. Test designers add test steps to tests to verify functionality. For example, the first test step of the **CSM: Create Product Case** test is to impersonate the demo user John Jason who is authorized for Case Management.

Step configuration

A step configuration is a specific test action the Automated Test Framework can run. Step configurations do not contain any runtime test data and can only be run when test designers add them as part of a test step. Each step configuration is a record in the Test Step Config [sys_atf_step_config] table that specifies the input variables used to run the step configuration and the output variables available to other step configurations. For example, the **Impersonate** step configuration allows a test to impersonate another user.

The Automated Test Framework provides a default list of step configurations for most use cases and allows test designers to create their own custom step configurations.

Step variable

A step variable stores step-specific input and output values. For example, the **Open a New Form** step configuration has variables to specify the table and form view names. Use step variables to specify a particular test step target or to pass information to other test steps.

Test result

A test result stores the output of a test or test suite run. Each test result is a record in the Test Result [sys_atf_test_result] table that specifies the duration of the test run, the status of the test, and screenshots where available. Use test results to identify failing or non-running tests, and use the test logs to see more information about test results. By default, the system deletes test and test suite results 30 days after creation unless you enable the option to retain the test result indefinitely.

Step result

A step result stores the output of a test step run. Each step result is a record in the Step Result [sys_atf_test_result_step] table that specifies the status of the test step, a summary of the output, and a complete log of the output generated by the test step. Use step results to identify failures and functionality needing review.

Assert type

The **Assert type** field specifies the conditions that must be met for a test to pass. Test designers can use assertions to specify whether the results of an operation are expected or unexpected. For example, suppose you want to test that a record cannot be updated. In this case, you would add a Record Insert test step and set the **Assert type** field to **Record was not inserted**. The test passes when the record insert fails.

Some test step categories that include steps with an **Assert type** field include:

- Server category: Assert which CRUD operations cause a test to pass or fail.
- Custom UI category: Assert which component states cause a test to pass or fail, and whether visible text causes a test to pass or fail.
- Forms in Service Portal category: Assert whether a form canceled in the browser due to validation errors, or a form successfully submitted to the server causes a test to pass.

Client test runners

A client test runner is a browser tab that runs client-side test steps within a ServiceNow AI Platform user interface. Client test runners require a browser tab to function. If no client test runner is available when you run a test, the system prompts you to open one. Testers can manually start a client test runner or select an existing client test runner. Test designers can schedule starting client test runners when they schedule running a test suite.

User roles

Assign roles to define Automated Test Framework permissions.

Role Title [name]	Role Description
atf_test_admin	Create or edit Automated Test Framework properties. Has permission to:

Role Title [name]	Role Description
	• View the tests page • Create/edit/delete tests • Create/edit/delete test steps • View the step config page • View the test runner page • View the test suite results, test results and result items pages • Execute user tests • View, create, edit, delete and execute test suites • Create/edit step config records • Create/edit Automated Test Framework properties
atf_test_designer	View Automated Test Framework properties only (cannot create or edit properties). Has permission to: • View the tests page • Create/edit/delete tests • Create/edit/delete test steps • View the step config page • View the test runner page • View the test suite results, test results and result items pages • Execute user tests • View, create, edit, delete and execute test suites • View Automated Test Framework properties
atf_ws_designer	View or set basic authentication profiles needed for REST endpoints that require authentication. See REST category for more information.

ATF doesn't support these elements of Next Experience, but support for these features is planned for future releases:

- Pages built with UI Builder, including pages with lists and form components.
- Landing pages

Note:
ATF still supports the Core UI, including Classic Environment (such as classic lists and forms).

Getting started with the Automated Test Framework

If you are new to the Automated Test Framework, read this overview to learn what the framework can do. Next, follow the tutorial to create and run a test that uses the most basic of ATF features. After you feel comfortable with the basics, explore more advanced features provided by the ATF.

ATF features provide flexibility in how you test your instance.

Test step configuration categories

Category	Description
Service Catalog in Service Portal	Perform end-to-end testing for a catalog item in the Service Portal. • Open a record producer, catalog item, or order guide. • Set variable values and catalog item quantity. • Validate variable values, states, price, and items included in an order guide. • Navigate in an order guide. • Open and toggle catalog items in an order guide. • Add an item or an order guide to a shopping cart. • Order a catalog item or an order guide. • Submit a record producer.
Application Navigator	Create tests to check navigation features. • Verify that application menus are listed in the left navigation bar. • Verify that application modules are listed in the left navigation bar. • Navigate to a module as if a user clicked the module in the left navigation bar.
Custom UI	Create simple tests that mimic user actions with no scripting. • Set component values. • Assert that specified text is or is not on a page. • Validate component values. • Click components. • Validate the states of components (read-only or not read-only).
Form	Create tests of forms. • Open a new form or an existing record. • Set field values. • Validate field values or field states (such as mandatory, not mandatory, read only, not read only, visible, and not visible). • Validate whether a UI action is visible.

Category	Description
	• Click a button on a modal page. • Click a UI action. • Submit a form.
Service Catalog	Perform end-to-end testing for a catalog item. • Open a catalog item or a record producer. • Search for a catalog item. • Set variable values and catalog item quantity. • Validate variable values, states, and price. • Add an item to a shopping cart. • Order a catalog item. • Submit a record producer.
Forms in Service Portal	Create tests of forms in the Service Portal. • Open a form. • Set field values. • Validate field values or field states (such as mandatory, not mandatory, read only, not read only, visible, and not visible). • Validate whether a UI action is visible. • Click a UI action. • Submit a form.
REST	Create and send an Inbound REST request and verify the response. • Test any REST endpoint on the instance. • Use a REST request to create records, as well as retrieve, update, or delete records created in a previous test step or that already existed on the instance. • Verify the response status code, response headers, response time, and response payload.
Server	Perform more complex operations, including the following:

Category	Description
	• Perform unit tests using JavaScript, including tests using the Jasmine test framework. • Test business rules, script includes, and other scripts. • Create tests that operate on data that you define.

Output variables

Many test steps return output variables whose values you can use as inputs to a later step. For example, you can use output variables to accomplish the following tasks:

- Perform a server-side assert on a record that you previously inserted.
- Create a record as one user, and then reopen its form as a different user.

Custom test step configurations

In addition to the steps built into the Automated Test Framework, you can create custom test step configurations. These custom steps can take input variables and return output variables that you define.

Note:
You can only define custom test steps that run on the server. The Automated Test Framework does not support creating custom step configurations that run on the browser.

Data preservation

The Automated Test Framework automatically tracks and deletes any data created by running tests, and automatically rolls back changes after testing.

Test suites

Test suites enable you to execute a batch of tests in a specified order. In addition, test suites can be hierarchical, with suites nested within other suites. You can associate test suites with schedules that determine when the system runs the test suites.

Build and run your first automated test

Follow these step-by-step instructions to create and run your first automated test. This test creates a new user record.

- The Automated Test Framework (com.glide.automated_testing_framework) plugin must be activated. It is activated by default on zBoot or upgrade.
- If necessary, enable test execution. For instructions, see Enable or disable executing Automated Test Framework tests.

Note:
By default, the system property that is used to run automated tests is disabled to prevent you from accidentally running these tests on a production system. To avoid data corruption or an outage, run tests only on development, test, and other non-production instances.

- Role required: admin

Create new test

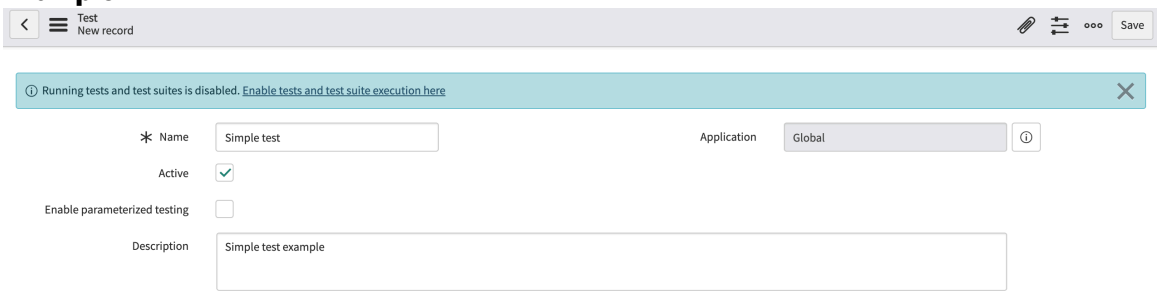
Create a new automated test record.

Before you begin
Role required: atf_test_admin or admin

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Click **New**.
3. On the Test new record form, enter a name for your test in the **Name** field.
   The system identifies this test by this name whenever it displays a list of tests (for example, under the Tests module).

Example



4. In the **Description** field, enter a description for your test.
5. Click **Save**.

Result
The system creates a new test record and returns to the list of tests. For more information about creating new automated tests, see Create a new automated test.

Add the first step to the new test

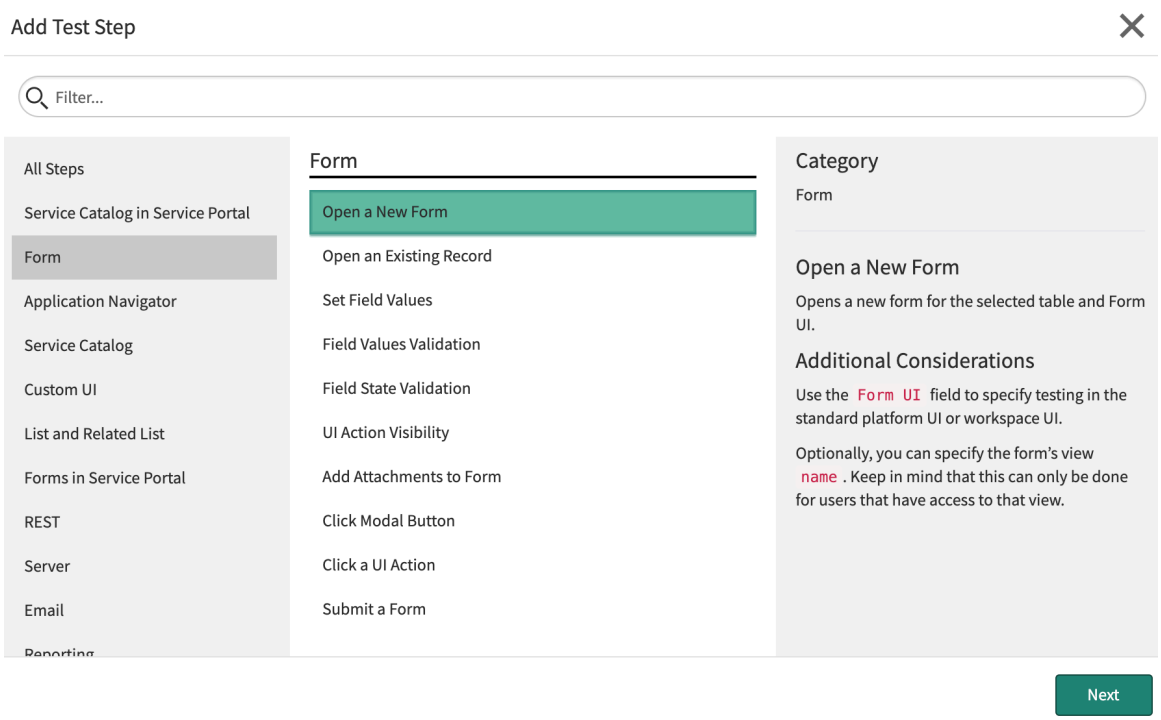
Add the first of three steps to the automated test.

Before you begin
Role required: atf_test_admin or admin

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Click the test that should contain the new test steps.
3. In the Test Steps related list at the bottom of the Test form, click **Add Test Step**.
4. In the middle column, click the row for the step type **Open a new form**, then select **Next**.

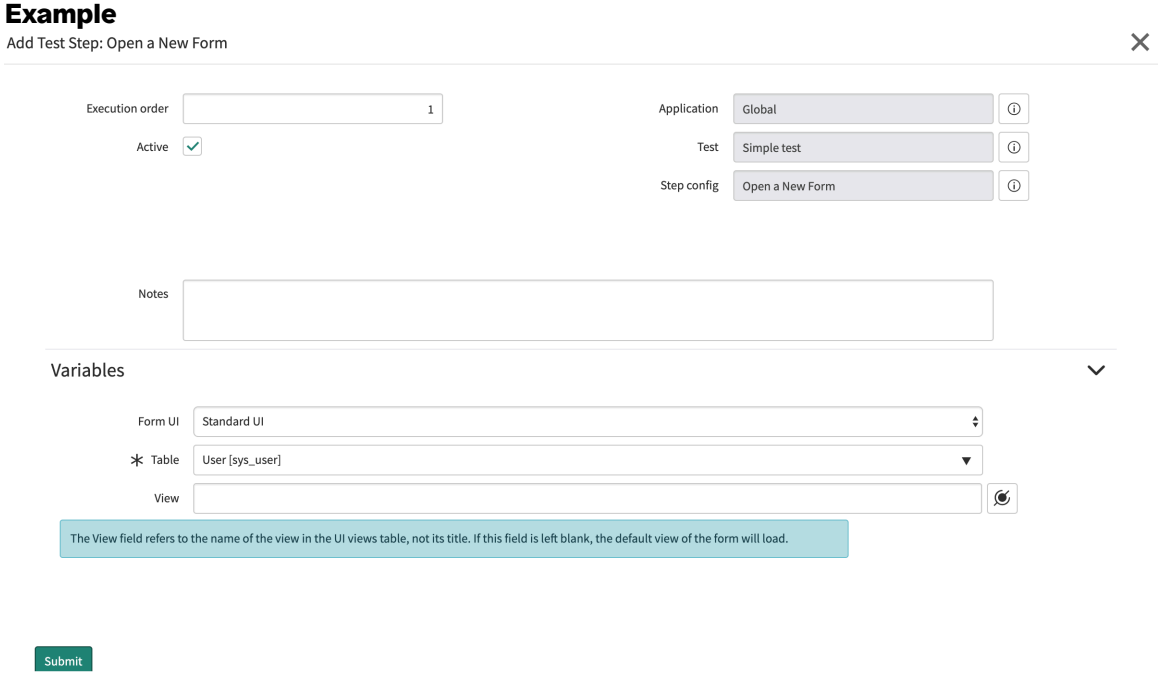
Example



The system displays the **Add Test Step** form for the Open a new form step.

5. From the **Table** field, select the **User [sys_user]** table and click **Submit**.

Example



The system creates the new step and returns to the test record.

6. Click **Update**.

Result

The system creates a new test record and returns to the list of tests. For more information about adding steps to automated tests, see Add steps to an automated test.

What to do next

For some ideas on how to continue learning about the Automated Test Framework, see Next steps with the Automated Test Framework.

Add the second step to your automated test

Add the second of three steps to the automated test.

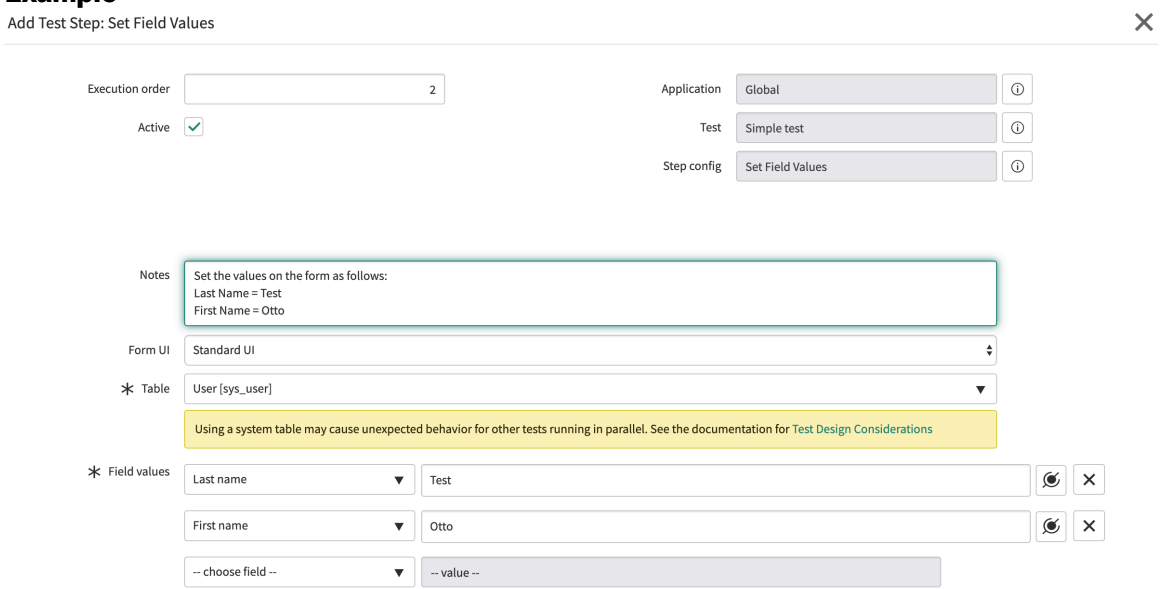
Before you begin

Role required: atf_test_admin or admin

Procedure

1. Click the test that should contain the new test steps.
2. In the Test Steps related list at the bottom of the Test form, click **Add Test Step**.
3. In the middle column, click **Set Field Values**, then click **Next**.
   The system displays the **Add Test Step** form for the Set values step.
4. In the field values section, set **Last name** to `Test` and **First name** to `Otto` (or other names of your choice).

Example



5. Click **Submit**.

Result

The system creates the new step and returns to the test record. For more information about adding steps to automated tests, see Add steps to an automated test.

Add the third step to your test

Add the last of three steps to the automated test.

Before you begin

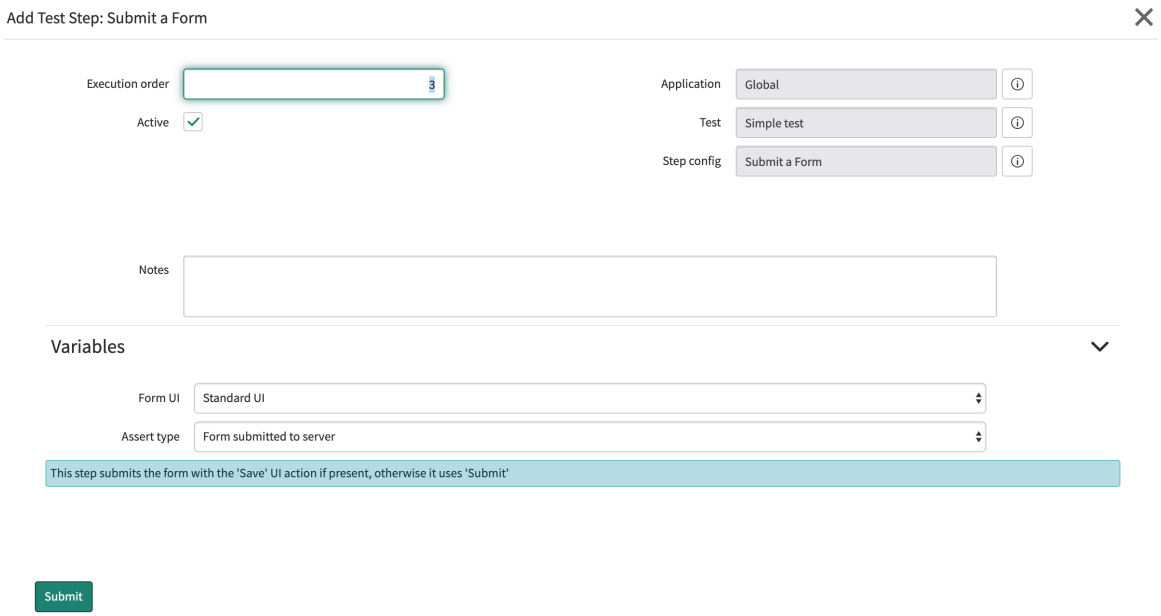
Role required: atf_test_admin or admin

Procedure

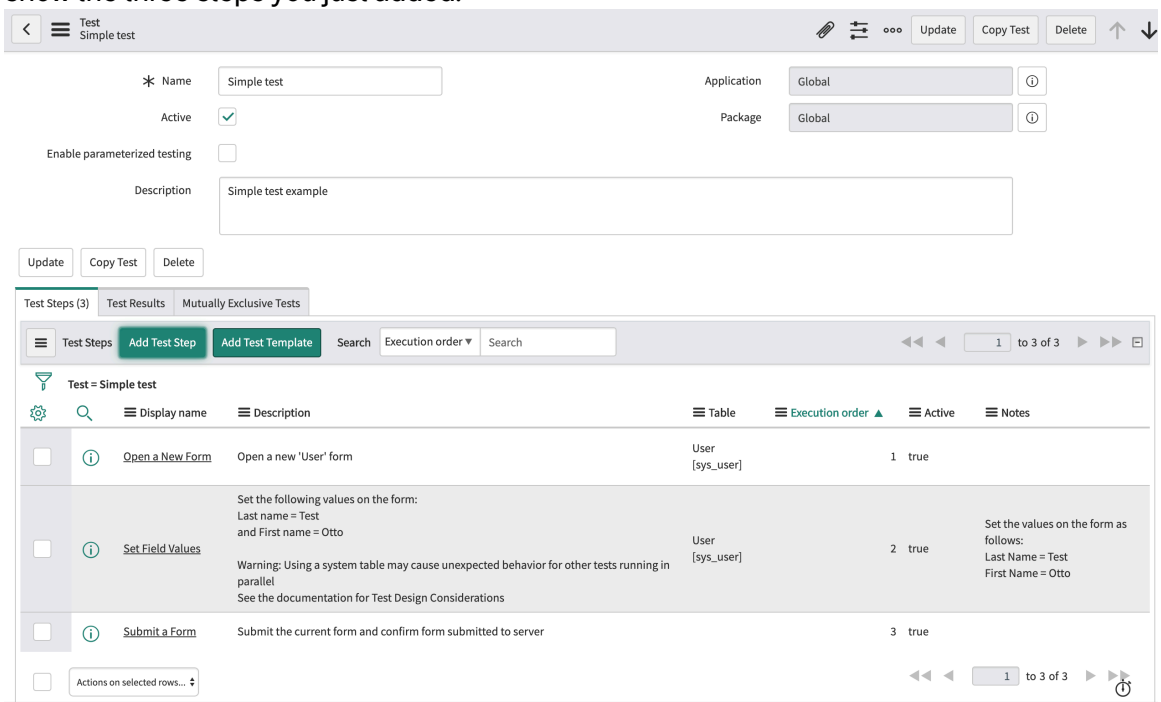
1. Click the test that should contain the new test steps.
2. In the Test Steps related list at the bottom of the Test form, click **Add Test Step**.

3. In the middle column, click **Submit a Form**, then click **Next**.
   The system displays the **Add Test Step** form for the Submit a form step.
4. Leave all values as set by default and click **Submit**.

Example



The system creates the new step and returns to the test record. The test record should now show the three steps you just added.



5. Click **Update**.

Result

The system returns to the list of tests. For more information about adding steps to automated tests, see Add steps to an automated test.

Run your test

After adding test steps, run and monitor the progress of the automated test.

Before you begin
Role required: atf_test_admin or admin

Procedure

1. If necessary to view the Tests list, click **Tests**.
2. Click the row containing the test you just created.
   The system displays the **Test** form.
3. Click **Run Test**.
   Because this test includes a form step (any step involving a UI), the system displays a dialog box asking you to choose among any currently-running test clients or start a new test runner. To continue, select **start a new test runner** and click **Run Test**.

Result
The system displays the Run Test progress dialog. For more information about running automated tests, see Run an automated test.

Monitor test progress and view test results

Monitor the progress of the automated test and view its test results.

Before you begin
Role required: atf_test_admin or admin

About this task
If needed, you can cancel a test even while it's running. For more information, see Cancelling automated tests and test suites.

Procedure

1. Monitor the progress of the test in the Run Test progress dialog.

   Note:
   If your test creates data, the system rolls back that data after all steps in the test complete.

2. When complete, click **Go to Results** on the Run Test progress dialog to display the **Test Results** list, where you can view and analyze the results.

Next steps with the Automated Test Framework

After you feel comfortable creating and running simple tests, explore the more advanced features of the Automated Test Framework.

Batch tests together with test suites
If you commonly run a set of tests together, you can group them using test suites. To learn about test suites, see Building and running automated test suites.

Pass data from one test step to another with input and output variables

You can pass data from one test step to another using input variables and output variables. For more information, see Passing data from one automated test step to another.

Reuse common sequences of steps with templates

If you frequently add the same sequence of steps to your tests, save time by creating a template. To learn more about templates, see Add a predefined list of steps (template) to an automated test

Domain separation and Automated Test Framework

Domain separation is supported in the Automated Test Framework. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Standard*

The support level is Standard but has some exceptions or special conditions.

- Includes all aspects of **Basic** level support.
- Business logic: The service provider (SP) creates or modifies processes per customer. The use cases reflect proper use of the application by multiple SP customers in a single instance.
- The instance owner must be able to configure minimum viable product (MVP) business logic and data parameters. This configuration is done per tenant, as expected for the specific application.

Sample use case: An admin must be able to make comments required when a record closes for one tenant, but not for another.

For more information on support levels, see Application support for domain separation.

ATF use case

Automated test framework design and runtime access are solely for the owner of the instance to validate domain-specific processes. By designing tests for my customers we confirm results per tenant.

Testing

When testing domain separation during ATF test steps, you must set the domain first. This should be part of the first impersonation step of each of the ATF test steps when they are dependent on a domain being set. To learn more about domain separation recommended practices, see Domain separation recommended practices for service providers

Domain separation for service providers

Headless Browser for Automated Test Framework

Improve your UI testing by automating the creation of browsers to process Automated Test Framework (ATF) User Interface (UI) tests. This feature is known as a headless browser, and helps you test UI functionality without having to manually open a browser to the Client Test Runner, which is what processes the UI tests in your local browser.

Important:
Headless Browser is a legacy feature of ATF; it is recommended to instead use the ATF Test Generator and Cloud Runner application. Cloud Runner offers you an easy setup and a seamless user experience. You can install Cloud Runner from the store app.

If you are an on-premise instance user, you must continue using the Headless Browser option. Cloud Runner is not currently available for on-premise instances.

Background

ServiceNow customers use Automated Test Framework (ATF) to test applications and instances. When developing in the ServiceNow platform, ATF ensures that your changes have both the desired behavior and don't break existing features.

Since the ServiceNow Orlando release, customers can automate the testing and deployment of their applications via the Continuous Integration/Continuous Delivery (CI/CD) API.

Overview

The automation provided by the ServiceNow Headless Browser for ATF skips the step of manually opening a browser during testing. There are several sequential procedures to follow in the one-time setup. Below are the instructions for both Linux and Windows setup.

See Headless Browser for ATF for more information on the Support Model.

Headless Browser setup for Linux

The ServiceNow® Headless Browser for Automated Test Framework provides automation so you can skip having to manually open a browser during testing. The Headless Browser setup is available in both Linux and Microsoft Windows. This topic covers the setup for Linux.

Important:
Headless Browser is a legacy feature of ATF; it is recommended to instead use the ATF Test Generator and Cloud Runner application. Cloud Runner offers you an easy setup and a seamless user experience. You can install Cloud Runner from the store app.

If you are an on-premise instance user, you must continue using the Headless Browser option. Cloud Runner is not currently available for on-premise instances.

There are several sequential procedures to follow in the one-time setup.

Prerequisites

Note:
MFA must be disabled in your instance to use the Headless Browser option.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

- Install the Docker application
- Install Java Runtime Environment (JRE) 1.8 - required for keytool utility

  Note:
  The version must be Java 1.8, or errors result in your ServiceNow instance when trying to validate the certificate created with the keytool utility. To learn more, see Create encryption keys using the Java KeyStore keytool.

- Install OpenSSL
- Two-way communication
  - There must be two-way communication between the instance URL and your server.
  - Find the IP address of your server and get your hostname. You can use one or both of them, but you need at least one. Make sure the address or hostname are visible from your ServiceNow instance.

- See My IP Address to find the IP address ranges of your instance. You can then configure your server to allow inbound access to all of the indicated IP addresses/ranges.
- Use Port 2376 or your own default port for this procedure. Make sure your server's firewall rules allow inbound requests on this port from the IP addresses you get from the instance.

Note:
If you don't have a hostname and are connecting via the IP address, you can enter the IP address and put "localhost" in the Hostname environment variable.

Steps to set up the Headless Browser for Linux

Follow these six steps (plus verification) to set up the Headless Browser for Linux.

Generate certificates for Headless Browser setup for Linux

Generate TLS/SSL certificates to secure the Docker REST API and authenticate HTTP requests.

Before you begin
Complete the prerequisites listed in the Headless Browser setup for Linux topic.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

About this task

Warning:
Get certificate authority keys from a trusted certificate authority.

By default when exposing the Docker API, requests are not authenticated, which can leave your host machine vulnerable to attack. Docker API, however, does support TLS authentication where requests are verified against public private keys provided in the HTTPS encryption. In this step you create those keys for the server and the client.

Tip:
To make remembering these easier, enter the following commands in your Linux terminal.
Note: Do not add these environment variables to your terminal profile. For security reasons, they should only exist for the duration of the current session.

- `export PASSWORD="<password to generate the certificates with>"`
- `export SERVERIP="<this server's IP address>"`
- `export HOSTNAME="<hostname of this server>"`

To learn more, see Use TLS (HTTPS) to protect the Docker daemon socket.

Procedure

1. Open a command line.
2. Generate a self-signed certificate authority key or retrieve a keypair from a trusted certificate authority.
   The following commands are an example. Note that your configuration might vary.
   - `openssl genrsa -aes256 -passout pass:$PASSWORD -out ca-key.pem 4096`
   - `openssl req -passin pass:$PASSWORD -new -x509 -days 365 -key ca-key.pem -sha256 -out ca.pem`

- `chmod 0400 ca-key.pem`
- `chmod 0444 ca.pem`

3. Generate the server keypair using the certificate authority key.
   The following commands are an example. Note that your configuration might vary.
   - `openssl genrsa -out server-key.pem 4096`
   - `openssl req -subj "/CN=$HOSTNAME" -new -key server-key.pem -out server.csr`
   - `echo "subjectAltName = DNS:$HOSTNAME,IP:$SERVERIP,IP:127.0.0.1" > extfile.cnf`
   - `openssl x509 -passin pass:$PASSWORD -req -days 365 -in server.csr -CA ca.pem -CAkey ca-key.pem -CAcreateserial -out server-cert.pem -extfile extfile.cnf`
4. Create the client keypair using the certificate authority key.
   The following commands are an example. Note that your configuration might vary.
   - `openssl genrsa -out client-key.pem 4096`
   - `openssl req -subj "/CN=$HOSTNAME" -new -key client-key.pem -out client.csr`
   - `echo "extendedKeyUsage = clientAuth" > extfile.cnf`
   - `openssl x509 -passin pass:$PASSWORD -req -days 365 -in client.csr -CA ca.pem -CAkey ca-key.pem -CAcreateserial -out client-cert.pem -extfile extfile.cnf`

   Now you've created all your encryption keys.
5. Import the CA Public Key and Client Keypair to a java keystore.
   The following commands are an example. Note that your configuration might vary.

   Create the keystore file and create a password for it (and save for later use): `keytool -genkey -keyalg RSA -alias dse -keystore my.keystore`

   Delete a default entry from the keystore file: `keytool -delete -alias dse -keystore my.keystore`

   Import the CA public key to the keystore: `keytool -import -keystore my.keystore -trustcacerts -alias ca -file ca.pem`

   Import the client keypair.

   Note:
   You are creating a new pkcs12 keystore file and importing the keypair to it. Then copy the contents to your original keystore file.

   - `openssl pkcs12 -export -name clientkeypair -in client-cert.pem -inkey client-key.pem -out clientkeypair.p12`
   - `keytool -importkeystore -destkeystore my.keystore -srckeystore clientkeypair.p12 -srcstoretype pkcs12 -alias clientkeypair`

   Now that you have added all of the certificates to the keystore file, save the file **my.keystore** for later, as it will be uploaded to the ServiceNow instance. In addition, be sure to remember the password that you entered when prompted to create the keystore file; you will need to enter that into a form in the ServiceNow instance.

Configure Docker for Headless Browser setup in Linux

Complete Step 2 in the Linux setup for the ServiceNow® Headless Browser for ATF: Configure Docker Server to authenticate all requests.

Before you begin

Complete Step 1: Generate certificates for Headless Browser setup for Linux

This task: After creating your client and server keys as directed in Step 1, now you configure the Docker Server to authenticate all requests using those keys, and expose the Docker API on Port 2376.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Procedure

1. Configure Docker to use the certificates that you generated in Step 1.
   a. Find or create the /etc/docker/daemon.json file. You can run: `touch /etc/docker/daemon.json`
   b. Edit the daemon.json file and add the following JSON values. Be sure to replace with the correct paths to your certificates:

```
{
"debug": true,
"tlscacert": "<path to your certificates>/ca.pem",
"tlscert": "<path to your certificates>/server-cert.pem",
"tlskey": "<path to your certificates>/server-key.pem",
"tlsverify": true
}
```

   To learn more, see Configure the Docker daemon.
2. Configure Docker to expose the remote API on a port (Port 2376 is suggested).
   You can configure Docker to accept remote connections with the docker.service systemd unit file for Linux distributions using **systemd**, such as recent versions of RedHat, CentOS, Ubuntu and SLES, or with the daemon.json file, which is suggested for Linux distributions that do not use systemd.

   If using **systemd (systemctl)**:

   a. Use the command `sudo systemctl edit docker.service` to open an override file for docker.service in a text editor.
   b. Add or modify the following lines, substituting your own port if not using 2376.

```
[Service]
ExecStart=
ExecStart=/usr/bin/dockerd -H tcp://0.0.0.0:2376
```

   c. Save the file.
   d. Reload the systemctl configuration.

```
sudo systemctl daemon-reload
```

   e. Restart Docker

```
sudo systemctl restart docker.service
```

3. To enable Docker access for the current user via a command line, copy certificates to the user's Docker home directory:
   - `mkdir -pv ~/.docker`
   - `cp ca.pem ~/.docker`
   - `cp client-key.pem ~/.docker/key.pem`
   - `cp client-cert.pem ~/.docker/cert.pem`
4. Set DOCKER_HOST and DOCKER_TLS_VERIFY environment variables for your user:
   - `echo "export DOCKER_HOST=tcp://${SERVERIP}:2376 DOCKER_TLS_VERIFY=1" >> ~/.bash_profile`
   - `source ~/.bash_profile`

   To learn more, see Manage Docker as a non-root user.

Create the Docker image and containers for Headless Browser setup in Linux

Pull the Docker image from the Public Registry.

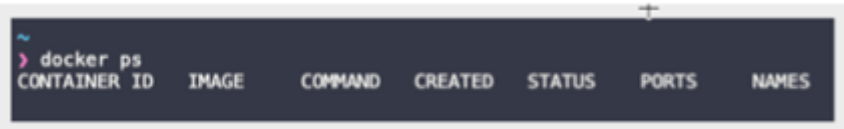
Before you begin

Complete Step 2: Configure Docker for Headless Browser setup in Linux

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Procedure

1. In the command line, run `docker ps` to verify that Docker is working.
   Your results should look like this:



2. Pull the latest Docker image from the GitHub repo ATF Headless Runner.
   This command is an example, as these images are subject to change.
   `docker pull ghcr.io/servicenow/atf-headless-runner:lin-1.0.0`

> **Note:**
> The instance-to-image compatibility makes sure that the automation script inside the Docker image is compatible with the instance code. Elements such as the user interface might change over time to support new features or upgrades.

Add secrets to Docker for Headless Browser setup in Linux

Create a Docker secret, which stores the password of the ServiceNow user who will log into the instance to execute the tests. Docker Secrets is a feature of ServiceNow® for securely storing the passwords that will be used in containers.

Before you begin

Complete Step 3: Create the Docker image and containers for Headless Browser setup in Linux

About this task

Inside of the Docker container is an automation script that opens a web browser, logs into the instance, and opens the client test runner page. In order to log into the ServiceNow instance, you will need a user password. In this procedure you use a Docker feature called **Docker Secrets**

so you can securely store passwords. When you run containers, the password is automatically available to log in to your instance.

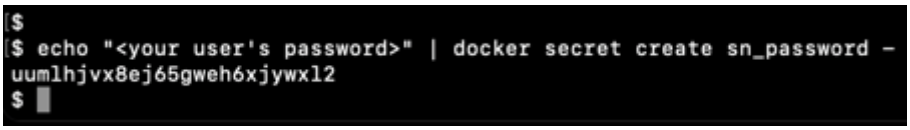
Role required: admin on your ServiceNow instance and local administrator on the host machine.

Procedure

1. At the command line, enter `docker swarm init`
2. Enter `echo "<your user's password>" | docker secret create sn_password -`

   Note:
   Replace `<your user's password>` with the user's ServiceNow password.

   Your results should look like this:



Result

The result is your secret ID, which you must save for later use. The secret ID will be added to the ServiceNow instance in the **sys_property** `sn_atf.headless.secret_id`.

Set up instance for Headless Browser in Linux

Step 5 in the Linux setup for the ServiceNow® Headless Browser for ATF: Set up your instance so it can support the Headless Browser.

Before you begin

Complete Step 5: Add secrets to Docker for Headless Browser setup in Linux

Role required: admin on your ServiceNow instance and local administrator on the host machine.

This task: Set up the instance so that it successfully communicates and authenticates with the host machine.

Procedure

1. Create user:
   a. Navigate to **User Administration** > **Users** and select **New**.
   b. Create a user - User ID, which can be whatever you want, as well as a user name and password. The password should be the same as the one you created for your Docker Secret container.
   c. Add the role **atf_test_designer** for this user. (To learn more, see the User Roles section in the Test your apps with the ATF topic.)
2. Create certificate:
   a. Navigate to **System Definition** > **Certificates** to open the **sys_ certificate** table. Create a new certificate (the name can be whatever you prefer):
      - **Type**: Java Key Store
      - **Password**: Password for the keystore that you created in Step 1 (Generate certificates for Headless Browser setup for Linux).
   b. Select the Attach (paper clip) icon to attach the keystore file you saved earlier to this record.

c. Select **Submit**.

d. Click **Validate certificate** and confirm that the success message displays.

3. Create protocol profile:

a. Navigate to **System Security** > **Protocol Profiles** to open the **sys_protocol_profile** table. Create a new protocol profile record:

Option	Description
Protocol	One word, lowercase: “docker”
Default port	2376 (or the one you chose to use)
Keystore	Docker host keystore

b. Select **Submit**.

4. Create a Docker spoke connection:

a. Navigate to **Connections & Credentials** > **Connection & Credential Aliases** to open the **sys_alias** table.

b. Select the alias with the name **Docker**.

c. Under the Connections related list, select **New**.

d. Fill in these fields:

- **Name**: Any text you prefer
- **Credential field**: Leave blank

e. Select the **URL Builder** check box.

f. Select the **Mutual authentication** check box.

g. In the **Protocol profile** field, select the protocol profile you created earlier.

h. In the **Host** field, add the IP address or Host name of your server.

i. Select **Submit**.

The Connection URL is automatically created by the system.

5. Modify properties:

> **Warning:**
> By default, the *com.glide.communications.trustmanager_trust_all* property is set to **false**. The ServiceNow AI Platform trusts only certificates that it can verify against the JVM certificate store. Self-signed and enterprise-signed certificates are not trusted.

You need to do this only when using self-signed certificates. To learn more, see Generate certificates for Headless Browser setup for Linux.

- `com.glide.communications.httpclient.verify_hostname`: false
- `com.glide.communications.trustmanager_trust_all`: true

Configure ATF for Headless Browser in Linux

Step 6 in the Linux setup for the ServiceNow® Headless Browser for ATF: Configure ATF with properties.

Before you begin

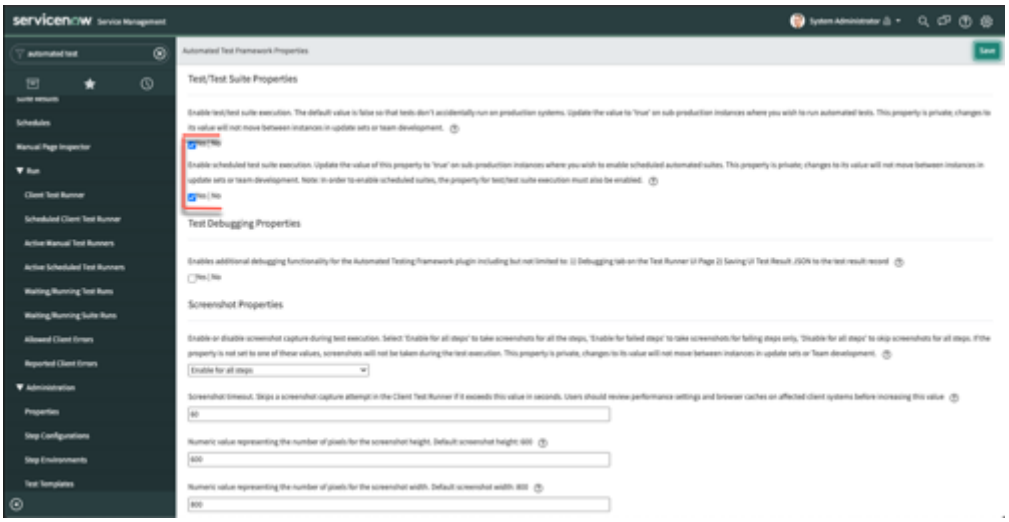
Complete Step 5: Set up instance for Headless Browser in Linux

Role required: admin on your ServiceNow instance and local administrator on the host machine.

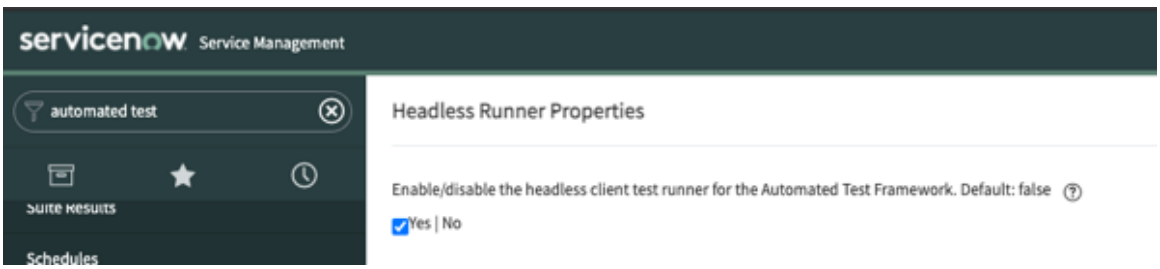
This task: Now that you've set up your connection and authentication, configure ATF with several properties so that it can start containers successfully on the host machine.

Procedure

1. In your instance, navigate to **ATF** > **Administration** > **Properties**.
2. Enable the top two properties: **Enable test/test suite execution** and **Enable scheduled test suite execution**.



3. Scroll down to the **Headless Runner Properties** section.
4. Enable the top check box.



5. Enter the following values in the Headless Runner Properties form:

Form Label	Property Name	Value to Imput
The user account used to login from the headless client test runner and begin the tests	sn_atf.headless.username	Username of the integration user that you created in Add secrets to Docker for Headless Browser setup in Linux

Form Label	Property Name	Value to Imput
The Docker secret ID that has the password stored of the user account	sn_atf.headless.secret_id	Docker "Secret ID" that you obtained earlier, as well as the Docker secret name that you created in Step 2 of the Add secrets to Docker for Headless Browser setup in Linux procedure.
The Docker image that is used for headless Client Test Runner	sn_atf.headless.docker_image_name	Image name with tag that you downloaded: `ghcr.io/servicenow/atf-headless-runner:<tagname>`

Note:
If you forgot the secret ID, go to the Docker host and run the command `docker secret list`

6. Leave the rest of the fields as they are.
7. Select **Save**.

Verify Headless Browser procedures in Linux

Step 7, the final step in the Linux setup for the ServiceNow® Headless Browser for ATF: Verify that your Headless Browser setup procedures are successful.

Before you begin
Role required: admin

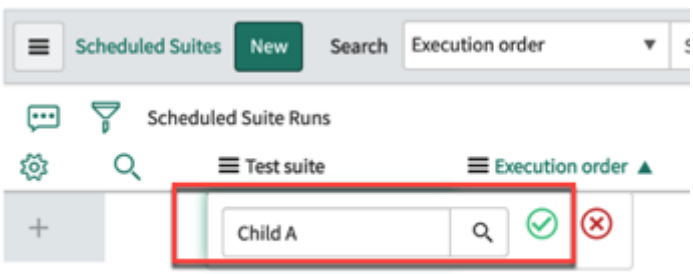
Complete Step 6: Configure ATF for Headless Browser in Linux

Role required: admin on your ServiceNow instance and local administrator on the host machine.

This task: Verify that Steps 1-6 in your Headless Browser setup procedures are successful.

Procedure

1. Go to **ATF Schedules** and next to the Suite Schedules link, select **New**.
2. In the Run box, select **On Demand**.
3. Select **Save**.
4. In the Scheduled Suite related list, add a new record for your test suite by double-clicking the **+** sign and choose your browser name of **Chrome** or **Firefox**.
   Use **Child A** as a good example to run.



5. Set the OS name to Linux.
6. Select **Execute Now**.
7. Verify that your test passed.
   When your verification is successful, any suites with UI tests run by scheduled suites or via CICD now automatically create headless test runners without the need to manually open the "scheduled client test runner" page.

Headless Browser setup for Microsoft Windows

The ServiceNow® Headless Browser for Automated Test Framework (ATF) provides automation so you can skip having to manually open a browser during testing. The Headless Browser setup is available in both Linux and Microsoft Windows. This topic covers the setup for Windows.

Important:
Headless Browser is a legacy feature of ATF; it is recommended to instead use the ATF Test Generator and Cloud Runner application. Cloud Runner offers you an easy setup and a seamless user experience. You can install Cloud Runner from the store app.

If you are an on-premise instance user, you must continue using the Headless Browser option. Cloud Runner is not currently available for on-premise instances.

There are several sequential procedures to follow in the one-time setup. Below are the instructions for the Microsoft Windows setup.

Prerequisites

Note:
MFA must be disabled in your instance to use the Headless Browser option.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Warning:
The only supported version of Microsoft Windows as a host is Windows Server 2019 v10.0.17763.737. No other versions are supported. If you are unable to meet these requirements, a Linux host is recommended.

- Make sure that the following programs are installed on your Windows server:
  - Docker: Install Docker for Headless Browser setup for Microsoft Windows
  - Java keytool: Chocolatey tool for javaruntime
  - OpenSSL: Chocolatey tool for openssl
- Two-way communication
  - There must be two-way communication between the instance URL and your server.
  - Find the IP address of your server and get your hostname. You can use one or both of them, but you need at least one. Make sure the address or hostname are visible from your ServiceNow instance.
  - See My IP Address to find the IP address ranges of your instance. You can then configure your server to allow inbound access to all of the indicated IP addresses/ranges.
  - Use Port 2376 or your own default port for this procedure. Make sure your server's firewall rules allow inbound requests on this port from the IP addresses you get from the instance.

Note:
If you don't have a hostname and are connecting via the IP address, you can enter the IP address and put "localhost" in the Hostname environment variable.

- To learn more, see Use TLS (HTTPS) to protect the Docker daemon socket.

Steps to set up the Headless Browser for Windows

Follow these seven steps (plus verification) to set up the Headless Browser for Windows.

Install Docker for Headless Browser setup for Microsoft Windows

Step 1 in the Windows setup for the ServiceNow® Headless Browser for Automated Test Framework: Install Docker.

Before you begin
Role required: admin

- See Prerequisites in the Headless Browser setup for Microsoft Windows topic.

- **Tip:**
  To make remembering these easier, set the following environment variables:
  - set PASSWORD=<password>
  - set SERVERIP=<server ip>
  - set HOSTNAME=<hostname>

Warning:
The only supported version of Microsoft Windows as a host is Windows Server 2019 v10.0.17763.737. No other versions are supported. If you are unable to meet these requirements, a Linux host is recommended.

Procedure

1. Open an elevated PowerShell session and install the Docker-Microsoft PackageManagement Provider from the PowerShell Gallery.
   PowerShell

   ```
   Install-Module -Name DockerMsftProvider -Repository PSGallery -Force
   ```

   If you're prompted to install the NuGet provider, type `Y` to install it as well.

2. Use the PackageManagement PowerShell module to install the latest version of Docker.
   PowerShell

   ```
   Install-Package -Name docker -ProviderName DockerMsftProvider
   ```

   When PowerShell asks you whether to trust the package source 'DockerDefault', type `A` to continue the installation.

3. After the installation completes, restart the computer.
   PowerShell

   ```
   Restart-Computer -Force
   ```

Generate certificates for Headless Browser setup for Microsoft Windows

Generate TLS/SSL certificates to secure the Docker REST API and authenticate HTTP requests.

Before you begin
Role required: admin on your ServiceNow instance and local administrator on the host machine.

> **Warning:**
> The only version of Microsoft Windows that ServiceNow supports as a host is Windows Server 2019 v10.0.17763.737. No other versions are supported. If you are unable to meet these requirements, a Linux host is recommended.

- Complete the prerequisites listed in the Headless Browser setup for Microsoft Windows topic. Make sure that the following programs are installed on your Windows server:
  - Docker: Docker application for Windows
  - Java keytool: Chocolatey tool for javaruntime
  - OpenSSL: Chocolatey tool for openssl

Note the following requirements:

- Two-way communication

  > **Warning:**
  > Be sure to get certificate authority keys from a trusted certificate authority.

  - There must be two-way communication between the instance URL and your server.
  - Find the IP address of your server and get your hostname. You can use one or both of them, but you need at least one.

    > **Note:**
    > If you don't have a hostname and are connecting via the IP address, you can enter the IP address and put "localhost" in the Hostname environment variable.

  > **Tip:**
  > To make remembering these easier, set the following environment variables:
  >
  > - `export PASSWORD="<password to generate the certificates with>"`
  > - `export SERVERIP="<this server's IP address>"`
  > - `export HOSTNAME="<hostname of this server>"`

- Port: Use Port 2376 or your own default port for this procedure.

  > **Note:**
  > Make sure your firewall rules allow inbound requests on this port

- To learn more, see Use TLS (HTTPS) to protect the Docker daemon socket.

About this task
By default when exposing the Docker API, requests are not authenticated, which can leave your host machine vulnerable to attack. Docker API, however, does support TLS authentication where requests are verified against public private keys provided in the HTTPS encryption. In this step you create those keys for the server and the client.

Procedure

1. Open a command line.
2. Generate a self-signed certificate authority key or retrieve a keypair from a trusted certificate authority.
   The following commands are an example. Note that your configuration might vary.

```
openssl genrsa -aes256 -passout pass:%PASSWORD% -out ca-key.pem
 4096
openssl req -passin pass:%PASSWORD% -new -x509 -days 365 -key
 ca-key.pem -sha256 -out ca.pem
```

3. Generate the server keypair using the certificate authority key.
   The following commands are an example. Note that your configuration might vary.

```
openssl genrsa -out server-key.pem 4096
openssl req -subj /CN=%HOSTNAME% -new -key server-key.pem -out
 server.csr
echo extendedKeyUsage = clientAuth > extfile.cnf
openssl x509 -passin pass:%PASSWORD% -req -days 365 -in
 server.csr -CA ca.pem -CAkey ca-key.pem -CAcreateserial -out
 server-cert.pem -extfile extfile.cnf
```

4. Create the client keypair using the certificate authority key.
   The following commands are an example. Note that your configuration might vary.

```
openssl genrsa -out client-key.pem 4096
openssl req -subj /CN=%HOSTNAME% -new -key client-key.pem -out
 client.csr
echo subjectAltName = DNS:%HOSTNAME%,IP:%SERVERIP%,IP:127.0.0.1
 > extfile.cnf
openssl x509 -passin pass:%PASSWORD% -req -days 365 -in
 client.csr -CA ca.pem -CAkey ca-key.pem -CAcreateserial -out
 client-cert.pem -extfile extfile.cnf
```

5. Import the CA Public Key and Client Keypair to a Java keystore.
   This instructions are an example Your configuration might vary.

   Create the keystore file and create a password for it (and save for later use): `keytool -genkey -keyalg RSA -alias dse -keystore my.keystore`

   Delete a default entry from the keystore file: `keytool -delete -alias dse -keystore my.keystore`

   Note:
   This entry is auto-generated, s.o is not needed.

   Import the CA public key to the keystore: `keytool -import -keystore my.keystore -trustcacerts -alias ca -file ca.pem`

   Import the client keypair.

   Note:
   You are creating a new pkcs12 keystore file and importing the keypair to it. Then copy the contents to your original keystore file.

- `openssl pkcs12 -export -name clientkeypair -in client-cert.pem -inkey client-key.pem -out clientkeypair.p12`
- `keytool -importkeystore -destkeystore my.keystore -srckeystore clientkeypair.p12 -srcstoretype pkcs12 -alias clientkeypair`

Now that you have added all of the certificates to the keystore file, save the file **my.keystore** for later, as it will be uploaded to the ServiceNow instance. In addition, be sure to remember the password that you entered when prompted to create the keystore file; you will need to enter that into a form in the ServiceNow instance.

Configure Docker for Headless Browser setup in Microsoft Windows

Configure Docker Server to authenticate all requests.

Before you begin

Complete Step 2: Generate certificates for Headless Browser setup for Microsoft Windows

Role required: admin on your ServiceNow instance and local administrator on the host machine.

About this task

After creating your client and server keys, now you configure the Docker Server to authenticate all requests using those keys, and expose the Docker API on Port 2376.

Procedure

1. Configure Docker to use the certificates you generated in Step 2.
2. Find or create the `C:\ProgramData\docker\config\daemon.json` file.
3. Add the following properties to the daemon.json file.
   Be sure to replace items in these commands with the correct paths to your certificates:

   Note:
   The double slashes are important to copy exactly.

   ```
   {
   "tlscacert": "C:\\Users\\Administrator\\certs\\ca.pem",
   "tlscert": "C:\\Users\\Administrator\\certs\\server-cert.pem",
   "tlscert": "C:\\Users\\Administrator\\certs\\server-cert.pem",
   "tlskey": "C:\\Users\\Administrator\\certs\\server-key.pem",
   "tlsverify": true,
   "hosts": ["tcp://0.0.0.0:2376", "npipe://"]
   }
   ```

   To learn more, see Configure the Docker daemon.
4. In administrator PowerShell, run `restart-service *docker*`

Create the Docker image and containers for Headless Browser setup in Microsoft Windows

Pull the Docker image from the Public Registry.

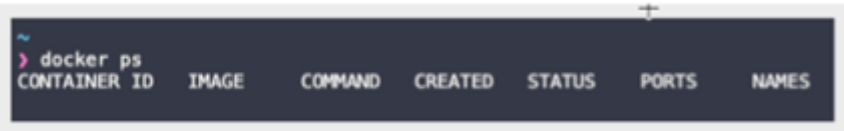
Before you begin

Complete Step 3: Configure Docker for Headless Browser setup in Microsoft Windows

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Procedure

1. In an administrator command line, run `docker ps` to verify that Docker is working.
   Your results should look like this:



2. Pull the latest Docker image from the GitHub repo ATF Headless Runner.
   This command is an example, as these images are subject to change:
   `docker pull ghcr.io/servicenow/atf-headless-runner:win-1.0.0`

> **Note:**
> The instance-to-image compatibility makes sure that the automation script inside the Docker image is compatible with the instance code. Elements such as the user interface might change over time to support new features or upgrades.

Add secrets to Docker for Headless Browser setup in Microsoft Windows

Create a Docker secret that stores the password of the ServiceNow user who will log into the instance to execute the tests. Docker Secrets is a feature of ServiceNow® for securely storing the passwords that will be used in containers.

Before you begin

Complete Step 4: Create the Docker image and containers for Headless Browser setup in Microsoft Windows

Role required: Go to your ServiceNow instance and create a new user to be used by the Docker container to log in. Give this user the roles of **admin** or **atf_test_admin**. Save the password to be used in Step 2 of the following procedure.

About this task

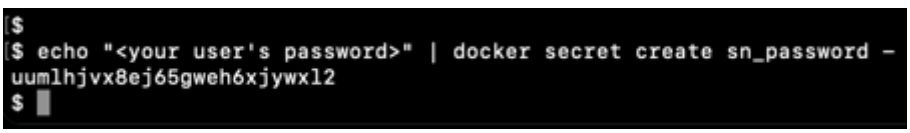
Inside the Docker container is an automation script that opens a web browser, logs into the instance, and opens the Client Test Runner page. In order to log into the ServiceNow instance, you will need a user password. In this step you use a Docker feature called Docker Secrets so you can securely store passwords. Then when you run containers, the password is automatically available to log in to your instance.

Procedure

1. In the admin command line, enter `docker swarm init`
2. In the admin command line, enter `echo <your user's password> | docker secret create sn_password -`

> **Note:**
> Replace `<your user's password>` with the user's ServiceNow password.

Your results should look like this:



Result

The result is your secret ID, which you must save for later use. The secret ID will be added to the ServiceNow instance in the sys_property `sn_atf.headless.secret_id`.

Set up instance for Headless Browser in Microsoft Windows

Step 6 in the Microsoft Windows setup for the ServiceNow® Headless Browser for ATF: Set up your instance so it can support the Headless Browser.

Before you begin

Complete Step 5: Add secrets to Docker for Headless Browser setup in Microsoft Windows.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

This task: Now that you have configured the host machine, you will set up the instance so that it successfully communicates and authenticates with the host machine.

Procedure

1. Create user:
   a. Navigate to **User Administration** > **Users** and select **New**.
   b. Create a user - User ID, which can be whatever you want, as well as a user name and password. The password should be the same as the one you created for your Docker Secret container.
   c. Add the role **atf_test_designer** for this user. (To learn more, see the User Roles section in the Test your apps with the ATF topic.
2. Create certificate:
   a. Navigate to **System Definition** > **Certificates** to open the **sys_ certificate** table. Create a new certificate (the name can be whatever you prefer):
      - **Type**: Java Key Store
      - **Password**: Password for the keystore that you created in Step 2 (Generate certificates for Headless Browser setup for Microsoft Windows).
   b. Select the Attach (paper clip) icon to attach the keystore file you saved earlier to this record.
   c. Select **Submit**.
   d. Click **Validate certificate** and confirm that the success message displays.
3. Create protocol profile:
   a. Navigate to **System Security** > **Protocol Profiles** to open the **sys_protocol_profile** table. Create a new protocol profile record:

Option	Description
Protocol	One word, lowercase: “docker”
Default port	2376 (or the one you chose to use)
Keystore	Docker host keystore

   b. Select **Submit**.
4. Create a Docker spoke connection:

a. Navigate to **Connections & Credentials** > **Connection & Credential Aliases** to open the **sys_alias** table.

b. Select the alias with the name **Docker**.

c. Under the Connections related list, select **New**.

d. Fill in these fields:

- **Name**: Any text you prefer
- **Credential field**: Leave blank

e. Select the **URL Builder** check box.

f. Select the **Mutual authentication** check box.

g. In the **Protocol profile** field, select the protocol profile you created earlier.

h. In the Host field, add the IP address or Host name of your server.

i. Select **Submit**.

The Connection URL is automatically created by the system.

5. Modify properties:
   - `com.glide.communications.httpclient.verify_hostname`: false
   - `com.glide.communications.trustmanager_trust_all`: true

> **Warning:**
> By default, the *`com.glide.communications.trustmanager_trust_all`* property is set to **false**. The ServiceNow AI Platform trusts only certificates that it can verify against the JVM certificate store. Self-signed and enterprise-signed certificates are not trusted.

You need to do this only when using self-signed certificates. To learn more, see Generate certificates for Headless Browser setup for Microsoft Windows.

Configure Automated Test Framework (ATF) for Headless Browser in Microsoft Windows

Step 7 in the Microsoft Windows setup for the ServiceNow® Headless Browser for ATF: Configure ATF with properties.

Before you begin

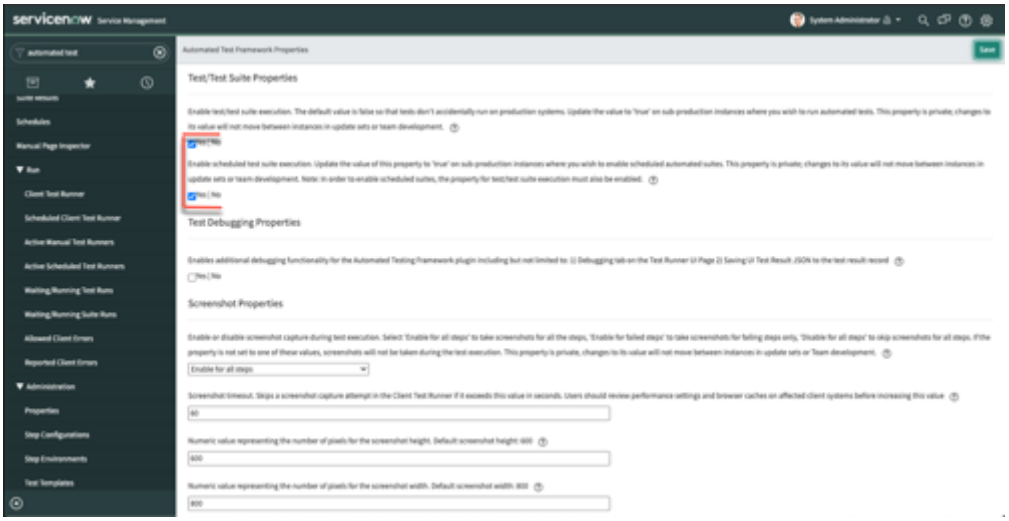
Complete Step 6: Set up instance for Headless Browser in Microsoft Windows

Role required: admin on your ServiceNow instance and local administrator on the host machine.

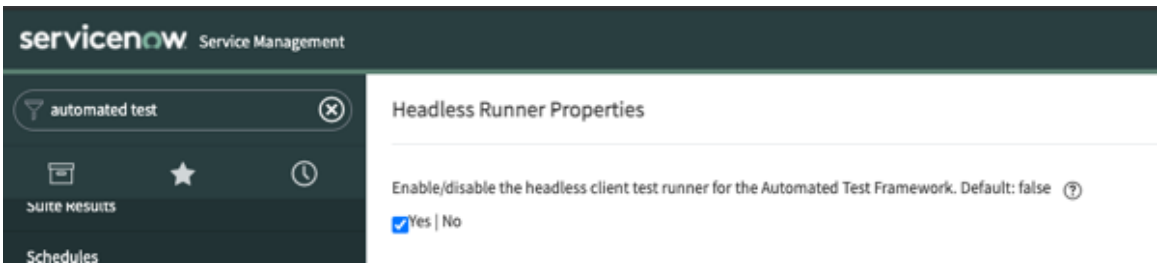
Now that your connection and authentication are set up, you will configure ATF with several properties so that it can start containers successfully on the host machine.

Procedure

1. In your instance, navigate to **ATF** > **Administration** > **Properties**.
2. Enable the top two properties: **Enable test/test suite execution** and **Enable scheduled test suite execution**.



3. Scroll down to the **Headless Runner Properties** section.
4. Enable the top check box.



5. Enter the following values in the Headless Runner Properties form:

Form Label	Property Name	Value to Imput
The user account used to login from the headless Client Test Runner and begin the tests	sn_atf.headless.username	Username of the integration user that you created in Add secrets to Docker for Headless Browser setup in Microsoft Windows
The Docker secret ID that has the password stored of the user account	sn_atf.headless.secret_id	Docker “secret ID” that you obtained earlier, as well as the Docker secret name that you created in Step 2 of the Add secrets to Docker for Headless Browser setup in Microsoft Windows procedure.
The Docker image that is used for headless Client Test Runner	sn_atf.headless.docker_image_name	Image name with tag that you downloaded: `ghcr.io/servicenow/atf-headless-runner:<tagname>`

Note:
If you forgot the secret ID, go to Windows host and run the command docker secret list.

6. At the **The absolute path of the secret file on a docker container** field, enter: `C:\ProgramData\Docker\secrets\<YOUR SECRET NAME>`
7. Leave the rest of the fields as they are.
8. Select **Save**.

Verify Headless Browser procedures for ATF in Microsoft Windows

Verify that your Headless Browser setup procedures have been successful.

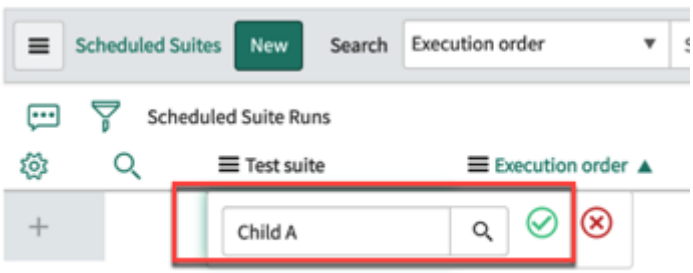
Before you begin

Complete Step 7: Configure Automated Test Framework (ATF) for Headless Browser in Microsoft Windows

Role required: admin

Procedure

1. Go to **ATF Schedules** and next to the Suite Schedules link, select **New**.
2. In the Run box select **On Demand**.
3. Select **Save**.
4. In the Scheduled Suite related list, add a new record for your test suite by double-clicking the **+** sign and choose your browser name of **Chrome** or **Firefox**.
   Use **Child A** as a good example to run.



5. Set the OS name to Windows.
6. Select **Execute Now**
7. Verify that your test passed.
   When your verification is successful, any suites with UI tests run by scheduled suites or via CICD now automatically create headless test runners without the need to manually open the "scheduled client test runner" page.

Headless Browser system properties

Below is a table of the properties you must have as you set up the ServiceNow® Headless Browser for Automated Test Framework.

System properties

Property name	Type	Default value	Purpose
sn_atf.headless.browser_options	string	"--no-sandbox,--disable-gpu"	The CLI options are passed to the browser on startup
sn_atf.headless.default_browser	string	Chrome	Default browser used when starting up headless requests
sn_atf.headless.default_os	string	Linux	Operating system of host machine
sn_atf.headless.docker_image	image_name		Name:tag of the Docker image on the host machine
sn_atf.headless.docker_init_window_seconds	integer	60	If the Docker container fails to start up twice in this amount of time, the service will not attempt to restart
sn_atf.headless.enabled	true/false	false	Determines whether the instance attempts to create headless client test runners for scheduled UI test runs
sn_atf.headless.heartbeat_enabled	true/false	true	When property is true, Docker container sends a REST API request every minute to the instance to check that the sys_atf_agent is still online, and stops the container if the record status is "offline" or the record no longer exists.
sn_atf.headless.heartbeat_uri	string	/api/now/atf_agent/online	The URL of the heartbeat endpoint so container can verify browser is still responsive
sn_atf.headless.images_check_enabled	true/false	false	When this property is true, the instance verifies that the requested Docker image:tag is present on the host before test execution

System properties (continued)

Property name	Type	Default value	Purpose
sn_atf.headless.login_button_id	string	sysverb_login	The HTML ID of the login page Submit/Login button
sn_atf.headless.login_page	string	login.do	URL of login page that the browser navigates to
sn_atf.headless.password_field_id	string	user_password	The HTML ID of the input field for the password on the Login page
sn_atf.headless.request_timeout_sec	integer	200	Number of seconds that HTTP requests being sent to the Docker host have until timeout
sn_atf.headless.retry_count	integer	10	Number of times the instance checks for agent coming online before cancelling the test run
sn_atf.headless.runner_banner_id	string	test_runner_banner	The ID of the element verifying that client test runner page loaded correctly
sn_atf.headless.runner_url	string	atf_test_runner.do?sysparm_nostack=true&sysparm_scheduled_tests_only=true&s	URL of the scheduled client test runner page and its query parameters
sn_atf.headless.secret_gid	string	1000	The GID of the Docker container default user
sn_atf.headless.secret_id	string		The ID of the Docker secret on host machine
sn_atf.headless.secret_name	string		Name of the Docker secret on host machine
sn_atf.headless.secret_path	string	/run/secrets/<secret_name>	Path where Docker secret file exists: (Learn more: https://docs.docker.com/engine/swarm/secrets/#how-docker-manages-secrets)
sn_atf.headless.secret_uid	string	1000	The UID of the Docker container default user

System properties (continued)

Property name	Type	Default value	Purpose
sn_atf.headless.service_cleanup_exclude_list	string		Service ID exceptions that should NOT be deleted during the instance service cleanup job. This job runs every night and deletes any services that are on the host and past their expiration time.
sn_atf.headless.service_stop_deletes	true/false	false	On completing of a test execution, if this property is true the instance will NOT send the service delete requests thus keeping the service and containers around on the host. Useful for debugging.
sn_atf.headless.timeout_mins	integer	1440	Number of minutes before Docker service automatically shuts down
sn_atf.headless.user_field_id	string	user_name	The HTML ID of the input field for the username on the Login page
sn_atf.headless.username	string		Username of user who logs in to the instance
sn_atf.headless.validation_id	string	headless_vp_validation	The ID of the element confirming verification page has loaded
sn_atf.headless.validation_page	string	atf_headless_validation_page	The URL of the validation page on the instance
sn_atf.headless.vp_has_role_id	string	headless_vp_has_role	The ID of the element verifying that the user has correct roles
sn_atf.headless.vp_success_id	string	headless_vp_success	The ID of the element signifying entire page loaded correctly

Headless Browser troubleshooting

These tips can help you troubleshoot your Linux or Microsoft Windows setup of the ServiceNow® Headless Browser for Automated Test Framework.

There are three basic areas to examine when troubleshooting your Headless Browser setup.

Docker container

Error logs: When the headless test completes, if there are errors they are generated in the Docker container. Whether the operation fails or succeeds, the container's **stdout/stderr** logs are placed in the **sn_atf_docker_service** table.

Headless client test runner did not start in the time allotted message: This message generally means an error occurred in the Docker container while it was initializing or starting up. This may indicate something is incorrect in your Docker container setup. Navigate to the **sn_atf_docker_service** table to read the logs and see the error message.

Instance

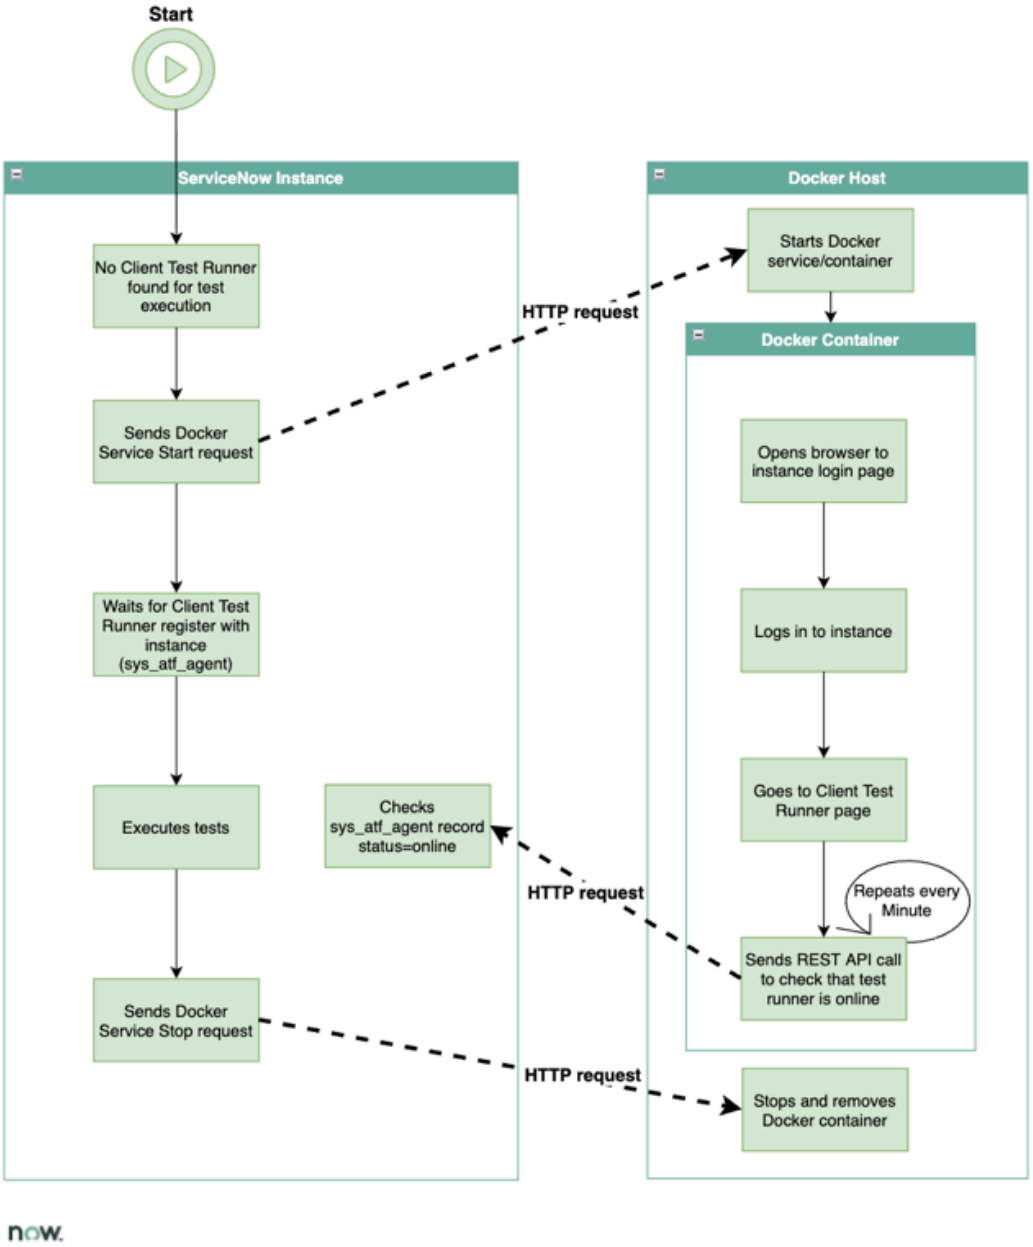
Error caught running Docker flow when starting the ATF tests messages: Follow the URL address to find the flow context, which contains the error logs. For example, the above error message can display when the instance can't access the Docker host.

Network errors

Firewalls: Make sure your firewalls are set up so that the instance can access the host and port and the server can access the instance.

Headless Browser action flow diagram

Example flow diagram



Building and running automated tests with the Automated Test Framework

Basic tasks in the Automated Test Framework.

To build and run any test, you always perform certain operations:

- Create a new automated test
- Add steps to an automated test
- Run an automated test
- View the progress of automated tests
- View test results and automated test results

You perform other operations often, but not necessarily for every test.

- For tests involving form steps, you might need to View results screenshots from an automated test.
- For some tests, you might need to know about Passing data from one automated test step to another.
- Some steps frequently occur in the same sequence in many different tests, so you can Add a predefined list of steps (template) to an automated test.

Create a new automated test

Create a named automated test containing a series of steps to execute.

Before you begin

Role required: atf_test_admin or atf_test_designer

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Click **New**.
3. On the Test new record form, enter a **Name** for your test.
   The system identifies this test by this name wherever it displays a list of tests (for example, in the Tests module).
4. **Optional:** Enable parameterized testing to run a test multiple times with different test data for each run.
   For more information, see Parameterized tests.
5. Enter a **Description** for your test.
6. Click **Save**.
   The system creates a new test record and returns to the list of tests.

What to do next

Add steps to an automated test.

Add a predefined list of steps (template) to an automated test

With test templates you can add a predefined list of steps to a test. Any list of steps that follows a set pattern makes a good candidate for a template.

Before you begin

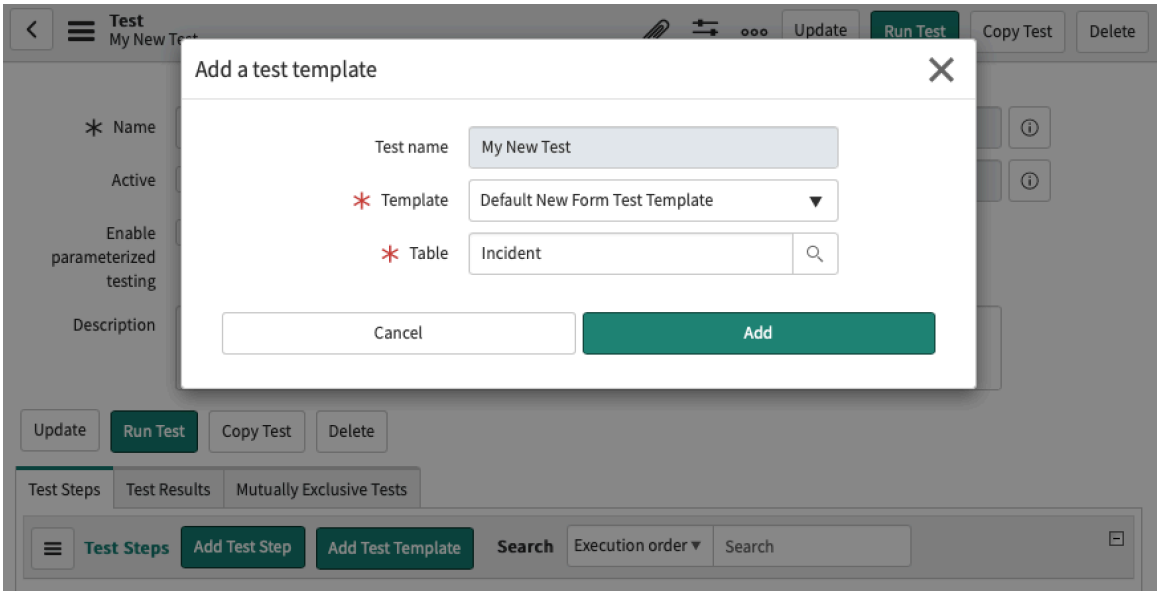
You must have created the test to which you want to add steps.
Role required: atf_test_admin or atf_test_designer

About this task

Many tests follow similar patterns. One common pattern, for example, is to open a form, set some field values, validate some field values, click a UI action, and submit the current form. If a template exists containing these steps, you can add them to a test all at once. The Automated Test Framework comes with default templates. You can also create custom test templates.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Click the row for the test to which you want to add steps.
   The system displays the Test form.
3. On the **Test Steps** related list, click **Add Test Template**.
   The system displays the **Add a test template** dialog.



4. From the **Table** field, select the table you want to test with these steps.
5. From the **Template** field, select the template containing the steps you want to add.
6. Click **Add**.
   The system adds the template steps to the test. It also adds to the test description a set of instructions on how to complete the test from this template.
7. Following the instructions in the test description, edit each step added by the template to include the necessary information.

What to do next

Proceed to edit or save the test as you normally would.

Related topics

Create an automated test steps template

Add steps to an automated test

Create a series of steps for an automated test to run in a specified order.

Before you begin

You must create a test before you can add steps to the test.
Role required: atf_test_admin or atf_test_designer

About this task

This procedure lets you add one step at a time. You can also add a batch of steps at once. For more information, see Add a predefined list of steps (template) to an automated test.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Click the test that should contain the new test steps.
3. In the Test Steps related list at the bottom of the Test form, click **Add Test Step**.
4. From the left panel of the Add Test Step form, select the test step category, or select **All Steps** to view all available test steps for all test categories.

For example, if selecting a specific test step category, select **Form** for form-related test steps, **Application Navigator** to test application menu or module visibility, or **Server** for tests executed on the server.

Note:
When selecting certain types of server tests, you can specify whether a positive or negative test result constitutes a successful test outcome. For more information, see Assert type in Test your apps with the ATF.

5. Click the type of test step you want to select.
   For example, if you select the **Form** category, select **Set Field Values** to set the field values on a form.

   Start any sequence of steps that work with forms with the **Open a new form** or **Open an existing form** step. Close with the **Submit form** step.
6. If applicable, from the **Insert after** drop-down list, select the step that you want to precede this step.
   If this is the first step in a test, the **Insert after** drop-down list does not appear.
7. Click **Next**.
8. From the **Table** list on the Add Test Step form, select the table that you want to test in this step.
9. **Optional:** In the **Execution Order** field, enter an integer representing the order in which you want the test to execute this step.
   For more information on **Execution Order**, see Edit automated test step order.
10. Fill in the fields that apply to this step.

    For instructions, see Test step categories.

    Some steps return output values that you can pass to the inputs for a subsequent step. For more information, see Pass values from one automated test step to another.
11. Click **Submit**.
    The system creates the step and displays the test record.
12. Repeat Steps 3 through 11 to add additional steps for this test.

What to do next

Run an automated test.

Related topics

Automated Test Framework use case examples

Change automated test step

If necessary, edit a test step after you create it.

Before you begin

Role required: atf_test_admin or atf_test_designer

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Click the row containing the test you want to edit.
3. On the **Test Steps** related list, click the row containing the step you want to edit.
   The system displays the **Set Field Values** form.

4. Edit the fields you want to change.
5. Click **Update**.

Edit automated test step order

By default, steps execute in the order in which you created them. You can change this order by editing the **Execution Order** field.

Before you begin
Role required: atf_test_admin or atf_test_designer

About this task
By default, the system assigns the value 1 to **Execution Order** for the first step created for a test. When you add a step, the system assigns it the next-highest available integer value. In other words, if the highest **Execution Order** for any step in the test has the value 7, the system assigns 8 to the new step. By editing these values, you can change the order in which the test executes the steps.

Procedure
1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Click the row containing the test you want to edit.
   The system displays the **Test**form.
3. In the **Test Steps** related list, edit the values in the **Execution order** column to determine the new order for the steps.
4. Click **Update**.

Copy automated test

Copy an existing test, which you can then re-name and modify.

Before you begin
Role required: atf_test_admin or atf_test_designer

Procedure
1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Click the row containing the test you want to copy top open it.
3. Near the top-right of the Test record form, click **Copy Test**.
   An annotation displays confirming that the system has copied the test. After you dismiss this annotation, the system displays a new test record identical to the copied record, with the exception of the **Name**.
4. In the **Name** field, enter the name you want to assign to this new test.
5. Edit the test steps as desired and proceed as you would for any new test.
6. When you are finished making changes, click **Update**.

> **Note:**
> Scope management in ATF tests helps identify and restrict copying of tests in other scopes. If you want to copy a test, you must be in the same scope as the test. See Application Scope for more information.

Run an automated test

After creating an automated test, run it on a non-production instance.

Before you begin

You must have created the test you want to run.
The test execution property must be enabled. You must have an admin or atf_test_admin role to do so.

Note:
The test execution property is disabled by default to prevent running tests on a production system. Run tests only on development, test, and other sub-production instances.

Role required: atf_test_admin, atf_test_designer, or admin

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. If necessary to view the tests list, click **Tests**.
3. Click the row containing the test that you want to run.
   The system displays the **Test** form.
4. Click **Run Test**.

Note:
If the test execution property is not enabled, the **Run Test** button does not appear. In this case, see the annotation at the top of the form, and click the link to enable running tests.

If the test includes a form step (any step involving a UI), or other kinds of UI test steps, the Pick a browser dialog appears before executing the tests. Use it to choose among any currently running test clients, or start a new runner. For more information, review Browser recommendations for all tests and suites. If the test only includes server test steps, the system executes the tests without displaying the Pick a Browser dialog.

What to do next

Monitor the progress of the test in the Run Test progress dialog. When complete, click **Go to Results** (on the Run Test progress dialog) to display the **Test Results** list, where you can view and analyze test results.

Note:
If your test creates data, the system rolls back that data after all steps in the test complete.

Related topics

Cancelling automated tests and test suites

Implementing breakpoints

Breakpoints allow you to pause your test at any step of a test run in order to troubleshoot and test authoring.

Breakpoints are useful when a test fails. You can add breakpoints to the test steps to debug the test. You can also look at the test steps again to find the reasons of the test failure.

Note:
Breakpoints are user-specific. You can see only your self-created breakpoints.

Rollback of test data

Test runs can also be paused immediately before rollback of test data. Check the **Pause before rollback** option to pause the test just before rollback of test data happens after the completion of the test. See Debug an automated test using breakpoints to learn more about using rollback option in a test run.

Debug an automated test using breakpoints

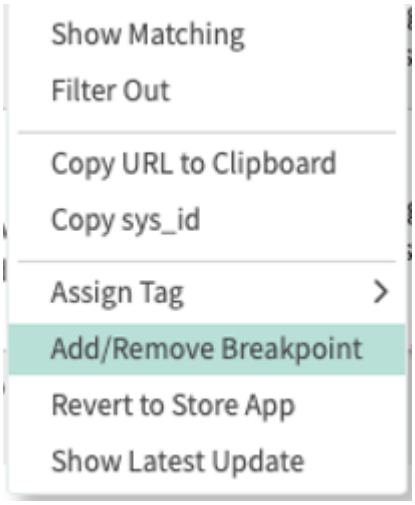
Pause a test to troubleshoot failures or unexpected behavior by adding a breakpoint for a particular test step.

Before you begin

Role required: admin

Procedure

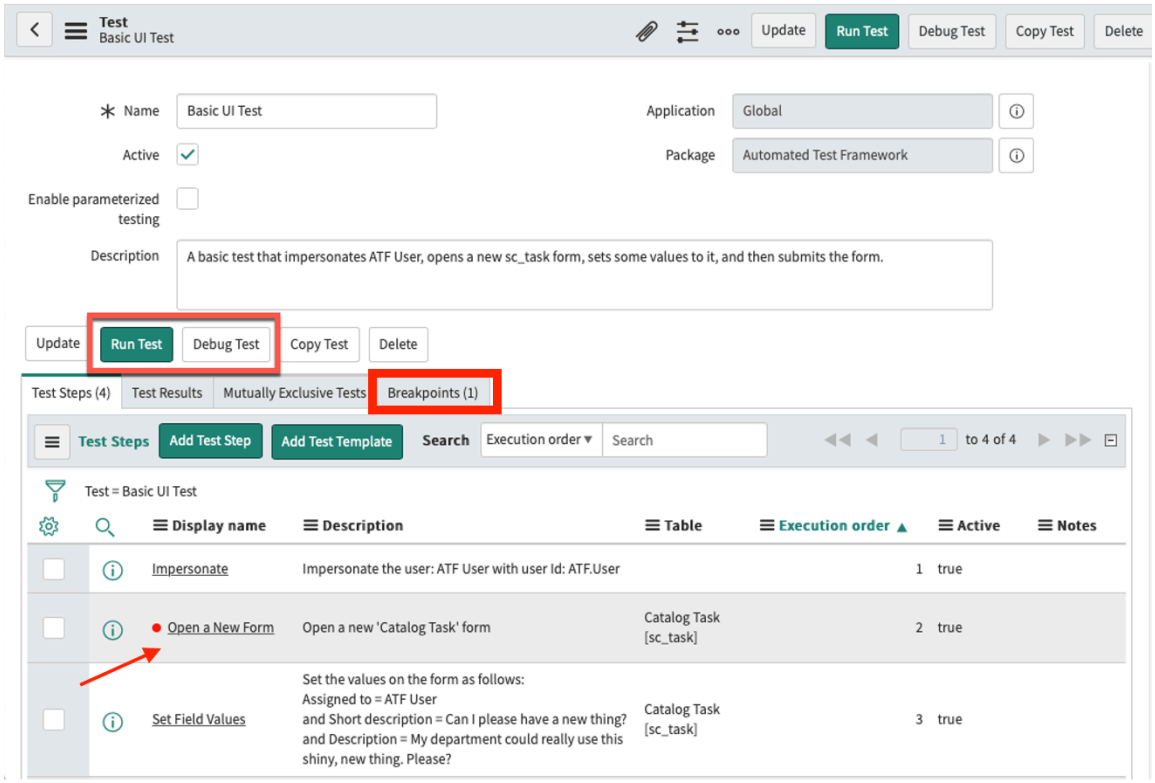
1. Navigate to **All** > **Automated Test Framework (ATF)** > **Tests**.
2. Select the test you want to run.
3. Select Test Steps related list to list out all the test steps for the selected test.
4. Right-click the test step where you want to add or remove a breakpoint.
5. Select Add/Remove Breakpoint from the list.



The test step gets marked for the modified breakpoint.

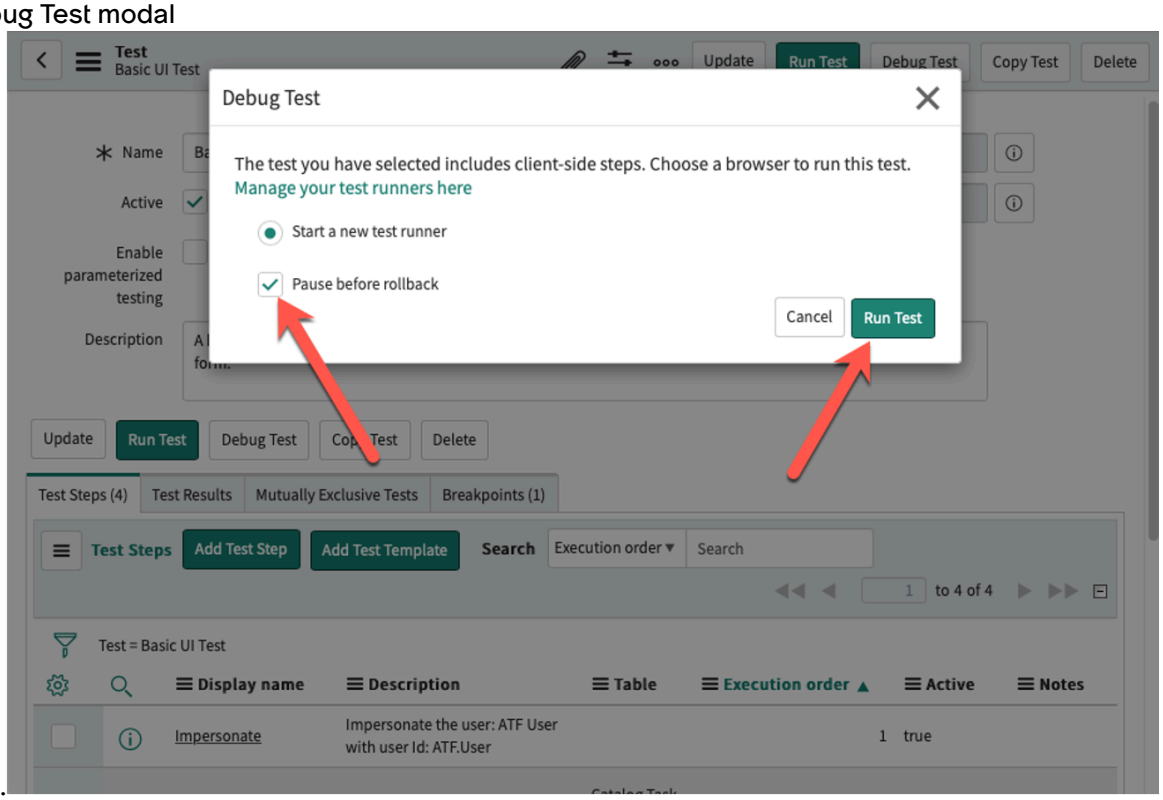
Note:
The breakpoint mark on a step states that if the breakpoint is active and the test is run using **Debug Test**, the test pauses just before the breakpoint test step. The breakpoints are not considered if you click **Run Test** to run the test.

The breakpoints you set on a test are user-specific. Other users can't see and modify your breakpoints on a test, and vice versa.



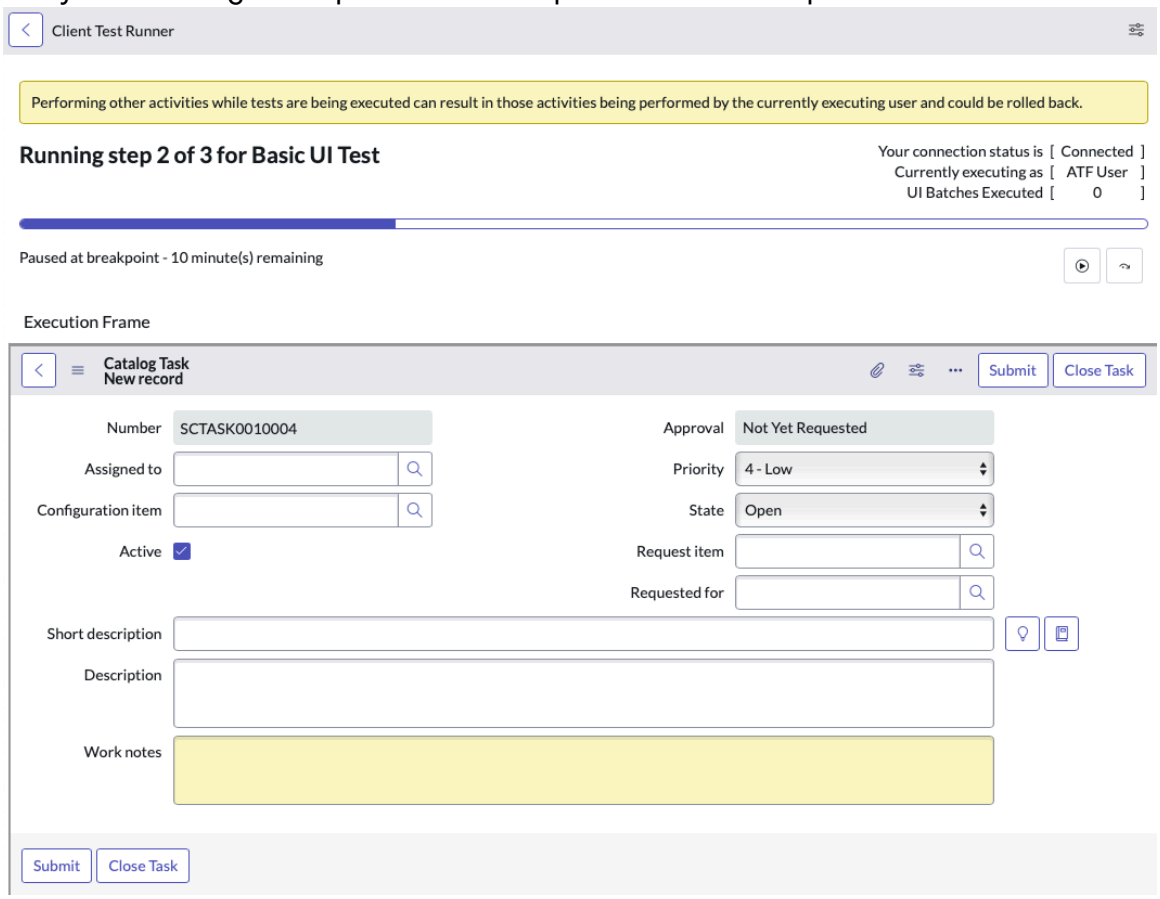
Note:
You can set multiple breakpoints for a test but can have only 1 breakpoint every test step.

6. **Optional:** Click the Breakpoint related list to show all the test steps within a test that have breakpoints.
7. Click **Debug Test** to run the test with breakpoints.
   The Debug Test modal displays.



- Safari – the browser used to run the client-side steps of the selected test
- Pause before rollback – Option to pause the test just before rollback happens after the completion of the test

8. Analyze and debug the steps at which breakpoints have been implemented.



Note:
Every breakpoint causes the running of the test to pause for 10 minutes. You can debug the test step within the allocated 10 minutes and then the test starts running again until it reaches the next breakpoint.

The following options display only when the test is paused for a breakpoint:

- Continue: Test execution continues until the next breakpoint.
- Step over: Test pauses at every step. If you don't want to pause in the current step, select the Step over option to jump to the next step.

View test results and automated test results

View test results from completed test and test suite runs. Carefully consider the results of automated test runs and perform any corrective actions required to resolve any revealed issues.

Before you begin
Role required: none

About this task
Test and test suite results show how long it took the system to execute a test and which steps failed. They can include screenshots of form steps. You can also view reports comparing different runs of the same test suites.

You have multiple options for navigating to the test results, depending on where you are in the user interface. For example, if the Run Test progress dialog is displayed, you can select **Go to Result**. This procedure enables you to view test results from any location in the user interface.

Procedure

1. Navigate to **Automated Test Framework** > **Test Results**.
2. Click a row to access the results for a specific test.
   The system displays the Test results record.
3. View step results for the selected test.
   a. Click the Step Results related list.
   b. Scroll down and click the row for the step result you want to view.
   The system displays the Step results record.
4. View test logs for this test result.
   a. Click the Test Log related list.
   b. Scroll down and click the row for the test log you want to view.
   The system displays the Test logs record.

View automated test results

When viewing test results, step results or test logs, you can allow client errors as ignored or warning entries in the Allowed Client Errors table. This allows test executions to continue past client errors in future test runs.

View results screenshots from an automated test

If the test has a UI component, the system takes screenshots of the UI. View these screenshots to gain further insight into the test results.

Before you begin

You must have run the test whose results screenshots you want to view.

Note:
For best results with screen shots, leave the browser zoom level set to 100%.

Role required: atf_test_admin or atf_test_designer

Procedure

1. Navigate to **Automated Test Framework** > **Test Results**.
2. Click the row containing the test whose results you want to view.
   The system displays the **Test Results**form.
3. View a screenshot taken during the test by finding the screenshot you want in the attachments list.
   Screenshots are named with the word **screenshot** followed by the timestamp (always in UTC time) for when the system recorded the shot. You can match the screenshot to the test step by comparing the step and screenshot timestamps.

View automated test suite results

View results from an automated test suite.

About this task

Note:
You have multiple options for navigating to the test suite results, depending on where you are in the user interface. For example, if the Run Test progress dialog is displayed, you can click **Go to Result** instead. The procedure described here enables you to view test suite results from any location in the user interface.

Procedure

1. Navigate to **Automated Test Framework** > **Suite Results**.
2. Click the row containing the test whose results you want to view.
   The system displays the Test suite results record.

Related topics

Identify and resolve client errors

Allow client errors from test results

Allow client errors from step results

Allow client errors from the test logs

Identify and resolve client errors

Identify client errors and resolve them in client-side scripts.

Before you begin
Role required: admin

About this task
When client errors occur, the Automated Test Framework fails the test on the step that was executing when the error occurred. Even though client-side scripts can fail silently on JavaScript errors while procedures are executing, the error may still impact data, and the procedure being executed. The Automated Test Framework considers these errors as validation failures.

Procedure

1. Navigate to **All** > **Application** > **Automated Test Framework** > **Tests** and run an Automated Test Framework test that interacts with a form.
2. In the test results for this test, check for a step result with the following summary:

   ```
   This step failed because the client error 'DETAILED ERROR
   MESSAGE' was detected on the page being tested. See failing Test
   Logs. To ignore these errors in the next test run, use ‘Add all
   client errors to warning/ignored list’ links.
   ```

   This step result appears only on a step that interacts with the UI.

3. To identify and resolve these script errors, open the developer tools browser console on the Client Test Runner page.

   Note:
   For information about how to open the browser console, see the following article: http://webmasters.stackexchange.com/questions/8525/how-to-open-the-javascript-console-in-different-browsers

4. If you can see the error, try to identify and troubleshoot the problematic client-side script, which may be on any of the following base system tables:

- ServiceNow Client Script
- UI Action
- UI Macro (HTML script)
- UI Page (HTML script)
- UI Policy
- UI Script
- Tables that extend the preceding base system tables

5. Review the script for errors and once you've fixed them, run your test again.

What to do next

Determine the source of the client error by reviewing the script version history. If you customized a base system script, it's possible that the script has new versions that were skipped during upgrade.

Example client errors

There are several types of common client error.

Client JavaScript errors

When a client script causes an error, the browser console displays an error similar to the following example:

```
*********************************************************
A script has encountered an error in render events
TypeError: Cannot read property 'id' of undefined
Script ends. Continuing happily
*********************************************************
[00:00:00.002] onLoad Modify Comments Label
```

In this example, the client script Modify Comments Label caused the error.

Other client script errors

Any other type of script error reports directly to the browser console with any formatting upon occurrence.

```
TypeError: callbacks(id) is undefined
```

Script resource links by Sys ID

In some cases, the console error provides a link to the script resource file using its Sys ID. Following this link may give context to which script had executed it.

```
Uncaught ReferenceError: myobj is not defined
    at incident.do?sys_id=12345678901234567890123456789012
(anonymous)
 @ incident.do?sys_id=12345678901234567890123456789012  <----
 LINK
```

Script access permissions

While identifying problematic scripts, be sure the script has permission to access data. Check:

- Access control rule permissions for tables and fields.
- Application access permissions if the script accesses applications in a private scope.
- Domain separation permissions if domain separation is configured.

Related topics

Allowed client errors

UI test steps

Test user interfaces by mimicking user actions and interacting with the visible components of a page.

Client test runner dependency

UI test steps require an active client test runner to act directly on the visible components of a page. A tester must manually start one or more client test runners for UI testing. Test designers can schedule selecting an open client test runner from a test suite. See Working with client test runners.

Intelligent wait mechanism

UI test steps have an intelligent wait mechanism triggered by UI changes such as clicking a component or setting a value. The wait mechanism requires the UI change to complete before the next UI test step can proceed. Test designers do not need to manually add wait mechanisms between UI test steps.

Custom UI test steps

Test customized user interfaces such as UI pages and UI macros by retrieving their HTML and JavaScript page components and identifying the test actions they support.

Custom UI test steps require the Automated Test Framework to retrieve and identify the testable components from a target web page.

Note:
Now UI is not supported by the Custom UI test steps.

Testable components

Testable page components consist of standard HTML and JavaScript with these characteristics.

Are set or clicked by user interaction

Testable page components allow users to set a value or click them.

Are accessible from the Document Object Model (DOM)

Testable page components are accessible from the DOM and support JavaScript manipulation of the DOM. Custom UI test steps cannot access page components in the shadow DOM.

Are accessible to JavaScript

Testable page components are accessible to JavaScript. Custom UI test steps cannot access page components that interact directly with the operating system such as file fields or display non-HTML content such as Excel or PDF files.

New browser tabs or windows are not supported by Custom UI test steps.

Are not excluded from custom UI testing

Testable page components are not excluded from custom UI testing. Automated Test Framework excludes page components that are already testable by other test step categories and also excludes page components associated with ServiceNow AI Platform features.

Are accessible to the Page Inspector

Testable page components must return results when viewed from the Page Inspector. Test designers can use the Page Inspector to identify the testable components of a page.

Examples of testable page components include these UI elements.

- Buttons
- Links
- Page text
- UI controls
- UI macros
  - ui_date
  - ui_date_time
  - ui_reference
- UI pages
- Wizards

Examples of untestable page components include these UI elements.

Example untestable page components

Reason untestable	Untestable page components
Are not settable or clickable	Hidden controls
	HTML comments
	HTML layout elements such as div, section, and span.
	HTML script elements
Are inaccessible from DOM	Dashboards
	Images
	Lists
	Reports
	Shadow DOM
Are inaccessible to JavaScript	Excel files
	File fields
	PDF files
Are ServiceNow AI Platform features	Flow Designer
	Studio
	Upgrade Monitor

Example untestable page components (continued)

Reason untestable	Untestable page components
Are testable by other test step categories	Form field labels
	Form field values
	Service Catalog
	Workspaces

Settable page components

A settable component is a UI element that has a dynamic value such as a text input field. Settable components support these test actions and test steps.

Test options for settable components

Page Inspector actions	Custom UI test steps
Set Component Value	Set Component Values (Custom UI)
Get Component Value	Assert Text on Page (Custom UI)
	Component Value Validation (Custom UI)
Is Component Disabled	Component State Validation (Custom UI)

Settable components have a data type that determines what values a Custom UI test step can set. For example, a page component intended to display a reference to a particular record can have a reference data type to only display Sys ID values.

Automated Test Framework allows UI developers to specify a data type to use during custom UI testing. UI developers can assign page components a data type to ensure that a test step sets a valid value. These data types are supported.

- Date
- Date Time
- Reference

See Override component data type for more information.

Clickable page components

A clickable component is a UI element that users can interact with by clicking, such as inputs of type check box or radio. Clickable components support these test actions.

Test options for clickable components

Page Inspector actions	Custom UI test steps
Click On Component	Click Component (Custom UI)
Get Component Value	Assert Text on Page (Custom UI)
	Component Value Validation (Custom UI)
Is Component Disabled	Component State Validation (Custom UI)

Clickable components do not have a data type since they do not have dynamic values.

Retrieved page components

Automated Test Framework stores a list of the retrieved page components for each custom UI page you test. Custom UI test steps display the list of retrieved components from the **Component** and **Component values** fields.

By default, the list of page components is static and is only updated when Test designers manually click **Retrieve Components**. Administrators can enable the system property *sn_atf.page_data_capture.enabled* to refresh the list of page components every time a Custom UI test step is run. Enabling this property during test design ensures that your test designers always have access to the most current list of page components. Disabling this property after test design is complete allows your tests to run faster because test steps can use the previously retrieved list of page components.

The ServiceNow AI Platform treats the list of retrieved page components as data and does not include them in update sets or applications files. When transferring tests from one instance to another, test designers must manually retrieve page components again.

Design considerations

Follow these design considerations when testing custom UI pages and page components.

Use the page inspector to identify testable page components

The page inspector determines which page components are available for custom UI testing. Page components that are unavailable to the page inspector are unavailable to custom UI testing.

Navigate to the custom UI you want to test

Use existing test steps to navigate to the target custom UI. For example, to test a Knowledge Base article, use the existing test steps to navigate to a module or to open an existing record. Most custom UI testing requires using existing test step categories as part of the test.

Use the component area to identify page components

The component area describes the HTML layout element containing the component such as a `<div>` or `<section>` element. The area helps test designers distinguish between components by providing the location in the page layout.

Test your custom UI rather than ServiceNow AI Platform UI

The Automated Test Framework prevents custom UI testing of ServiceNow AI Platform features. For example, you cannot test dashboards or graphical designers. Instead, build tests to validate your custom UI pages and elements since you have direct control over these user interfaces.

Use HTML attributes to override page component testing properties

Change the testing properties of a particular page component using HTML attributes that are specific to Automated Test Framework. See Override component test actions.

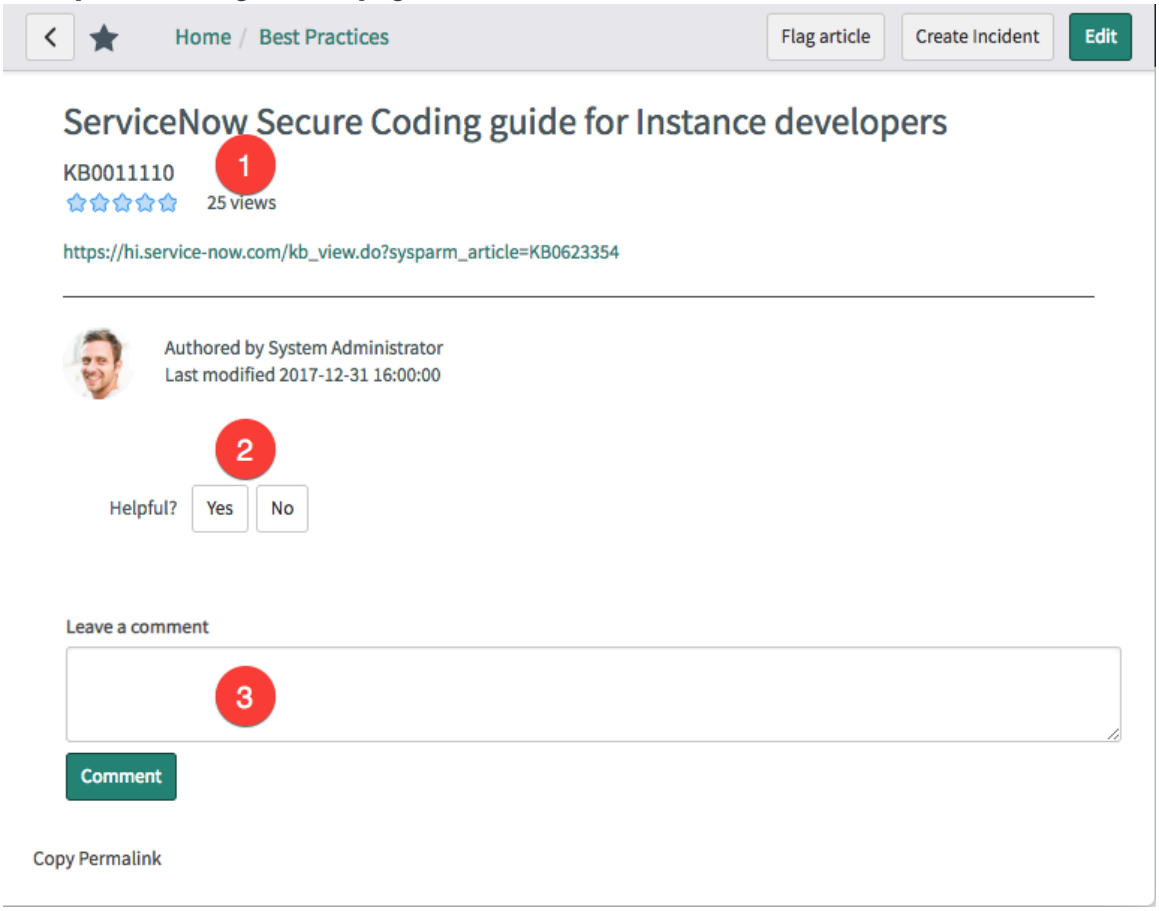
Retrieve page components again when you move tests to another instance

Custom UI test steps do not store UI components as metadata. Testers must manually retrieve page components again when moving tests between instances.

Example custom UI testing

You can use the list of retrieved components to design custom UI test steps. For example, suppose that you want to test reviewing and commenting on a Knowledge Base article. A Knowledge Base article contains several page components that require custom UI steps to test.

Example Knowledge article page



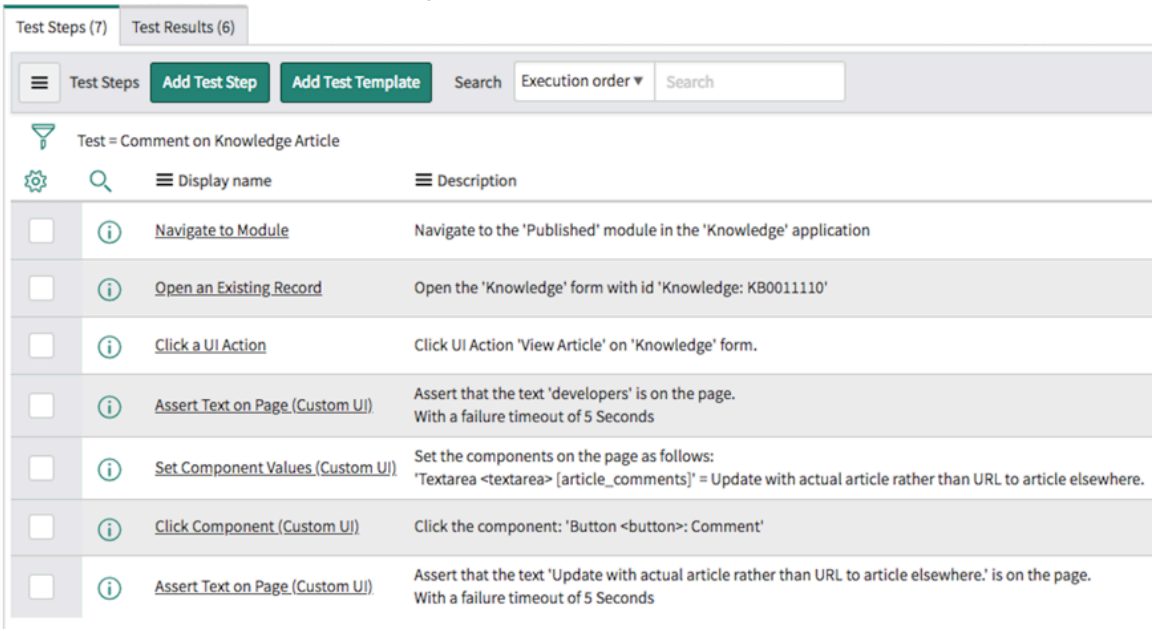
For example, these page components require custom UI test steps.

1. The number of article views.
2. The buttons to mark the article as **Helpful**.
3. The text area to **Leave a comment**.

These steps demonstrate custom UI testing on a Knowledge Base article. The example test consists of these existing and custom UI test steps.

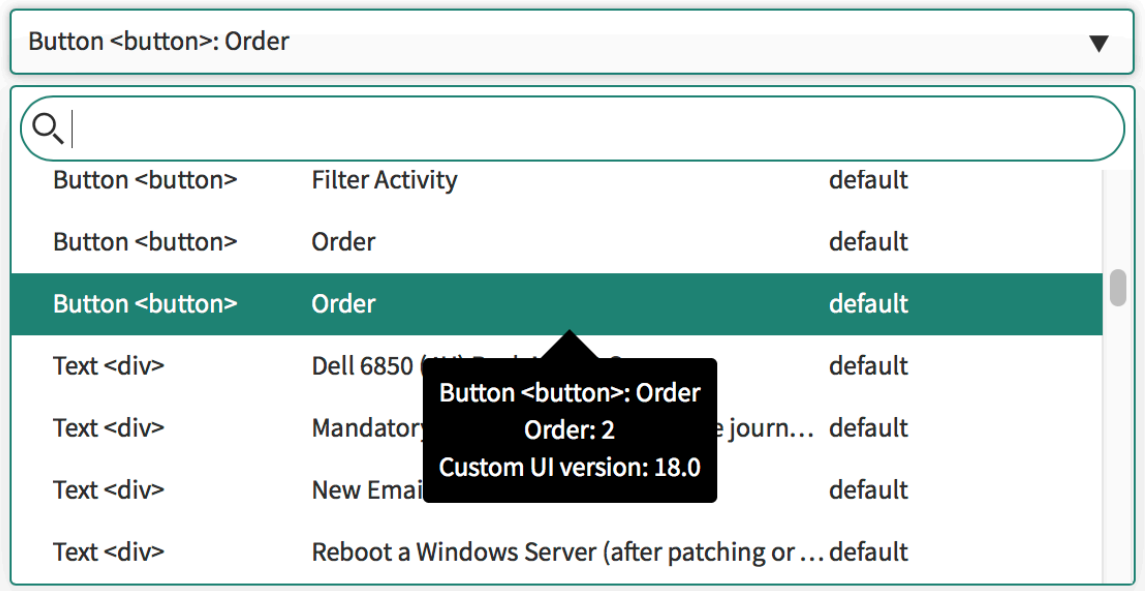
1. **Navigate to Module**. Navigate to the 'Published' module in the 'Knowledge' application.
2. **Open an Existing Record**. Open the 'Knowledge' form with id 'Knowledge: KB0011110'.
3. **Click a UI Action**. Click UI Action 'View Article' on 'Knowledge' form.
4. **Assert Text on Page (Custom UI)**. Assert that the text 'developers' is on the page.
5. **Set Component Values (Custom UI)**. Set the components on the page as follows: 'Textarea <textarea> [article_comments]' = Update with actual article rather than URL to article elsewhere.
6. **Click Component (Custom UI)**. Click the component: 'Button <button>: Comment'.
7. **Assert Text on Page (Custom UI)**. Assert that the text 'Update with actual article rather than URL to article elsewhere.' is on the page.

Example test steps for a knowledge base article test



Custom UI component version and order

When you select a component in any of the custom UI test steps, the Custom UI version might show up. If there are multiple duplicate components, the order of the components show up.



Note:

- The Custom UI version shows up only if there are at least two different components with different Custom UI versions.
- The Order shows up only if there are duplicate components in the component drop-down menu. You can disambiguate them according to the displayed order.
- Both Custom UI version and Order show up if there are multiple duplicate components from different versions.

Identifying components

Implement an alternative way to identify your component by using the sn-atf-id attribute. This is useful if the name or id attribute of your component is dynamic and changes every time a test runs. Add the sn-atf-id attribute with a consistent value to allow ATF identify your component when running a test. It also allows you to identify your component when building a test. For example, in a button component

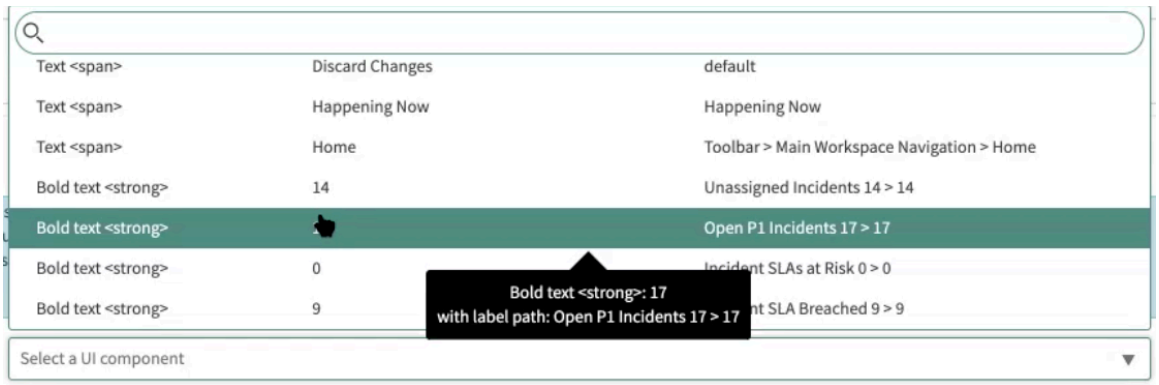
```
<button sn-atf-id="consistentValue">Test</button>
```

Note:
Starting with the Rome release, if you have exactly one component on the page that has sn-atf-id attribute, ATF finds that component irrespective of any other attributes on that component.

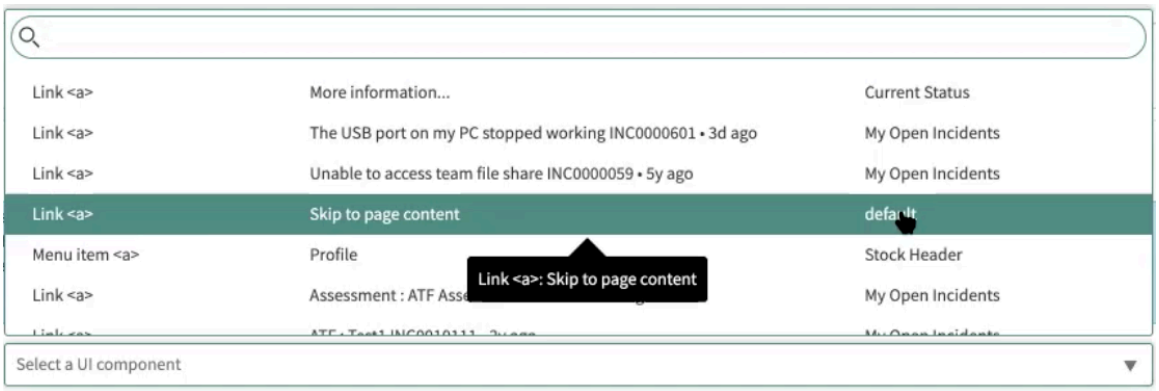
Improve ATF component identification

Identify your component using the label path included in the **Page area** column. Starting with the Rome release, the `sn_atf.element.use_label_path` property has been set to true by default.

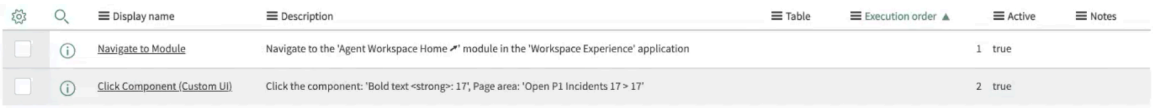
If a component has the `sn-atf-area` attribute, the **Page area** column displays the `sn-atf-area` value. If the `sn-atf-area` attribute is not present, the label path for that component is shown in the Page area column.



Note:
If you have multiple, identically named **Label** values, the label path helps you identify the correct component. If a component doesn't have an `sn-atf-area` attribute or a label path, the value is displayed as default.



When you select the required component from the list and click **Submit**, the description of the test step also gets updated with more details.

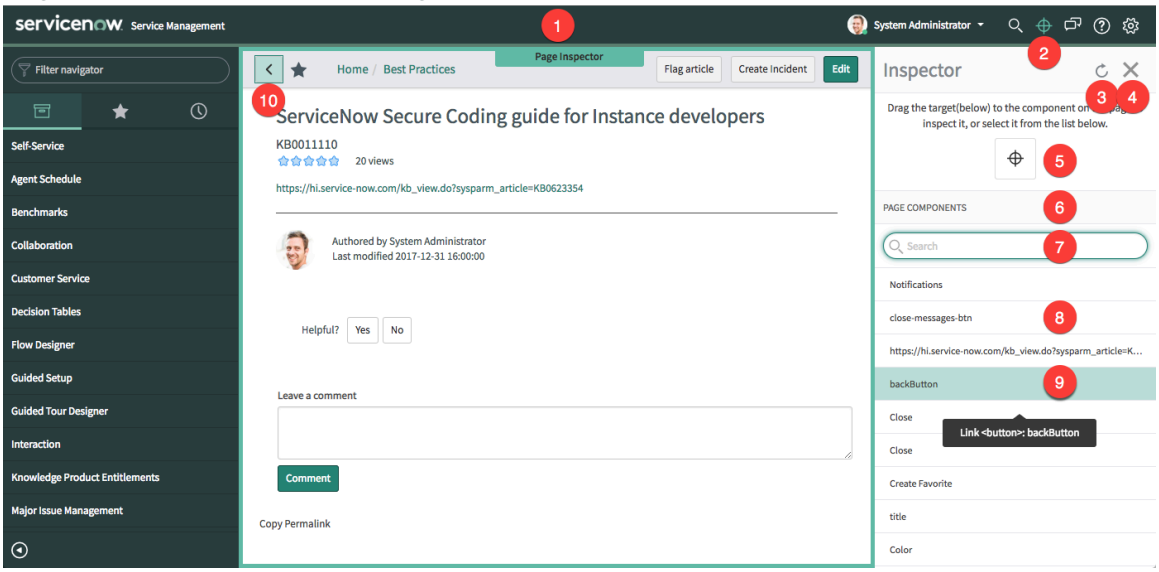


Page Inspector

Identify the HTML and JavaScript page components in your user interfaces that are available for custom UI testing. Enable automated testing by ensuring that your user interfaces only contain testable page components.

The Page Inspector is a developer setting that opens a new pane beside any currently displayed ServiceNow AI Platform page.

Page Inspector view of Knowledge Base article KB0011110



The Page Inspector provides these features.

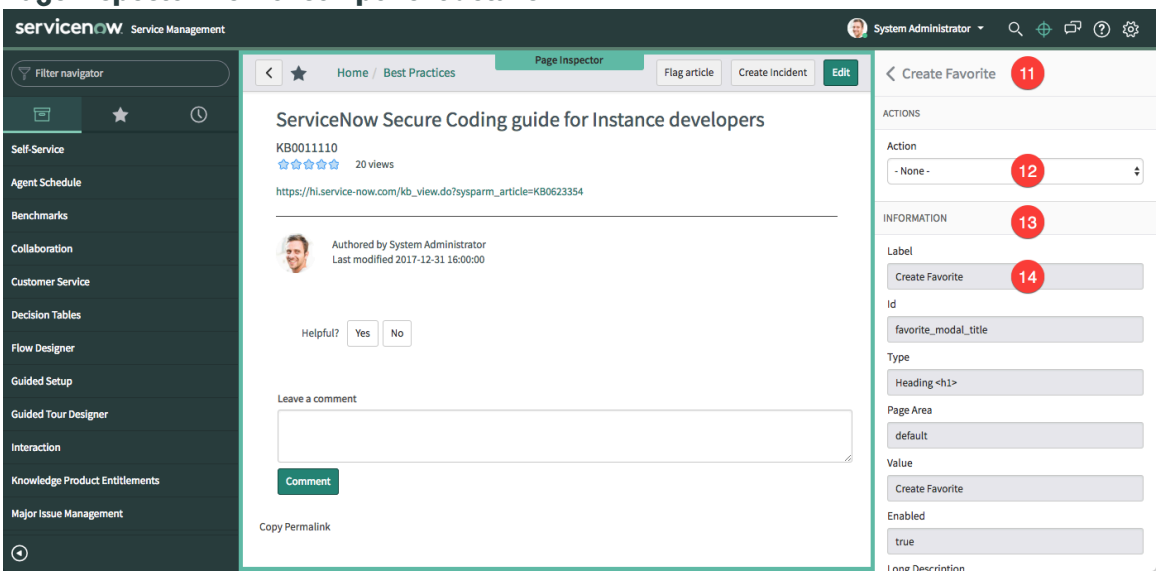
1. A highlighted frame to identify the currently inspected page.
2. A banner icon to display or hide the Inspector pane.
3. A button to refresh the list of page components.
4. A button to hide the Inspector pane.
5. An inspector button to identify specific components on a page.
6. A list of page components available for custom UI testing.
7. A page component search filter.
8. A row to click to see more information about a page component.
9. A highlighted row and tooltip to preview information about the currently inspected component.
10. A highlighted page component to identify the currently inspected component on the page.
11. A component label and back button to return to the list of page components.
12. A list of actions to take on the current page component.
13. A list of attribute information for the current page component.

14. An attribute name and value pair for a page component.

Note:
You can use the Label Path field to show the hierarchical page context around an element while inspecting a component on a page. If there are many "ancestor" label paths of an element, it can display only three. Each label path element is separated by a >. It can be used to differentiate between two similar looking components.

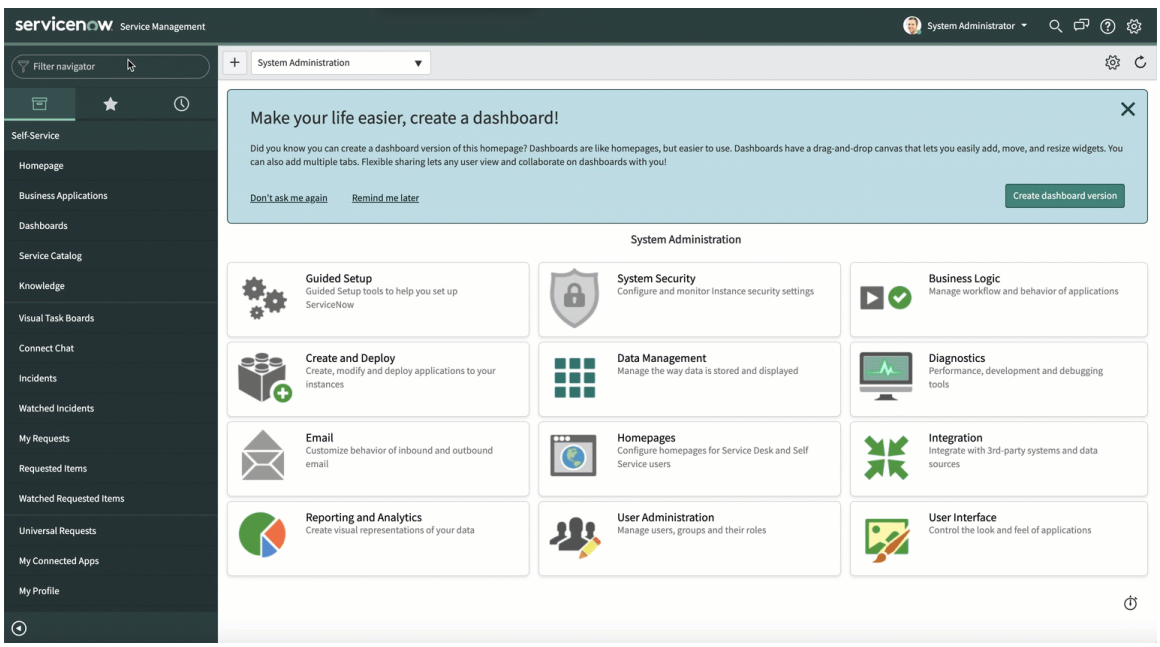
Note:
UI buttons with icons are now visible in the page inspector.

Page Inspector view of component details



Page inspector launcher

The page inspector launcher helps you select and launch a specific page within the page inspector. See Inspect different page types for more information.



Testable page components

The Page Inspector retrieves the list of testable page components when you first load a page. Testable components consist of standard HTML and JavaScript that are accessible to the Automated Test Framework. Test designers can use these components as part of custom UI testing.

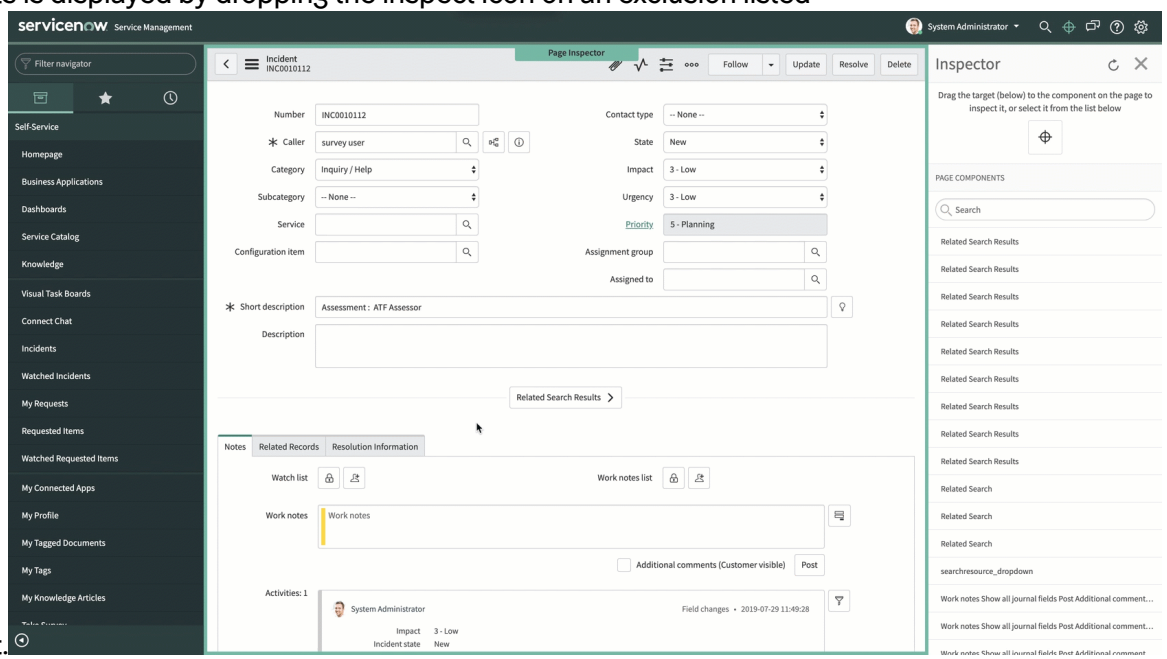
Untestable page components

The Page Inspector identifies these types of untestable page components.

Exclusion listed

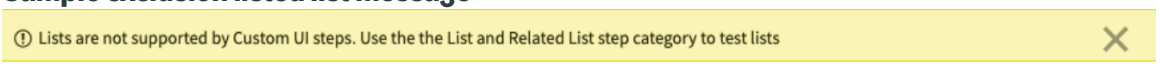
Exclusion listed page components can't be tested using any **Custom UI** test steps. Exclusion listed page components typically include specialized ServiceNow AI Platform user interfaces and components already testable by other means. Test designers can't create custom UI tests for exclusion listed page components. To test these components, they must use another supported test category such as Forms or Service Catalog.

In the Page Inspector, the exclusion listed interfaces are indicated by a grey background color when the inspect icon is dragged over them. A detailed message about the step category that needs to be used to test these components is displayed by dropping the inspect icon on an exclusion listed component.



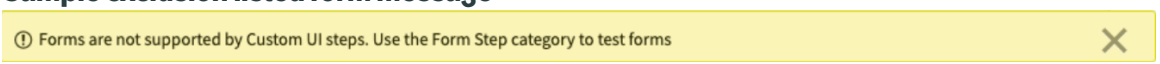
- Lists can't be tested using custom UI test steps. Use List and Related List test step category to test lists.

Sample exclusion listed list message



- Forms can't be tested using custom UI test steps. To test forms, use Form category test steps.

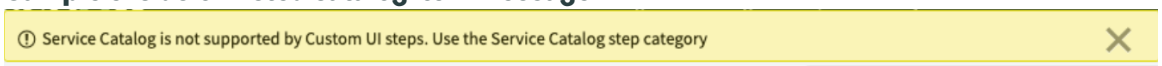
Sample exclusion listed form message



Note:
The UI formatters within forms can be accessed and tested using custom UI test steps. See Create a custom UI test for more information.

- Service Catalog items can't be tested using custom UI test steps. To test catalog items, use Service Catalog category test steps.

  Sample exclusion listed catalog item message

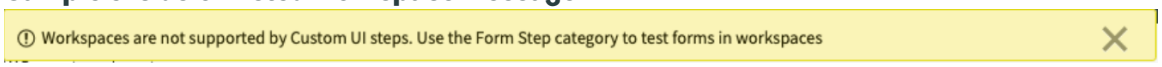
  


- Certain components are excluded from custom UI pages and are forbidden from being tested.

  Sample exclusion listed component message

  
- Workspaces can't be tested using custom UI test steps. To test forms in an available workspace, use Form category test steps.

  Sample exclusion listed workspace message

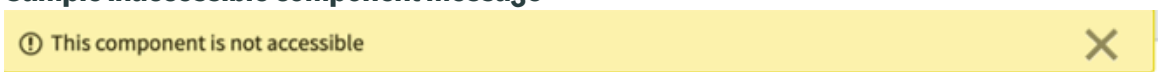
  


Inaccessible

Inaccessible page components are elements that Automated Test Framework either cannot identify or does not have permission to test because of some configuration issue. Inaccessible page components typically include third-party JavaScript libraries or elements with a Shadow DOM. Test designers cannot create custom UI tests for inaccessible page components, but may be able to redesign the page to use components accessible to Automated Test Framework.

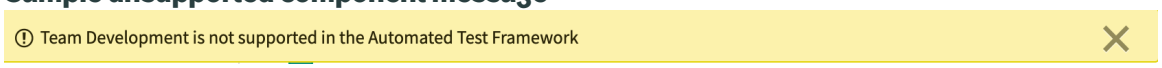
- Certain components are not accessible in the Automated Test Framework

  Sample inaccessible component message

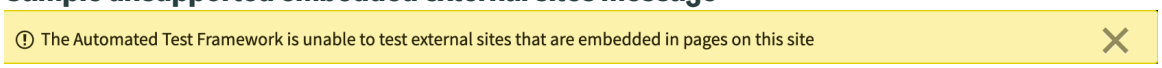
- Team development is not supported in the Automated Test Framework

  Sample unsupported component message

- Testing external sites that are embedded in platform pages is not supported in the Automated Test Framework

  Sample unsupported embedded external sites message

Inspect different page types

Inspect and troubleshoot the functionality of different page types like **UI Pages**, **Service Portal**, **Standard UI**, and **Custom URL** using the Page Inspector.

Before you begin
Role required: admin, atf_test_designer, atf_test_admin

Procedure

1. Navigate to **All** > **Page Inspector** > **Manual Page Inspector**.
2. Select the **Page Type** you want to inspect.

Inputs

Field	Description
UI Pages	Existing UI pages. Select a starting page from the available list.
Standard UI	Standard platform forms, lists, and some UI pages. Select a form or a list or a UI page in the **Starting Page** field. **Note:** The optional **Record** field shows up only if you select a form in the **Starting Page** field.
Service Portal	Any available portal in the instance. Select an available portal and a starting page to be inspected. **Note:** Portal field shows up only if you select Service Portal as the **Page Type**.
Custom	Custom Platform URL to be inspected. **Note:** Don't copy-paste the complete URL onto the **Starting Page URL** field. For example, include only `/home.do` as the input if you want to inspect `https://instance.service-now.com/home.do`

3. Click **Inspect**.

Enable and use the page inspector

Enable a developer setting to inspect UI pages that open within the platform. Use the Manual Page Inspector to inspect pages that open in a new tab, such as Service Portal pages.

Before you begin
Role required: admin

About this task
Identify the HTML and JavaScript page components in your user interfaces that are available for custom UI testing. Enable automated testing by ensuring that your user interfaces only contain testable page components.

Procedure

1. Enable the Page Inspector depending on the type of custom UI page you need to inspect.
   Note that some custom UI pages open in a new tab and can be inspected only manually.

2. Select a component to inspect.
   - Drag the inspect icon ( ) from the Page Inspector pane to a component on the page.
   - Select an available component from the Page Inspector pane.

   The Page Inspector retrieves the list of testable page components when you first load a page. Testable components consist of standard HTML and JavaScript that are accessible to the Automated Test Framework. Test designers can use these components as part of custom UI testing.
3. View component information and perform actions available in the **Action** field.
   Performing available actions helps you manually confirm which test steps are available to a component. For example, when you select **Click On Component**, the Page Inspector selects the component and displays the resulting page.

What to do next

Create a custom UI test

Create a custom UI test

Test components in custom UI pages.

Before you begin

- Use the Page Inspector to identify testable custom UI components. See Enable and use the page inspector.
- Role required: admin

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Click **New**.
3. Enter a name and description for your test.
4. Click **Save**.
5. In the Test Steps related list, click **Add Test Step**.
6. Add test steps to navigate to the target custom UI page.

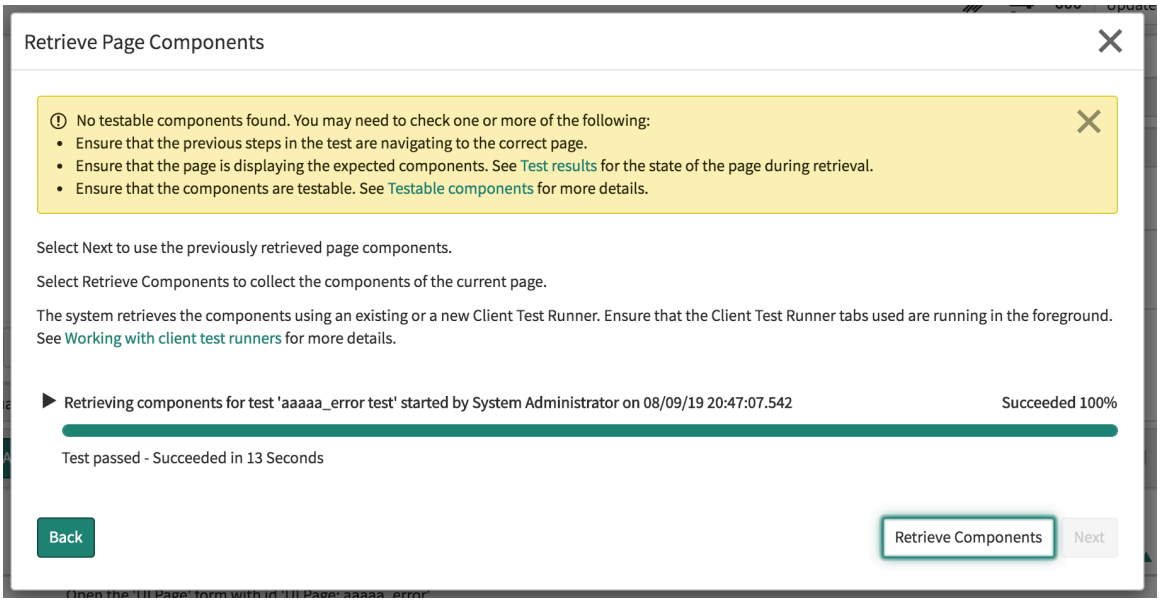
   Example
   Use the **Navigate to Module** step to open a page that has an application navigator module.
   Use the **Open Service Portal Page** step to open a portal page.
   To open a UI page, use these test steps:

   a. **Open an Existing Record**: Open the record for the page.

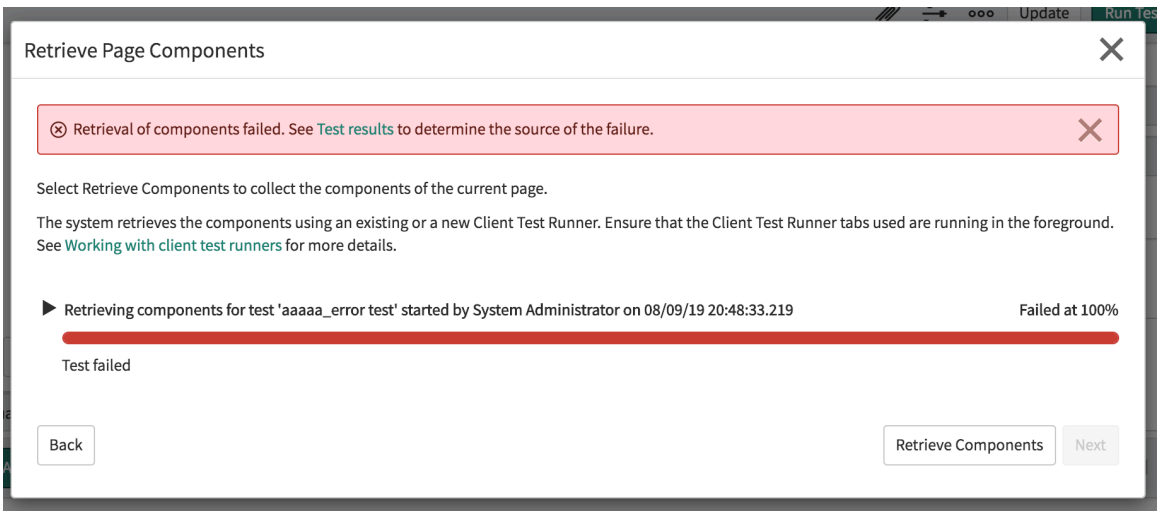
   b. **Click UI Action**: Click the **Try It** UI action to open the page.
7. Add test steps from the Custom UI category to validate the behavior of custom UI components.
   For a list of available Custom UI test steps, see Custom UI category.
8. Retrieve UI components when adding a test step.

Identify the testable page components on a custom UI page by retrieving a list of UI components for test steps. You can collect the components of the current page by selecting **Retrieve Components**.

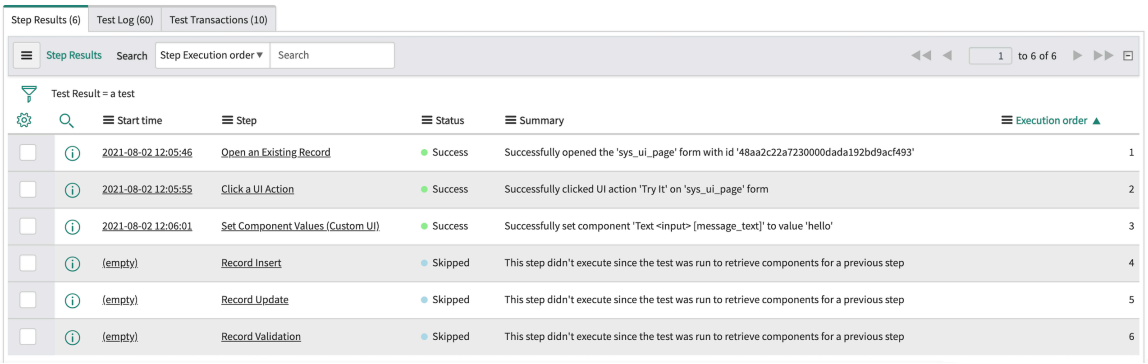
The system retrieves the components using an existing or a new client test runner. Ensure that the client test runner tabs used in the retrieval process are running in the foreground. For tests that don't yield any components after selecting **Retrieve Components**, the following warning message is displayed and the **Next** button is disabled.



If you have already retrieved a list of page components, click **Next** to use the previously retrieved list. You can also click **Retrieve Components** to rerun the current steps and refresh the list of testable page components. If the test fails while retrieving components, the following warning notification is displayed. You can review the test results by clicking the link in the notification.



Note:
If you need to update a step in a test, click **Retrieve Components** for that step and the test runs only up to that particular step. The steps beyond the selected step don't run. The test passes if all the updated steps pass without failure.



Automated Test Framework stores the list of page components and displays the list in the **Component values** or **Component** field on the test step form. The field displays this information about each component:

Field	Description
Type	HTML element description and tag. For example, `Text<input>`.
Label	HTML component label.
Value	Value of the component. For example, if the component is a search input, the value might be **Search**.
Page area	HTML layout element that contains the component such as a `<div>` or `<section>` element.

If you create a parameterized test that includes Custom UI test steps, the system only uses the first data set to retrieve components.

What to do next
Consider adding tests to a test suite. For more information, see Building and running automated test suites.

Override component test actions

Change the testing properties of a particular page component using HTML attributes that are specific to Automated Test Framework.

Before you begin
Role required: admin

About this task
When Automated Test Framework retrieves a component, it determines which interactions it supports, such as whether it is a settable or clickable component. If the component is settable, Automated Test Framework determines the field type that can be set. If Automated Test Framework incorrectly determines your custom component's actions or field types, or your component contains multiple DOM elements that should be treated as one entity, explicitly set them using HTML attributes that are specific to Automated Test Framework.

Using sn-atf-clickable and sn-atf-settable attributes

Use `sn-atf-clickable` and `sn-atf-settable` attributes to specify that an element and its child elements should be treated as a custom clickable or custom settable component.

Before you begin

Role required: admin

Procedure

1. Open the custom UI page you would like to test.
2. Add the `sn-atf-clickable` or `sn-atf-settable` attribute to the element being tested.

Example

```
<div sn-atf-clickable="true" sn-atf-disabled
 id="customClickable">
 <button id="customButton">Click me</button>
</div>
```

```
<div sn-atf-settable="true" id="customSettable"
 sn-atf-component-value="A default value">
 <input id="customInput" value="A default value"></input>
</div>
```

Note:
You can use either `sn-atf-clickable` or `sn-atf-settable` attribute to specify if an element should be treated as a custom clickable or custom settable component. You can't use both attributes on the same element.

3. Use either the `sn-atf-clickable` or `sn-atf-settable` attribute.

   - `sn-atf-clickable`: If you added the `sn-atf-clickable` attribute, ATF clicks the component by sending an `sn-atf-click` event to the DOM element with the `sn-atf-clickable` attribute. You should add an event listener (for example, using `addEventListener`) to this DOM element, and implement your custom click logic for the component. You can interact with a custom clickable component using Click Component test step.

     Clickable component attributes

Attribute name	Description
sn-atf-disabled	The presence of this optional attribute (regardless of its value) tells ATF that this component is disabled **Note:** If this attribute is missing, ATF considers that this component is enabled by default.
sn-atf-component-value	A string or JSON object that tells ATF the current value of this component

   - `sn-atf-settable`: If you added the `sn-atf-settable` attribute, ATF sets the component value by sending an `sn-atf-setvalue` event to the DOM element with the `sn-atf-settable` attribute. You should add an event listener (for example,

using `addEventListener`) to this DOM element, and implement your custom set value logic for the component. The value that needs to be set can be accessed with `event.detail.newvalue`. The `event` argument is passed to your event handler. You can interact with a custom settable component using Set Component Values test step.

Settable component attributes

Attribute name	Description
sn-atf-disabled	The presence of this optional attribute (regardless of its value) tells ATF that this component is disabled. **Note:** If this attribute is missing, ATF considers that this component is enabled by default.
sn-atf-component-value	A string or JSON object that tells ATF the current value of this component.
sn-atf-data-type	Optional type of field to present to user when building a step. It defaults to string. For example, `glide_date_time`, reference, boolean, etc.
sn-atf-data-type-params	JSON object with more data type details.

Example:

```
//A custom clickable component

<div sn-atf-clickable="true" sn-atf-disabled
 id="customClickable">
 <button id="customButton">Click me</button>
</div>
<script>
 var customClickableDiv =
 document.getElementById("customClickable");
 customClickableDiv.addEventListener('sn-atf-click', function()
 {
  document.getElementById('customButton').click();
 });
</script>
```

```
//A custom settable component

<div sn-atf-settable="true" id="customSettable"
 sn-atf-component-value="A default value">
 <input id="customInput" value="A default value"></input>
</div>
<script>
 var customSettableDiv =
 document.getElementById("customSettable");
 customSettableDiv.addEventListener('sn-atf-setvalue',
 function(event) {
  var newValue = event.detail.newValue;
  document.getElementById("customInput").value = newValue;
```

```
 });
</script>
```

Using sn-atf-class attribute

Use the `sn-atf-class` attribute to specify the JavaScript object to use when testing a custom clickable or settable component. Write a custom JavaScript object to specify the test actions available for a custom component.

Before you begin

Role required: admin

About this task

Test designers can manually specify the test actions available for a custom component by writing a custom JavaScript object and assigning the component a `sn-atf-class` attribute. Set the value of the attribute to the name of the JavaScript object containing the component test actions. Testable custom components must be either clickable or settable, and this classification determines the functions and properties your JavaScript object requires. See Custom UI test steps for testable page component requirements.

Procedure

1. Open the custom UI page you would like to test.
2. Add the `sn-atf-class` attribute to the element being tested and set the value to the name of the JavaScript object embedded in the page that handles getValue(), setValue(), click(), or isDisabled() functions.

   Example

   ```
   <div sn-atf-class="MyClickableComponent">
       <label
    for="a_clickable_checkbox">MyClickableComponent</label>
       <input type="checkbox" id="a_clickable_checkbox"
    checked="true"/>
   </div>
   ```

3. Create the JavaScript object specified in the `sn-atf-class` attribute and add the functions and attribute needed to identify your custom page component as either a clickable or settable page component.

   Clickable component functions

Function name	Description
initialize()	Gets the initial values of the component. Enter: `$super(element, area)`
click()	Selects the component. Returns a JSON object with these properties: `success`: true if the component can be clicked. **Note:** Triggers the UI test step intelligent wait mechanism.
getValue()	Gets the value of the element. Returns a JSON object with these properties:

Function name	Description
	○ `success`: true if the value is retrieved. ○ `result`: the value of the component.
`isDisabled()`	Whether the component is disabled. Returns a JSON object with these properties: ○ `success`: true if the component is disabled. ○ `result`: true if the component is disabled.

Settable component functions

Function name	Description
`initialize()`	Gets the initial values of the component. Enter: `$super(element, area)`
`setValue(newValue)`	Sets the value of the component. See the second example below. Returns a JSON object with these properties: `success`: true if the value is set. **Note:** Triggers the UI test step intelligent wait mechanism.
`getValue()`	Gets the value of the element. Returns a JSON object with these properties: ○ `success`: true if the value is retrieved. ○ `result`: the value of the component.
`isDisabled()`	Whether the component is disabled. Returns a JSON object with these properties: ○ `success`: true if the component is disabled. ○ `result`: true if the component is disabled.

Settable component attribute

Attribute name	Description
`isSettable: true`	Identifies the component as a settable page component.

4. When creating your custom component in Jelly, add `<g2:atf_only>` tags around the JavaScript object specified in the `sn-atf-class` attribute.
These tags ensure the system only runs the JavaScript object during automated testing.

Example:

```
//A custom clickable component

<form>
```

```
    <div sn-atf-class="MyClickableComponent">
        <label
 for="a_clickable_checkbox">MyClickableComponent</label>
        <input type="checkbox" id="a_clickable_checkbox"
 checked="true"/>
    </div>
</form>
<script>
var MyClickableComponent = {

    // The constructor must have this signature, but you can
 perform additional setup after the $super(element, area) call
    initialize: function($super, element, area) {
        $super(element, area);
    },

    click: function() {
        document.getElementById('a_clickable_checkbox').click();
        return {success: true};
    },

    // The function returns an object with a result attribute of
 type String
    getValue: function() {
        var isChecked =
 document.getElementById('a_clickable_checkbox').checked ?
 "true" : "false";
        return {success: true, result: isChecked};
    },

    // The function returns an object with a result attribute of
 type Boolean
    isDisabled: function() {
        if
 (document.getElementById('a_clickable_checkbox').disabled)
            return {success: true, result: true};

        return {success: true, result: false};
    },

};
</script>
```

```
//A custom settable component

<form>
    <div sn-atf-class="MySettableComponent">
        <label
 for="a_settable_checkbox">MySettableComponent</label>
        <input type="checkbox" id="a_settable_checkbox"
 checked="true"/>
    </div>
</form>
<script>
var MySettableComponent = {

    // This attribute is required for settable components
```

```
    isSettable: true,

    // The constructor must have this signature, but you can
 perform additional setup after the $super(element, area) call
    initialize: function($super, element, area) {
        $super(element, area);
    },

    // The value parameter is a string
    setValue: function(value) {
        document.getElementById('a_settable_checkbox').checked =
 (value == "true");
        return {success: true};
    },

    // The function returns an object with a result attribute of
 type String
    getValue: function() {
        var isChecked =
 document.getElementById('a_settable_checkbox').checked ?
 "true" : "false";
        return {success: true, result: isChecked};
    },

    // The function returns an object with a result attribute of
 type Boolean
    isDisabled: function() {
        if
 (document.getElementById('a_settable_checkbox').disabled)
            return {success: true, result: true};

        return {success: true, result: false};
    },

};
</script>
```

Reference and record picker

Use custom UI steps to manipulate the values of the `sn-reference-picker` and `sn-record-picker` angular directives. The value on a reference picker returns the `sys_id` of the chosen record. The value on a record picker returns the value field chosen for that record picker. Both elements can be set by selecting a record to set as their value.

Override component data type

Use the `sn-atf-data-type` and `sn-atf-data-type-params` attributes to override the type of field displayed in a Set Component Value test step.

Before you begin

Role required: admin

About this task

Settable components have a data type that determines what values a Custom UI test step can set. For example, a page component intended to display a reference to a particular record can have a reference data type to only display Sys ID values.

Procedure

1. Open the custom UI page you would like to test.
2. Add the `sn-atf-data-type` attribute to the settable component and set the value to the field type you would like displayed in the Set Component Value test step.

   This attribute contains a string of the testable data type. The available values include those listed in the following table.

Attribute value	Description
glide_date	Contains a string specifying a particular day.
glide_date_time	Contains a string specifying a particular day and time of day.
reference	Contains a Sys ID to a related record. This data type requires specifying additional information in the `sn-atf-data-type-params` attribute.

3. Add the `sn-atf-data-type-params` attribute to provide additional information when the value of `sn-atf-data-type` is `reference`.

   This attribute contains a string of JSON formatted key-value pairs. Available key-value pairs include those listed in the following table.

Key	Value
reference	Name of the table that contains the records you want the reference field to display. For example, add `"reference":"incident"` to display records from the Incident table.
reference_qual	Filter to apply to the query. For example, add `"reference_qual":"active=true"` to display only active Incident records. See Reference qualifiers

Example:

```
<input id="someTextField" value="someSysId"
 sn-atf-data-type="reference"
 sn-atf-data-type-params='{"reference":"incident","reference_qua
l":"active=true"}'/>
```

Select2 functionalities in ATF

Use the Select2 component to search and select your option from a drop-down menu easily.

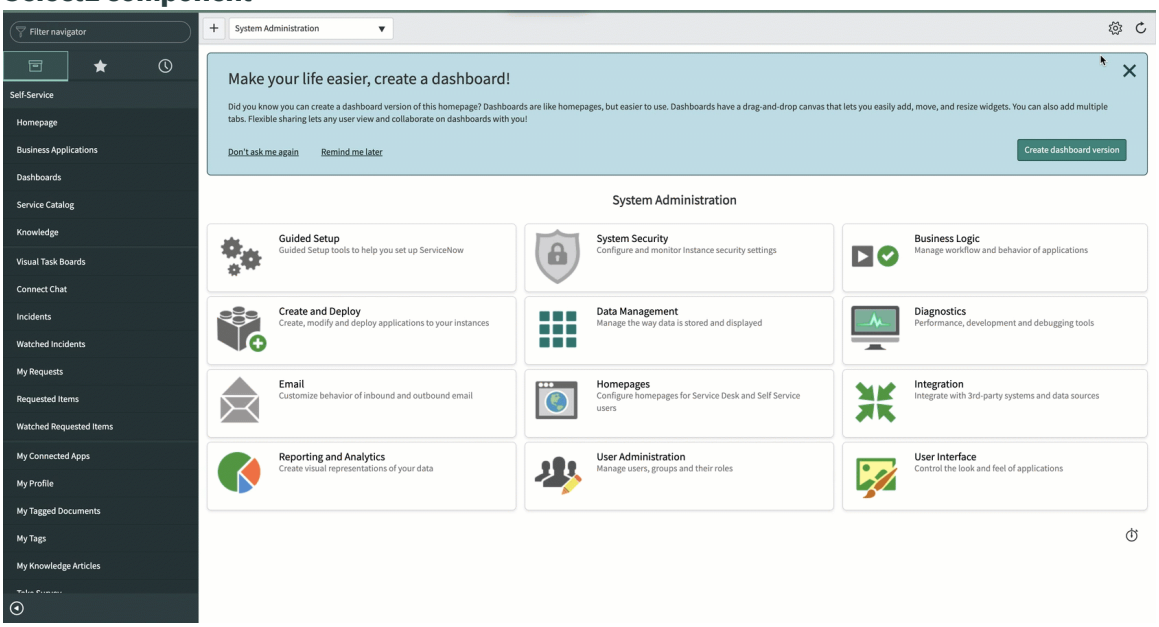
You can set the value of select2 in a test. The test then searches for the value in the search bar of Select2. The first valid result in the component drop-down gets selected.

Drag and drop the page inspector on the required drop-down menu. The right panel for the selected component opens. You can specify the text you want to search in the set component value step within the page inspector.

Select the **Set Component Value** option under **Action** to search for a component. Type in the text in the right panel and click **Submit**. This enables the code to open the select2 to search for that component and pick the first option that shows up.

Note:
If multiple, similarly named component options show up on searching a term, only the first option is selected.

Select2 component



Limitations of the select2 support

- Only certain versions (3.5.1-3.5.4 and 4.0.0-4.0.13) of the select2 library are supported.
- The select2 support depends on the jquery library. So, if you try to set a value of select2 and the name of the jquery library is changed, it causes the test to fail.
- Searching through Select2 won't work when there is no search bar.

Design considerations

Search and select your options efficiently with the following design considerations:

- It is recommended to use uniquely searchable test data
- Wait for the current element to be set before proceeding to set the next element while setting the value of Select2 via the Set Component Values (Custom UI) test step
- Prevent failing of tests by avoiding jquery library name change
- Select2 Adapter and Decorator features are not supported

Browser recommendations for Automated Test Framework

Configure client test runner browsers to run automated tests and avoid performance degradations.

Periodic browser restarts

These browsers have memory-management limitations that make it necessary to occasionally close and restart the browser when running the client test runner.

- Internet Explorer
- Edge
- Older versions of Firefox

How often you should close the browser depends on the memory allocation in the browser application.

Browser CPU throttling

Some browsers throttle CPU usage for windows that are out of focus. Follow these guidelines to avoid CPU throttling issues.

- Run each client test runner in its own browser window.
- Ensure that the client test runner browser window is always partially visible on the screen.
- Ensure that the system screen is not locked or shut off.

Browser zoom level

Client test runners take screen shots as they run tests. For best results with screen shots, leave the browser zoom level set to 100%.

OS X CPU throttling

On OS X with the client test runner on Chrome or Safari: If the screen is locked or the client test runner tab is not shown, when the system attempts to run the test suite, tests run significantly slower and may time out. For best performance, run client test runners for scheduled suites in a virtual machine (VM) environment in which the screen does not become locked or disabled.

Rollback in browser sessions

The session cookies roll back all the changes made during a test. When a test is running, everything performed in that session is recorded for rollback. Don't modify your instance when a test is running in the same browser session. For example, if you modify records while a test is running in the same session, the changes are rolled back after the test completes. If you navigate around in other tabs in the same session, your work may be rolled back and interfere with tests that rely on implicit navigation.

Parallel testing

Follow these guidelines to avoid issues when running multiple tests in parallel.

Run each client test runner in an incognito or private window

Because parallel tests roll back all changes tied to the same browser session, it's possible for legitimate changes made in another browser tab to be rolled back during parallel testing. To prevent unwanted rollback of changes, always run client test runners in their own browser session. Opening client test runners in an incognito or private window ensures that they always have their own browser session.

Close client test runner windows when testing is complete

To prevent unwanted rollback of changes, always close client test runners after testing is complete. Closing the browser window ensures that test rollback doesn't revert any legitimate changes made in another browser tab.

Working with client test runners

If an automated test includes steps that involve a form or any other user-interface (UI) element, it runs those steps in a browser tab or window called a test runner or client test runner.

The Automated Test Framework supports two types of client test runners: Client Test Runners for manually started tests and Scheduled Client Test Runners for tests started by a schedule.

When test execution is enabled, clicking the Client Test Runner module opens the client test runner in the current browser session. If tests are waiting to be run, the Client Test Runner runs a waiting test. If no test is running, the message Waiting for a test to run displays in the client test runner.

While the client test runner is idle, it checks every five seconds for waiting tests to start. This ensures that the system runs any tests it may have been unable to start because no client with the proper configuration was available.

Note:
The client test runner monitors for tests from the current session and runs those tests as the logged-in user (unless it executes an Impersonate User step). If you start a client test runner, log out from the current session, and then log in again, the client test runner executes using the new session.

When the client runner is active, it displays the activity of the currently running test in the **Execution Frame**.

Note:
You are now allowed to execute multiple tests at a given time.

Test execution property

To work with the client test runner module, the test execution property must be enabled.

Note:
By default, the system property that is used to run automated tests is disabled to prevent you from accidentally running these tests on a production system. To avoid data corruption or an outage, run tests only on development, test, and other non-production instances.

If the test execution property is disabled when you select this module, the system displays a message and a link to the automated test framework properties page where you can enable it.

Additional debugging functionality

If you have enabled additional debugging functionality, the client test runner module displays two tabs: **Execution Frame** and **Debug Info**. The **Execution Frame** displays the information normally shown by the client test runner and the **Debug Info** displays additional debugging information.

The system takes screen shots from the tests in the **Execution Frame** tab and records them to the test result record.

Browser recommendations for all tests and suites

- Some browsers have memory-management limitations that make it necessary to occasionally close and restart the browser when running the client test runner. These browsers include Internet Explorer, Edge, and older versions of Firefox. How often you should close the browser depends on the memory allocation in the browser application.
- Some browsers have features that throttle CPU time. To avoid problems, follow these guidelines:
  - Run the client test runner in its own browser window.
  - Keep the client test runner at least partially visible on the screen.
  - Make certain the screen is not locked or shut off.
- The client test runner takes screen shots as the tests run. For best results with screen shots, leave the browser zoom level set to 100%.

Browser recommendations for scheduled suites

The client test runners for scheduled suites have additional browser requirements.

- On OS X with the client test runner on Chrome or Safari: If the screen is locked or the client test runner tab is not shown, when the system attempts to run the test suite, tests run significantly slower and may time out. For best performance, run client test runners for scheduled suites in a virtual machine (VM) environment in which the screen does not become locked or disabled.
- The browser must meet the criteria you specified on the Scheduled suite run record.
- A client test runner meeting the criteria you specified on the Scheduled suite run record must be available to run the test suite at the scheduled time. The system cannot automatically open a client test-runner session.

Javascript window command intercepts

The Client Test Runner captures window object commands including console.log, console.error, alert, confirm, and prompt, with default responses where necessary.

- Any script that calls **window.confirm** receives a boolean response of **true**.
- Any script that calls **window.prompt** receives the string response **test value**.
- Any script call to **alert** is ignored.

Active Test Runners table

When you start a client test runner, the system registers that runner in the Active Test Runners table. You can view this table in the Active Manual Test Runners module and the Active Scheduled Test Runners module. These two modules provide views of the same table, filtered to show only manual or only scheduled test runners.

The Active Scheduled Test Runner module is useful when you create a scheduled suite run. For scheduled suite runs, you can specify the browser to use. To determine the name and version of a browser you want to use, start a scheduled test runner with that browser, then inspect that runner's record in the Active Scheduled Test Runners module.

The data in this table is transient. While the runner is active, it reports in to the system at a specified interval. If the runner does not report in at the expected time, the system marks the runner as inactive. After a period of time the system deletes the runner. You can modify these intervals on the Automated Test Framework properties page.

Allowed client errors

Pick a browser

If the test or test suite you are running contains steps that work with a form (any step involving a UI), or any other UI test step element (such as Automated Service Catalog test steps), work with the Pick a Browser dialog.

Before you begin

You must have created the test you want to run.

The test execution property must be enabled. You must have an admin or atf_test_admin role to do so.

Note:
The test execution property is disabled by default to prevent running tests on a production system. Run tests only on development, test, and other sub-production instances.

Role required: atf_test_admin, atf_test_designer, or admin

About this task

The Pick a Browser dialog appears after you click **Run Test** or **Run Test Suite**. The dialog asks you to choose among any currently-running test clients or start a new test runner.

Procedure

1. Choose the browser in which the test or test suite should run or be rerun again in the case of failed tests.
   All registered client test runners that are currently active appear in the Pick a Browser dialog. (Current session) indicates that the browser is currently running. See Working with client test runners.
2. Click **Manage your test runners here** as needed to view all client test runners registered for the current user.
   See Active manual test runners.
3. If you want to open a client test runner in this browser session, click **Start a new test runner**, which appears when client test runners are only available in other browsers for the current user.
4. Click the appropriate button to run the test.
   - If you are running a single test, click **Run Test**.
   - If you are running a test suite, click **Run Test Suite**.
   - If you are running failed tests again, click **Re-run failed tests**.

Result

The test, test suite or failed tests run in the selected browser or client test runner. The Progress viewer appears for monitoring of the progress of the test run.

Cloud Runner browser

If you are running a test or a test suite, select the Cloud Runner browser option to run your tests in a cloud browser.

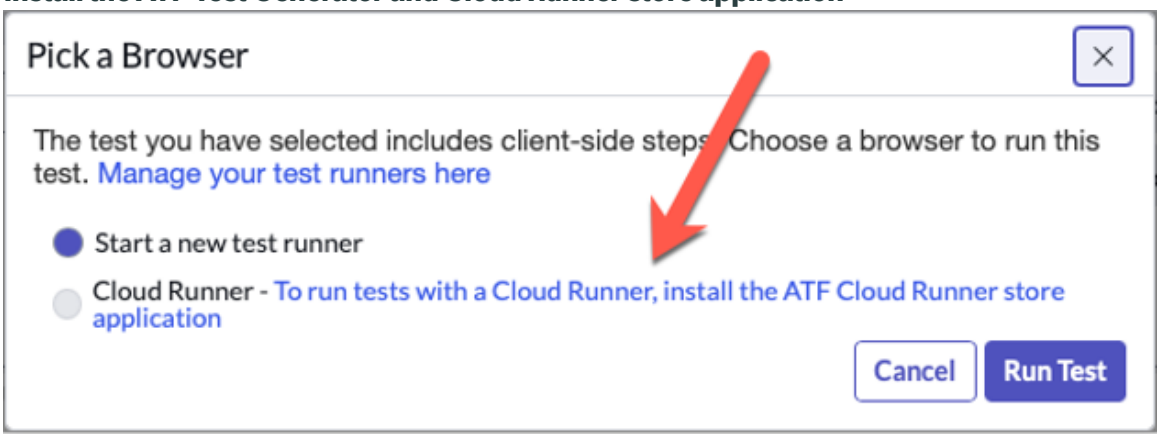
If you want to use the Cloud Runner browser option, you are required to complete the following:

- Install the ATF Test Generator and Cloud Runner store application.
- Configure a user to run and generate a test.

Use cases for Cloud Runner browser

- When you haven't installed the ATF Test Generator and Cloud Runner store application

Install the ATF Test Generator and Cloud Runner store application

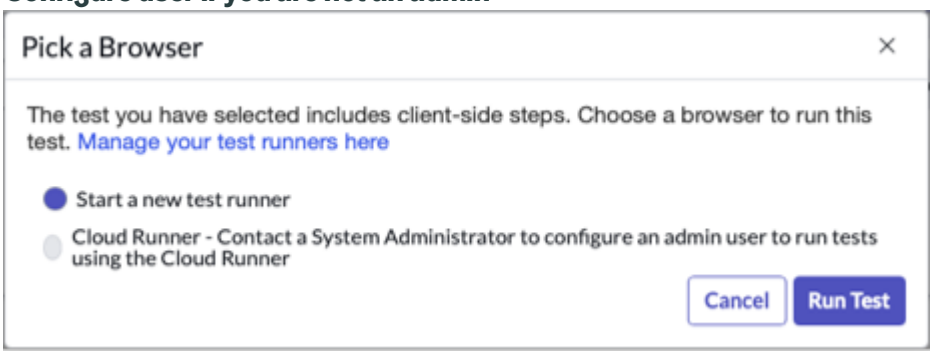


- When you haven't configured the user to run and generate tests
  - If you are an admin

Configure user if you are an admin

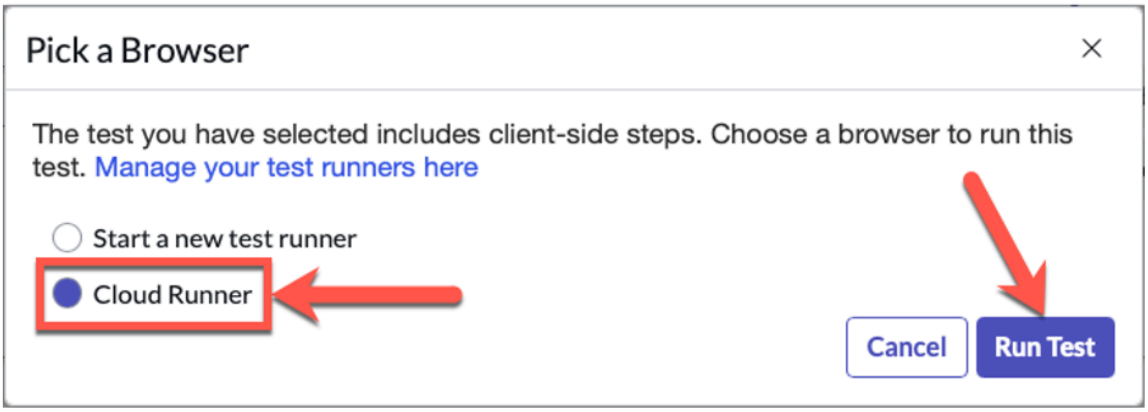
  - If you are not an admin

Configure user if you are not an admin



- When the application is installed and the user is configured

Use the cloud runner option



Server test steps

Test business logic and background processes by performing operations on the server.

Server test steps mimic non-interactive actions such as impersonating users, submitting or saving records, running server-side script, or making REST calls. Since server test steps run directly on the server, they do not require a client test runner. For more information about the server test steps, see Server category.

REST test steps

Test custom inbound web services and backwards compatibility by making REST calls.

REST requests can only be sent to the current instance. You cannot send a request to another instance or third-party at a remote address.

The REST test configuration only supports the XML and JSON response formats. Binary formats are not supported.

You can create tests that include steps from each of the test step configuration categories. The REST test configuration category contains the Send REST Request - Inbound and assert test configurations. Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories. For more information about the REST test steps, see REST category.

Authentication

As part of the Automated Test Framework, there are two situations when you send REST requests:

- When you use the REST API Explorer to create and test a request
- When you run a test that contains a **Send REST Request - Inbound** step

When you use the REST API Explorer to create and test a request, and the request requires authentication, the REST API Explorer uses your credentials. When the ATF runs the test, the REST API Explorer uses the credentials of the user who scheduled the test. This means that a test might fail unintentionally because of the difference in privileges between the user who created the test and the user who runs the test.

To address the issue of user credentials, you can create a basic-authentication profile for a test user and then on the **Send REST Request - Inbound** form, specify that the profile be used when the test is run.

Attachment test steps

Test an attachment-dependent business rule by uploading an attachment either from a form or from a server-side API call. For example, you can have a business rule that doesn't let you close an incident without an attachment such as a screenshot.

Upload from form

As a UI test step, the upload attachment step requires navigation to a form, which you can open using either **Open a New Form** or **Open an Existing Record**. Use **Upload Attachments** to select from the attachments that the test step adds to the form. When you select attachments to add to a form, the system waits to load the attachments before proceeding to the next test step. For more information on UI test dependency and wait mechanism, see UI test steps.

Upload from Server API

As a Server test step, the upload attachment step has no UI dependencies. Use **Upload Attachments** to select from the attachments that the test step adds to the record. When you select attachments to add to a form, the system waits for the attachments to be loaded before proceeding to the next test step. For more information, see Server test steps.

Design considerations

Follow these design considerations for attachment test steps:

- All attachment steps require adding one or more attachments.
- The system rolls back any attachments by the step after the test completes.
- The system cannot roll back any existing attachments after the test completes.
- Avoid testing records with existing attachments to eliminate data dependency.
- If UI testing is involved, add the attachment to a form.
- When no UI is involved, add the attachment to the Server API.

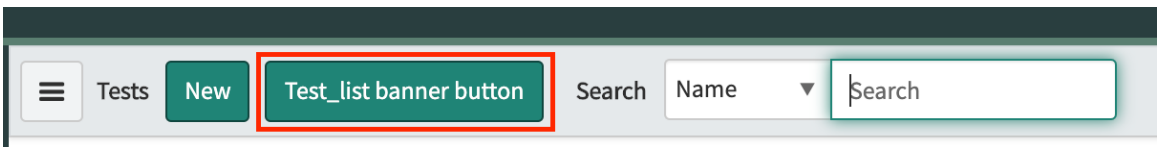
List UI actions test steps

Select a UI action from a list to perform different actions on a list or a related list.

You can create a new UI action of the following types. See Create a UI action for more information.

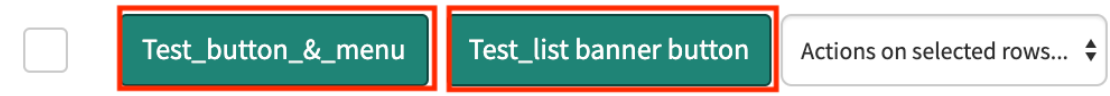
- **List banner button**: Creates a button on the banner of a list.

List banner button



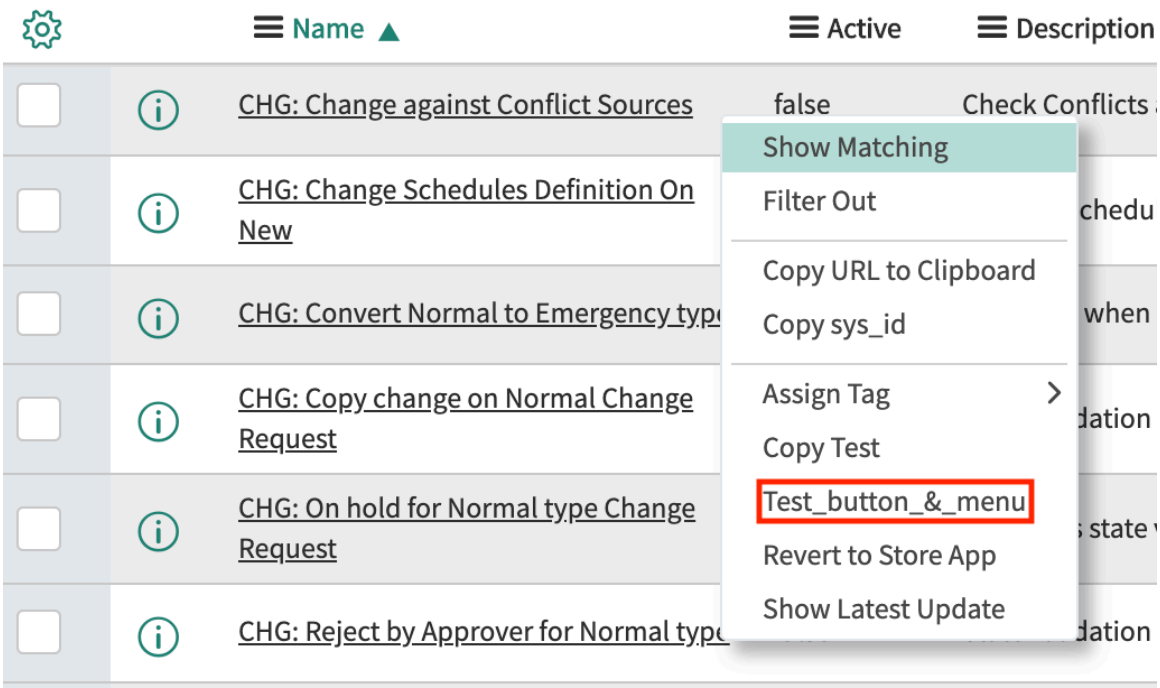
- **List bottom button**: Creates a button at the bottom of the list.

List bottom button



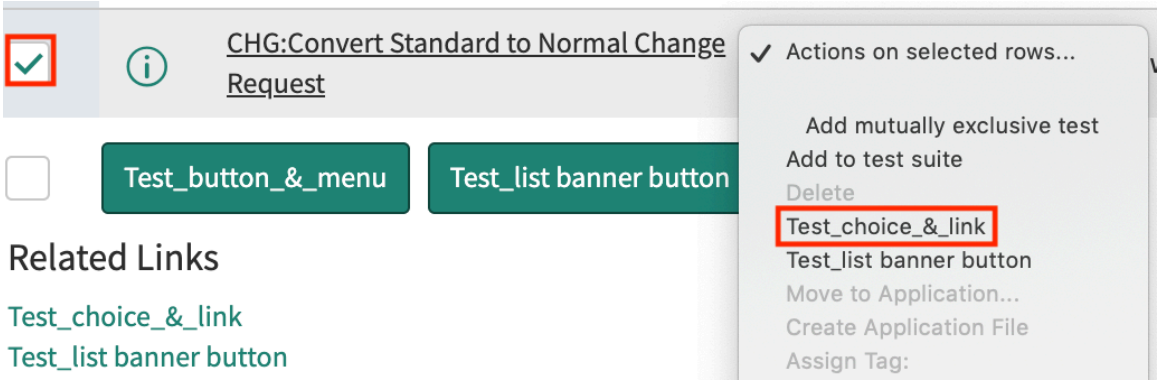
- **List context menu**: Adds an option to the context menu of the list.

List context menu



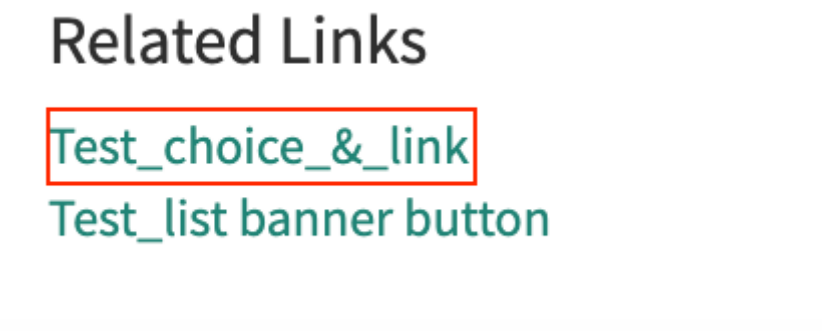
- **List choice**: Adds an option to the list choice at the bottom of the list. You need to select one or more tests to enable the recently added list choice.

List choice



- **List link**: Adds a link to the **Related Links** list.

List link



Design considerations

- To use the **Click a List UI Action** test step, the test first needs to navigate to the list or the form with the related list containing the UI action.
- The **Related list** field appears only when you select Related list as the **List type**.
- **Action type** is mostly auto-filtered depending on the **List action** chosen.
- The **Record** field appears only when you select **Single record** for the UI action to be applied.
- Identify the specific record if you have selected **Single record** to apply the UI action.
- For the **Timeout** field to appear, select **Page reloaded or redirected** as the **Assert** type.

Parameterized tests

Run a test multiple times with different test data for each run. Create parameters to store test data for each test run.

Parameterized testing offers test designers these benefits.

- Eliminates the need to duplicate test steps just to change test data.
- Increases test reuse by separating test actions from test data.
- Produces a separate test result for each data set.

When the test runs, Automated Test Framework replaces the parameters with data set values. For example, you can create a test of the incident form that uses parameter values for the subcategory and priority fields. You can use one data set to test that the Antivirus category produces a high priority incident, and another data set to test that the Email category produces a low priority incident.

Note:
The Run Server Side Script test step is not supported in parameterized tests.

Parameterized test components

Parameterized tests consist of these components.

Parameter

A parameter is a variable that stores a particular type of test data. Each parameter has a unique label and a data type. For example, you can create a parameter to

store the Sys ID of a reference field or the integer value of a choice field. Define parameters during test design.

Parameters can be shared or exclusive. Shared parameters can be used in any parameterized test. Exclusive parameters can only be used with the test for which they were created. Each shared parameter is a column in the Test Run Data Sets [sys_atf_parameter_set] table. Each exclusive parameter is a record in the Parameter Variables [sys_atf_parameter_variable] table.

Data set

A data set, also known as a test run data set, includes runtime data used when the test runs. You can set a value for every parameter available to the current test. Data sets specify the parameter value during test runs. You can manually create data sets for a test, or import data from a file. Each data set is a record in the Test Run Data Sets [sys_atf_parameter_set] table.

Parameterized tests fail if data sets are not defined.

Design Considerations

Follow these design considerations when creating parameterized tests.

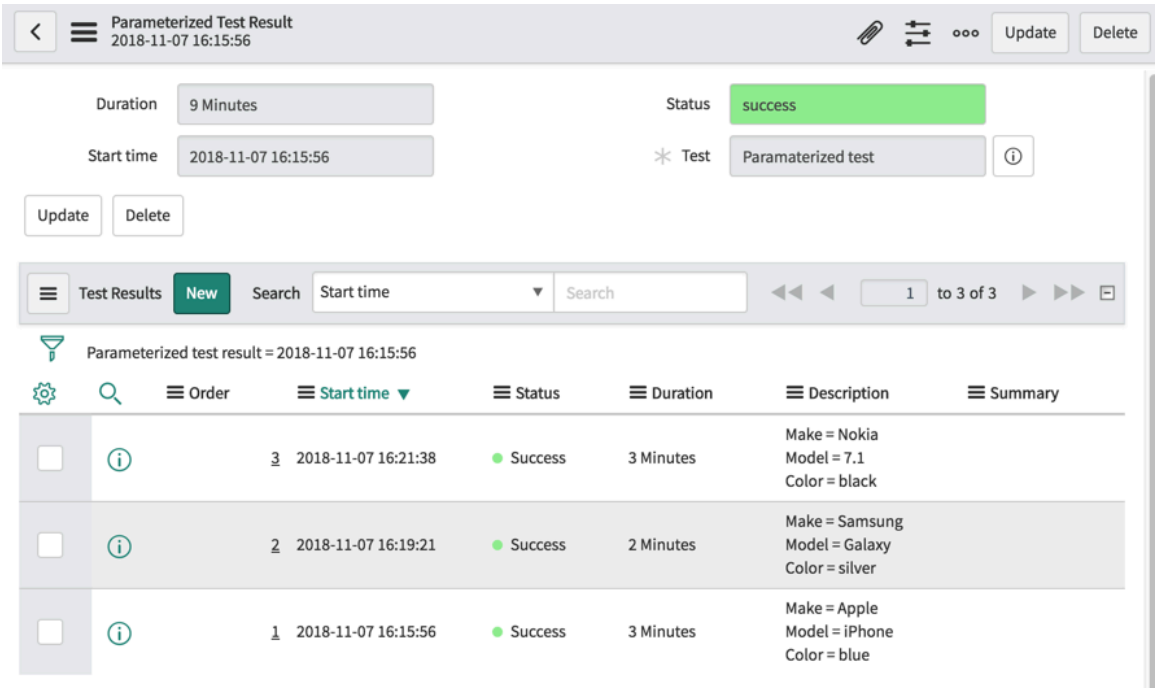
- Parameterized tests support standard Automated Test Framework features, such as reports, test suites, and data rollback. Copying a parameterized test copies all parameters, test run data sets, and test steps.
- If you create a parameterized test that includes Custom UI test steps, the system only uses the first data set to retrieve components.

Parameterized test runs

Automated Test Framework runs each parameterized test once per data set, using the same test steps and execution order. For example, if a parameterized test has five data sets, Automated Test Framework runs the test five times, once for each data set.

Parameterized test results

Parameterized tests display test results by the execution order of the data sets. Open each test result record to view the test details.



The Parameterized Test Result record **Description** field lists the parameters and data sets used in the test run.

Create a parameterized test

Build a test that uses variables to store test data.

Before you begin

Role required: atf_test_admin, atf_test_designer, or admin

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Click **New**.
   A blank Test record opens.
3. On the form, fill in the fields.

Field	Description
Name	Enter a name for the test.
Active	Enable
Enable parameterized testing	Enable
Description	Enter a description for the test.

4. Click **Save.**
   Parameterized testing related lists appear.
5. Create a parameter to hold test run data.
   A parameter is a variable that stores a particular type of test data. Each parameter has a unique label and a data type. For example, you can create a parameter to store the Sys ID of a reference field or the integer value of a choice field.

a. In the Parameter Definitions related list, add a parameter.
   - **Add Exclusive Parameters**: Adds a parameter available to this test only.
   - **Add Shared Parameters**: Adds a parameter available to any parameterized test.

b. Define the name of the variable and the data type.
   When creating parameters for a form, the parameter data type must match the field data type. For example, if you are creating a parameter to test a reference field on a form, you must create a parameter of type Reference. For more information on ServiceNow AI Platform data types, see Field types.

c. Click **Submit**.

What to do next
Add a parameter to a test step

Add a parameter to a test step

Add a variable to a test step to hold a particular type of data when the test runs.

Before you begin

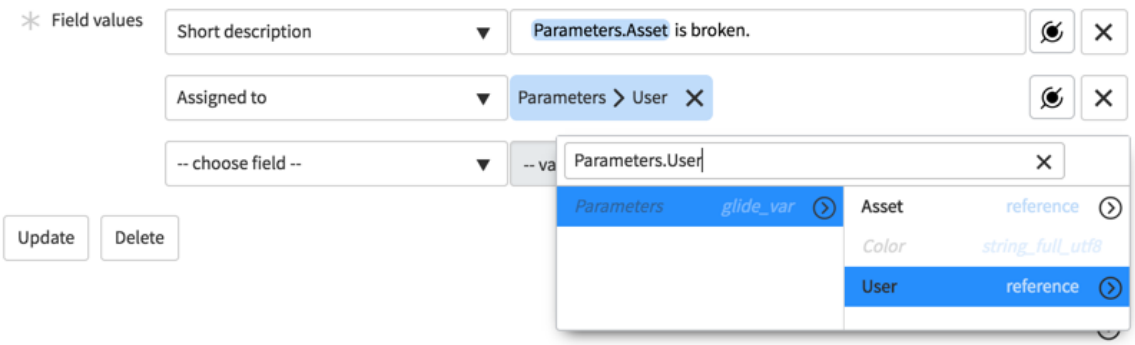
- Create a parameterized test
- Role required: atf_test_admin, atf_test_designer, or admin

About this task

Note:
The Run Server Side Script test step is not supported in parameterized tests.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Open a parameterized test.
3. In the Test Steps related list, create a test step or open an existing step.
4. Click and select a parameter to add it to a field.
   The parameter displays in the field.



Result
When the test runs, Automated Test Framework replaces the parameter with test run data.

What to do next
Add parameterized data sets.

Add parameterized data sets

Add or import test data to specify parameter runtime values.

Before you begin

- Create a parameterized test
- Add a parameter to a test step
- Role required: atf_test_admin, atf_test_designer, or admin

About this task

A data set, also known as a test run data set, includes runtime data used when the test runs. You can set a value for every parameter available to the current test. Data sets specify the parameter value during test runs.

Test designers can add data sets manually, or import data from a file.

Note:
If you create a parameterized test that includes Custom UI test steps, the system only uses the first data set to retrieve components.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Open a parameterized test.
3. In the Test Run Data Sets related list, add or import data sets.

What to do next

Click **Run Test**. Automated Test Framework runs each parameterized test once per data set, using the same test steps and execution order. For example, if a parameterized test has five data sets, Automated Test Framework runs the test five times, once for each data set.

Parameterized tests display test results by the execution order of the data sets. Open each test result record to view the test details.

Allowed client errors

Add known client errors to the allowed client errors list to allow tests and steps to continue running when a specific error occurs. Set the report level to specify what the Automated Test Framework does when the error occurs in future tests.

Scenarios for allowing client errors

Test designers and developers typically allow client-side JavaScript errors to prevent certain types of known failures from impacting test design and results. Scenarios to allow client errors include:

Timing constraints

Temporarily allow a client error until your developers have time to investigate and resolve the issue. For example, when testing an old form containing a longstanding bug.

Minimizing the impact of old libraries

Ignore client errors that cannot be fixed or are unimportant to your operations to eliminate their impact on future test runs. For example, when you find a bug in an old library.

Test design time

Temporarily allow client errors until you finish writing tests and have time to investigate the error. For example, one of your developers modifies a UI policy and the change generates an error.

Possible platform bug

Temporarily allow client errors until a fix is available. Prior to reporting a platform bug to ServiceNow Technical Support, investigate the error, verify it is not a customization error, and identify the type of platform bug involved. For example, a UI policy generates an error during a test. Your investigation verifies that the issue is not a customization error and identifies a platform issue with the UI policy.

Note:
While adding client errors to the allowed client errors list allows the test framework to continue testing, it does not guarantee that your tests pass. Test designers and developers should always investigate client errors to determine if there are issues with your business process. For more details, see Identify and resolve client errors.

Report levels for allowed client errors

The report level indicates whether the test framework reports future occurrences of the error as a warning or ignores them altogether. You can change the report level of an allowed error at any time. For example, if you originally add an error as a warning, you can later change the report level to ignored.

Report level	Description
Warning	Test steps containing the allowed client error report a status of `Success with warning(s)`. The error message appears in the test result output, and is recorded in the test logs with the status `Warning`.
Ignored	Test steps containing the allowed client error report a status of `Success`. The error is recorded in the test logs with an `Ignored` status.

Matching process

The Automated Test Framework identifies allowed client errors using a contains search rather than an exact string match. A match occurs when a client error contains a message from an Allowed Client Error [sys_atf_whitelist] record. For example, if you create an Allowed Client Error record for the error message "`Test message`" with a report level of Ignored, then any client error containing this string is ignored.

Note:
When you create or modify an Allowed Client Error record, the Client Test Runner automatically gets the update.

Identifying and resolving client errors

When client errors occur, the Automated Test Framework fails the test on the step that was executing when the error occurred.

Allow client errors from test results

Allow client errors as you review test results.

Before you begin
Role required: atf_test_admin, atf_test_designer, or admin

About this task
You can allow multiple or individual client errors. For each client error, you must decide how to report future instances of the client error. Report level options include:

- Warning: Test steps containing the allowed client error report a status of `Success with warning(s)`. The error message appears in the test result output, and is recorded in the test logs with the status `Warning`.
- Ignored: Test steps containing the allowed client error report a status of `Success`. The error is recorded in the test logs with an `Ignored` status.

Procedure
1. Navigate to **All** > **Automated Test Framework** > **Test Results**.
2. Select the test result for a specific test.
   The system displays the Test Result record.
3. From the Related links, select one of the following options:
   - **Add all client errors to warning list**: Allow all client errors in this test with a report level of Warning.
   - **Add all client errors to ignored list**: Allow all client errors in this test with a report level of Ignored.

   The Automated Test Framework allows the selected client errors and displays a status message at the top of the form.

Allowed client errors

Allow client errors from step results
Allow client errors as you review step results.

Before you begin
Role required: atf_test_admin, atf_test_designer, or admin

About this task
You can allow multiple or individual client errors. For each client error, you must decide how to report future instances of the client error. Report level options include:

- Warning: Test steps containing the allowed client error report a status of `Success with warning(s)`. The error message appears in the test result output, and is recorded in the test logs with the status `Warning`.
- Ignored: Test steps containing the allowed client error report a status of `Success`. The error is recorded in the test logs with an `Ignored` status.

Procedure
1. Navigate to **All** > **Automated Test Framework** > **Test Results**.
2. Select the test result for a specific test.
   The system displays the Test Result record.
3. Select the client errors to be allowed.

Option	Description
Specific step result from Step Results related list	**a.** In the Step Results related list, right-click the step result containing client errors you want to allow. **b.** From the context menu, select one of the following options: ▪ **Add all client errors to warning list**: Allow all client errors in this step with a report level of Warning. ▪ **Add all client errors to ignored list**: Allow all client errors in this step with a report level of Ignored.
Multiple step results from Step Results related list	**a.** In the Step Results related list, select the check box in the first column for each step result containing client errors you want to allow. **b.** From the **Actions on selected rows** list, select one of the following options. ▪ **Add all client errors to warning list**: Allow all client errors in this step with a report level of Warning. ▪ **Add all client errors to ignored list**: Allow all client errors in this step with a report level of Ignored.
Specific step result from Step Result record	**a.** In the Step Results related list, select the Step Result record containing a client error you want to allow. **b.** From the Related links, select one of the following options: ▪ **Add all client errors to warning list**: Allow all client errors in this step with a report level of Warning. ▪ **Add all client errors to ignored list**: Allow all client errors in this step with a report level of Ignored.

The Automated Test Framework allows the selected client errors and displays a status message at the top of the form.

Related topics

Allowed client errors

Allow client errors from the test logs

Allow client errors as you review test logs.

Before you begin

Role required: atf_test_admin, atf_test_designer, or admin

About this task

You can allow multiple or individual client errors. For each client error, you must decide how to report future instances of the client error. Report level options include:

- Warning: Test steps containing the allowed client error report a status of `Success with warning(s)`. The error message appears in the test result output, and is recorded in the test logs with the status `Warning`.
- Ignored: Test steps containing the allowed client error report a status of `Success`. The error is recorded in the test logs with an `Ignored` status.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Test Results**.
2. Select the test result for a specific test.
   The system displays the Test Result record.
3. Select the client errors to be allowed.

Option	Description
Specific test log from the Test Log related list	**a.** In the Test Log related list, right-click the test log client error you want to allow. **b.** From the context menu, select one of the following options: ▪ **Add client error to ignored list**: Allow the client error with a report level of Ignored. ▪ **Add client error to warning list**: Allow the client error with a report level of Warning.
Multiple test logs from the Test Log related list	**a.** In the Test Log related list, select the check box in the first column for each test log client error you want to allow. **b.** From the **Actions on selected rows** list, select one of the following options: ▪ **Add client error to ignored list**: Allow the client error with a report level of Ignored. ▪ **Add client error to warning list**: Allow the client error with a report level of Warning.
Specific test log from Test Result Item record	**a.** In the Test Log related list, select the test log (Test Result Item record) containing a client error you want to allow. **b.** From the Related links, select one of the following options: ▪ **Add all client errors to warning list**: Allow all client errors in this step with a report level of Warning. ▪ **Add all client errors to ignored list**: Allow all client errors in this step with a report level of Ignored.

The Automated Test Framework allows the selected client errors and displays a status message at the top of the form.

Related topics

Allowed client errors

Manually allow client errors

Manually create allowed client error entries as needed in the Allowed Client Errors table.

Before you begin

Role required: atf_admin, atf_test_designer, or admin

About this task

You normally allow client errors directly from a test result, step result, or test log, but you can manually allow them.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Run** > **Allowed Client Errors**.
2. Click **New**.
3. On the form, fill in the fields.

Allowed Client Error form

Field	Description
Report level	Report action to take when the client error is encountered. Options include: ○ **Warning – Step & Test will report Success with Warning(s)**: Test steps containing the allowed client error report a status of `Success with warning(s)`. The error message appears in the test result output, and is recorded in the test logs with the status `Warning`. ○ **Ignored – Step & Test will report Success**: Test steps containing the allowed client error report a status of `Success`. The error is recorded in the test logs with an `Ignored` status.
Active	Check box to enable or disable allowing a client error.
Error message	Message of the client error you want to allow.
Description	Description of the error you want to allow. If this client error was allowed from a test result, step result, or a test log, the test log description is copied into this field.

4. Click **Submit**.

Allowed client errors

View the progress of automated tests

When an automated test is running, view its progress in the Run Test progress dialog.

Before you begin

The system must be running a test.
Role required: atf_test_admin or atf_test_designer

About this task

When you execute a test or test suite, the system automatically displays the Run Test progress dialog. If you close this dialog, you can re-display it from either the results list or the results page for the currently-running test or test suite.

Procedure

1. If necessary, navigate to the Test Results list or Test Results page for the currently-running test or test suite.
   - If the system is currently running a test suite, navigate to **Automated Test Framework** > **Suite Results**. If desired, you can click the row for the running test suite to view the Suite Results page for that test suite.
   - If the system is currently running a test that's not part of a test suite, navigate to **Automated Test Framework** > **Test Results**. If desired, you can click the row for the running test to view the Test Results page for that test.

2. Display the Run Test dialog.
   - If you are currently viewing the Test Results page or the Suite Results page, click **Show Progress** under Related Links.
   - If you are currently viewing the Test Results list or Suite Results list, right-click the row for the running test or test suite, then click **Show Progress**.

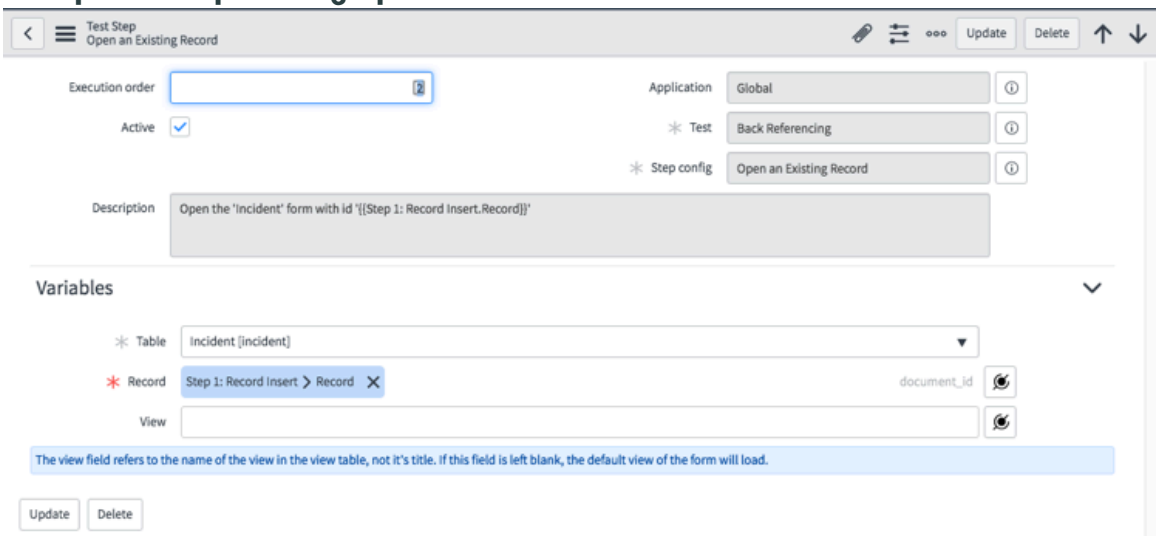
Passing data from one automated test step to another

Some automated test steps create data that you can use as an input to a subsequent step.

You can pass data from one test step to another using input variables and output variables.

The term input variables is another name for the field values associated with a step. These values are input variables because they provide the input the step needs to accomplish its task. For example, the Open Form step has these input variables: **Table**, **Record**, and **View**.

Example test step showing input variables

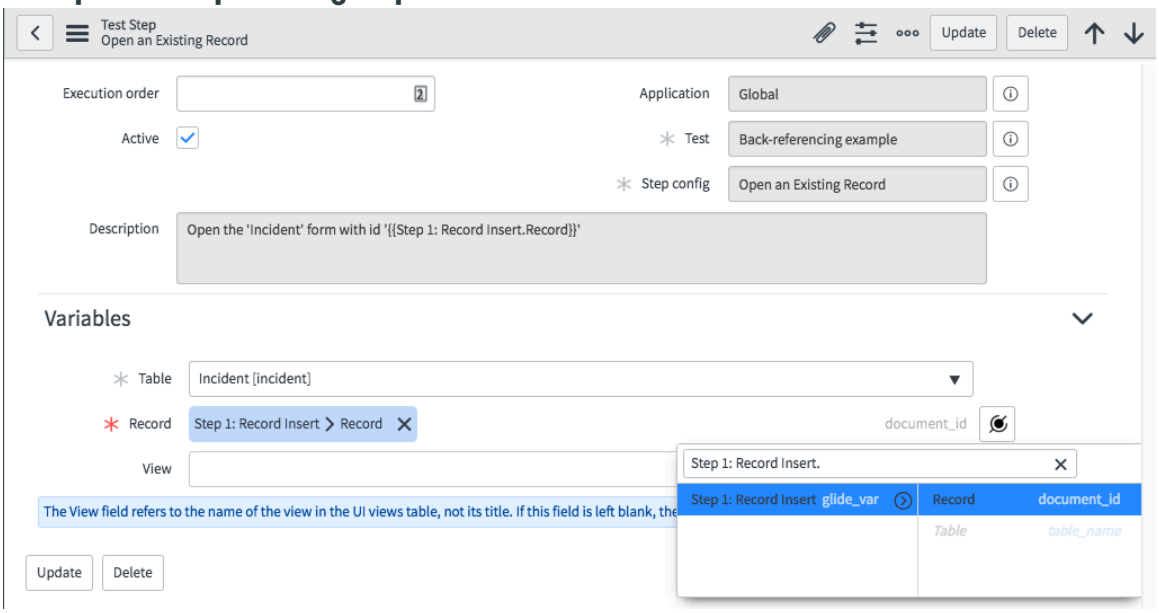


Some step types also have output variables. These are the values that later steps in the same test can use as input. For example, the Record Insert step has an output variable called Record which contains the sys_id of the newly created record.

Note:
Input data can also be passed to an automated test case from an external source such as a .csv file.

The test step form doesn't indicate if a test step has output variables or not. You can easily tell if any output variables are available to provide a value to any given input variable. If you can map the value of one step's output variable to the current step's input variable, the system displays the mapping icon ( ) to the right of that input field. When you click the variable mapping icon, the system displays a tree giving you access to any available output variables from previous steps.

Example test step showing output variables



For step-by-step instructions on how to assign the value of an output variable to another step's input variable, see Pass values from one automated test step to another.

For an example of a test that passes variables using input and output variables, see Automated Test Framework use case: reference a value from a previous step.

Pass values from one automated test step to another

Assign a form field the value of an output variable returned from a previous step.

Before you begin

You must have a previous test step that returns an appropriate output variable.

Role required: admin, atf_test_admin and atf_test_designer

Procedure

1. To the right of the field whose value you want to assign, click the input value icon ( ).
   The input value mapping control lists previous steps that create an output variable. If no previous steps create an output variable, the control displays the message: There are no elements to show .
2. Click the row for the step that contains the output variable you want to use as an input.
3. Click the output variable you want to use.
   If the output variable is an id for a glide record, the control displays a tree picker providing access to fields for this record.
4. Navigate through the tree picker hierarchy until you find and select the value you want.

Related topics

Automated Test Framework use case: reference a value from a previous step

Building and running automated test suites

Run a group of tests in a specific order to test an application or a group of related features.

A test suite can contain both individual tests and other test suites. A test suite that contains another test suite is called a parent, and the test suite contained within the parent is called a

child. While a test suite can have both individual tests and test suites as children, tests cannot have other tests as children. Tests can only contain test steps.

Benefits

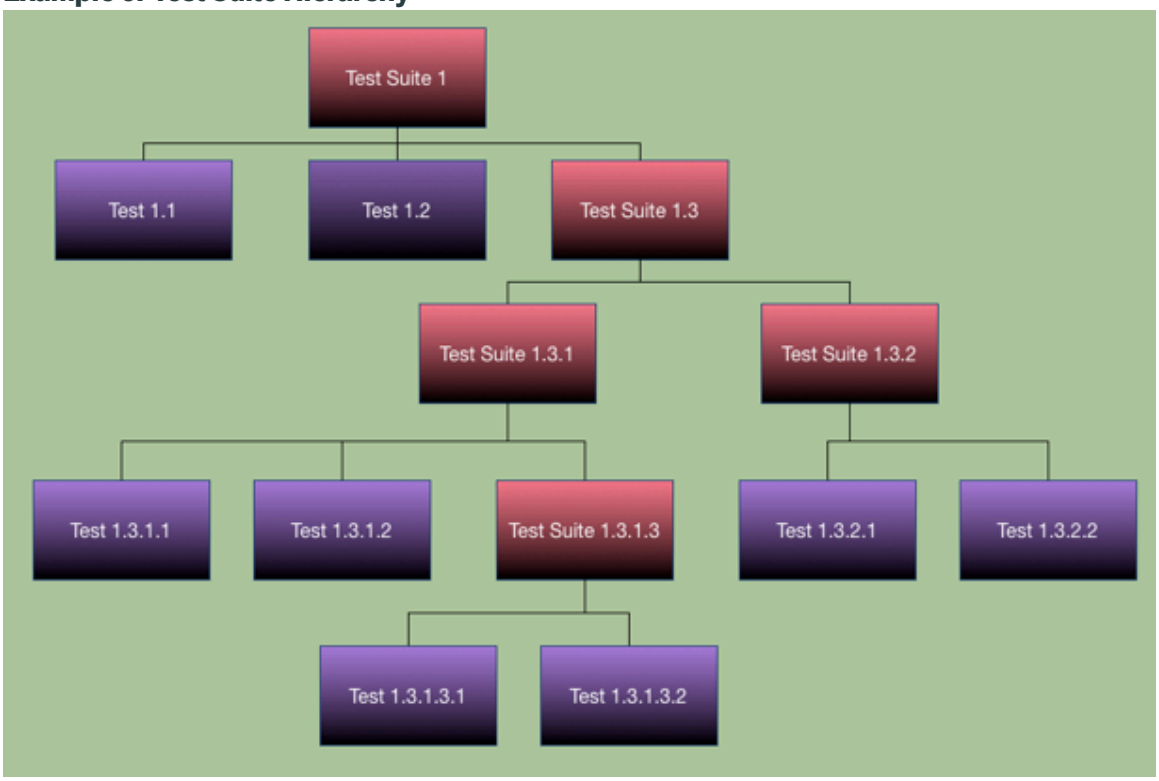
Grouping tests into test suites offers these benefits.

- Allows testers to run every test in a test suite with one action.
- Allows testers to run all child test suites in a parent test suite.
- Allows testers to see test results for every test in a test suite.
- Allows test designers and testers to schedule when to run test suites.
- Allows test designers and testers to schedule starting client test runners to support test runs.

Hierarchies

Automated Test Framework supports building a multi-level hierarchies where a test suite can be both a parent and child. For example, this figure illustrates Test Suite 1 as the parent at the top of the hierarchy. Test Suite 1.3 is a child of Test Suite 1 and also a parent of Test Suite 1.3.1 and Test Suite 1.3.2.

Example of Test Suite Hierarchy



Schedules

To schedule a test suite, you need three components:

- a test suite record
- a schedule record specifying when you want the system to run the test suite
- a scheduled suite run record that associates the test suite to run with the schedule for running it

With this model, you can associate a schedule with many different test suites, and vice versa.

Note:
You can schedule only test suites, not individual tests. Scheduled tests will run only if there is an open Scheduled Client Test Runner page matching the scheduled suite's browser conditions. Scheduled tests cannot run on a machine that is locked, powered down, or does not already have the browser open.

The watchlist on the test suite run record also allows you to specify users to receive an email when the system finishes executing the test suite run.

If the test suite contains one or more form steps (steps involving a user interface), you must ensure that a scheduled client test runner is actively running in a browser when the schedule triggers the suite run.

Note:
See Browser recommendations and requirements for recommendations and requirements for running the client test runner.

For step-by-step instructions on how to schedule a test suite, see Schedule an automated test suite.

Filters

Automate the creation of test suites by using a filter to dynamically add tests to a test suite when they match the filter conditions. Reduce the time that your test designers spend manually creating and maintaining test suites.

Related topics

Suites

Step results record

Create an automated test suite

Group automated tests into a suite you can execute as a batch.

Before you begin

The tests you want to include in the test suite must exist.
Role required: atf_test_admin or atf_test_designer

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Suites**.
2. Click **New**.
   The system displays the Test Suite New Record form.
3. In the **Name** field, enter a name for this suite.
4. Select the tests to be included in this suite.

Option	Description
Filter	Add tests dynamically using a filter: **a.** In the **Filter** field, use the condition builder to create the conditions a test must match for inclusion in the test suite. **b.** Click **Save**.

Option	Description
	All tests that match the filter conditions appear in the **Test Suite Tests** related list. Because the suite is dynamic, any new test that matches the conditions is automatically added to the suite.
Test Suite Tests	Add tests manually: **a.** In the **Test Suite Tests** related list, click **Insert a new row...**. **b.** In the **Test** field, enter the name of the test to add to this test suite.

5. In the **Description** field, enter a description for this test suite.
6. In the **Test Suite Tests** related list, specify options for a test.

Option	Description
Execution order	Enter a value to specify the order in which this test should execute within the test suite.
Abort on Failure	Enter a value that indicates whether you want the test suite to stop or continue if this test fails. ○ By default, the system assigns the value **false** to this field. If this test fails, the system still executes any further tests in the test suite. ○ Set the value to **true** to stop the test suite if this test fails.

7. Repeat steps 4 - 6 for every test you want to include in this test suite.
8. Click **Submit**.

Copy an automated test suite

Reduce time when creating tests by copying an entire test suite. Rename and modify the test suite after copying. The **Copy Test Suite** button on the Test Suite form copies all the nested tests and child test suites within the text suite.

Before you begin

Role required: atf_test_admin or atf_test_designer

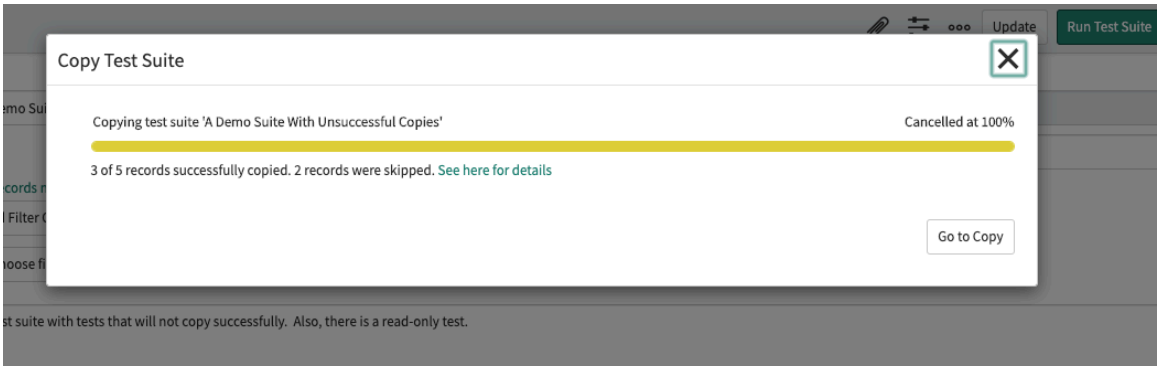
Procedure

1. Navigate to **All** > **Automated Test Framework** > **Suites**.
2. Select the row containing the test suite that you want to copy.
3. Near the top corner of the Test Suite form, select **Copy Test Suite**.
   A progress tracker appears to confirm the status. If you select **Go to Copy**, the system displays a new test suite record identical to the copied record, except for the **Name**.

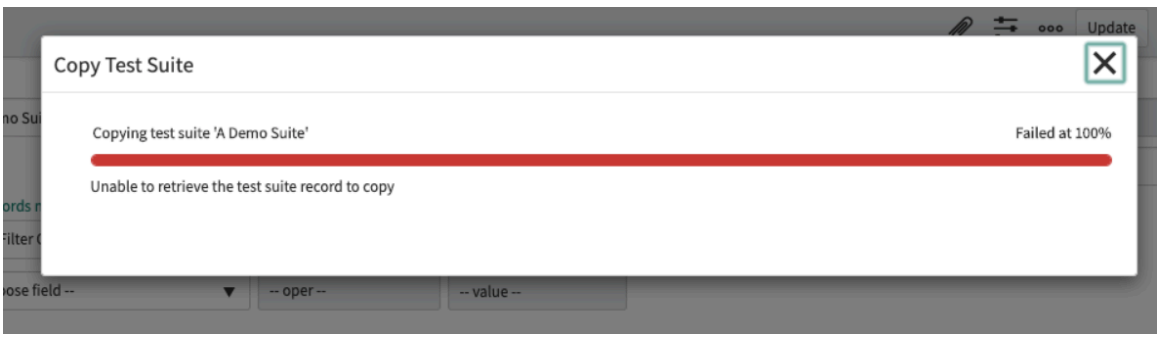
   Note:
   If you apply filter conditions, copied tests are added to the test suite if the conditions are met.

   If any tests or child test suites fail to copy, they are skipped and copying of the remaining tests and child test suites continues. A warning message showing a partial success appears below the progress bar.

Note:
You can copy a test suite only when it's in the same scope as the current scope. The **Copy Test Suite** button appears only when the test suite is in the same scope. The scopes of the tests in a suite are preserved when copying a test suite. See Application Scope for more information.



If the copy operation fails, an error message appears below the progress bar.



4. In the **Name** field, enter the name that you want to assign to this new test suite.
5. Edit the tests and test suites within the copied test suite.
6. When you are finished making changes, select **Update**.

Result
A copy of the test suite along with all the nested tests and child test suites is created.

Add tests to a suite with a filter

Automate the creation of test suites by using a filter to dynamically add tests to a test suite when they match the filter conditions. Reduce the time that your test designers spend manually creating and maintaining test suites.

Before you begin
The tests you want to include in the test suite must exist.
Role required: atf_test_admin or atf_test_designer

Procedure
1. Navigate to **All** > **Automated Test Framework** > **Suites**.
2. Click **New**.
   The system displays the Test Suite New Record form.
3. In the **Name** field, enter a name for this suite.

4. For **Filter**, use the condition builder to specify the conditions a test must meet to be added to the test suite.

   Note:
   If you don't have a filter condition set, it is ignored and you can build the suite manually.

5. Click **Save**.

Result
All tests that match the filter conditions appear in the **Test Suite Tests** related list. Because the suite is dynamic, any new test that matches the conditions is automatically added to the suite.

Add test to an existing automated test suite

Add a test to a test suite that already exists.

Before you begin
The tests you want to include and the test suite must exist.
Role required: atf_test_admin or atf_test_designer

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Suites**.
2. Click the row containing the test suite you want.
   The system displays the Test Suite form.
3. In the **Test Suite Tests** related list, click **Insert a new row...**.
4. In the **Test** field, enter the name of the test to add to this test suite.
5. In the **Order** field for this row, enter a value to determine the order in which this test should execute within the test suite.
   By default, the system assigns a value to this field according to the order in which you add the tests.
6. In the **Abort on Failure** field for this row, enter a value that indicates whether you want the test suite to stop or continue if this individual test fails.
   By default, the system assigns the value **false** to this field. **False** means that if this test fails, the system still executes any further tests in the test suite.
7. Repeat steps 3 - 6 for every test you want to include in this test suite.
8. Click **Submit**.

Add child test suite to parent test suite

Add to a multi-level test suite by including a child test suite within a parent test suite.

Before you begin
The parent test suite must exist.
Role required: atf_test_admin or atf_test_designer

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Suites**.
2. Access a child test suite.
   - If the child test suite exists, open the child test suite form for editing.
   - If the child test suite does not yet exist, create it.

3. In the test suite form in the **Parent suite** field, enter the name of the test suite you want to act as the parent to this child.
4. If desired, add one or more tests to the child test suite.
5. Click **Submit**.

Run an automated test suite

After creating an automated test suite, run it in a non-production instance.

Before you begin

You must have created the test suite you want to run.
The test execution property must be enabled. You must have an admin or atf_test_admin role to do so.

> **Note:**
> The test execution property is disabled by default to prevent running tests on a production system. Run tests only on development, test, and other sub-production instances.

Role required: atf_test_admin, atf_test_designer, or admin

About this task

This procedure outlines how to start a test suite manually. You can also schedule test suites to run at a later time. For more information, see Working with scheduled test suites.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Suites**.
2. If necessary to view the Test Suites list, click **Test Suites**.
3. Click the row containing the test suite you want to run.
   The system displays the Test Suite form.
4. Click **Run Test Suite**.

   > **Note:**
   > If the test execution property is not enabled, the **Run Suite** button does not appear. In this case, see the annotation at the top of the form, and click the link to enable running tests.

   If the tests associated with the test suite include a form step (any step involving a UI), or other kinds of UI test steps, the Pick a Browser dialog appears before executing the tests.
5. Choose among any currently running test clients, or start a new runner.

   For more information, review Browser recommendations for all tests and suites.

   If the tests associated with the test suite only include server test steps, the system executes the tests without displaying the Pick a Browser dialog.

What to do next

Monitor the progress of the tests. When complete, click **Go to results** on the progress dialog window to display the **Test Results** list, where you can view and analyze the results.

Schedule an automated test suite

Schedule one or more test suites to run at a specific date and time.

Before you begin

You must have created the test suites you want to schedule.
Role required: atf_test_admin or atf_test_designer

About this task

To schedule a test suite, you need three components:

- A test suite record
- A schedule record specifying when you want the system to run the test suite
- A scheduled suite run record that associates the test suite to run with the schedule for running it

For more information about the capabilities of and requirements for scheduled test suites, see Working with scheduled test suites.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Schedules**.
   The system displays the list of existing test suite schedules.
2. To create a new schedule, click **New**.
   The system displays the Suite Schedule record form.
3. On the Suite Schedule record form, enter the name of the schedule, the frequency with which to run associated suites, the time at which to run associated suites, and the timezone for this schedule.
4. **Optional:** Specify a condition that must be met for running associated test suites by selecting **Conditional**, then fill in the **Condition** text box with the appropriate script.
5. Add a test suite to run by navigating to the Scheduled Suites related list, then clicking **New**.
   The system displays the Scheduled Suite Run record form.
6. On the Scheduled Suite Run record form enter the appropriate data.

   a. Enter the test suite to run.

   b. If the suite contains UI steps, enter any client constraints you wish to apply (such as browser to use).
   For more information on client constraints, see Scheduled Suite Run.

   c. Add to the record's watchlist users you want the system to inform (by email) when the scheduled suite has finished.

   d. Click **Submit**.

7. **Optional:** Add more test suites to this schedule by repeating steps 5 and 6.
8. Click **Update**.
9. If your suite includes any test steps that work with a form – or any other element on the client side, open a browser window for running the client portion of the scheduled tests.
   a. Review Browser recommendations and requirements for all tests and suites, as well as those that apply only to scheduled suite runs.
   b. In the **Navigator**, right-click **Scheduled Client Test Runner**, and then click the option to open in a separate tab or window, as you prefer.
   c. Leave open the browser window that's running the client test runner and return to the browser window that contains the **Navigator**.

Run a scheduled test suite using a script

Execute a scheduled UI test suite immediately using a script without having to wait for the scheduled time. You can use this method while trying to automate the process of running a test.

Before you begin

You've created and scheduled the test suites that you want to run. See Create an automated test suite and Schedule an automated test suite, for more information.

Role required: atf_test_admin or atf_test_designer

About this task

The following steps might not be in line with your software configurations.

Procedure

1. Spin up a virtual machine (VM) on an operating system with the necessary browsers.
2. Open a browser on the instance and navigate to the Scheduled Client Test Runner.
3. Call the scriptable method `new sn_atf.ScheduledRunsExecutor().setScheduleSysId("SYS_ATF_SCHEDULE_SYS_ID_HERE").start();` to run the scheduled suite immediately.
   To run a test only when the script is called, set the **Run** field to **On Demand** in the Schedule form.

   Note:
   The `start()` method returns `sys_progress_worker.sys_id` of the progress worker.

Re-run failed tests in an automated test suite

Re-run failed tests within a test suite without rerunning the entire suite.

Before you begin

Role required: atf_test_admin, atf_test_designer, or admin

About this task

The **Re-run failed tests** button appears on the Suite Result form and on the Suite Execution Progress Viewer after a suite with failed tests completes. It does not appear if test execution is disabled, the suite is deactivated, the suite passed, or the user does not have one of the required roles.

The **Re-run failed tests** button re-runs all non-passing tests, which includes tests with the following status: canceled, skipped, failure, and error. It does not include the test results with a Success with warning(s) status.

Procedure

1. Navigate to either the suite result form or suite execution progress viewer for the completed suite that had failed tests.
2. Click **Re-run failed tests**.
   If the re-run tests include a form step (any step involving a UI) or other kinds of UI test steps, the Pick a Browser dialog appears before executing the tests.
3. In the dialog box, choose among any currently running test clients or start a new runner.
   If the re-run tests include only server test steps, the system executes the tests without displaying the Pick a Browser dialog. For more information, review Browser recommendations for all tests and suites and Server test steps.

Result
The system re-runs the failed tests.

- The system creates a new suite result hierarchy for the re-run tests. The Progress Workers, Test Result, and Test Suite Result forms show the same suite hierarchy as the previous test suite. They do not include the tests or suites that passed in a previous run.
- If you delete or deactivate a child suite or test that failed, and then re-run it, the system does not execute that suite or test in the re-run.
- If you add a child suite or test to the suite to a failed test, and then re-run it, the system does not execute the added suite or test in the re-run.

What to do next
To view the results from the previous run of a test or suite, click **Previous test result** on the test result form or **Previous suite result** on the testsuite result form. These fields only appear for tests and suites that have been re-run.

Auto-generate ATF tests

Auto-generate ATF tests by selecting the auto-generate option either from the Auto-generate Tests module or Tests/Suites modules.

Before you begin
Role required: admin

Procedure
1. Access the Auto-generate Tests feature using either of the following ways.

2. **Optional:** Install the ATF Test Generator and Cloud Runner store app.

Note:
This step is applicable only if the store app is not installed on your instance. You will be redirected to install the store app.

Parallel testing

Reduce test design time by running multiple tests and test suites in parallel. Design tests to run in parallel by avoiding resource conflicts and data dependencies.

Note:
If two or more users are developing tests simultaneously, parallel testing reduces test design time. After test design completes, it is recommended to organize tests into a single hierarchical suite structure, and run the tests as a single base suite.

Parallel testing limit

Parallel testing enables users to run multiple automated tests simultaneously. This process continues until the number of parallel running tests is as per the following formula.

```
Number of parallel tests = max(1, number of worker threads - 2)
```

Note:
If your instance has 2 or less worker threads, configuration improvements review is recommended.

The actual number of parallel tests that a non-production instance can support depends on the system resources that the instance has when it is provisioned. The parallel testing limit ensures that an instance always has system resources available for other non-testing tasks.

Test waiting queue

When the system reaches the parallel testing limit, it reschedules tests to run later. It automatically places the tests back in sys_trigger until a worker thread is available to pick them up. Each test in the waiting queue has a schedule the next time the test runs.

Design considerations

Run multiple tests and test suites in parallel to reduce test design time. Avoid resource conflicts and data dependencies by designing parallel running tests. Avoid resource conflicts and data dependencies by designing tests that rely only on newly generated or self-created data, or have mutual exclusion rules defined between tests that share resources.

Prevent resource conflicts between parallel tests

Prevent resource conflicts by running tests that create their own data. Tests that run with existing data prevent other tests that need the same data from running in parallel.

Note:
If you have two or more tests with resource conflicts, see Mark tests as mutually exclusive to create a mutual exclusion rule that prevents the tests from running in parallel.

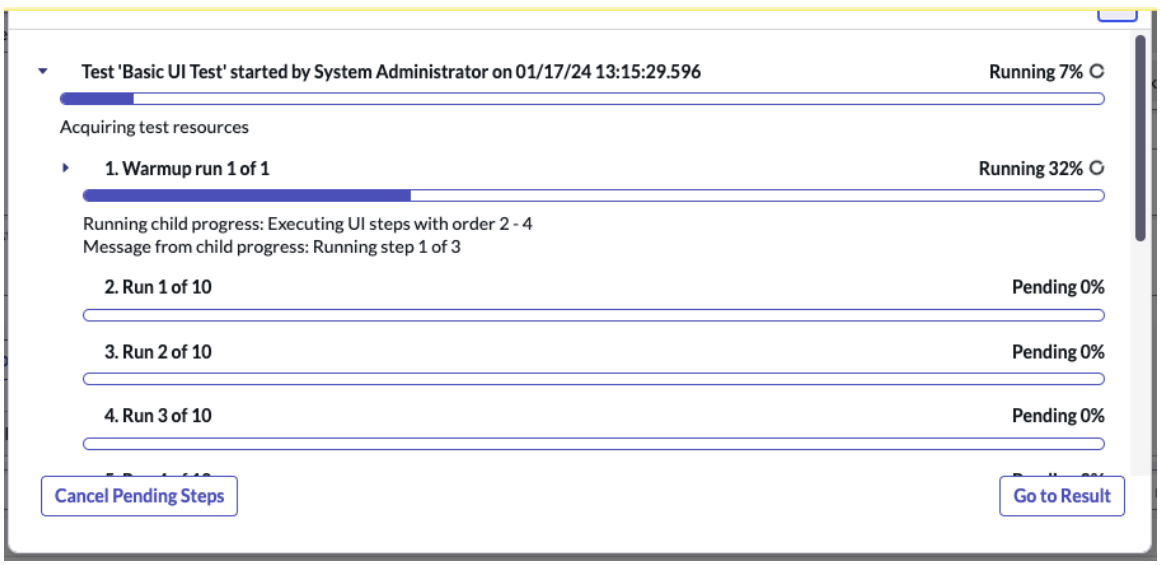
Performance profiling

Performance profiling allows you to do performance testing on your instances.

Apart from being a functional testing medium that ensures nothing breaks when any changes are made to an instance, ATF can also detect performance degradation during upgrades. You can know the cause, investigate, and fix the performance issue.

You can execute performance profiling on any of your ATF tests or suites. For each test or suite, the default test run is 10. In a suite, each test runs 10 times sequentially. The first run is a warmup that helps in warming up the cache values and is not counted to the 10 test runs of a test or suite.

Note:
Performance profiling can't be done on more than 1 test simultaneously. It doesn't support parallel performance assessment.



Note:
When you execute a performance test run, the system pauses and waits for any ongoing jobs to finish before starting the test run. This helps in avoiding any slowdown of your instance.

Execute performance profiling

Execute performance profiling on a test or a suite for performance testing on your instance. You can also detect performance degradation when you upgrade your instance and then investigate and fix the issues.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Automated Test Framework (ATF)** > **Test**.

   Note:
   You can also select the Suites module if you want to execute performance profiling on a suite.

   A list of tests or suites shows up.
2. Select the test you want to execute performance profiling on.
3. Select **Run Performance Test** on the Test form.
   A **Run Test** modal shows up. The modal shows the warmup run and all the 10 test runs of the selected test or suite. You can track all the test runs as they start executing.

   Note:
   You can select **Run Performance Suite** if you have selected a suite for performance profiling.

4. Scroll down and select the **Performance Test Results** related list.
5. Select the required performance number to view the results of all the test runs within the selected performance test.
   The Performance Run form shows up. You can also directly navigate to **All** > **Automated Test Framework (ATF)** > **Test** > **Performance Profiling** > **Performance Runs** to see the Performance Run form. Add a screenshot

   Note:
   You can view the test name, status of the test runs, and the duration of the test run. If the **Is warmup** value is true, its the first test run that is done to warmup the cache values. The rest of the test runs will have **Is warmup** value set to false. The warmup test is not counted as one of the 10 test runs for each test or suite.

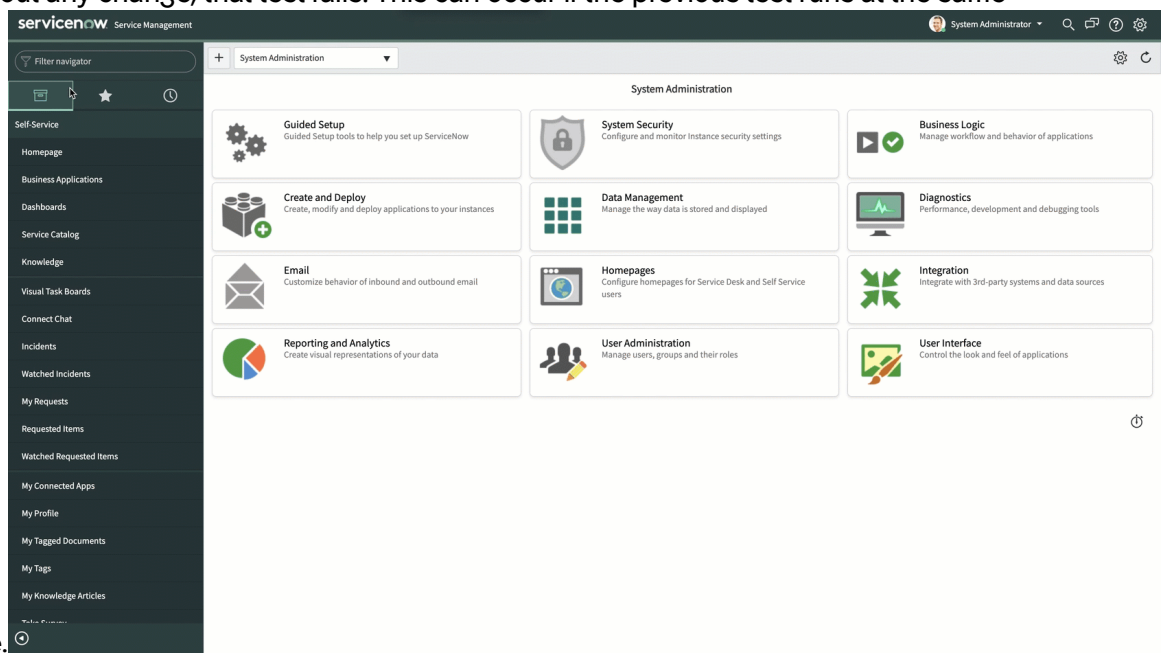
6. Navigate to **All** > **Automated Test Framework (ATF)** > **Test** > **Performance Profiling** > **Performance Comparisons**.
   The Performance Comparisons form shows up. <add a screenshot of the form>
7. Select the first and second run to view a comparison result.
   Add the complete screenshot. You can view information like performance means and the delta mean values.

   Note:
   You can compare only 2 test runs at one point of time. In the next comparison, you can consider one of the previous test run as the baseline to compare with the next test run.

Mutually exclusive tests

Prevent conflicting tests from running in parallel by marking them as mutually exclusive. For example, when the system identifies tests that modify the same record, the system makes these tests mutually exclusive. You can also manually mark tests as mutually exclusive.

The system marks tests as mutually exclusive when there is a potential resource conflict. When the system can't detect resource conflicts automatically, you can create your own mutual exclusion rules that can prevent conflicting tests from running in parallel. For example, if a test changes a sys_properties record, the record shows up under **Records Modified** of that test. If the validation path of another test depends on the same sys_properties record without any change, that test fails. This can occur if the previous test runs at the same time.



You can view mutually exclusive tests on the Mutually Exclusive Tests related list in the test form. This related list shows all tests that don't run in parallel with the current test and the reason. The same test might appear more than once in the list if there are multiple reasons.

Mutually exclusive tests reasons

Tests are marked mutually exclusive for the following reasons.

- Two or more tests modify the same record.
- A test that runs in parallel with itself.
- You can create your own mutual exclusion rules when the system can’t detect resource conflicts automatically.

Mark tests as mutually exclusive

You can mark tests as mutually exclusive using any of the following methods.

Mutually Exclusive Tests tab

Select a test from the Tests list and navigate to **Mutually Exclusive Tests** > **Add Mutual Exclusion** to make the selected test mutually exclusive with another test.

Tests list

Select one or more tests from the Tests list and choose **Add mutually exclusive test** from the Action on selected rows context menu. Enter one test in the Add mutually

exclusive test dialog box to make the selected tests mutually exclusive with the current test.

Parallel Test Runs tab

When two or more tests run in parallel, navigate to **Test Results** > **Parallel Test Runs**. Select one or more tests and choose **Add mutually exclusive test** from the Action on selected rows context menu to mark the selected tests as mutually exclusive.

Note:
The **Parallel Test Runs** tab is visible only if the test runs in parallel with one or more tests.

Automated Test Framework design considerations

Create reliable, scalable, and efficient tests by following these design considerations.

General testing

Avoid modifying ServiceNow system tables or tables extending the Application File [sys_metadata] that can potentially change the behavior of the system. Avoid using or modifying any existing records to prevent unexpected results between tests. The following are some of the common examples of system data changes that can cause unexpected results.

- Impersonate an existing account
- Delete an existing record.
- Run a test that disables a business rule or system property
- Validate with an existing record

Parallel testing

Reduce test design time by running multiple tests and test suites in parallel. Design tests to run in parallel by avoiding resource conflicts and data dependencies.

Prevent resource conflicts between parallel tests

Prevent resource conflicts by running tests that create their own data. Tests that run with existing data prevent other tests that need the same data from running in parallel.

Note:
If you have two or more resource conflicting tests, see Mark tests as mutually exclusive to create a mutual exclusion rule that prevents them from running in parallel.

Parameterized testing

Run a test multiple times with different test data for each run. Create parameters to store test data for each test run. See Parameterized test components for more information.

- Create parameters to store test data for each test run.
- Ensure that the parameterized tests support standard Automated Test Framework (ATF) features, such as reports, test suites, and data rollback. Copying a parameterized test copies all parameters, test run data sets, and test steps.

Note:
If a parameterized test including Custom UI test steps is created, the system only uses the first data set to retrieve components.

Custom UI testing

Test customized user interfaces such as UI pages and UI macros by retrieving their HTML and JavaScript page components and identifying the test actions they support.

Use the page inspector to identify testable page components

The page inspector determines which page components are available for custom UI testing. Page components that are unavailable to the page inspector are unavailable to custom UI testing.

Navigate to the custom UI you want to test

Use existing test steps to navigate to the target custom UI. For example, to test a Knowledge Base article, use the existing test steps to navigate to a module or to open an existing record. Most custom UI testing requires using existing test step categories as part of the test.

Use the component area to identify page components

The component area describes the HTML layout element containing the component such as a `<div>` or `<section>` element. The area helps test designers distinguish between components by providing the location in the page layout.

Test your custom UI rather than ServiceNow AI Platform UI

The Automated Test Framework prevents custom UI testing of ServiceNow AI Platform features. For example, you cannot test dashboards or graphical designers. Instead, build tests to validate your custom UI pages and elements because you have direct control over these user interfaces.

Use HTML attributes to override page component testing properties

Change the testing properties of a particular page component using HTML attributes that are specific to Automated Test Framework. See Override component test actions.

Retrieve page components again when you move tests to another instance

Custom UI test steps don't store UI components as metadata. Testers must manually retrieve page components again when moving tests between instances.

Clone tests from production system

Move your tests to the production system to clone the most updated instances for testing. Speed up the testing time by directly copying or cloning a test from the production system to a subproduction instance.

Note:
By default, the system property that is used to run automated tests is disabled to prevent you from accidentally running these tests on a production system. To avoid data corruption or an outage, run tests only on development, test, and other non-production instances.

Warning messages for all testing

Warning messages	Design considerations
`Impersonating an existing user may cause unexpected behavior for this test. Avoid potential issues by adding a 'Create a User' step instead. See the`	Create a new user to ensure proper roles and groups and avoid using existing records. See General testing for more information.

Warning messages	Design considerations
`documentation for Test Design Considerations.`	
`Using a table that extends Application File [sys_metadata] may cause unexpected behavior for other tests running in parallel. See the documentation for Test Design Considerations.`	Avoid running a test with a table that extends the Application File because it might affect other tests. See Parallel testing for more information.
`Using a system table may cause unexpected behavior for other tests running in parallel. See the documentation for Test Design Considerations.`	Avoid using a system table because it might affect other tests running in parallel. See Parallel testing for more information.
`Using an existing record may cause unexpected behavior for this test. See the documentation for Test Design Considerations.`	Avoid using existing records because these records might not have the state and values as expected by the test. Use records created during the test to ensure proper state and values. See General testing for more information.
`Modifying an existing record may cause unexpected behavior for other tests running in parallel. See the documentation for Test Design Considerations.`	Avoid using existing records because it might affect other tests. Use records created during the test. See General testing for more information.
`Using assert type '--None--' may cause unexpected behavior for server UI actions. Avoid potential issues by setting the assert type and using a timeout. See the documentation for Test Design Considerations.`	Server UI actions cause the current form to submit and the page to reload. Select an assert type other than **None** to avoid any unexpected behavior for server UI actions. Set a timeout to ensure that your test waits for the form to be submitted or not submitted before moving on to the next step. When testing server UI actions, the **None** assert type configures automatically to **Form submitted to server**.

Domain separation testing

When testing domain separation, you must set the domain first. This should be part of the first impersonation step of each of the ATF test steps when they are dependent on a domain being set. To learn more about domain separation recommended practices, see Domain separation recommended practices for service providers.

Cancelling automated tests and test suites

You can cancel automated tests and automated test suites that are running or are queued to run.

How you cancel an automated test or automated test suite depends on whether the test or test suite is currently running or is queued to run.

Cancel queued automated test suite

You can cancel an automated test suite that is queued but has not yet run.

Before you begin
Role required: atf_test_admin or atf_test_designer

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Run** > **Waiting/Running Test Runs**.
2. Select the action check boxes for the test suites to cancel.
3. From the action choice list, select **Delete**.

Cancel running and pending tests in an automated test suite

Cancel running and pending tests in a running suite test.

Before you begin
Role required: atf_test_admin or atf_test_designer

Procedure

1. If necessary, display the Run Test progress dialog.
2. Click **Cancel Pending Steps**.
   The system displays a dialog asking you to confirm that you want to cancel this test execution.
3. In the Confirmation dialog, click **Yes**.

Result
The system cancels any running and pending tests in this test suite and rolls back any data that tests in the test suite may have changed.

Cancel running automated test

You can cancel a running test from the Run Test progress dialog.

Before you begin
The system must be running a test.
Role required: atf_test_admin or atf_test_designer

Procedure

1. If necessary, display the Run Test progress dialog.
2. Click **Cancel Pending Steps**.
   The system displays a dialog asking you to confirm that you want to cancel this test execution.
3. In the Confirmation dialog, click **Yes**.

Result
The system cancels the running test and rolls back any data changes the test made.

Cancel waiting automated test

You can cancel a waiting automated test from the Waiting/Running Test Runs module.

Before you begin
Role required: atf_test_admin or atf_test_designer

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Run** > **Waiting/Running Test Runs**.
2. Select the action check boxes for the tests to cancel.
3. From the action choice list, select **Delete**.

Administering the Automated Test Framework

Enable or disable the Automated Test Framework, modify retention policies, move tests between instances, control user access to the Automated Test Framework, and create custom test step configurations and step environments.

For details about individual properties that control how the Automated Test Framework works, see Properties.

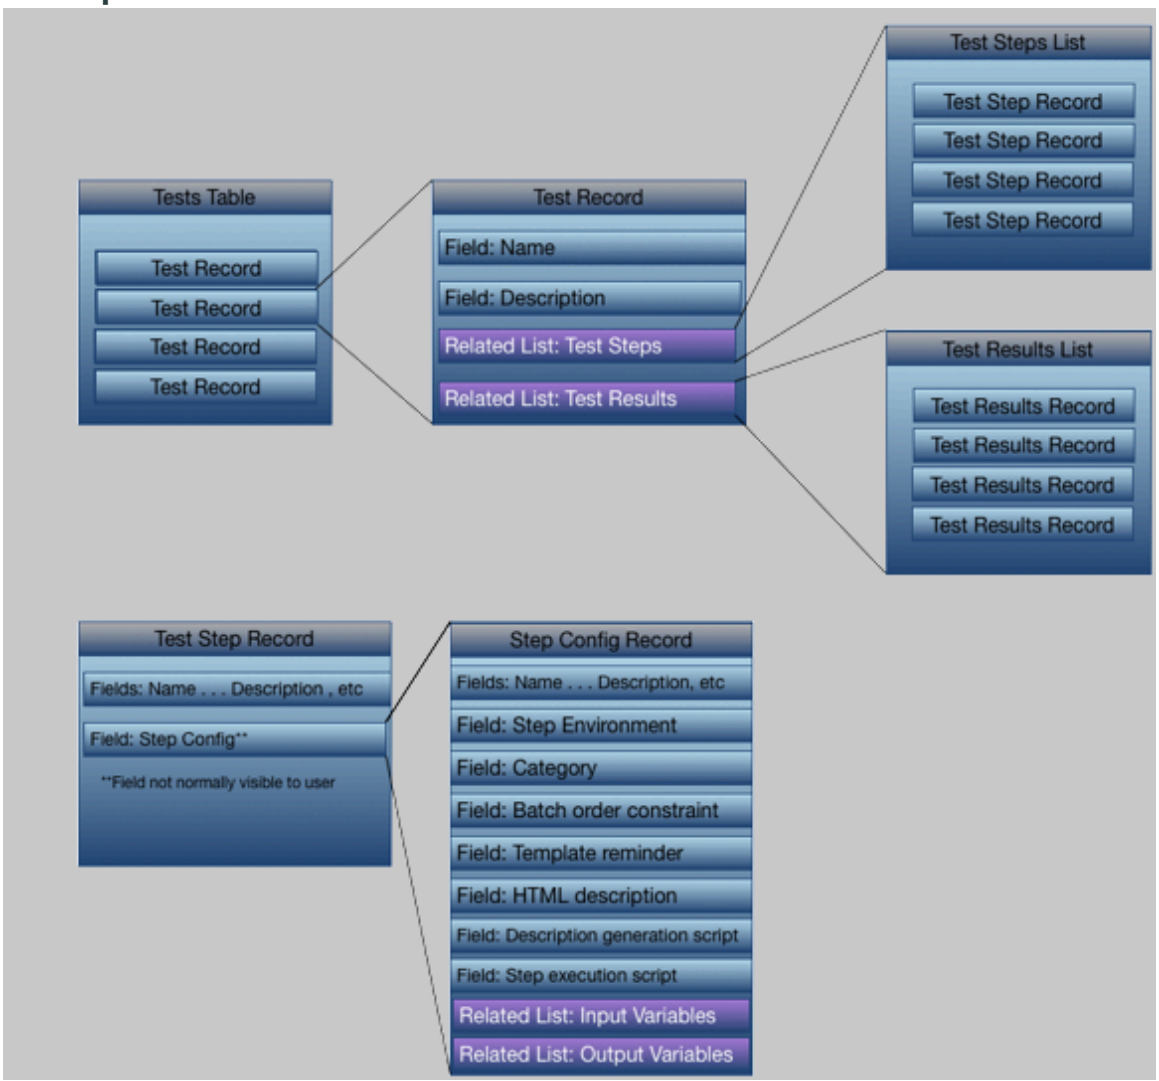
Creating custom test step configurations

Step configuration records (or step configs) define how each step type behaves. You can create new step configurations that define custom steps that run on the server.

When you add a step to an automated test, that step has a defined type such as Set Field Values, or Record Insert. Each step configuration has a number of characteristics that affect how steps of that type behave, including the inputs required, the actions performed, and so on.

These characteristics are defined in the step's step configuration record.

Test step architecture



TheStep execution scriptfield determines the actions the system executes when a step with this config runs.

Related topics

- Step configurations
- Step execution scripts

Create custom step configuration

Create a custom step configuration that can form the basis of new steps that run on the server.

Before you begin

Role required: atf_test_admin

> **Note:**
> Creating configurations are only supported in the server steps, the UI steps (running in the browser) are not supported. Also, only scripted steps are supported, custom Java-based steps are not supported.

About this task

The Automated Test Framework includes specific types of steps such as Open Form, Set Value, Assert Value and so forth. With the **Step Configurations** module, you can create steps that

perform actions you specify. You can only create configurations for steps that run on the Server. You cannot create configurations for steps that run on the browser.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Administration** > **Step Configurations**.
2. Click **New**.
   The system displays the **Test Step Config** form.
3. In the **Name** field, enter a name for your step type.
4. Leave **Active** checked.
5. Leave **Step environment** set to **Server-Independent**.
   You can define only step configurations that run on the server and not step configurations that run in the browser.
6. **Optional:** In the **Category** field, select the category to which you want to assign this step. Categories are used for filtering the step list in the Add Step dialog. For more information, see Category field example.
7. **Optional:** In the **Batch Order Constraint** field, choose one of the following values.
   - **None**: A step based on this configuration can appear at any point in a test.
   - **Start Batch Execution**: If this test includes a batch with this step, this step must be the first in the batch.
   - **Run in the middle of an execution**: If a test includes a batch with this step, this step must appear after the first and before the last step of the batch.
   - **Stop Execution**: If a test includes a batch with this step, this step must be the last step in the batch.
8. In the **Order** field, enter an integer specifying where steps with this configuration appear in the step list on the Add Test Step dialog.
   For more information, see the example using the **Order** field in Order field example.
9. In the **Template reminder** field, enter the instructions you want to appear when this step is included in a test as part of a template.
   For more information, see the example of using the Template reminder field.
10. In the **HTML description** field, enter the text you want to appear when the cursor highlights this step on the Create New Step dialog.

    For more information, see the example using the HTML description field in .

    Note:
    The next two steps involve writing scripts, which you should wait to complete until you have added input and output variables.

11. In the **Description generation script** field, add code to the provided template to generate the description assigned to a Test Step record when a step of this type is included in a test.
    For more information about writing this script, see Step description generation script. To see an example of where the system displays this description, see Description generation script example.
12. In the **Step Execution Script** field, add code to the provided template to define the script that executes when a step of this type runs.
    The script template provides instructions and examples for working with step inputs, outputs, and step results. For more details on the step execution script, see Step execution scripts.
13. Click **Submit**.
    The system creates a new test step configuration and returns to the list of test configurations.

14. **Optional:** Add input variables to this step config.
    a. Access the step config record.
    b. Scroll to the Input Variables tab, then click **New**.
    c. Fill in the required fields for the new variable.
    d. Click **Submit**.
    e. Repeat these steps until you have added all the input variables needed.
    f. **Optional:** Control the order in which input variables appear on the New Step form by editing the values in the **Order** column for the Input Variables related list.
15. **Optional:** Add output variables to this step config.
    a. Scroll to the Output Variables tab, then click **New**.
    b. Fill in the required fields for the new variable.
    c. Click **Submit**
    d. Repeat these steps until you have added all the output variables needed.

Step configurations

Automated Test Framework Step Config record

Add a predefined list of steps (template) to an automated test

Create a custom step configuration category

Create a custom step config category.

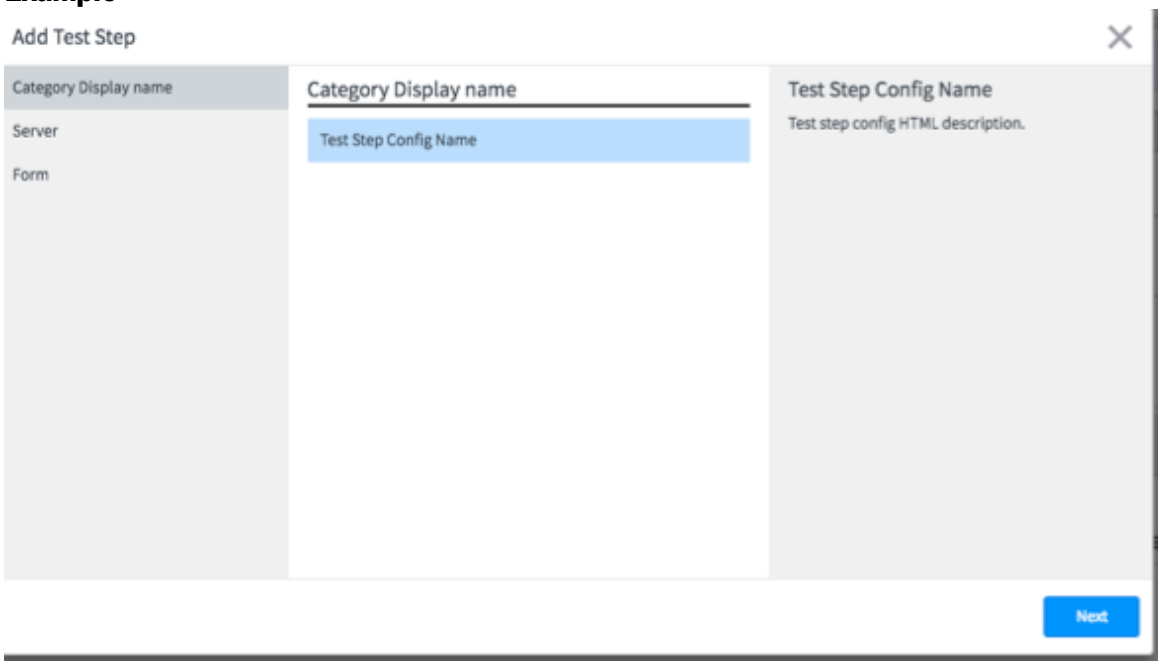
Before you begin
Role required: atf_test_admin

About this task
Categories are used for filtering the step list in the Add Step dialog. For more information, see Category field example.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Administration** > **Step Configuration Categories**.
2. Click **New**.
   The system shows the **Test Step Config Category** form.
3. In the **Name** field, enter a name for your step category.
4. In the **Step Environment** field, enter the step environment in which steps under this category execute:
   - Server - Independent, if you want this category to contain steps that execute on the Server.
   - UI, if you want this category to contain steps that execute on browser.
   - Server - REST, if you want this category to contain steps that send Inbound REST messages to the instance.
5. In the **Display name** field, enter the category name you want to appear in the middle column of the Add Test Step dialog when this category is selected.

Example



6. Click **Submit**.
   The system creates a test step category and returns to the list of test step environments.

Working with test step templates

Test step templates contain a list of steps to be added all at once to an automated test.

Related topics

Add a predefined list of steps (template) to an automated test

Create an automated test steps template

Reduce testing time by creating a template containing a list of steps to add all at once to an automated test.

Before you begin

Role required: atf_test_admin and atf_test_designer

About this task

Many tests follow similar patterns. One common pattern, for example, is to open a form, set some field values, validate some field values, click a UI action, open a record producer, open a catalog item, and submit the current form. If a template exists containing these steps, you can add them to a test all at once. The Automated Test Framework comes with default templates in the base system. With this procedure, you create your own templates.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Administration** > **Test Templates**.
   The system displays the Test Templates list.
2. Click **New**.
   The system displays the Test Template form.
3. In the **Name** field, enter a name for your template.
4. In the **Test Template** field, click the lock icon ( ).
   The **Test Template** field unlocks and expands to allow editing.

5. In the **Test Template** field, enter the name of the first test step to add to this template.
   The system adds the test step to the Test template list.
6. Continue adding test steps – in the order that you want them to appear – until you've added all the steps that you want to include in the list.

   Note:
   The test template supports tables, catalog items, and the record producer.

7. In the **Description** field, enter a description for this template.
8. Click **Submit**.

Related topics

Add a predefined list of steps (template) to an automated test

Edit automated test steps template

Edit an existing test template.

Before you begin
Role required: atf_test_admin and atf_test_designer

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Administration** > **Test Templates**.
   The system displays the **Test Templates** list.
2. Click the row for the test template you want to edit.
   The system displays the Test Template form.
3. In the **Test Template** field, click the lock icon ( ).
   The Test Template field unlocks and expands to allow editing.
4. **Note:**
   You can delete steps anywhere in the list, but you can add steps only to the end of the list. You can re-order steps in a test after you add them using the template, but you cannot re-order steps in the template itself.

   Add or delete steps to the template.
   - To delete a step, select that step, then click the **X** icon.
   - To add a step, in the **Test Template** field, enter the name of the step to add.
5. Continue adding and deleting test steps until it contains the steps you want.
6. Click **Submit**.

Related topics

Add a predefined list of steps (template) to an automated test

Enable or disable executing Automated Test Framework tests

Allow or prevent tests and test suites from executing on this instance.

Before you begin
Role required: atf_test_admin

About this task
By default, the system property that is used to run automated tests is disabled to prevent you from accidentally running these tests on a production system. To avoid data corruption or an outage, run tests only on development, test, and other non-production instances.

Procedure
1. Navigate to **All** > **Automated Test Framework** > **Administration** > **Properties**.
2. Set the test execution property.
   - To enable test and test suite execution, select **Enable test/test suite execution**.
   - To disable test and test suite execution, clear **Enable test/test suite execution**.
3. Select **Save**.

Modify data retention policy for ATF test results

Modify the Auto Flush data retention policy, which designates how long the system retains data, and referencing data, for test and test suite results. You can change the frequency of flushing for the sys_atf_test_result or sys_atf_test_suite_result base tables. This setting controls how far back in time test result data is available.

Before you begin
Role required: atf_test_admin

About this task
The system regularly flushes data in the sys_atf_test_result and sys_atf_test_suite_result base tables, (and optionally, referencing data). By default, the system deletes test and test suite results data 30 days after creation. This task enables you to modify the Auto Flush retention policy for data stored in a specific base table (sys_atf_test_result or sys_atf_test_suite_result).

Procedure
1. Navigate to **All** > **Automated Test Framework** > **Administration** > **Table Cleanup**.
   The system displays a list of the retention policies (Auto Flushes) it maintains for automated testing results tables.
2. Select the retention policy (sys_atf_test_result or sys_atf_test_suite_result) to modify.
   The system displays the record for this retention policy.

   Note:
   The **Tablename** field displays the name of the table to which the selected Auto Flush retention policy applies. Selecting another tablename in this field compromises the integrity of the Auto Flush record. Leave the tablename on existing ATF policies at the base system (default) value so it does not adversely affect ATF data retention behavior.

3. Specify how the system should determine the length of time for retention of data, and referencing data.

   a. In the **Matchfield** field, enter the field you want the system to use to monitor duration. For example, to specify that you want to delete data x amount of time after the system created it, leave **Matchfield** set to its default value of **sys_created_on**.

   b. In the **Age in seconds** field, enter the amount of time (in seconds) the system must wait before deleting the associated data and referencing data.

4. If you want to apply the policy to the specified data (for example, sys_atf_test_result), and to any data that references it, select **Cascade delete** (default value).
   Affected referencing data is stored the following tables: sys_atf_test_result_item, sys_atf_test_result_step, and sys_attachment (when table_name = sys_atf_test_result). If you want the policy to simply flush data in the selected table (for example, sys_atf_test_result), and skip flushing of the referencing data, then clear **Cascade delete**.
5. In the **Conditions** field, specify the filter conditions to use for selection of data (and optionally, referencing data) for this Auto Flush retention policy.
   The default is **Retain indefinitely is false**, because the Test results record also contains a **Retain indefinitely** check box that allows opting out of the auto flushes for specific test results.
6. Click **Update**.

Manage status and retention policies for automated test client runners

Modify how often active client test runners report in to the system and how long the system retains records for inactive client test runners.

Before you begin
Role required: atf_test_admin

About this task
When you start a client test runner, the system registers that runner as active, meaning that it is either running a test or is available to run a test. While the runner is active, it reports in to the system at a specified interval. If the runner does not report in at the expected time, the system marks the runner as inactive. After a period of time the system deletes the runner. This task enables you to modify the Automated Test Framework properties that control these intervals.

Procedure
1. Navigate to **All** > **Automated Test Framework** > **Administration** > **Properties**.
2. Navigate to the Test Runner Properties section.
3. To set the interval at which active client test runners report in to the system, enter the reporting interval in seconds in the **Test runner heartbeat interval** field.
4. To set the period of time a test runner can remain inactive before the system deletes it, enter the period of time in seconds in the **Test runner timeout** field.
5. Click **Save**.

Moving automated tests from one instance to another

Move automated tests from one instance to another using the normal process for update sets.

Role required: atf_test_admin

You can move automated tests, automated test suites, and related data using update sets. For more information, see System update sets.

Compare results and execution times for different automated test and suite results

You can compare execution times for different runs of an automated test or automated test suite. You can also compare results over time for a single automated test suite.

Before you begin

Role required: atf_test_admin or atf_test_designer

Compare execution times for different runs of an automated test

Compare how long it took the system to execute each test step across different runs of the same test.

Procedure

1. Navigate to **Automated Test Framework** > **Tests**.
2. Select the row for the test whose results you want to compare.
   The system displays the Test form.
3. Navigate to the **Test Results** related list.
4. Check the rows for the test results you want to compare.
5. From the **Actions on selected rows** control, click **Compare test step results**.
   The system displays the Compare test result execution times bar graph.

Compare execution times for different runs of the same automated test suite

Compare how long it took the system to execute each test across different runs of the same test suite.

Procedure

1. Navigate to **Automated Test Framework** > **Suites**.
2. Select the row for the test suite whose results you want to compare.
   The system displays the Test Suite form.
3. Navigate to the **Test Suite Results** related list.
4. Check the rows for the test suite results you want to compare.
5. From the **Actions on selected rows** control, click **Compare test results**.
   The system displays the Compare test result execution times bar graph.

Compare results for automated test suite runs (aging report)

Compare how many tests passed versus failed across different runs of the same test suite.

Procedure

1. Navigate to **Automated Test Framework** > **Suites**.
2. Select the row for the test suite whose results you want to compare.
   The system displays the Test Suite form.
3. Under Related Links, click **Display aging report**.
   The system displays the Test suite aging report.

Administering REST test step configurations

Set request and response payload sizes, filter request and response headers, and create basic auth profiles.

Create a basic auth profile using the Automated Test Framework

Create basic auth profiles to specify basic authentication credentials for Send Request - Inbound test steps.

Before you begin
Role required: web_service_admin

About this task
The user name and password must be valid credentials on the instance where the tests using the profile are run.

Procedure
1. Navigate to **All** > **Automated Test Framework** > **Tests**.
2. Select a test that uses a Send Request - Inbound step.
3. Select a Send Request - Inbound step.
4. In the **Basic authentication** field, select the hour glass to look up the available profiles.
5. On the **Basic Auth Configurations** form, select **New**.
6. In the **Name** field, enter a name for the profile.
7. In the **Username** field, enter a user name.
8. In the **Password** field, enter a password.
9. Click **Submit**.

Filter REST request and response headers
You can add a list of REST request and response headers that are not to be saved in step-result records. You can filter headers that might contain authentication credentials or other sensitive information. The phrase "Header redacted for security" is saved instead.

To specify headers to be filtered, create a system property `glide.atf.rest.log.header_blacklist` with a comma-separated list of header names to be filtered. For information on adding properties, see Add a system property.

Automated Test Framework REST properties
These properties are installed with ATF REST.

Note:
To open the System Property [sys_properties] table, enter `sys_properties.list` in the navigation filter.

Property	Usage
glide.atf.rest.log.header_blacklist	A list of headers whose content is not to be added to the log, or shown on a form. The phrase 'Header redacted for security' is saved instead. • **Type**: String • **Default value**: empty • **Other possible values**: A comma-separated list of header names. • **Location**: System Property [sys_properties] table
glide.atf.rest.request_payload_max_size	The maximum size of the request payload.

Property	Usage
	• **Type**: String • **Default value**: 100 Kb • **Maximum value**: 1024 Kb • **Location**: System Property [sys_properties] table
glide.atf.rest.response_payload_max_size	The maximum size of the response payload. • **Type**: String • **Default value**: 100 Kb • **Maximum value**: 5120 Kb • **Maximum value**: System Property [sys_properties] table

Optimizing automatic test performance

You can troubleshoot automatic test performance by inspecting system transaction log records and potentially shorten execution time by adjusting how often automatic tests capture screenshots.

Managing automatic test screenshot settings

Capturing many screenshots can impair test performance. You can control which types of screenshots the system captures to minimize this effect.

By default, the system captures a screenshot every time it executes a form test step. This information can be useful for understanding test results, but may slow down how fast the system executes the test.

You can change automatic test framework settings so that the system captures all screenshots (as it does by default), no screenshots, or just screenshots for failed test steps.

You can change these settings to affect all tests run on this instance, or to affect just the current client test runner session. To affect all tests run on this instance, set the automatic test framework property from the automatic test framework properties page. To affect just the current client test runner session, set the screenshot mode from client test runner browser window.

Set the system property to control when the Automated Test Framework captures screenshots

To control how often this instance captures screenshots for form test steps, set the screenshot capture mode on the automatic test framework properties page.

Before you begin

Role required: atf_test_admin or admin

About this task

Setting the screenshot mode from the automatic test framework properties page affects any new client test runners started on this instance. This setting does not affect currently-running test-runners.

Procedure

1. Navigate to **All** > **Automated Test Framework** > **Administration** > **Properties**.
2. Set the **Enable or disable screenshot capture** property from the drop-down menu.
   - To capture screenshots for all steps, select **Enable for all steps**.
   - To capture screenshots only for failed steps, select **Enable for all failed steps**.
   - To capture no screenshots, select **Disable for all steps**.
3. Set the **Screenshot timeout** time interval, in seconds.
   The Client Test Run does not take a screenshot capture if the length of the attempt exceeds this value. Users should review performance settings and browser caches on affected client systems before increasing this value.
4. Click **Save**.

Set the client test-runner property to control when the Automated Test Framework captures screenshots

To control how often the current client test runner captures screenshots for form test-steps, set the screenshot capture mode on the client test runner browser window.

Before you begin
Role required: atf_test_admin or admin

About this task
Setting the screenshot mode from the client test-runner browser window affects only this client test-runner and persists until this test-runner session is closed. This setting does not affect any other running test-runners or any future test runners.

Procedure

1. From the client test-runner browser window, click the form preferences icon ().
2. Click the **Screenshot mode** option.
   - To capture screenshots for all steps, select **Enable for all steps**.
   - To capture screenshots only for failed steps, select **Enable for all failed steps**.
   - To capture no screenshots, select **Disable for all steps**.
3. Click **Save**.

View transaction data for automated test results

To help troubleshoot performance issues with automatic tests, you can inspect related records from the transactions log entry [syslog_transaction] table.

Before you begin
Role required: test_admin or admin

About this task
Note:
The system may not be able to log some transactions with short durations.

Procedure

Navigate to related transaction record in the system transaction log.

- From the Step results record, view transactions in the Step transactions related list.
- From the Test Results record, view transactions in the Test Transactions related list.

Working with scheduled test suites

You can schedule a test suite to run at a specified date and time.

To schedule a test suite, you need three components:

- a test suite record
- a schedule record specifying when you want the system to run the test suite
- a scheduled suite run record that associates the test suite to run with the schedule for running it

With this model, you can associate a schedule with many different test suites and vice-versa.

Note:
You can schedule only test suites, not individual tests. Scheduled tests will only run if there is an open Scheduled Client Test Runner page matching the scheduled suite's browser conditions. Scheduled tests cannot run on a machine that is locked, powered down, or does not already have the browser open.

The watchlist on the test suite run record also allows you to specify users to receive an email when the system finishes executing the test suite run.

If the test suite contains one or more form steps (steps involving a user interface), you must ensure that a scheduled client test runner is actively running in a browser when the schedule triggers the suite run.

Note:
See Browser recommendations and requirements for recommendations and requirements for running the client test runner.

For step-by-step instructions on how to schedule a test suite, see Schedule an automated test suite.

Designate users to receive email when system finishes running a scheduled test suite

You can designate users to be notified when a scheduled test suite finishes executing.

Before you begin

Role required: atf_test_admin

Procedure

1. Navigate to the scheduled test suite run record.
2. Add to the record's **watchlist** all users you want the system to notify when this scheduled test suite run completes.

Automated Test Framework scheduled test suite completed email

When the system completes executing a scheduled test suite, it sends an email to users on the Scheduled Suite Run record watchlist. This email contains information and links to further information about the Scheduled Suite Run and its results.

Note:
Email functionality must be enabled in order to send an email.

Suite Stats

The Suite Stats section of the email reports the number of suites and individual tests broken down by result status: Failed (F), Error (E), Skipped (S), Canceled (C), or Passed (P). For a description of what each status means, see Test suite results record.

Test Suite Results

The Test Suite Results section of the email reports test suite results over time.

Note:
By default, this report includes only suites with failed tests, but you can change this setting with the **Email properties** field on the Properties page. If set to default, only the failed tests within a test suite are reported.

Preview email report

Note:
ATF reports only recent tests results on the email report. All the previous test results still exist if it's within the set retention time limit. See Table cleanup for more information on retention policy for ATF test results.

Test Results Key

Letter	Color	Description
F	red	Test failed
P	green	Test passed

Test Results Key (continued)

Letter	Color	Description
S	white	Test skipped
C	white	Test canceled
E	orange	Test has error

Each entry acts as a link to the result record for that run. If you point the mouse to any of these entries, the system displays the parent suite number, the parent suite end time, and the test result output.

Properties affecting email content

On the Automated Test Framework Properties form, you can set options affecting the format and content of the email.

Automated Test Framework use case examples

Use cases can help you construct tests for common scenarios.

Automated Test Framework use case: test basic form operations

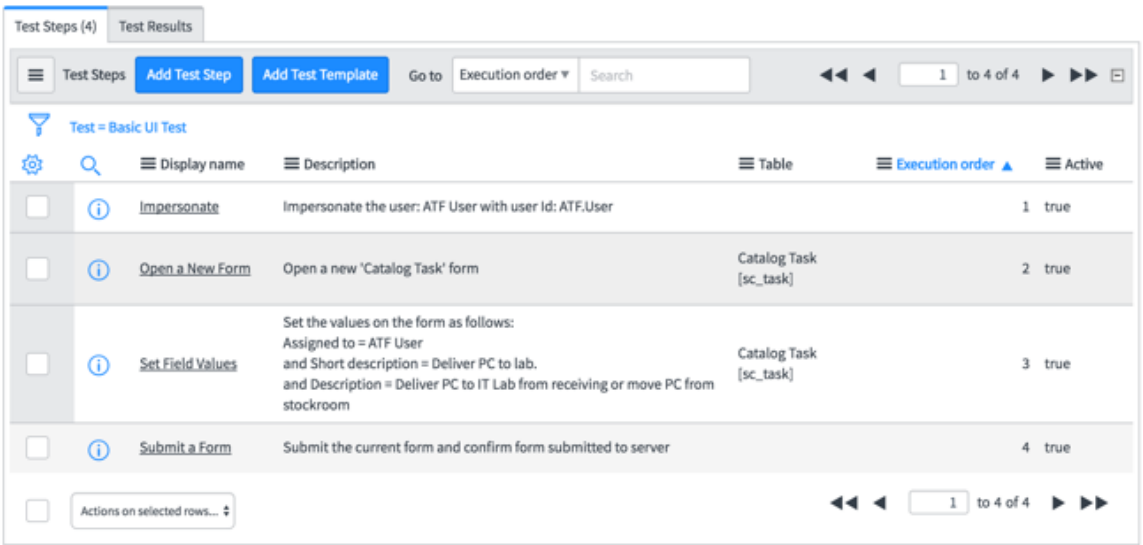
This use case illustrates testing basic form operations with the Automated Test Framework.

Before you begin

Role required: atf_test_admin

About this task

Steps in test

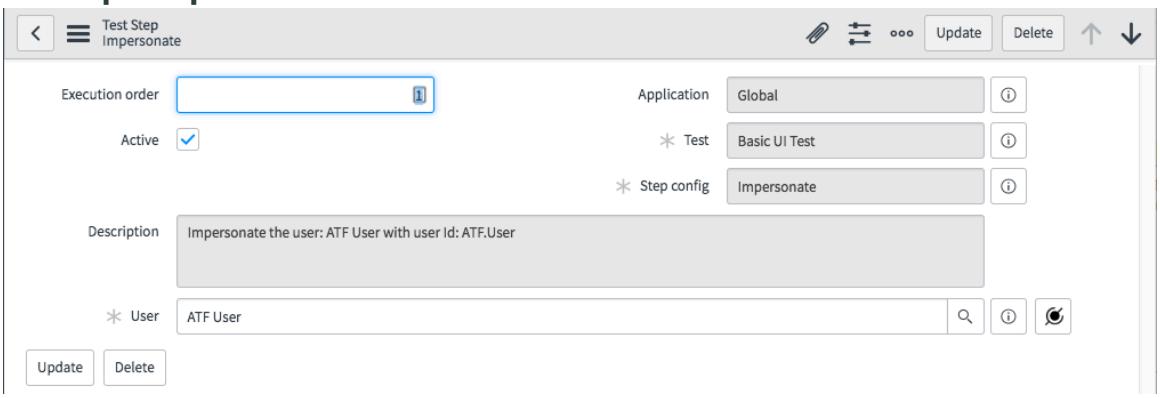


Procedure

1. Impersonate a user with the permissions needed to perform these steps, in this example ATF.User.

   Example

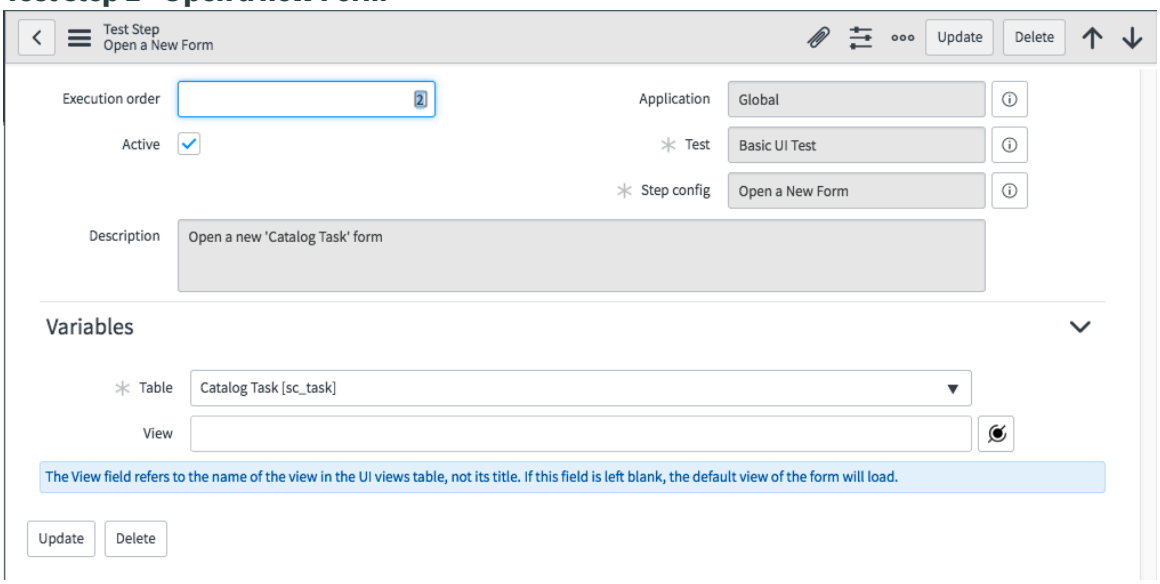
   Test step 1 - Impersonate

2. Open a form, in this example a Catalog Task form.

   Example

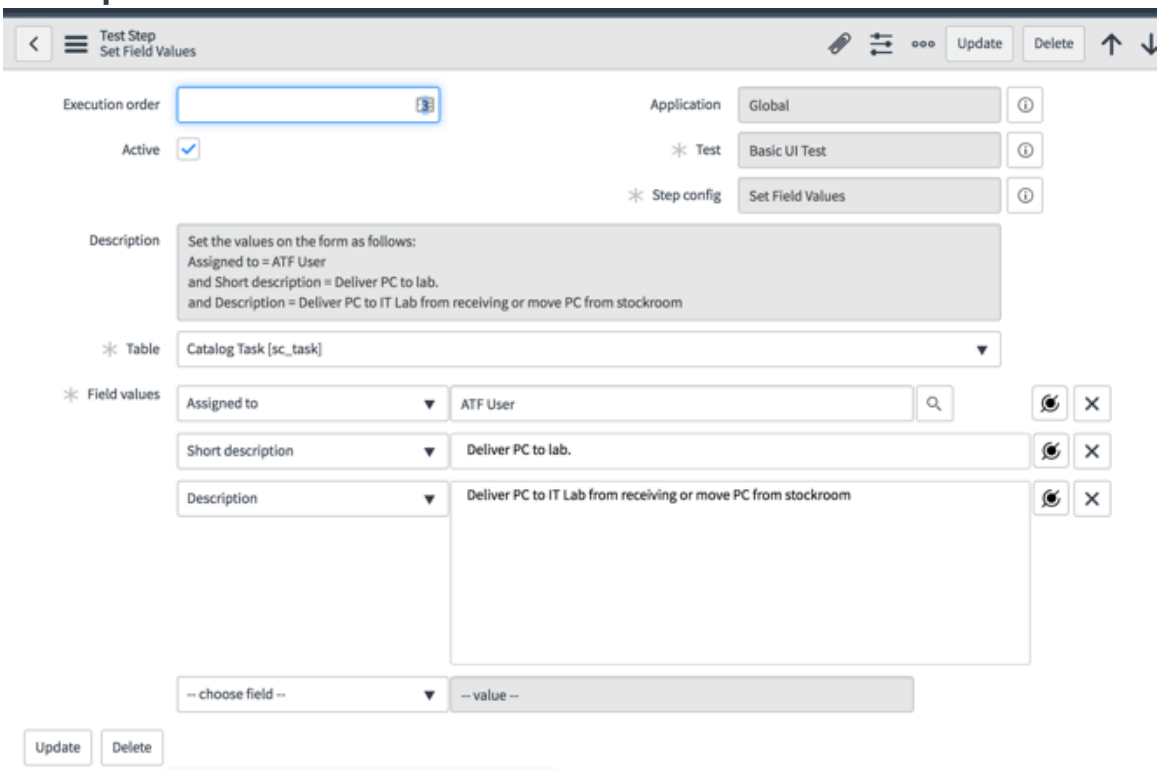
   Test step 2 - Open a new Form

3. On the open form, set field values, including for any mandatory fields.
   This example sets field values for **Assigned to**, **Short description**, and **Description**.

Example

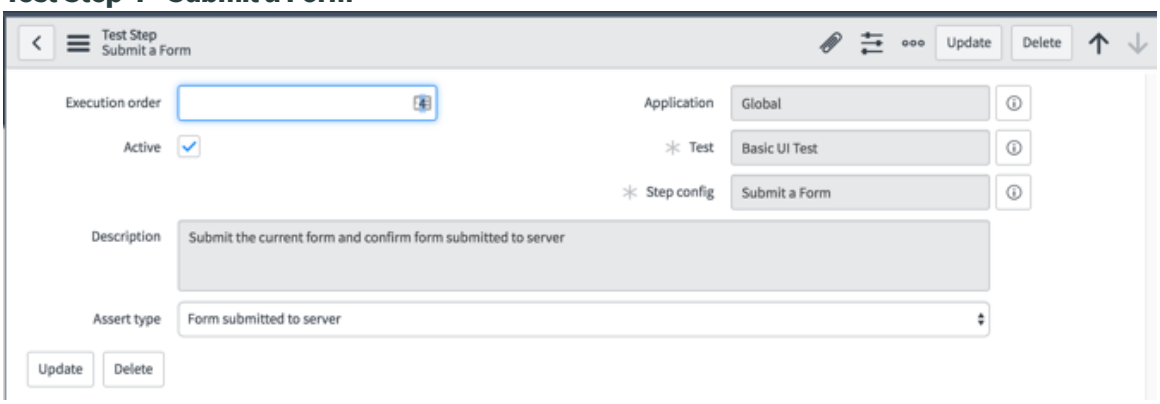
Test step 3 - Set Field Values



4. Submit the open form.

Example

Test Step 4 - Submit a Form



Automated Test Framework use case: reference a value from a previous step

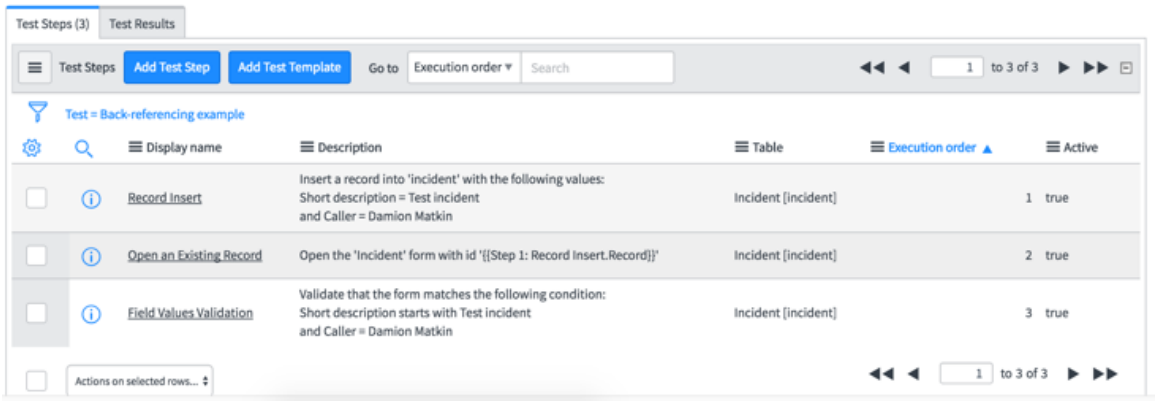
This use case illustrates assigning a form field the value of an output variable from a previous step.

Before you begin

Role required: atf_test_admin

About this task

Automated Test Framework: In this example, the second step references an output value from the first step. Pass values from one step to another example.

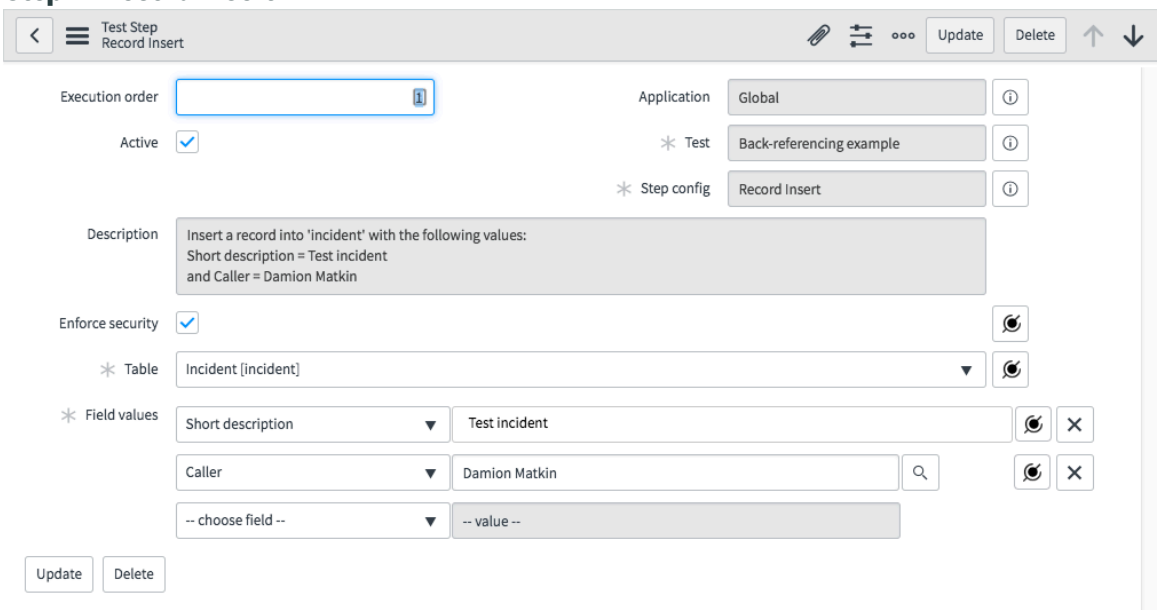


Procedure

1. Insert a record into the incident table.
   This example inserts a record into the Incident table.

   ### Example

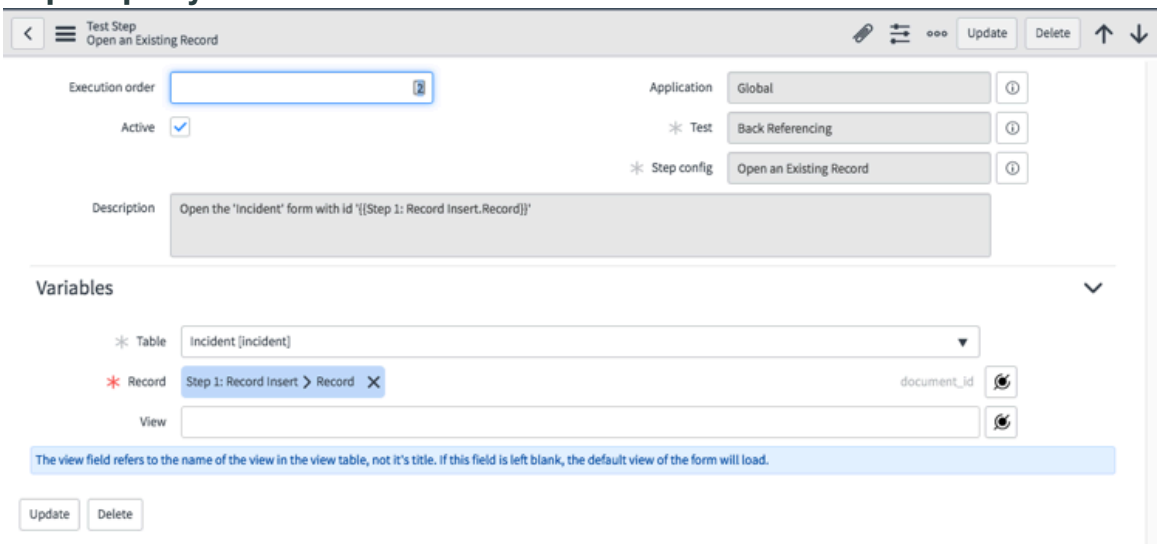
   Step 1 - Record Insert

2. Open the record just inserted by assigning to the *Record* field the output variable from Step 1.

Example

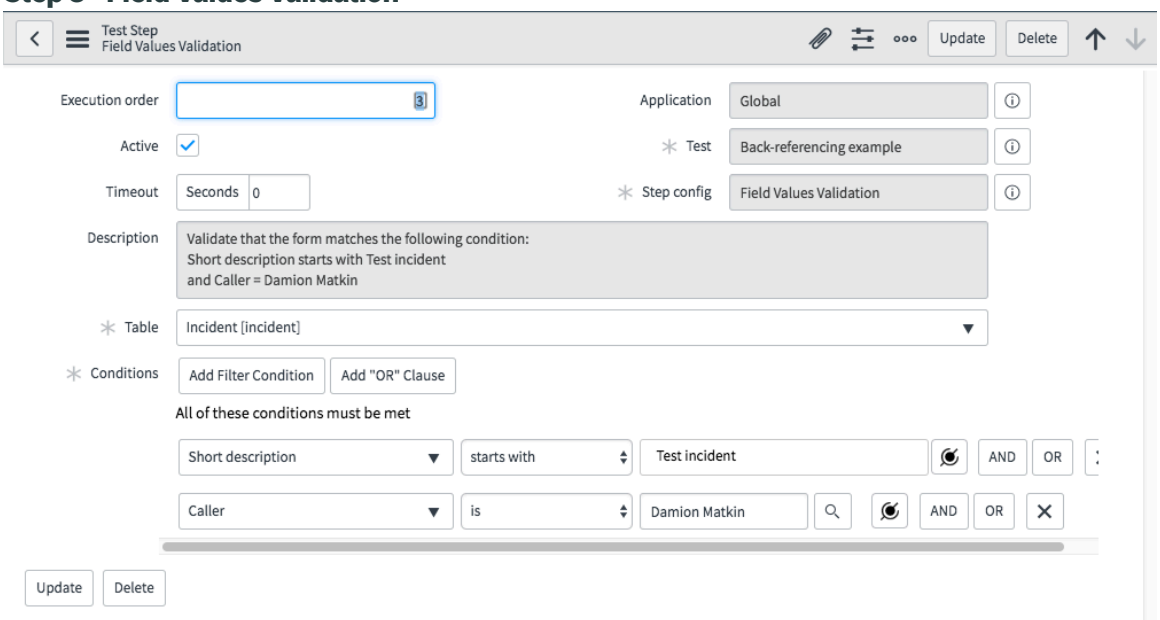
Step 2 - Specify the record



3. Validate that fields on the open record have the values you expect.

Example

Step 3 - Field Values Validation



Related topics

Pass values from one automated test step to another

Automated Test Framework use case: test a business rule

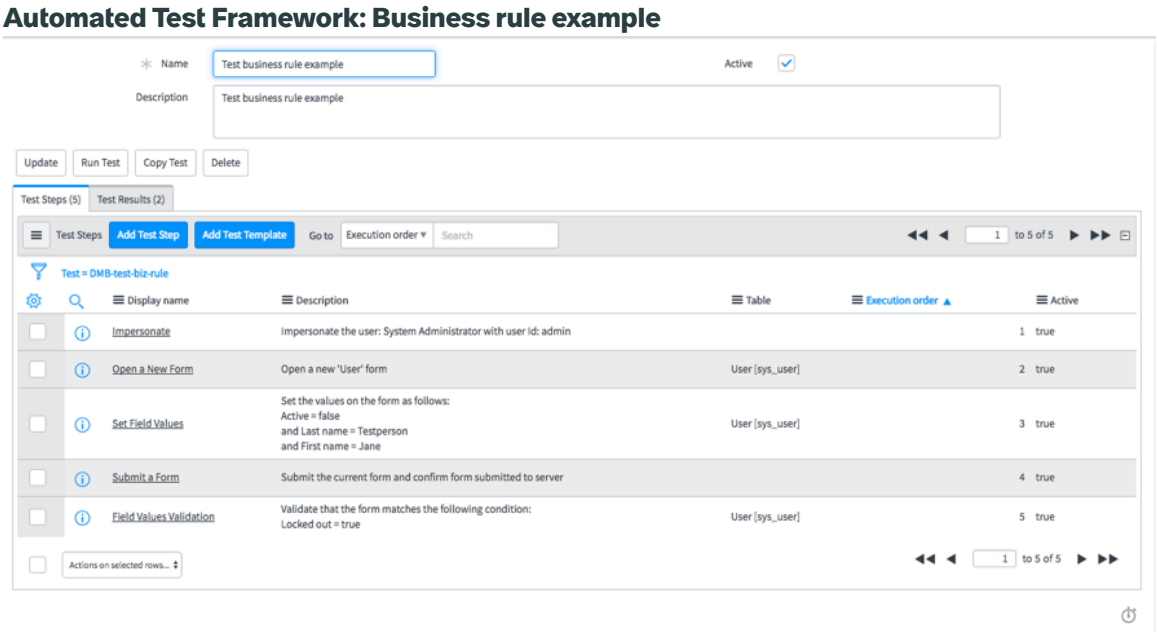
This use case illustrates testing a business rule with the Automated Test Framework.

Before you begin

Role required: atf_test_admin

About this task

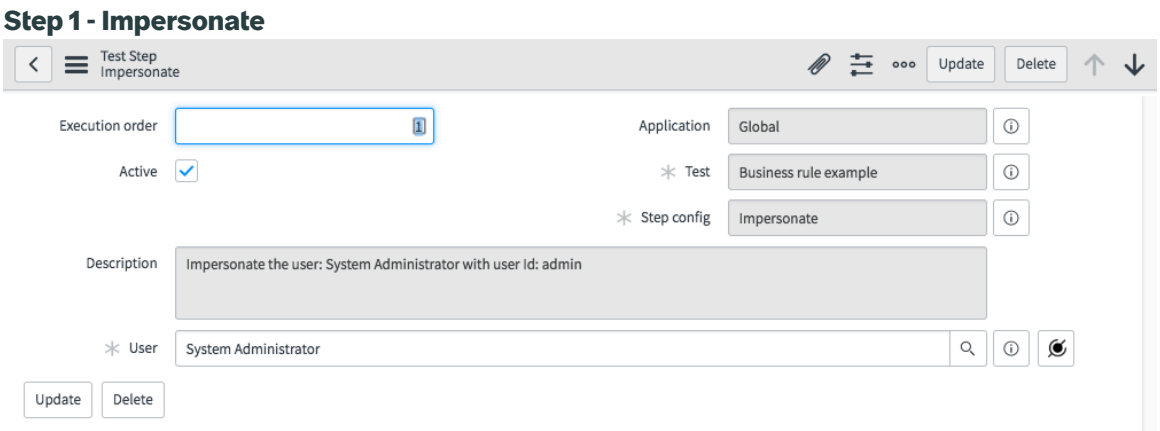
This example tests a business rule that sets the value of **Locked out** to **true** when **active** is set to **false**.



Procedure

1. Impersonate a user with the necessary permissions.
   In this example, the step impersonates the admin user.

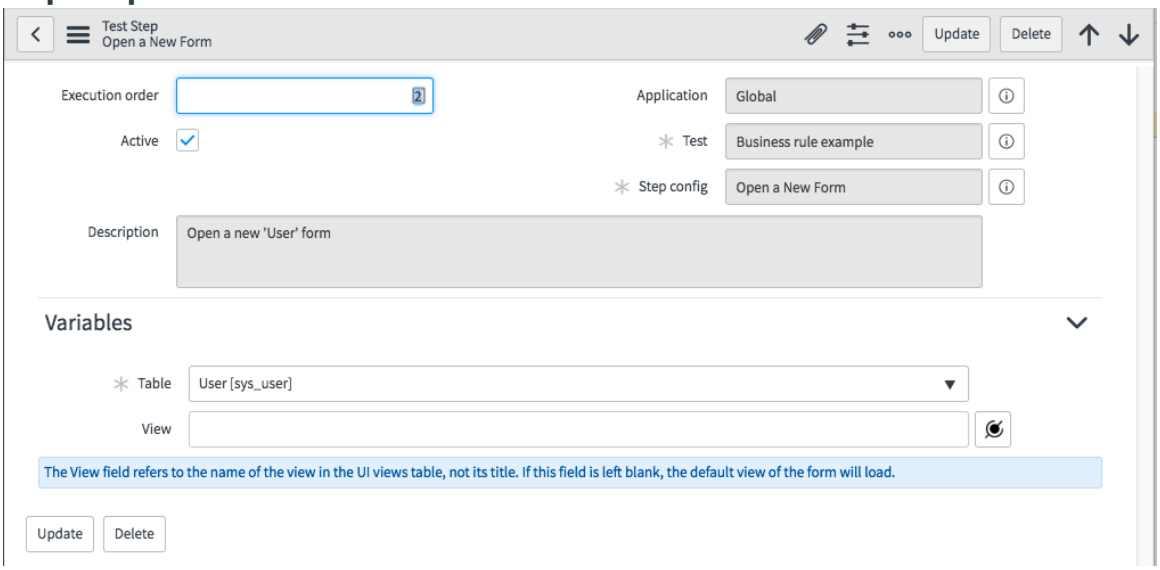
   Example



2. Open a form for the table to which this business rule applies.
   This example opens a new User form.

Example

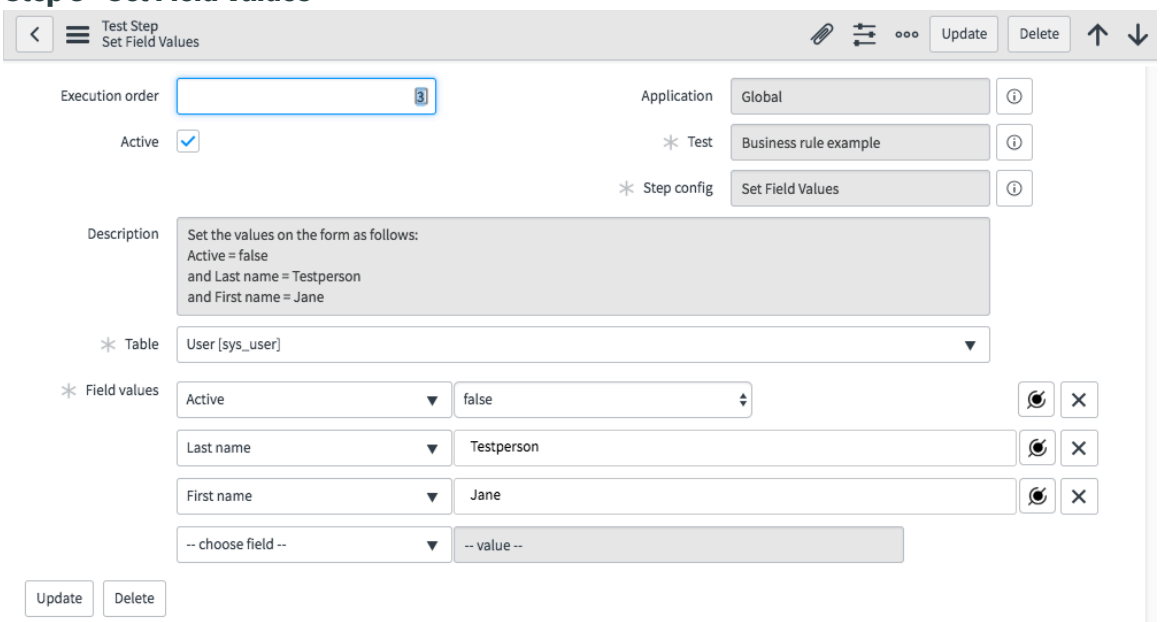
Step 2 - Open a New Form



3. Set values on the form that meet the requirements for submitting the form and for triggering the business rule.
   This example sets values for the **Active**, **Last name**, and **First name** fields.

Example

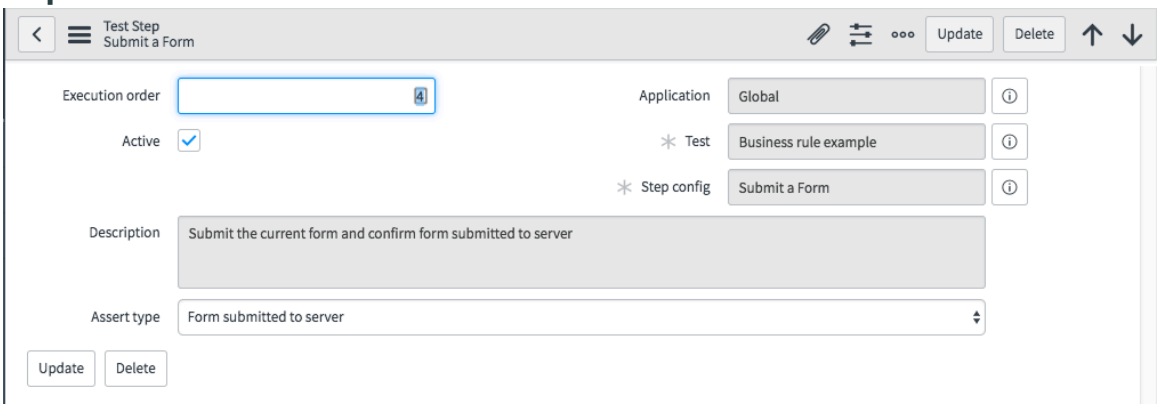
Step 3 - Set Field Values



4. Submit the form.

Example

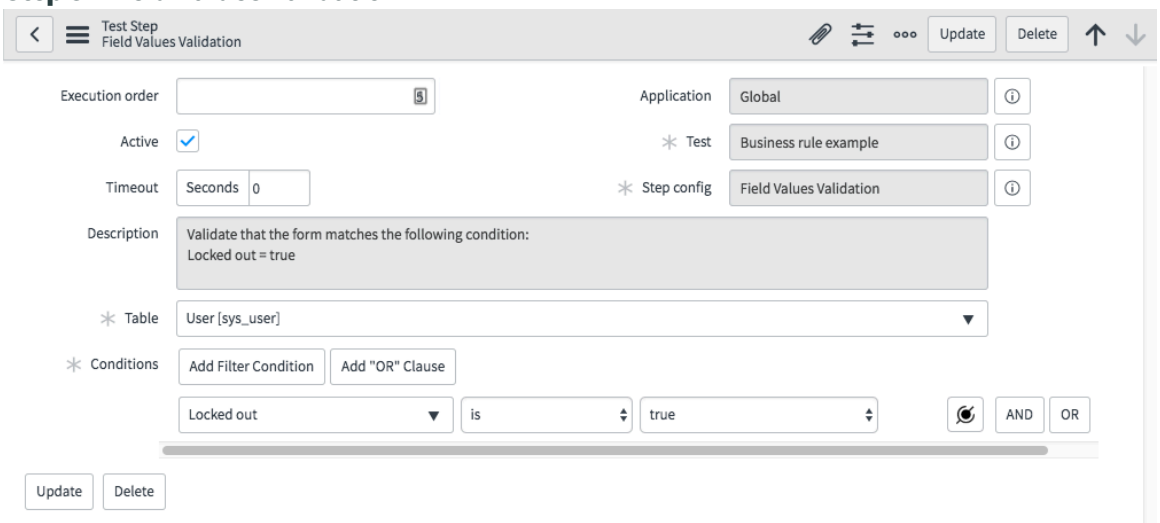
Step 4 - Submit Form



5. Validate that the business rule ran.
   In this example the business rule tested sets **Locked out** to **true** if **Active** is set to **false**.

Example

Step 5 - Field Values Validation



Automated Test Framework use case: test a data policy

This use case illustrates testing a data policy with the Automated Test Framework.

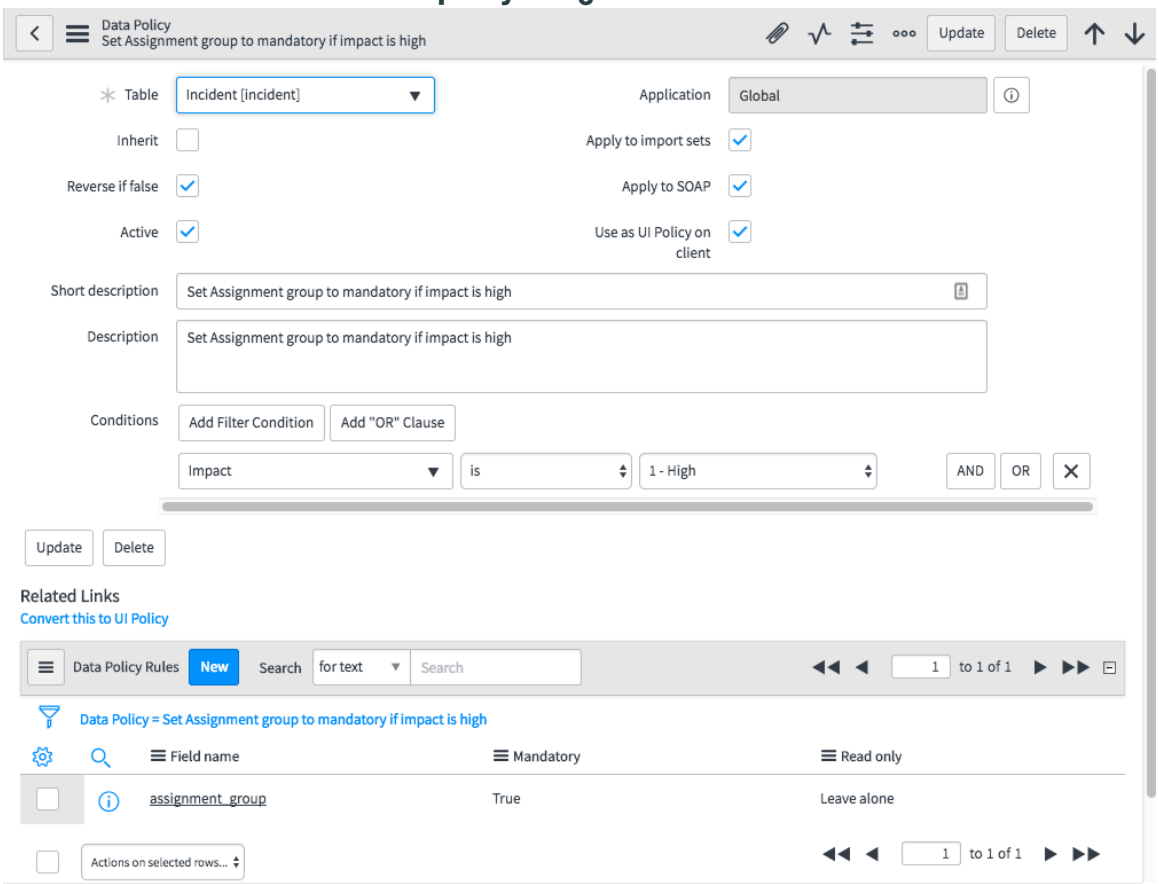
Before you begin

Role required: atf_test_admin

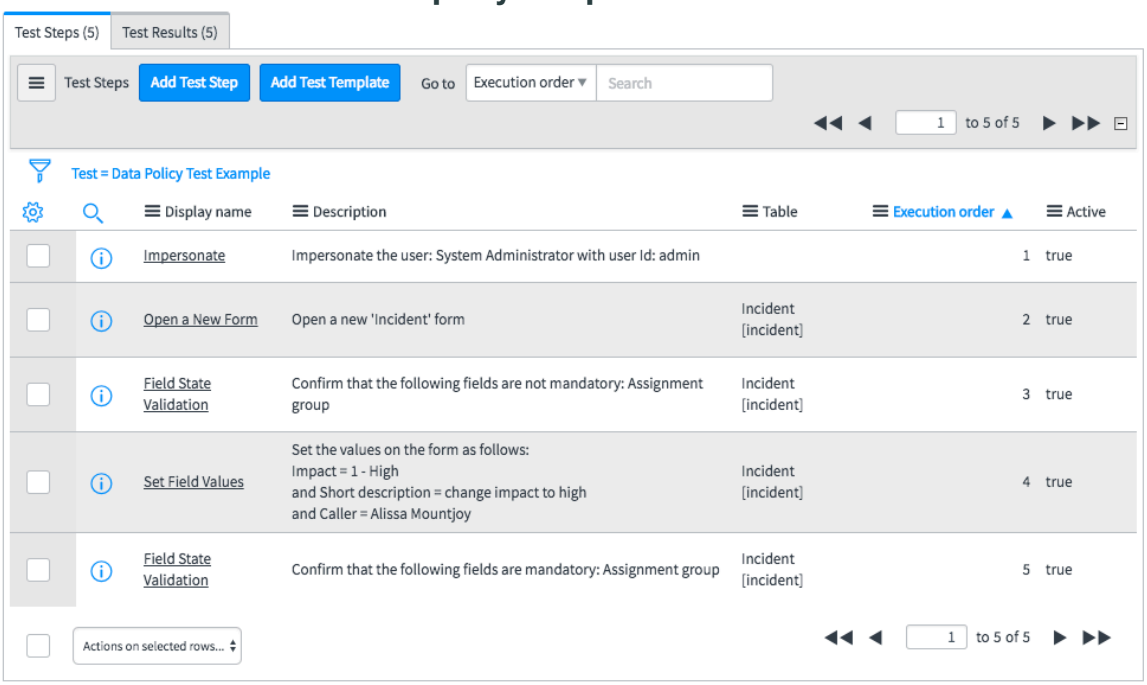
About this task

This example tests the data policy that sets the field **Assignment Group** to **mandatory** if **impact** is **high**.

Automated Test Framework: Data policy being tested



Automated Test Framework: Data policy example

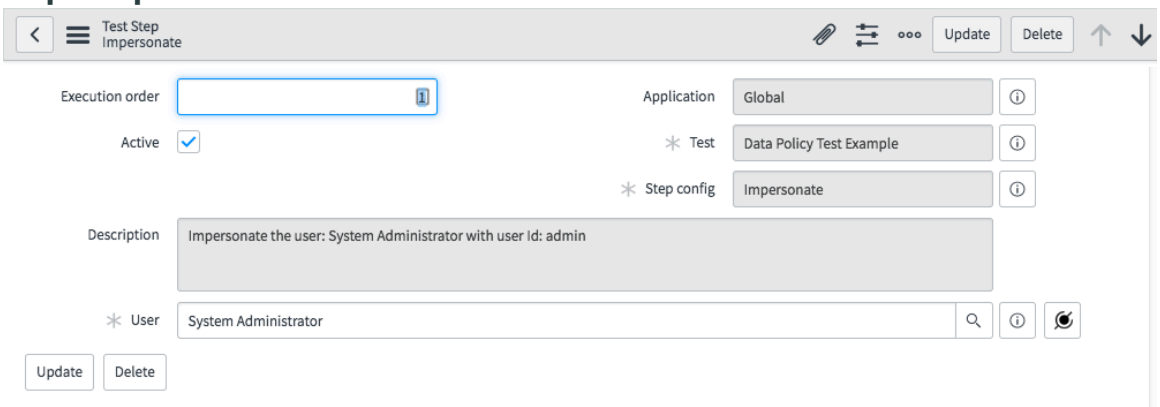


Procedure

1. Impersonate a user with the necessary permissions.
   In this example, the step impersonates an admin user.

Example

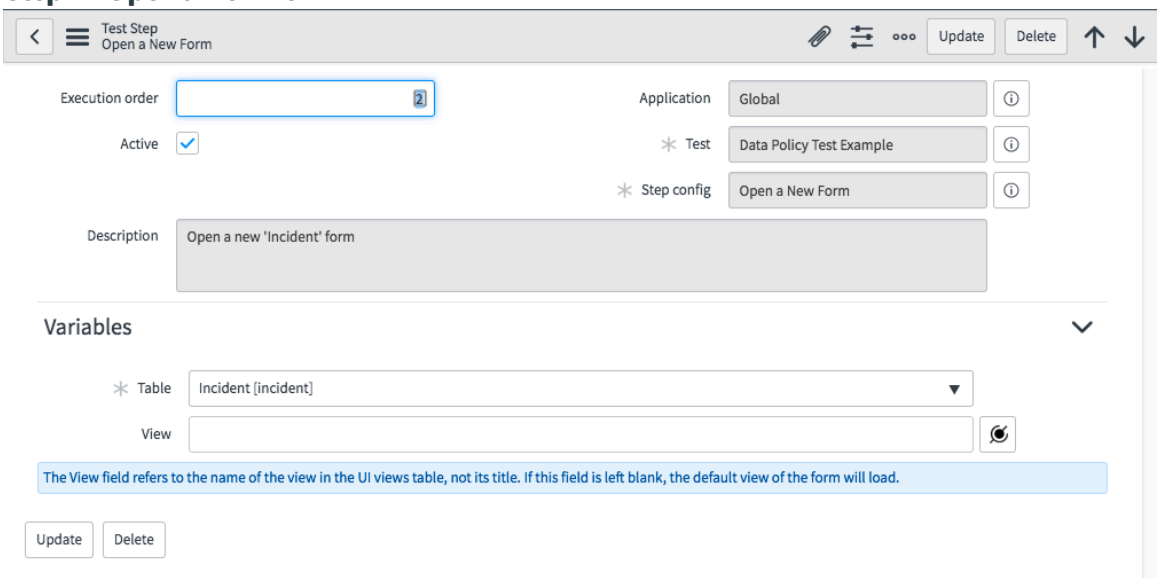
Step 1 - Impersonate



2. Open a form for the table to which this data policy applies.
   This example opens a new incident form.

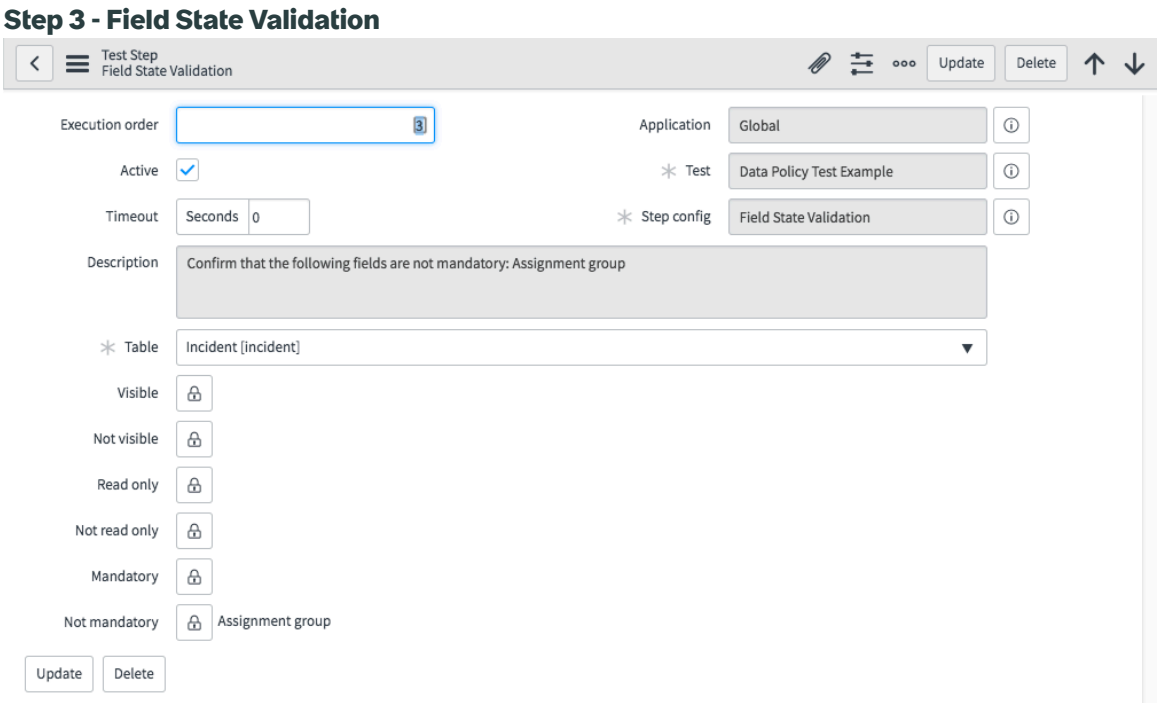
Example

Step 2 - Open a New Form



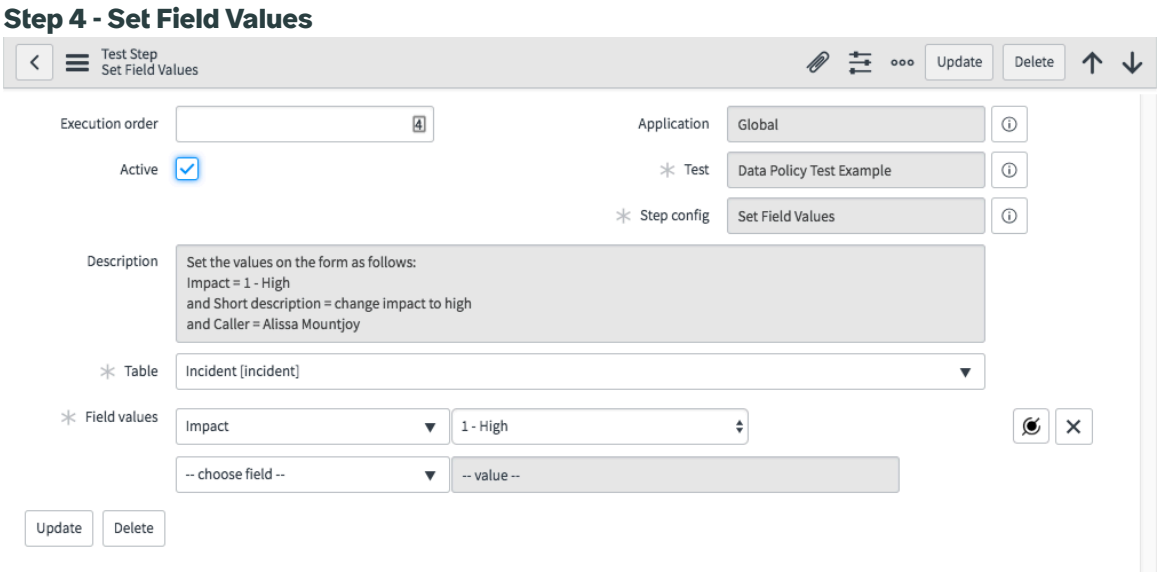
3. Check that the data policy has not yet been triggered.
   In this example, the step checks to confirm that **Assignment group** is not **mandatory**.

Example



4. If applicable, set the conditions that trigger the data policy.
   This example sets **Impact** to **High**.

Example

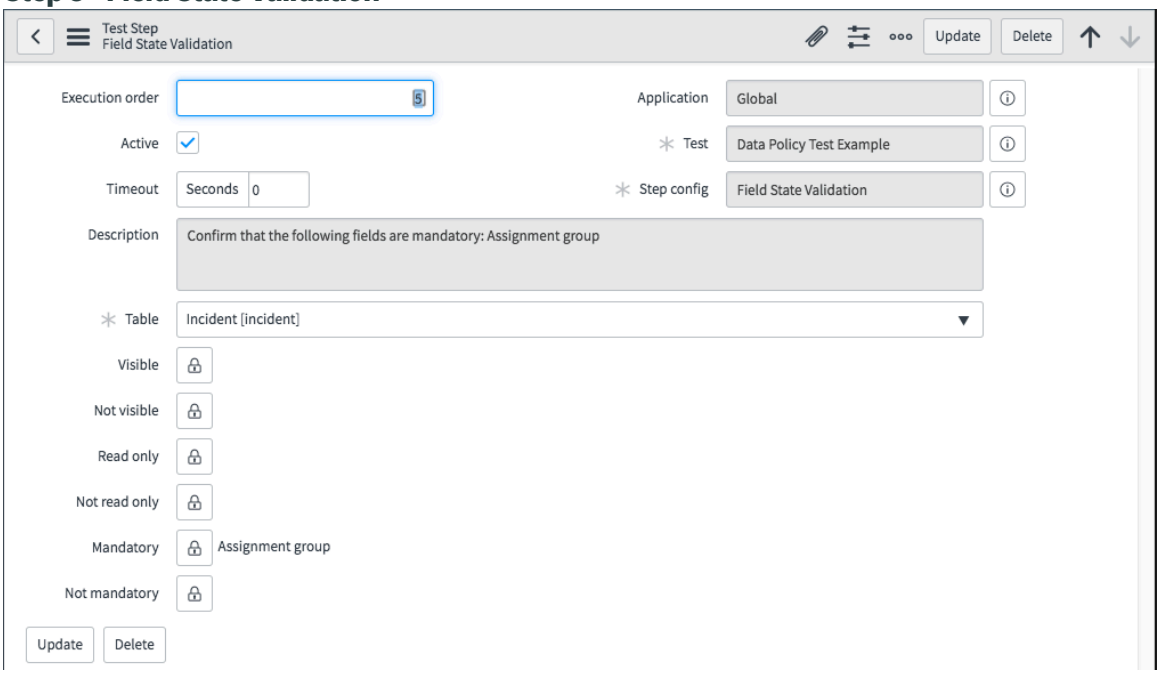


5. Validate that the data policy is enforced.

In this example, the test confirms that the data policy set **Assignment group** to **High** after the previous step set **Impact** to **High**.

Example

Step 5 - Field State Validation



Automated Test Framework use case: test a script include

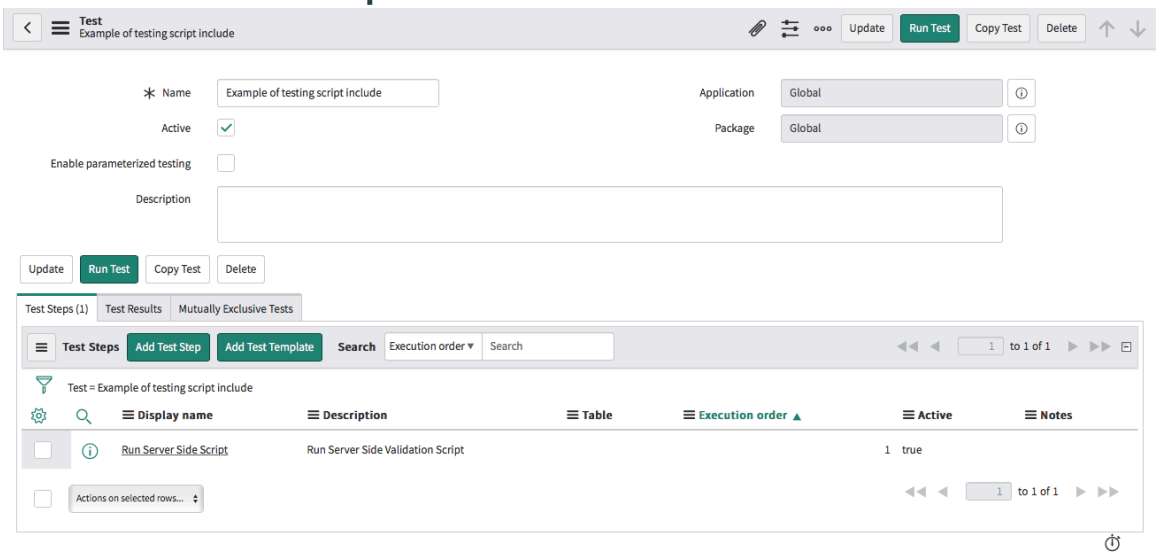
This use case illustrates testing a script include with the Automated Test Framework.

To test a script include with the Automated Test Framework, create a test that performs these steps:

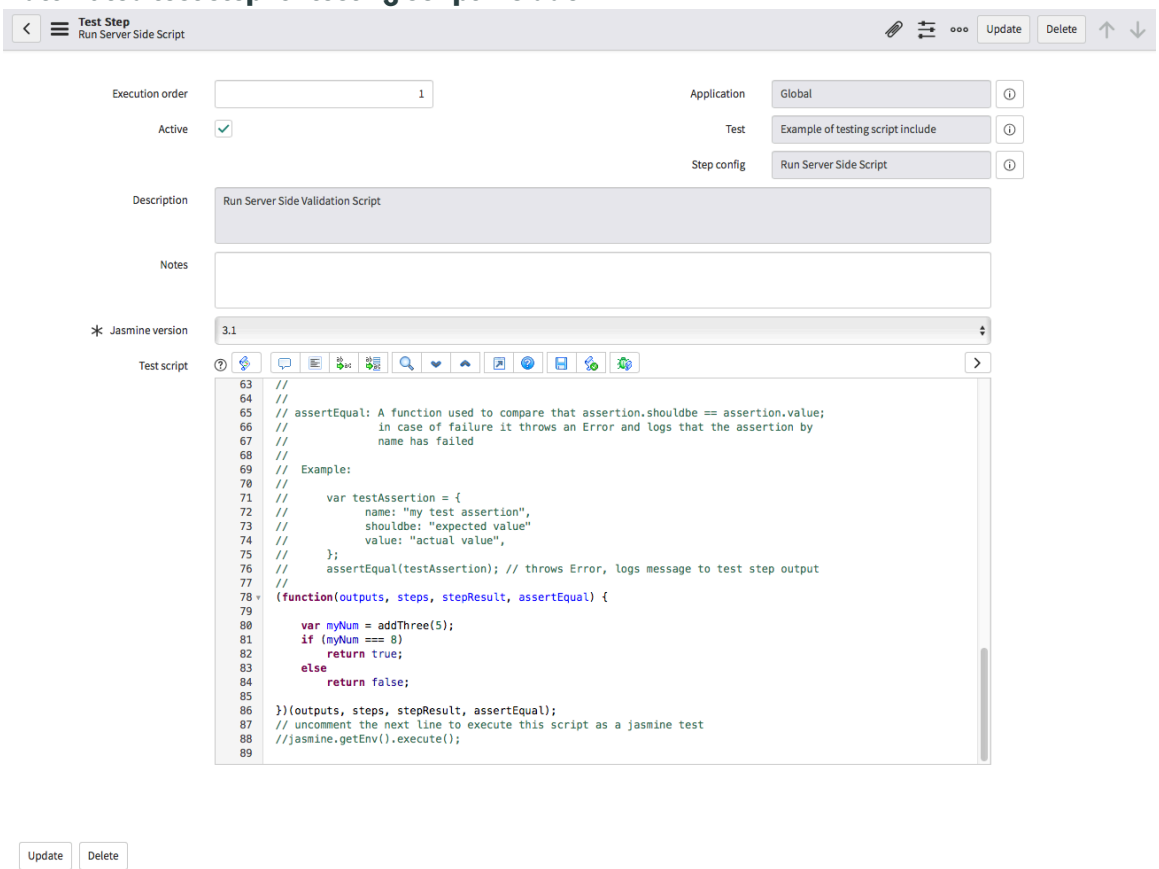
- a step that causes the system to execute the script include. Examples:
  - Run Server Side Script test step that calls the script include.
  - Form action step script – such as open a form, submit or form, or set a field value – that invokes the script include.
- A step that validates that the script include took the expected actions. The specific test step for this validation depends on what the script include is designed to do. Examples:
  - Field values validation, if the script sets a field value
  - Field state validation, if the script changes a field state
  - Record Query, if the script generates a new record

This example shows a test with one test step: Run Server Side Script. The script associated with this test step calls a script include that returns the value of its argument plus three. If the value returned from the script include is 8, the script include has worked as intended and the test passes.

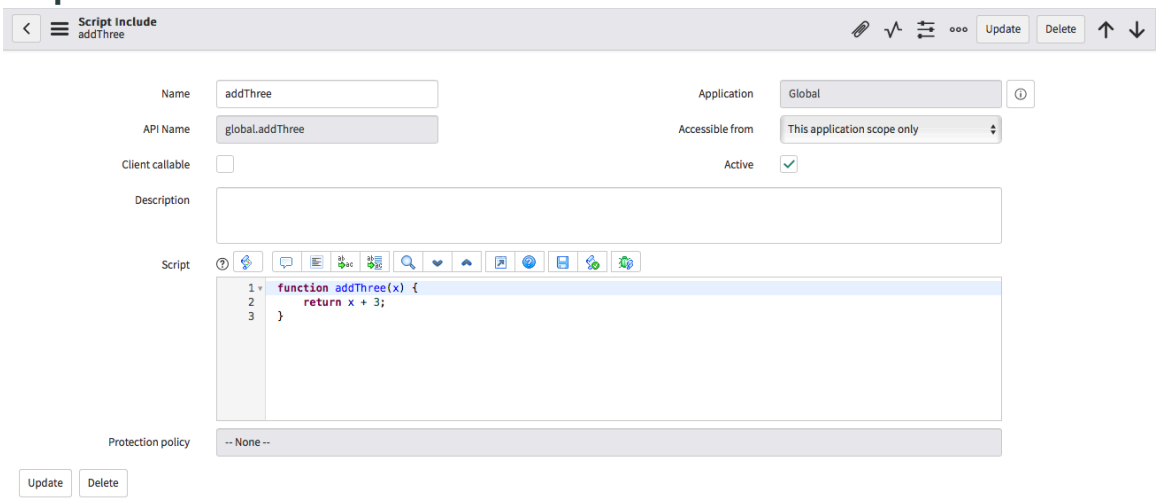
Automated Test to test a script include



Automated test step for testing script include



Script include to test with Automated Test Framework



Automated Test Framework use case: test a Service Catalog request

This use case illustrates testing a service catalog request with the Automated Test Framework.

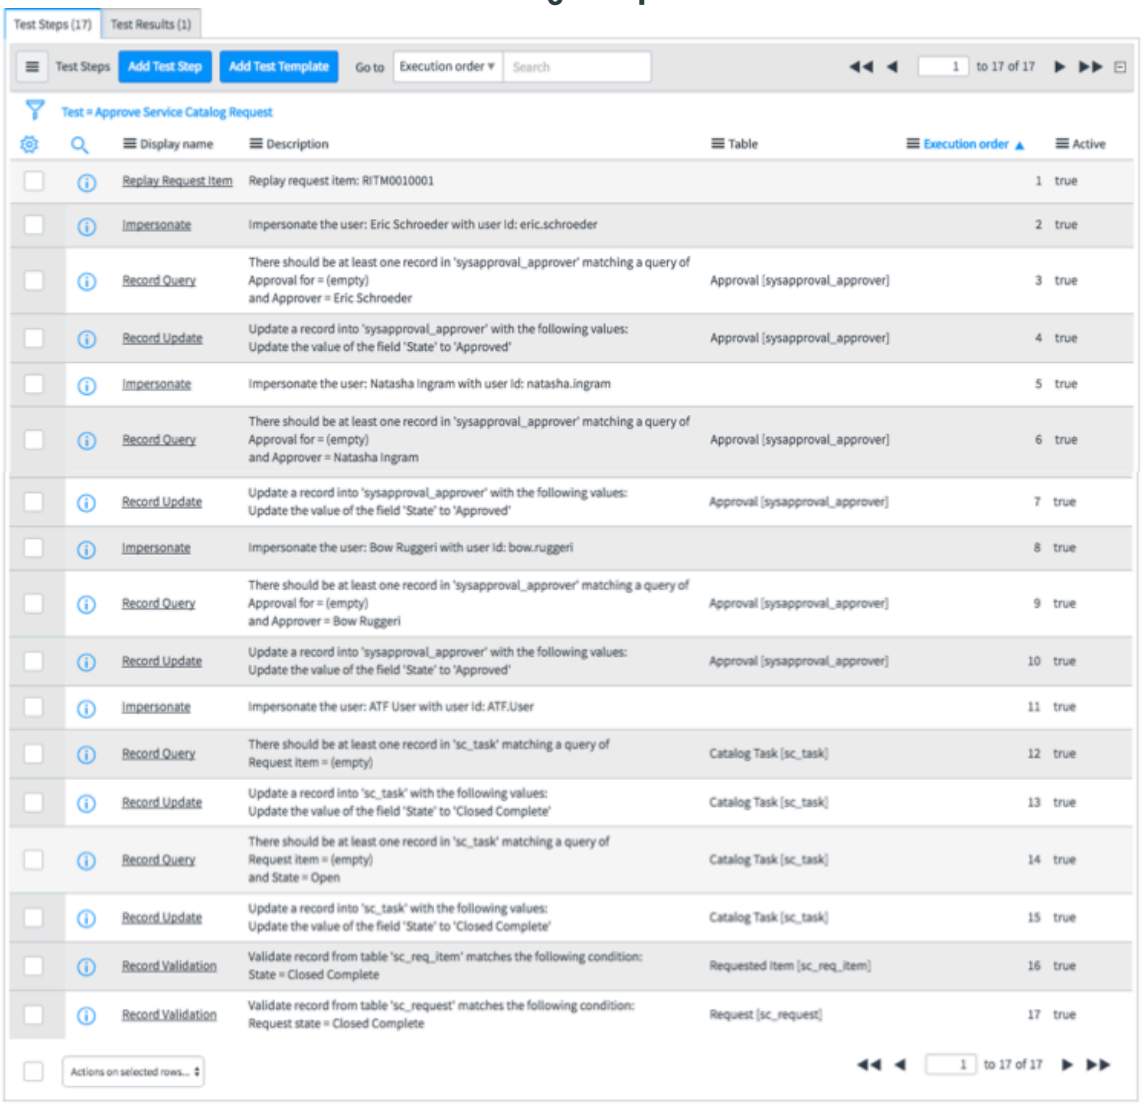
Before you begin

Role required: atf_test_admin

About this task

With the Replay Request Item test step, you can test the service catalog ordering process once a request exists and has a record in the request item table. In the Xanadu release, you cannot create an automated test for the process by which the user creates a new request.

Automated Test Framework: Service catalog example



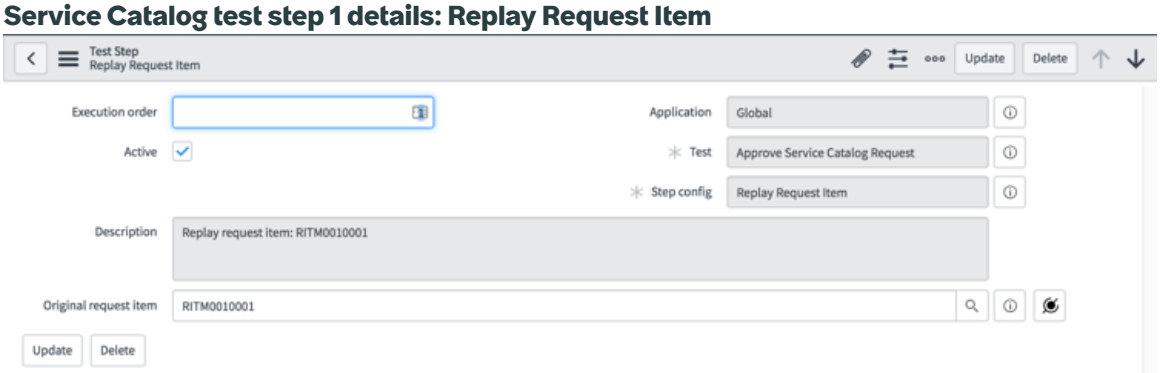
Procedure

1. Replay an existing service catalog request item.

   This test step inserts a new record in the [sc_request] table for the catalog request item RITM0010001.

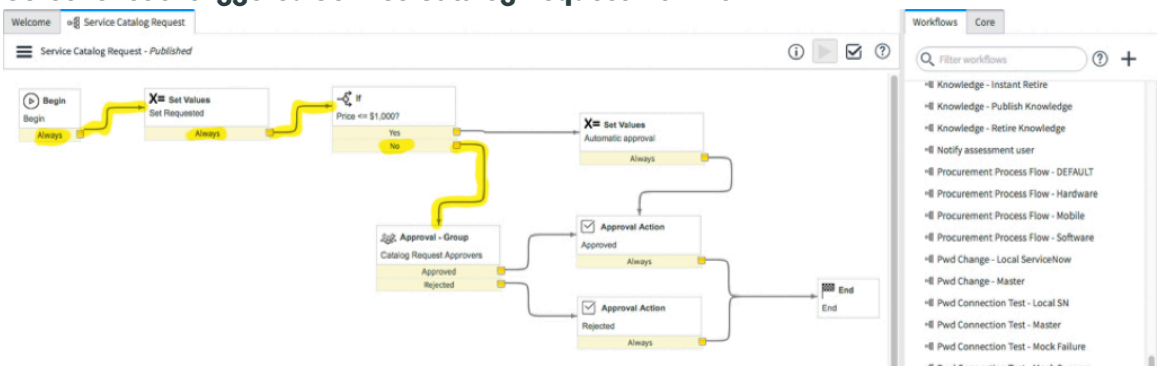
Example

Service Catalog test step 1 details: Replay Request Item



This insertion triggers the Service Catalog Request workflow, which checks the price of the item, determines that it exceeds $1000.00, and therefore generates approval records for users belonging to the Catalog Request Approvals group. In this example, only one user– Eric Schroeder – belongs to this group.

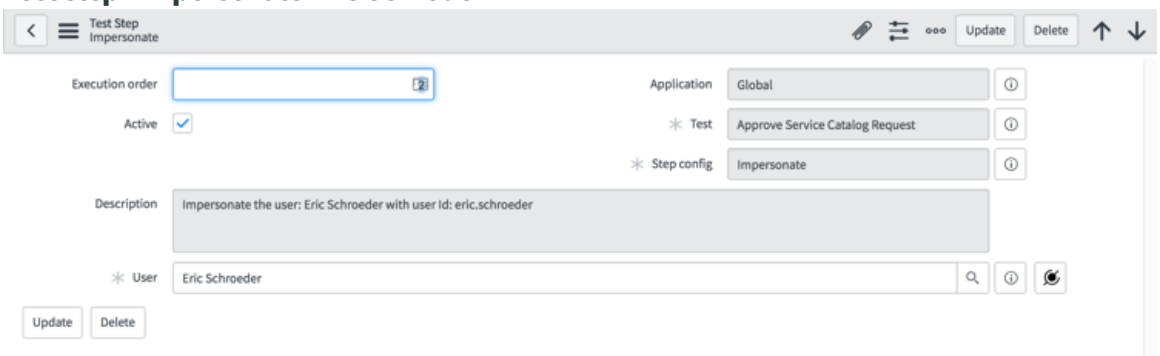
Screenshot of triggered Service Catalog Request workflow



2. Impersonate Eric Schroeder, the user who needs to approve this Service Catalog Request.

Example

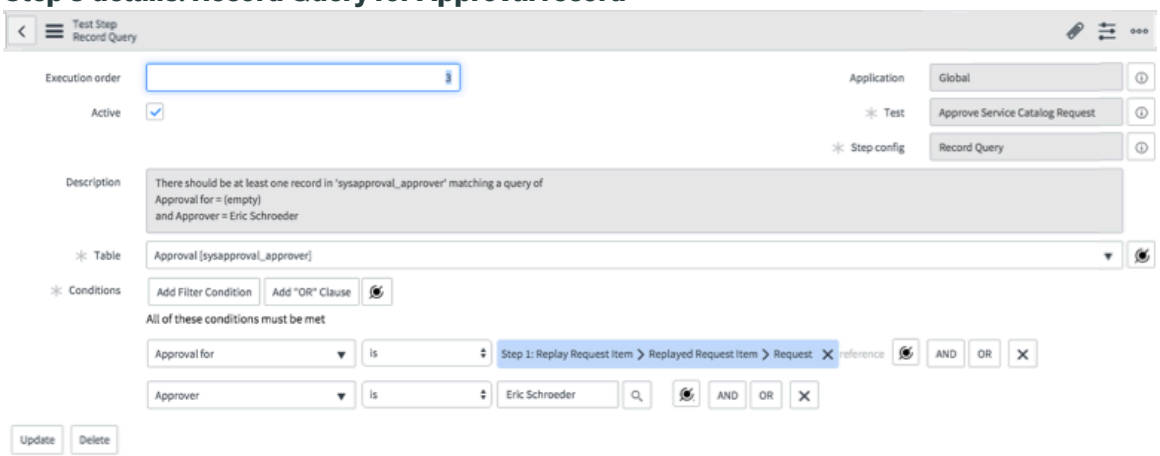
Test step - Impersonate Eric Schroder



3. Verify that the system created an approval record for Eric Schroeder and this request. Note that for the **Approval for** field, you assign the output value from Step 1.

Example

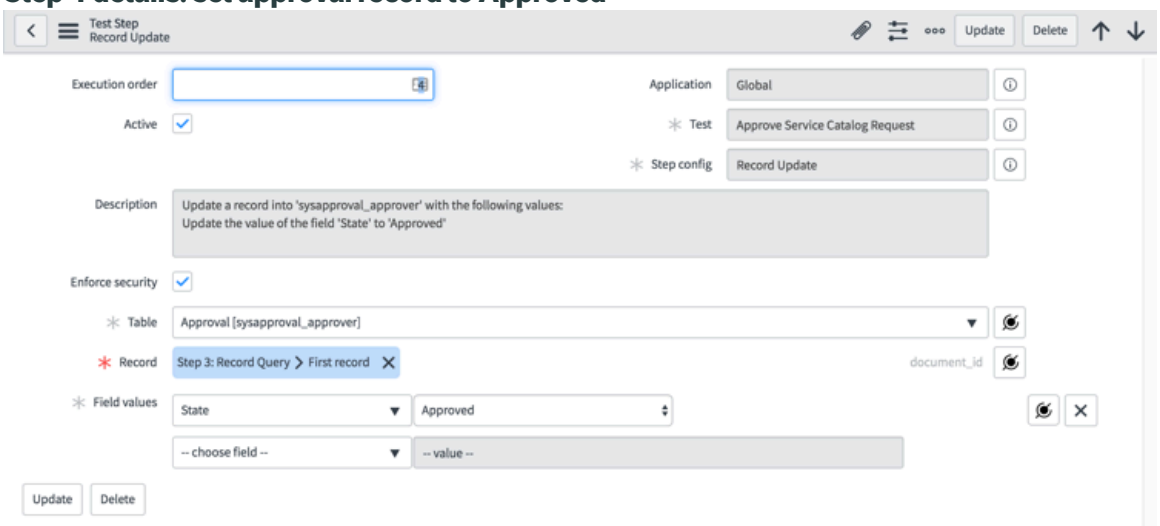
Step 3 details: Record Query for Approval record



4. Set the state of this approval record to Approved.

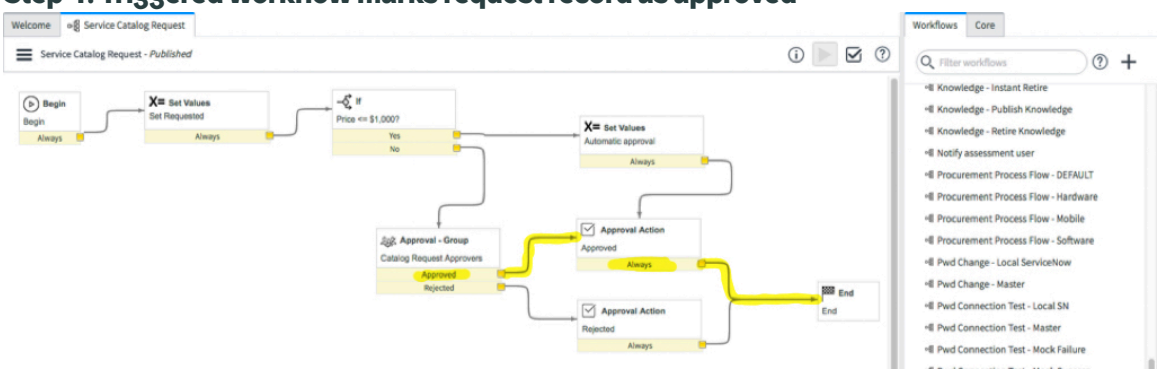
Example

Step 4 details: set approval record to Approved



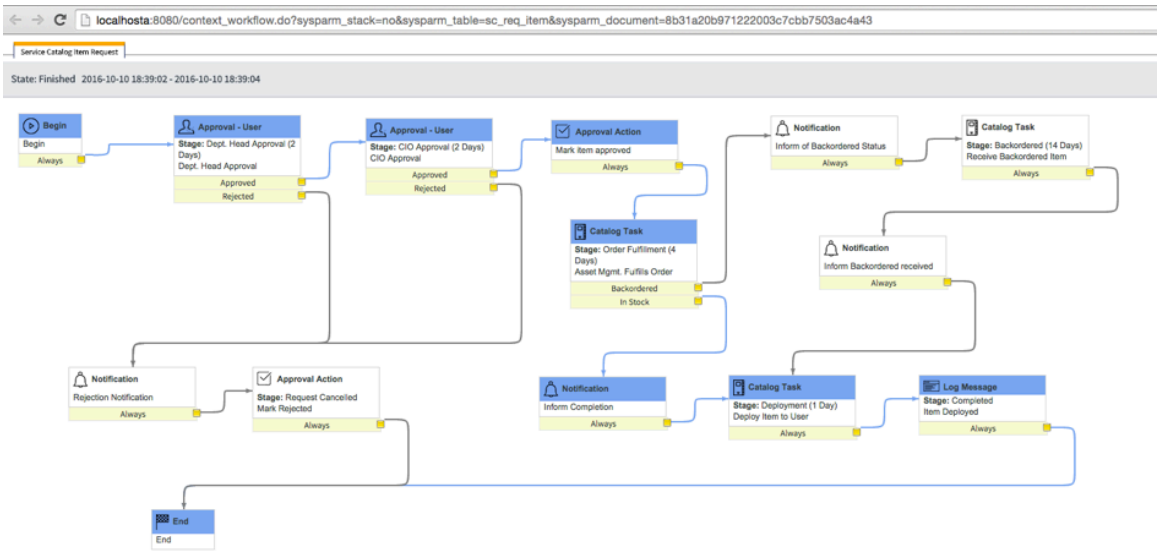
The Service Catalog Request workflow sees that all required approval records have the state of Approved and transitions to the Approval Action which marks the request record [sc_request] as Approved.

Step 4: Triggered workflow marks request record as approved



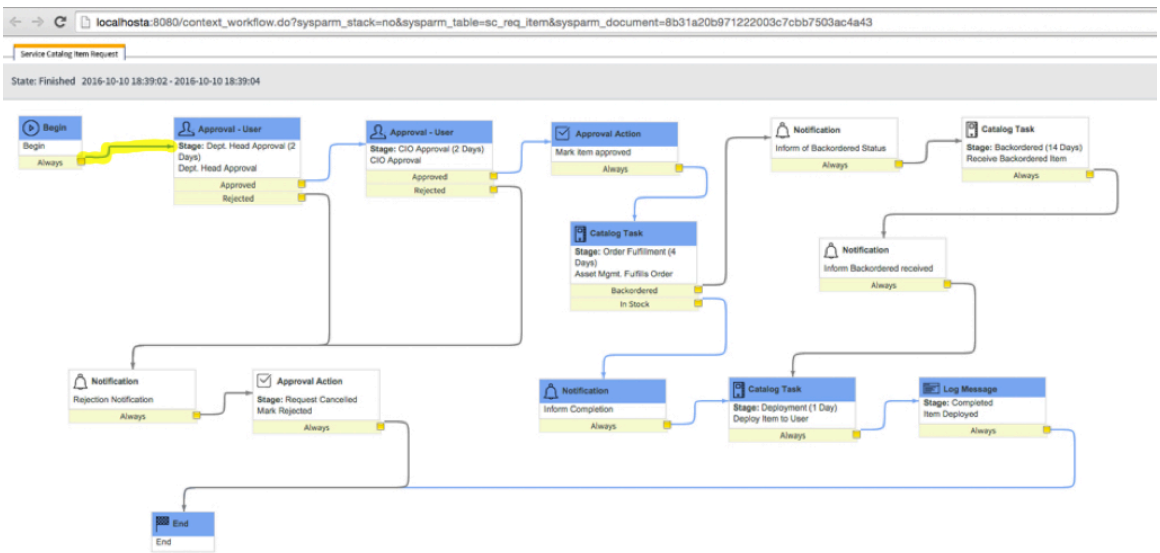
When the record in [sc_request] changes to the Approved state, an associated business rule generates request items [sc_request_item] for each item in the request. In this example, the request contains only one item, so the business rule inserts one record into the [sc_request_item] table. This insertion triggers the Service Catalog Item Request workflow.

Service Catalog Item workflow



The first activity in the Service Catalog Item Request workflow generates an approval record for the head of the department in which the requesting user works. In this example, the department head is Natasha Ingram.

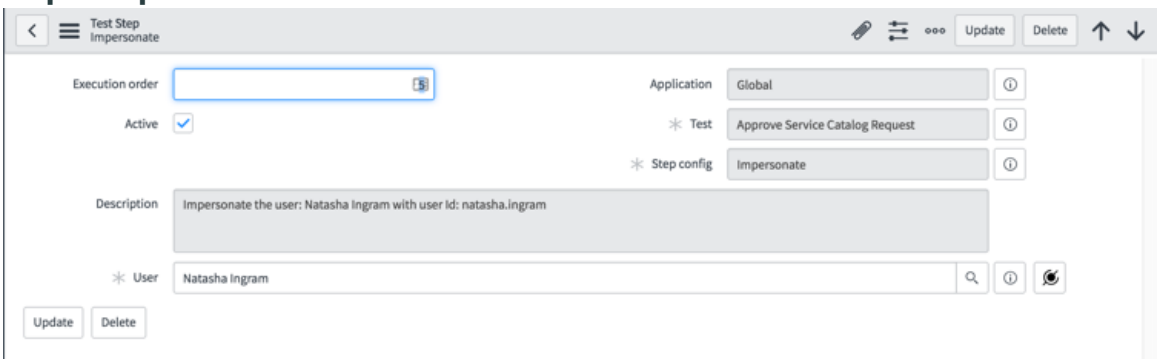
Service Catalog Item workflow: step 4



5. The workflow does not continue until the department head approves it, so the next test step impersonates Natasha Ingram.

Example

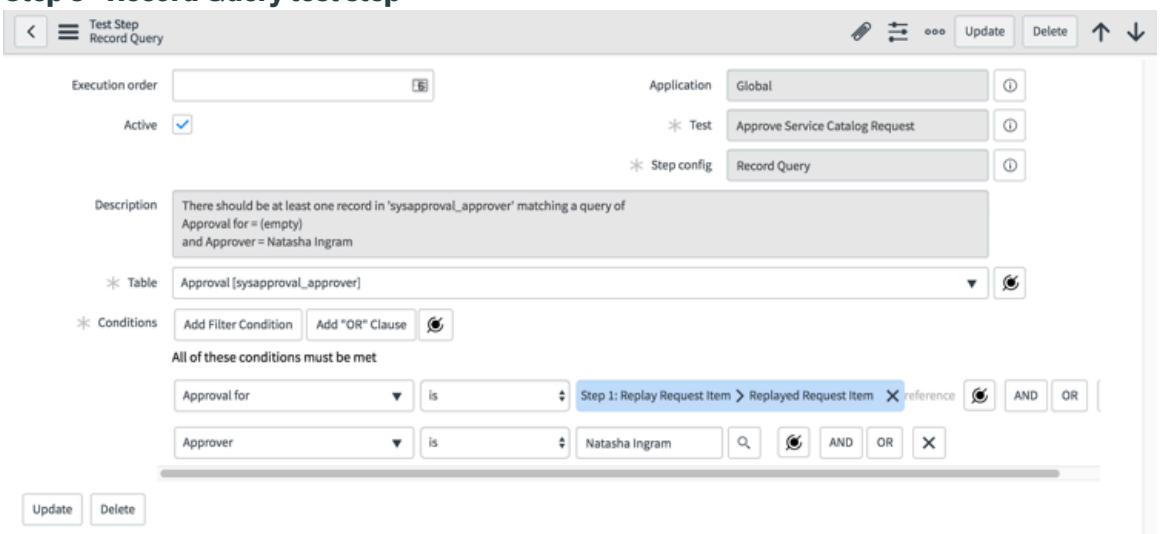
Step 5 - Impersonate User



6. Obtain the sys_id for the new approval record with the Record Query step.
   Note that Record Query creates an output variable with the sys_id of the first record returned from the query.

Example

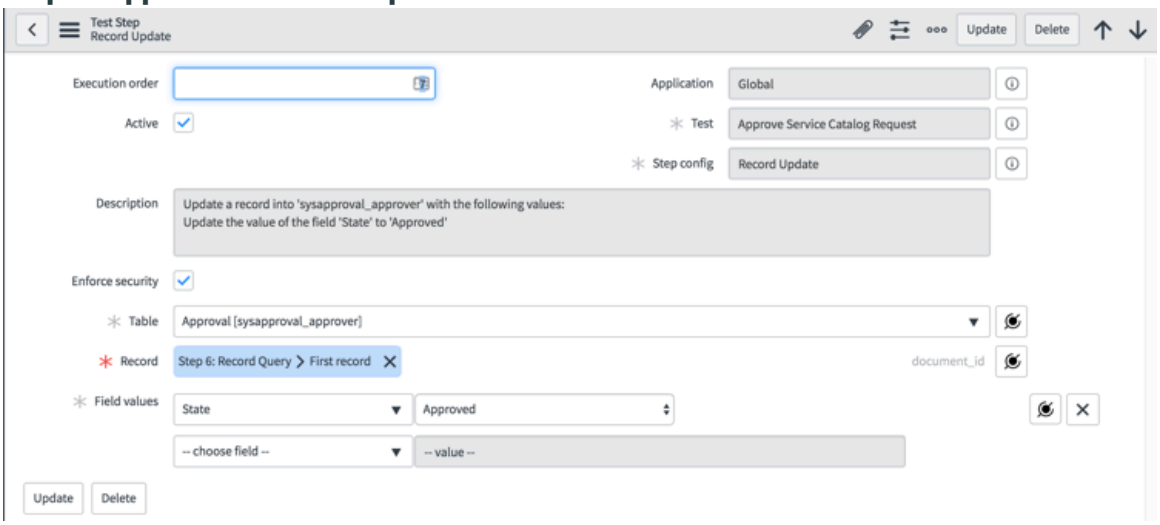
Step 6 - Record Query test step



7. Set the approval record to Approved.

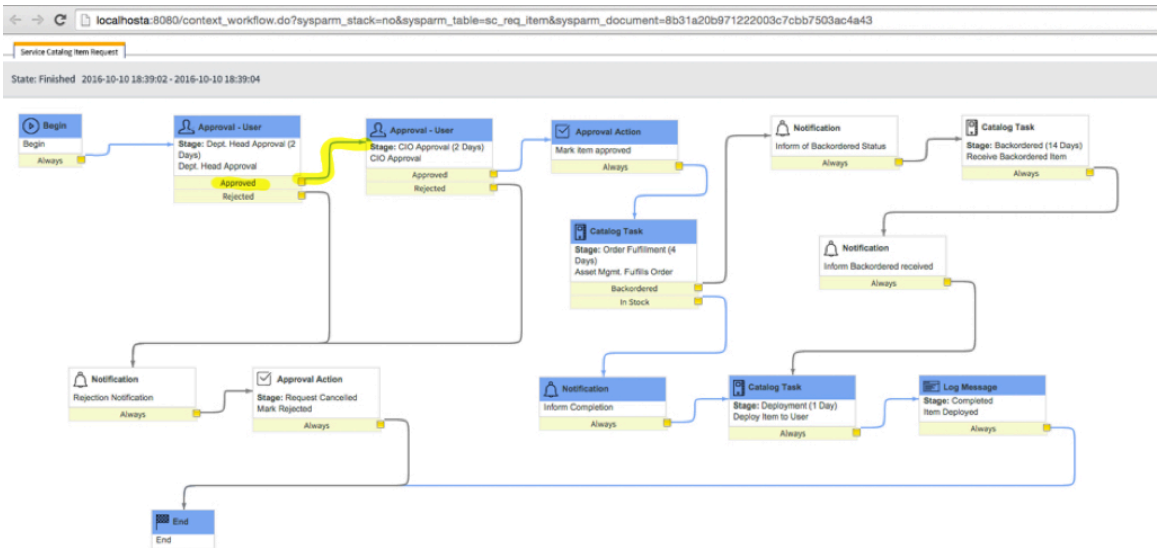
Example

Step 7 - Approval User test step



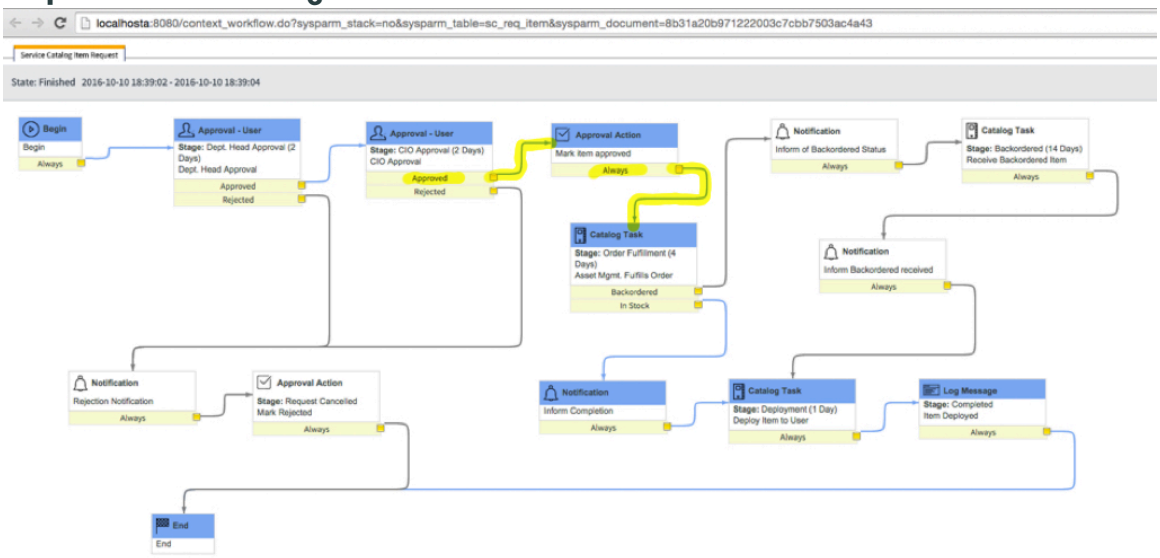
Note how Step 7 refers to the *`First record`* output variable from Step 6 to specify which record to approve. When the record is approved, the workflow transitions to the next Approval - User activity, which generates an approval record for the CIO. In this example, the CIO is Bow Ruggeri.

Step 7 details - Service Catalog Item workflow



8. Impersonate Bow Ruggeri.
9. Obtain the sys_id for the approval record for Bow Ruggeri.
10. Set the approval record to Approved.
    When the record is approved, the workflow transitions to the Approval Action activity which sets the record for this item in the [sc_request_item] table to *`Approved`*. The workflow transitions to the Catalog Task activity labelled Asset Mgmt. Fulfills Order. This Catalog Task activity generates a new record in the [sc_task] table that instructs a user in the Fulfillment group to order the item.

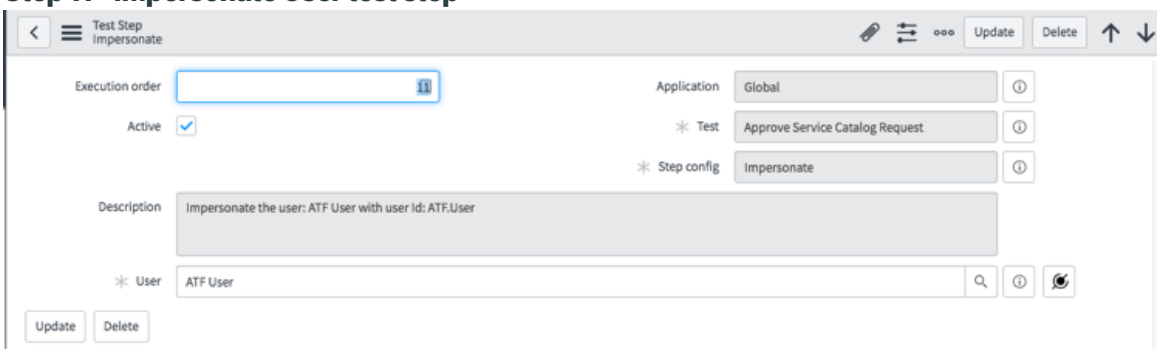
Step 10 - Service Catalog Item workflow



11. Impersonate a user in the Fulfillment group, in this example ATF.User.

Example

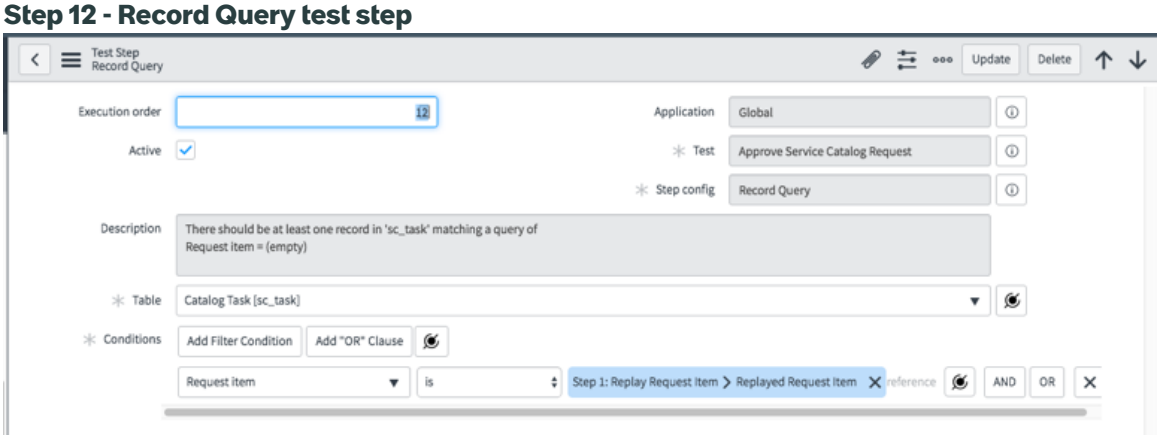
Step 11 - Impersonate User test step



12. Obtain the sys_id for the new catalog task with the Record Query step.
Note that Record Query creates an output variable with the sys_id of the first record returned from the query.

Example

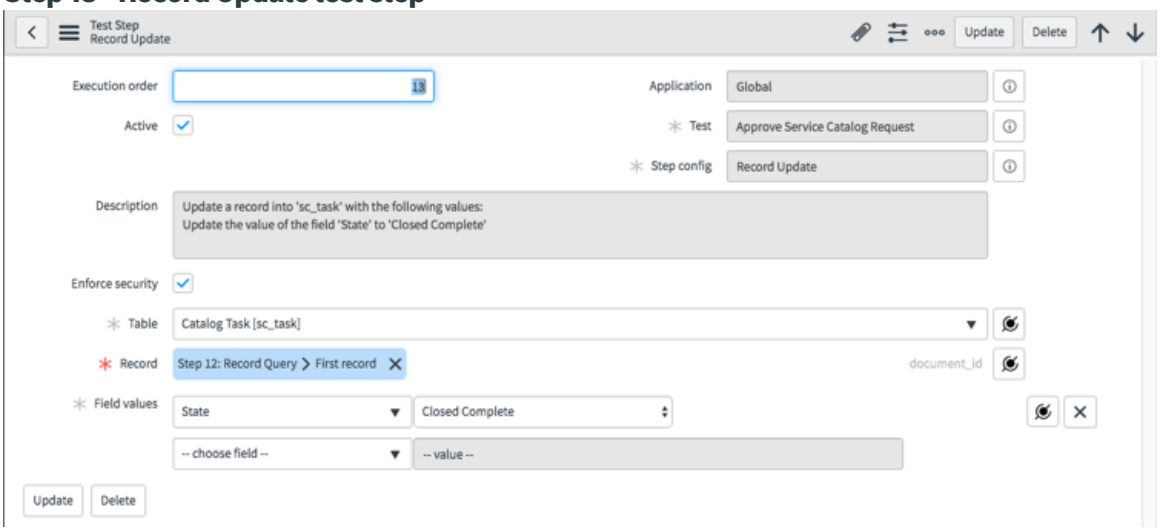
Step 12 - Record Query test step



13. Mark the [sc_task] record as *`Closed Complete`*.

Example

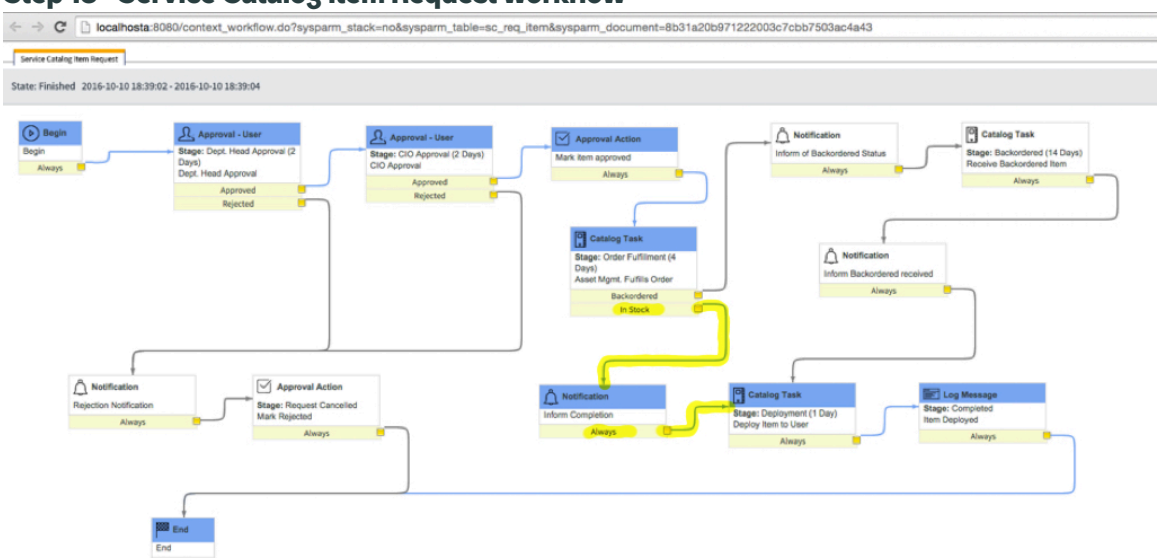
Step 13 - Record Update test step



Note how Step 13 uses the *`First record`* output variable from Step 12 to specify which record to mark as *`Closed Complete`*.

When the record is marked *`Closed Complete`*, the workflow exits the Catalog Task activity along the In Stock exit path.

Step 13 - Service Catalog Item Request workflow

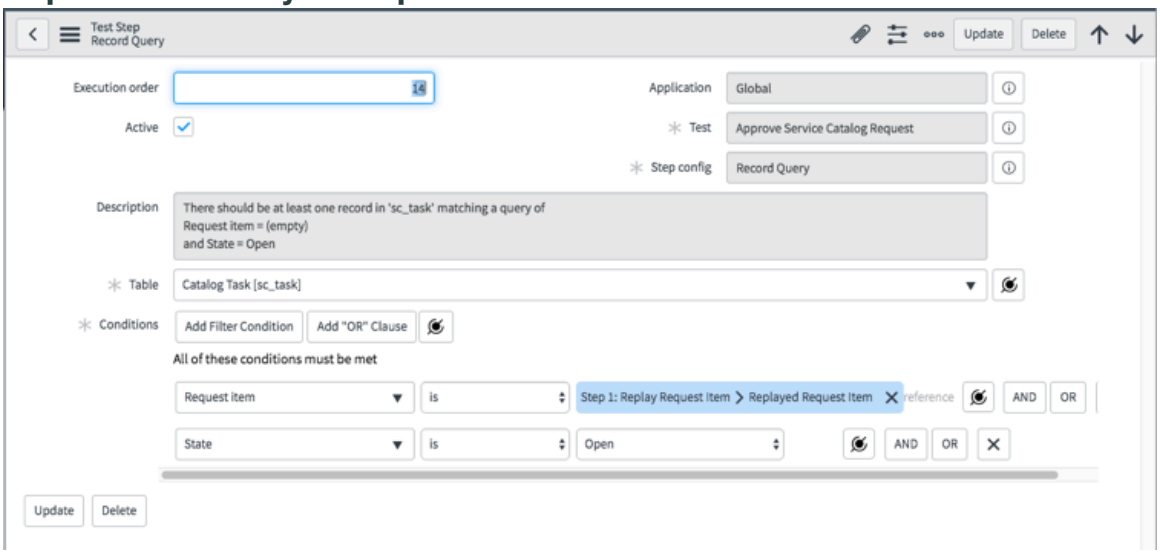


The workflow transitions to the Notification activity, then to the Catalog Task activity labelled Deploy Item to User.The Deploy Item to User Catalog Task activity inserts a new record into the [sc_task] table that instructs a user in the Deployment group to deliver the item.

14. Obtain the sys_id for the new catalog task with the Record Query step.
Note that Record Query returns an output variable with the sys_id of the first record returned from the query.

Example

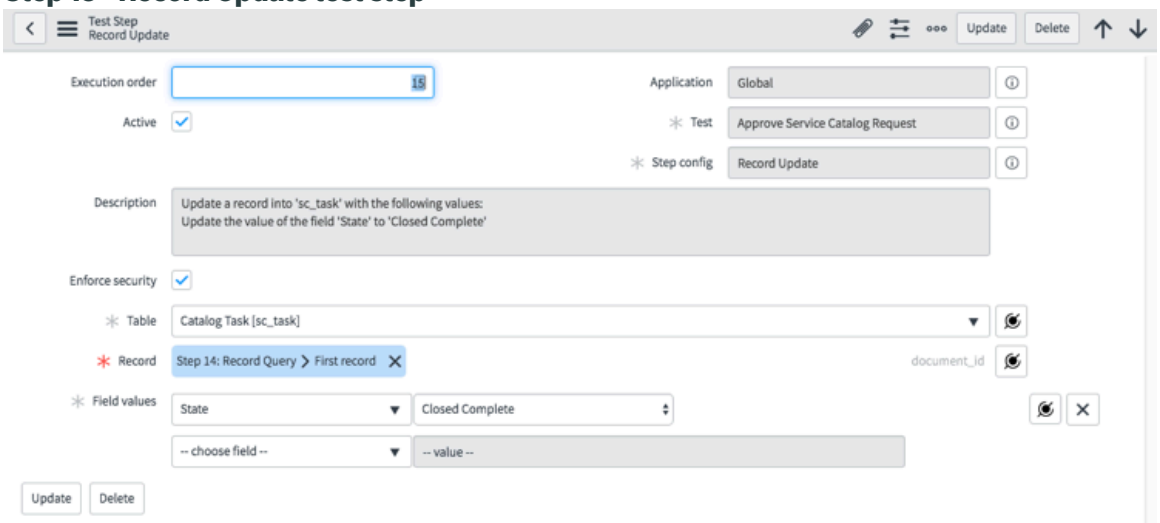
Step 14 - Record Query test step



15. Mark the [sc_task] record as Closed Complete.
    Note how Step 15 uses the *`First record`* output variable from Step 14 to specify which record to mark as Closed Complete.

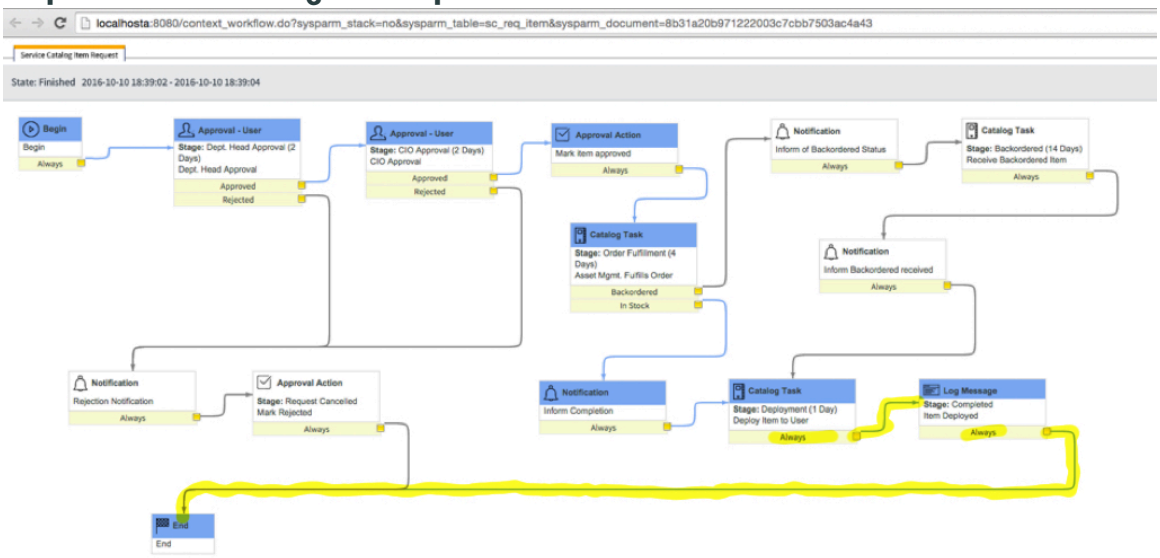
Example

Step 15 - Record Update test step



When the record is marked Closed Complete, the workflow exits the Catalog Task activity, logs a message, and exits.

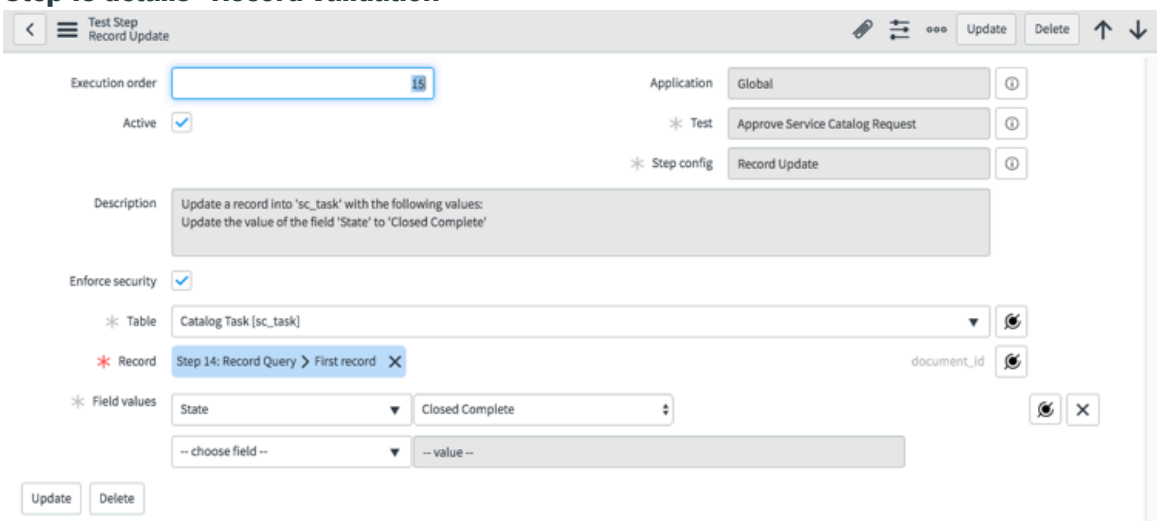
Step 15 - Service Catalog Item Request workflow



16. Verify that the request item in [sc_request_item] has the state Closed Complete.

Example

Step 15 details - Record Validation



17. Verify that the request [sc_request] has the state Closed Complete.

Example

Step 16 - Record Validation test step

Automated Test Framework use case: retrieve an incident using REST-Inbound

The **Get Newly Created Resource via REST API Test** test is provided with the Automated Test Framework, and uses the REST - Inbound and assert steps.

Before you begin

Review the REST APIs and the Send REST Request- Inbound- REST API Explorer configuration step information before creating this test.

Role required: atf_ws_designer

About this task

This test creates an incident record, uses a REST- Inbound step to retrieve the record, and then uses assert steps to determine whether the request was successful.
You can use the Send REST Request- Inbound REST API Explorer step to build and test the request, or you can manually create the request using the Send REST Request- Inbound step. In either case, you must specify the basic authentication information on the Send REST Request- Inbound step form.

When creating your test, start with your REST API and determine what behavior you want to validate. You can then determine what test data to create. You can use other test step configuration categories to create, update, or delete records, and then use a Send REST Inbound step to retrieve, update, or delete the test data. Conversely, you can use the Send REST Inbound step to create records, and then use other test step configuration categories to validate that the records were created correctly.

This task steps you through creating the **Get Newly Created Resource via REST API Test** test.

Procedure

1. Create a test.

   a. Navigate to **Automated Test Framework** > **Tests**, click **New**.
   The **Test** new record form is shown.

   b. Enter a test name and a description, and click **Submit**.

   c. Click the test created in the previous step.
   The **Test** form is shown.

2. Create test data.

   a. Click the **Add Test Step** button.
   The **Add Test Step** form is shown.

   b. Click a test configuration category, and then click a test configuration.
   To replicate the **Get Newly Created Resource via REST API Test** test, click **Server** > **Record Insert**, and then **Next**.
   The test configuration form you selected is shown.

   c. Fill in the information needed for the test configuration you selected.
   To replicate the **Get Newly Created Resource via REST API Test** test, on the **Record Insert** form, specify the incident table, and add a value for the **Short description** field, and click **Submit**.

3. Create the REST request.

   a. Click the **Add Test Step** button.
   The **Add Test Step** form is shown.

   b. Click a test configuration category, and then click a test configuration.
   To replicate the **Get Newly Created Resource via REST API Test** test, click **REST** > **Send REST Request - Inbound REST API Explorer**, and then **Next**.
   The **REST API Explorer** is shown.

   c. Fill in the information needed for the REST request, and click **Send**.
   To replicate the **Get Newly Created Resource via REST API Test** test, fill in the fields.

Name	Value
Namespace	now
API Name	Table API
API Version	latest
tableName	incident

   When you do not specify the **Basic authentication**, the REST API Explorer uses your credentials.

   The **Create Automated Test Step** is shown after you click **Send**.

d. When ready, click **Create Automated Test Step**.
The Send REST Request - Inbound test step is created.

e. Click the Send REST Request - Inbound step, and in the **Basic authentication** field, specify a basic auth configuration.
If no configurations are available, you can create a basic auth configuration by clicking **New** on the **Basic Auth Configurations** form.

f. To replicate the **Get Newly Created Resource via REST API Test** test, in the **Path** field, click the contextual search button, and then click **Record Insert** > **Record**.

g. Click **Update**.

4. Create assert steps to verify the REST response.

a. Click the **Add Test Step** button.
The **Add Test Step** form is shown.

b. Click a test configuration category, and then click a test configuration.
To replicate the **Get Newly Created Resource via REST API Test** test, click **REST** > **Assert Status Code**, and then **Next**.
The **Assert Status Code** form is shown.

c. Enter the information needed for the form, and click **Submit**.
To replicate the **Get Newly Created Resource via REST API Test** test, in the **Operation** field, select **is** and in the **Status Code** field, enter **200**.

To replicate the **Get Newly Created Resource via REST API Test** test, repeat this step to create **Assert Response JSON Payload is Valid**, and **Assert JSON Response Payload Element** test steps.

Quick start tests

Copy and customize quick start tests provided by the ServiceNow AI Platform® to validate that your instance works after you make any configuration changes. For example, if you apply an upgrade or develop an application.

The tests can only produce a pass result when you run them with the default demo data that's provided with the application or feature plugin.

Note:
If your QST fails, it can be that the test doesn't match your instance customizations. Use the **Notes** field for each test step to update the test to pass with your data. If you have customized the business process associated with a test, revise the test to match your customizations.

To apply a quick start test to your instance-specific data, copy the quick start test and add your custom data.

Note:
You can copy either an individual quick start test or the entire quick start tests suite.

See Getting started with quick start tests for more information.

Activation

Each application or feature has its own plugin activation requirements for enabling quick start tests. See Available quick start tests by application or feature for activation information.

Managing copies

When you copy a test, Automated Test Framework populates the **Copied from** field with the name of the copied test. When an upgrade changes, a quick start test Automated Test Framework notifies test designers about the change in a notification on the test form. Test designers can revert the copied test to the upgraded version with the **Revert Copy to Base System** UI action.

Tip:
If a QST is updated, the previously copied versions of the QST does not have the recent changes. Review the old copies using **Copies to Review** for all the tests that have an associated warning message.

Available quick start tests by application or feature

Validate that your instance still works after you make any configuration change such as apply an upgrade or develop an application. Copy and customize the ServiceNow -provided quick start tests to pass when using your instance-specific data.

Danger:
By default, the system property that is used to run automated tests is disabled to prevent you from accidentally running these tests on a production system. To avoid data corruption or an outage, run tests only on development, test, and other non-production instances. See Enable or disable executing Automated Test Framework tests.

Agile Development 2.0

Agile Development 2.0 quick start tests require activating the Agile Development 2.0 plugin (com.snc.sdlc.agile.2.0) and the Agile Development 2.0 - ATF Tests plugin (com.snc.sdlc.agile.2.0.atf).

Agile Development 2.0 quick start test suite

Test	Description	Release version
Verify that global rank is populated when a story is created	Verify the global rank of a story after creation.	Madrid
Verify that closing a sprint with active stories is prevented	Verify that a sprint with active stories cannot be closed.	Madrid
Verify that sprints cannot overlap in the same group	Verify that sprints in the same group do not overlap.	Madrid
Verify that sprint points are updated	Verify that changes to stories produce accurate sprint point totals.	Madrid
Verify that only one sprint in a group can have the current state	Verify sprint statuses.	Madrid

Agile Development 2.0 quick start test suite (continued)

Test	Description	Release version
Verify sprint end date is after the sprint start date	Verify sprint start and end dates.	Madrid
Verify that any update on story rolls up to Epic	Verify that adding, estimating, removing, deleting, updating, or cancelling a story updates the epic-level roll-ups correctly.	Orlando
Verify changes to the scope of a current sprint do not alter the value of the Total Committed Points	Verify that the value of Total Committed Points does not change with change in the scope of a sprint after its state is changed to Current.	Orlando
Verify active flag is set false when Agile Story state is changed to Completed/ Cancelled	Verify that active flag of an Agile story is set to the following: • False, if the state is changed to Completed or Cancelled • True, for all other states	Orlando
Verify that updating the team/ group capacity overrides the capacity on all the future sprints	Verify that any update to the **Group capacity** field of the assignment group results in the following changes to the **Group capacity** field of the various sprints associated with this assignment group: • For the sprints that are in the Draft and Planning state: ○ The group capacity is updated to the new value. ○ The **Group capacity** field is editable. • For the sprints in the Current, Complete, or Cancelled state: ○ The group capacity remains the old value. ○ The **Group capacity** field is read-only. For the sprints in the Draft or Planning state, you can individually edit the group capacity of the sprint anytime later. This would not change the group capacity of the	Paris

Test	Description	Release version
	assignment group associated with this sprint.	
Verify create and edit functionality of an epic backlog on the scrum program board	• Verify that you can create an epic backlog for scrum programs from the Backlog tab of Agile Board. • Verify that you can update an existing epic backlog for scrum programs from the Backlog tab of Agile Board. • The epics listed in the backlog must belong to the selected epic backlog.	Quebec
Verify a Demand is converted to a scrum story	If the PPM Standard plugin (com.snc.financial_planning_pmo) is active, verify that a Demand can be converted to an Agile 2.0 story using the **Create Story** related link on the Demand form. For more information on how to create an Agile 2.0 story from a demand, see Create an artifact from a demand.	Quebec
Verify a Demand is converted to a scrum epic	If the PPM Standard plugin (com.snc.financial_planning_pmo) is active, verify that a Demand can be converted to an Agile 2.0 epic using the **Create Epic** related link on the Demand form. For more information on how to create an Agile 2.0 epic from a demand, see Create an artifact from a demand.	Quebec

To learn more about Agile Development 2.0, see Agile Development 2.0.

Enterprise Architecture (formerly Application Portfolio Management)

Enterprise Architecture quick start tests require enabling the Enterprise Architecture – ATF Tests plugin (com.snc.apm.atf).

Enterprise Architecture: Create Business application and capability test suite

Test	Description	Release version
Enterprise Architecture: Create Business Application	Verify the creation of an application category and then the creation of a business application with users having apm_user role.	Madrid
Enterprise Architecture: Create Business Capability	Verify the creation of a parent and child business capability and verify its field values.	Madrid
Enterprise Architecture: Test relating Business Service, Business Application, and Software Models	Verify the creation of a business application, business service, using the existing software model, and a relationship between them.	Orlando
Enterprise Architecture: Test for Indicator Score and Application Score generation	Verify the creation of indicator, scoring profile, and generation of indicator scores and application scores.	Paris
Enterprise Architecture: Business Application with Information Object and Data Domain	Verify the creation of business application, information object, and addition of the CRUD operations in relation attributes.	Quebec

To learn more about Enterprise Architecture (formerly Application Portfolio Management), see Application Portfolio Management.

Assessments and Surveys

Assessments and Surveys quick start tests require activating the Automated Test Framework for Survey plugin (com.glide.automated_testing_impl. Survey).

Test Suite for Survey

Name	Description	Release version
Survey: Basic Platform Based Test	Create a survey using Platform UI actions.	Madrid
Survey: Platform test for Dynamic Validation	Validate a survey dynamically.	Madrid
Survey: Clone Action	Clone a survey and validate the records of the original survey and the cloned survey.	New York
Survey: Question Bank Flow	Verify the addition of a question bank to a survey.	New York
Survey: Survey Creator Work Flow	Survey creator can create a survey and assign to the user who can take the survey and submit it.	New York

Test Suite for Survey (continued)

Name	Description	Release version
Assessment: Assign assessment to assessor	Assign an assessment to an assessor and verify that the instance is created for the assessor.	Orlando
Assessment: Create assessment as survey creator	Create an assignment as a survey creator.	Orlando
Assessment: Scale and Template support	Create, publish, and assign the assessment. Then take the assessment.	Rome
Assessment: Basic test flow	Verify the basic flow of an assessment.	Orlando

To learn more about Assessments and Surveys, see Service administration.

Change Management

Change Management quick start tests require activating the Change Management - ATF Tests plugin (com.snc.change_management.atf).

CHG: Emergency Type Change Request test suite

Test	Description	Release version
Emergency Type Change Request workflow	Process an emergency change request from new to closed.	Madrid
On Hold for Emergency type Change Request	Validate the approval state of an on-hold emergency change request.	Madrid
Copy Change For Emergency type Change Request	Validate the state of a copied emergency change request.	Madrid
Reject By Approver for Emergency type	Validate the state of a rejected emergency change request.	Madrid
Revert to new for emergency type	Validate the state of an emergency change request after using the Revert to new UI action.	Madrid
Convert Emergency to Normal type	Validate the conversion of an emergency change request to a normal change request.	Madrid
Cancel Change Request For Emergency Type	Validate the state of a canceled emergency change request.	Madrid

CHG: Normal Type Change Request test suite

Test	Description	Release version
Normal Type Change Request Workflow	Process a normal change request from new to closed.	Madrid
Convert Normal to Emergency type	Validate the conversion of a normal change request to an emergency change request.	Madrid
Copy change on Normal Change Request	Validate the state of a copied normal change request.	Madrid
On hold for Normal type Change Request	Validate the approval state of an on-hold normal change request.	Madrid
State validation when Reject Normal type Change request by Approver.	Validate the state of a rejected normal change request.	Madrid
Revert to New Functionality for Normal Type Change Request	Validate the state of a normal change request after using the Revert to new UI action.	Madrid
Cancel Change Request For Normal type	Validate the state of a canceled normal change request.	Madrid

CHG: Standard Change Proposal test suite

Test	Description	Release version
Standard Change Proposal	Determine whether a user can successfully perform standard change proposal creation, approval, and template publishing processes.	Madrid

CHG: Standard Type Change Request test suite

Test	Description	Release version
Standard Change Request Workflow	Process a standard change request from new to closed.	Madrid
Convert Standard to Emergency Change Request	Validate the conversion of a standard change request to an emergency change request.	Madrid
Convert Standard to Normal Change Request	Validate the conversion of a standard change request to a normal change request.	Madrid

CHG: Unauthorized Change Request and Outage test suite

Test	Description	Release version
Unauthorized change request Workflow	Process a unauthorized change request from new to closed.	Orlando
Create Outage of type planned outage from change request	Validate the creation of an outage of type planned outage from a change request.	Orlando

CHG: Unauthorized Change Request and Outage test suite (continued)

Test	Description	Release version
Create Outage of type outage from change request	Validate the creation of an outage of type outage from a change request.	Orlando

CHG: Risk Conditions with Best practice plugin test suite

Test	Description	Release version
Moderate Risk with UI Action Property	Process a moderate risk with UI action property.	Orlando
Low Risk with UI Action Property	Process a low risk with UI action property.	Orlando
Leave Alone Risk with UI Action Property	Process a leave alone risk with UI action property.	Orlando
High Risk with UI Action Property	Process a high risk with UI action property.	Orlando
High Risk with Business Rule Property	Process a high risk with Business rule property.	Orlando
Moderate Risk with Business Rule property	Process a moderate risk with Business rule property.	Orlando

CHG: Change Request against Conflict Sources test suite

Test	Description	Release version
Change against Blackout window	Process a change request against a blackout window.	Orlando
Check conflicts for CI Already Scheduled	Validate the conflicts for CI already scheduled.	Orlando
Change against Conflict Sources	Validate the change request against conflict sources.	Orlando

CHG: Change Schedule Definition and Sharing test suite

Test	Description	Release version
Change Schedules Definitions on New	Process the creation of change schedules definitions from New button on Change Schedules landing page.	Orlando
Share Panel On Change Schedules Definition	Validate the share panel on change schedules definition.	Orlando
Share Change Schedule Definition	Validate the sharing of change schedules definitions.	Orlando
Create Standard Change via Service Portal	Create Standard Change from Service Portal	Xanadu

To learn more about Change Management, see Change Management.

Cloud Provisioning and Governance

Cloud Provisioning and Governance quick start tests require activating the following Cloud Provisioning and Governance plugins:

- Cloud Provisioning and Governance (com.snc.cloud.mgmt)
- Domain Support- Domain Extensions Installer plugin (com.glide.domain.msp_extensions.installer)
- Service Catalog- Domain Separation plugin (glideapp.servicecatalog.domain_separation)

Cloud Provisioning and Governance: Azure test suite

Test	Description	Release version
CMP: Add Azure Credentials	Add Azure credentials by inserting the fields into the Credentials table.	Orlando
CMP: Azure Service Account	Add Azure service account by inserting the fields into the service account table.	Orlando
CMP: Update datacenter type	Update the Cloud Service account with the datacenter type.	Orlando
CMP: Creating Resource Group	Creating Resource Group to provision Azure stack via ARM Template.	Orlando
CMP: Create Azure Logical datacenter.	Create Azure Logical datacenter for provisioning resources.	Orlando
CMP: Create "Contains: Contained by" relationship.	Create "Contains: Contained by" relationship between Resource Group and Azure datacenter.	Orlando
CMP: Create 'Hosted on' relationship.	Create hosted on relationship between logical datacenter and Cloud Service account.	Orlando
CMP: Create Cloud Account	Create cloud account by inserting the fields into the cloud account table.	Orlando
CMP: Cloud account and Logical datacenter association	Create an association between CMP cloud account and Logical datacenter.	Orlando
CMP: Create Catalog Item	Create Cloud Catalog Item with ARM Template.	Orlando
CMP: Create template version.	Create Cloud Template Version for Cloud Catalog Item.	Orlando

Cloud Provisioning and Governance: Azure test suite (continued)

Test	Description	Release version
CMP: ARM template body	Update Cloud Template Version with ARM template body.	Orlando
CMP: Open the 'ServiceNow Cloud Template Versions'	Open the 'ServiceNow Cloud Template Versions' GUI page.	Orlando
CMP: Activate Cloud Template Version	Activate Cloud Template Version to create resource block, blueprint, and catalog.	Orlando
CMP: Verify the Cloud Template Version.	Validate whether status is Success and state is active in the Cloud Template Version after Activation operation.	Orlando
CMP: Activate Cloud Catalog Item	Activate Cloud Catalog Item to display catalog order form to the cloud user.	Orlando
CMP: Add stack and resource group name in Catalog item	Set the default value for stack name and resource group in the catalog item.	Orlando
CMP: Verify whether stack is present	Validate whether stack is available with name "ATFARMStack".	Orlando
CMP: Open Cloud Catalog Item page	Open Cloud Catalog Item page in the Service Portal.	Orlando
CMP: Submit Catalog form	Submit the Catalog Form to start provisioning ARM stack.	Orlando
CMP: Verify whether stack status is active	Validate the status of a stack after provisioning the stack.	Orlando
CMP: Verify stack status after Day2 - Stop operation	Validate the status of the stack status changed from 'On' to 'Off' after the Stop operation.	Orlando
CMP: Verify stack status after Day2 - Start operation	Validate the status of the stack status changed from 'Off' to 'On' after the Start operation.	Orlando
CMP: Verify stack status after Day2 - Deprovision operation	Validate the status of the stack status changed from 'On' to 'Terminate' after the de-provisioning operation.	Orlando

Cloud Provisioning and Governance: AWS test suite

Test	Description	Release version
CMP: Add AWS Credentials	Add AWS credentials by inserting the fields into the credential table.	Orlando

Cloud Provisioning and Governance: AWS test suite (continued)

Test	Description	Release version
CMP: AWS Service Account	Add AWS service account by inserting the fields into the service account table.	Orlando
CMP: Update datacenter type	Update the cloud service account with the datacenter type.	Orlando
CMP: Create logical datacenter	Create Logical datacenter for provisioning the resources.	Orlando
CMP: Create hosted on relationship	Create hosted on relationship between logical datacenter and Cloud Service account.	Orlando
CMP: Create Cloud Account	Create cloud account by inserting the fields into the cloud account table.	Orlando
CMP: Cloud account and Logical datacenter association	Create an association between CMP cloud account and logical datacenter.	Orlando
CMP: Create Catalog Item	Create Cloud Catalog Item with the CFT Template.	Orlando
CMP: Create template version	Created Cloud Template Version for a Cloud Catalog Item.	Orlando
CMP: CFT template body	Update Cloud Template Version with the CFT template body.	Orlando
CMP: Open the ' ServiceNow Cloud Template Versions'	Open the ' ServiceNow Cloud Template Versions' GUI page.	Orlando
CMP: Activate Cloud Template Version	Activate Cloud Template Version to crate resource block, blueprint, and catalog.	Orlando
CMP: Verify the Cloud Template Version	Validate the Cloud Template Version whether status is Success and state is active after Activation operation.	Orlando
CMP: Activate Cloud Catalog Item	Activate Cloud Catalog Item to display the catalog order form to the cloud user.	Orlando
CMP: Add stack name in Catalog item	Set the default value for stack name in the catalog item.	Orlando
CMP: Verify whether stack is present	Validate whether stack is available with name "ATFCFTStack".	Orlando
CMP: Open Cloud Catalog Item page	Open the Cloud Catalog Item page in the Service Portal.	Orlando

Cloud Provisioning and Governance: AWS test suite (continued)

Test	Description	Release version
CMP: Submit Catalog form	Submit the Catalog Form to start provisioning CFT Stack.	Orlando
CMP: Verify whether stack status is active	Validate the status of the stack after provisioning the stack.	Orlando
CMP: Verify stack status after Day2 - Stop operation	Validate the status of the stack status changed from 'On' to 'Off' after the Stop operation.	Orlando
CMP: Verify stack status after Day2 - Start operation	Validate the status of the stack status changed from 'Off' to 'On' after the Start operation.	Orlando
CMP: Verify stack status after Day2 - De-provision operation	Validate the status of the stack status changed from 'On' to 'terminate' after the de-provisioning operation.	Orlando

To learn more about Cloud Provisioning and Governance, see Cloud Provisioning and Governance.

Coaching

Coaching quick start tests requires activation of the Coaching plugin (com.sn_coaching).

Coaching test suite

Test	Description	Release version
Coaching: Create an assessment manually when logged in as a coach.	As a coach, verify that you can create an assessment and assign it to trainees.	Orlando
Coaching: Add skills to an opportunity and verify those skills awarded to trainee.	Add skills to a coaching opportunity and verify that those skills have been awarded to trainees after they complete an assessment.	Orlando
Coaching: Complete an assessment as a virtual coach.	Verify that the virtual coach completes an assessment and provides feedback to the trainee when a virtual coach is attached to an opportunity.	Orlando
Coaching: Add skills to an assessment and verify those skills awarded to trainee.	Add skills to a coaching assessment and verify that those skills have been awarded to trainees after they complete an assessment.	Orlando
Coaching: Add skills to a recommendation and verify those skills awarded to trainee.	Add skills to a coaching recommendation and verify that those skills have been	Orlando

Coaching test suite (continued)

Test	Description	Release version
	awarded to trainees after they complete an assessment.	
Coaching: Move assessments from one state to another when logged in as a coach.	As a coach, verify that you can move an assessment from one state to another.	Orlando
Coaching: Attach a recommendation learning to an assessment.	Verify that a recommendation learning on an opportunity gets attached to an assessment when an assessment is generated.	Orlando
Coaching: When a coaching opportunity is inactive, assessments are not generated.	Verify that when a coaching opportunity is in inactive state, it does not generate assessments.	Orlando
Coaching: Submit Coaching survey as a Coach user.	Verify that coach can submit survey for a trainee.	Quebec
Coaching: Submit Coaching survey as a Traineer user.	Verify that trainee can submit survey for a coach.	Quebec

To learn more about coaching, see Coaching.

Communities

Communities quick start tests require activating the Customer Communities plugin (com.sn_customer_communities) and the Communities Demo Data plugin (com.sn_communities_demo).

Communities: Community test suite

Test	Description	Release version
Post question and validate feed	Verify that a question is posted in the community and validate whether it appears in the content feed.	Madrid
Post video	Verify that a video is posted in the community.	Madrid
Forum membership approval	Verify that a membership request to a forum is approved.	Madrid
Forum membership reject	Verify that a membership request to a forum is rejected.	Madrid
Approve a moderation task	Verify that a moderation task is approved.	Madrid
Reject a moderation task	Verify that a moderation task is rejected.	Madrid

Communities: Community test suite (continued)

Test	Description	Release version
Topic subscription and activity feed validation	Verify that a topic is subscribed to and the topic activities appear in the activity feed.	New York
Approve content approval workflow task on question	Verify the content approval workflow of a question.	New York
Question auto-subscription and activity feed validation	Verify that the author is automatically subscribed to the question and the question activities appear in the activity feed.	New York
Follow a user	Verify that a community user is able to follow another community user.	New York
Reject content approval workflow task on question	Verify the content approval workflow of a question when content is rejected.	New York
Gamification on video posting	Verify the gamification points gained when posting a video.	New York
Forum subscription and activity feed validation	Verify that a forum is subscribed to and the forum activities appear in the activity feed.	New York
Question subscription and activity feed validation	Verify that a question is subscribed to and the question activities appear in the activity feed.	New York
Post a video with 'Disable comment' option	Verify a video is posted with *`Disable comments`* option as selected.	Orlando
Pin a video as Featured	Verify that a video is marked as featured by community administrator in the forum and community home page.	Orlando

To learn more about Communities, see Communities.

Configuration Compliance

Configuration Compliance quick start tests require activating the Configuration Compliance application (sn_vulc) and loading the demo data.

Configuration Compliance quick start tests

Test	Description	Release version
Configuration Compliance Assignment Rules	Create an assignment rule.	Xanadu
Configuration Compliance - Reapply Group Rule	Reapply a test result group rule.	Xanadu
Configuration Compliance - Delete Group Rule	Delete a test result group rule.	Xanadu

To learn more about Configuration Compliance, see Configuration Compliance.

Configuration Management Database (CMDB)

Configuration Management Database (CMDB) quick start tests require activating the Configuration Management (CMDB) plugin (com.snc.cmdb) and the CMDB - ATF Tests plugin (com.snc.cmdb.atf).

CMDB BSM: Dependency Views test suite

Test suite to check functionality of Dependency Views APIs.

Test	Description	Release version
CMDB BSM: Dependency Views	Test functionality of Dependency Views APIs. These APIs retrieve Dependency Views map and associated map items such as context menu items, for a given CI sys_id and using itil user role.	New York

CMDB HEALTH: CMDB Health Dashboard test suite

Test suite to check whether CMDB CMDB Health Dashboard is functional at a basic level.

Test	Description	Release version
CMDB HEALTH: Health Job Status	Checks whether any CMDB Health dashboard jobs, which were started 30 or more days ago, are still in progress.	New York
CMDB HEALTH: CMDB Health Completeness/ Recommended	Checks whether the recommended metric (included in the CMDB Health completeness KPI) is fully functional. This test validates:	New York

CMDB HEALTH: CMDB Health Dashboard test suite

Test suite to check whether CMDB CMDB Health Dashboard is functional at a basic level.

(continued)

Test	Description	Release version
	• Creation of a health inclusion rule for the recommend metric. • Creation of a recommended field that satisfies the health inclusion rule. • Validate that the health inclusion rule is correctly applied to a test record with missing data in the recommended field.	

CMDB IRE: Identification Reconciliation Engine test suite

Test suite to check Identification and Reconciliation Engine (IRE) functionality.

Test	Description	Release version
CMDB IRE: IRE Validation	Validate CI identifiers and reconciliation definitions and check indexes for CI identifiers.	Madrid
CMDB IRE: Reconciliation Rule	Check operations on a reconciliation rule, in CI Class Manager, using itil and itil_admin roles. Operations include create, edit, and delete a reconciliation rule. Also, check for active and not active setting, and derived rules.	Paris
CMDB IRE: Identification Rule	Check operations on an identification rule, in CI Class Manager, using itil and itil_admin roles. Operations include create, edit, and delete an identification rule. Also, check for active and not active setting, and derived rules.	Paris

CMDB QB: Query Builder test suite

Test suite to verify CMDB Query Builder functions such as create query, read query, and execute query using two related user roles - cmdb_query_builder and cmdb_query_builder_read.

Test	Description	Release version
CMDB QB: Query Builder - cmdb_query_builder Role	Verify that cmdb_query_builder user role can save queries, and access and run all saved queries, in CMDB Query Builder.	New York
CMDB QB: Query Builder - cmdb_query_builder_read Role	Verify that cmdb_query_builder_read user role can access and run all saved queries, and cannot save any query, in CMDB Query Builder.	New York

CMDB REL: Relationship Editor and Formatter test suite

Test suite to verify functionality of Relationship Editor and Relationship Formatter.

Test	Description	Release version
CMDB REL EDITOR:Relationship Editor	Check addition of relations to a CI and deletion of relations from a CI using itil user role.	New York
CMDB REL FORMATTER:Relationship Formatter	Check accuracy of CI information, relationship types, relationships, associated records such as change tickets, and settings such as CMDB views (relationship filters), displayed for a specific CI in relationship formatter using itil user role.	New York

CMDB SDK: SDK REST API test suite

Test suite to verify functionality of CMDB SDK Rest APIs.

Test	Description	Release version
CMDB SDK: Query CMDB Metadata	Test querying CMDB metadata.	New York
CMDB SDK: Create a relation for a CI using REST APIs	Test creation of a relationship for a CI in the CMDB using the CMDB REST APIs.	New York

CMDB SDK: SDK REST API test suite

Test suite to verify functionality of CMDB SDK Rest APIs.

(continued)

Test	Description	Release version
CMDB SDK: Delete a relation for a CI using REST APIs	Test deletion of a relationship for a CI using CMDB REST APIs.	New York
CMDB SDK: Create a CI using REST API	Test creation of a CI using CMDB REST APIs.	New York
CMDB SDK: Query CMDB using REST APIs	Test querying the CMDB using CMDB REST APIs.	New York
CMDB SDK: Update a CI using REST APIs	Test updating of a CI using CMDB REST APIs.	New York
CMDB SDK: Query for a CI using REST APIs	Test querying a CI using CMDB REST APIs.	New York

To learn more about Configuration Management Database, see Configuration Management Database.

Continual Improvement Management

Continual Improvement Management quick start tests require activating the Continual Improvement Management Automated Tests plugin (com.sn_cim.atf)

Continual Improvement Management tests

Test	Description	Release version
CIM: Inbound integration from Assessments	Create an improvement initiative from an assessment.	Paris
CIM: Inbound integration from Incident Management	Create an improvement initiative from an incident.	Paris
CIM: Inbound integration from Problem Management	Create an improvement initiative from a problem.	Paris
CIM: Inbound integration from Survey Management	Create an improvement initiative from a survey.	Paris

To learn more about Continual Improvement Management, see Continual Improvement Management.

Customer Service Management

All Customer Service Management quick start tests require activating the Customer Service Management Demo Data plugin (com.snc.customerservice.demo). Some quick start tests also require activating the following plugins:

- Business Location (com.snc.business_location)
- Case Playbook for Complaints (sn_complaint)
- Case Playbook for Onboarding (sn_onboarding)

- Consumer Service Portal (com.glide.service-portal.consumer-portal)
- CSM Contributor User (com.snc_csm_contributor_user)
- CSM Extension for Proxy Contacts (com.snc.csm_proxy_contacts)
- Customer Service Household (com.snc.household)
- Customer Service Management for Orders (com.snc.csm.order)
- Customer Service Portal (com.glide.service-portal.customer-portal)
- Customer Service with Request Management (com.sn_cs_sm_request)
- Customer Service with Service Management (com.sn_cs_sm)
- Guided Decisions Experience (com.snc.guided_decisions_playbook_experience)
- Guided Decision - Next Best Action (com.snc.next_best_action)
- Major Issue Management (com.sn_majorissue_mgt)
- Proactive Customer Service Operations with Event Management (com.snc.proactive_cs_itom)
- Skill Determination (com.snc.skill_determination)
- Walk-Up for CSM (com.snc.walkup_for_csm)

CSM: Case Management test suite

Test	Description	Release version
CSM: Create Product Case	Create a case for a product.	Madrid
CSM: Assign Case to an Agent	Create a case and assign it to a customer service agent.	Madrid

- Content Publishing [app-content-publishing]
- Content Experiences [app-content-experiences]

Essential SAFe

Essential SAFe quick start tests require activating the Agile - Scaled Agile Framework - Essential SAFe plugin (com.snc.sdlc.safe) and the Agile - Scaled Agile Framework - Essential SAFe - ATF Tests plugin (com.snc.sdlc.safe.atf).

Essential SAFe test suites

Test	Description	Release version
Essential SAFe: Feature tests	Verify feature global rank updates.	Madrid
Essential SAFe: Feature tests	For a SAFe feature, verify that: • Actual start date is populated after the state is changed to Implementation, Validation on Staging, or Deployment. • Actual end date is populated after the state is changed to **Released** or **Cancelled**. • Active flag is set to the appropriate value: ○ **False**, if the state is changed to **Released** or **Cancelled**. ○ **True**, for all other states.	Orlando
Essential SAFe: Feature tests	If the PPM Standard plugin (com.snc.financial_planning_pmo) is active, verify that a Demand can be converted to a SAFe feature using the **Create SAFe Feature** related link on the Demand form. For more information on how to create an SAFe feature from a demand, see Create an artifact from a demand.	Quebec
Essential SAFe: Program increment tests	Verify program increment date overlapping.	Madrid
Essential SAFe: Sprint tests	Verify the generation of ART sprints and team sprints as well as updates to sprint points and dates.	Madrid

Essential SAFe test suites (continued)

Test	Description	Release version
Essential SAFe: Sprint tests	Verify that any update to the **Group capacity** field of the assignment group results in the following changes to the **Group capacity** field of the various sprints associated with this assignment group: • For the sprints that are in the **Draft** or **Planning** states: ○ The group capacity is updated to the new value. ○ The **Group capacity** field is editable. • For the sprints in the **Current**, **Complete**, or **Cancelled** states: ○ The group capacity remains the old value. ○ The **Group capacity** field is read-only. For the sprints in the **Draft** or **Planning** state, you can individually edit the group capacity of the sprint anytime later. This would not change the group capacity of the assignment group associated with this sprint.	Paris
Essential SAFe: Story tests	Verify story global rank updates.	Madrid
Essential SAFe: Story tests	Verify that active flag of the SAFe story is set to the appropriate value: • **False**, if the state of the state is changed to Completed or Cancelled. • True, for all other states.	Orlando
Essential SAFe: Story tests	Verify that adding, estimating, removing, deleting, updating, or cancelling a SAFe story updates the SAFe feature-	Orlando

Essential SAFe test suites (continued)

Test	Description	Release version
	level and then the epic-level roll-ups correctly.	
Essential SAFe: Story tests	Verify that adding, updating, or deleting the feature on a SAFe story updates the Epic field on the SAFe story form.	Orlando
Essential SAFe: Story tests	If the PPM Standard plugin (com.snc.financial_planning_pmo) is active, verify that a Demand can be converted to a SAFe story using the **Create SAFe Story** related link on the Demand form. For more information on how to create a SAFe story from a demand, see Create an artifact from a demand.	Quebec
Essential SAFe: Team tests	Verify team association with an ART.	Madrid
Essential SAFe: Epic tests	For a SAFe epic, verify that: • Actual start date is populated after the state is changed to **Implementation**. • Actual end date is populated after the state is changed to **Complete**. • Active flag is set to the appropriate value: ○ **False**, if the state is changed to **Released** or **Cancelled** states. ○ **True**, for all other states.	Orlando
Essential SAFe: Epic tests	If the PPM Standard plugin (com.snc.financial_planning_pmo) is active, verify that a Demand can be converted to a SAFe epic using the **Create SAFe Epic** related link on the Demand form. For more information on how to create a SAFe epic agile	Quebec

Essential SAFe test suites (continued)

Test	Description	Release version
	from a demand, see Create an artifact from a demand.	
Essential SAFe: Program PI Objective tests	Verify the functionality of creating and updating PI objectives • Verify that you can create a program increment-level objective • Verify that you can update the created PI objective with the planned business value (PBV) and actual business value (ABV) • Verify that the percentage of business value achieved is computed as the percentage of ABV complete, for only the committed PI objectives, as compared to the PBV of the program in the PI	Rome
Essential SAFe: Team PI Objective tests	Verify the functionality of creating and updating team PI Objectives • Verify that you can create a team-level PI objective • Verify that you can update the created PI objective with the planned business value (PBV) and actual business value (ABV) • Verify that the percentage of business value achieved is computed as the percentage of ABV complete, for only the committed PI objectives, as compared to the PBV of the team in the PI	Rome

To learn more about Essential SAFe, see Essential SAFe.

Event Management

Event Management quick start tests require activating the Event Management plugin (com.glideapp.itom.snac).

Event Management quick start tests

Test	Description	Release version
EMSelfMonitoring	Track problems with the Event Management plugin after upgrade. To understand the details of issues found, open the All Alerts list and search for alerts that failed, whose source is `EMSelfMonitoring`, and that were opened or reopened since the upgrade. The exact time for filtering can be found in the error message.	Madrid

To learn more about Event Management, see Event Management.

Field Service Management

Field Service Management quick start tests are available when you enable the Field Service Management plugin (com.snc.work_management). Enable the demo data plugin (com.snc.work_management.demo) in a non-production instance to start using the quick start tests available with your application. Activate Field Service Contractor Management plugin (com.snc.fsm_contractor_management) to execute the External contractor related tests. You can also modify existing data and customize it to run the quick tests.

FSM: Field Service Management test suite

Test	Description	Release version

On-Call: Roster Details for overlapping shifts with the escalation rule 'Escalate to all shifts'	Verify the roster details for overlapping shifts when the escalation rule is set to **Escalate to all shifts**.	Orlando
On-call: Verify On-Call workbench	Test to verify the On-Call workbench layout.	Orlando
On-call: Hide or show shifts	Verify whether you can hide or show shifts from On-Call calendar	Orlando

To learn more about On-Call Scheduling, see On-Call Scheduling.

Metric Intelligence

Metric Intelligence quick start tests require activating the Metric Intelligence plugin (com.snc.sa.metric).

Metric Intelligence quick start tests

Test	Description	Release version
OI: Health Metrics Collection	An individual test that verifies the following: • There is at least one Metric Intelligence Metrics extension that is running. • There are entries for the 'Health Metrics' in the Metric to CI table. • For each of the Metric Intelligence Metrics extensions that are currently running, that there is data stored in MetricBase. If the test initially fails, wait until the Metric Intelligence Metrics extension runs for at least 10-15 minutes. Then try again.	Madrid

To learn more about Metric Intelligence, see Metric Intelligence.

Predictive Intelligence

Predictive Intelligence quick start tests require activating the Predictive Intelligence [com.glide.platform_ml] plugin. In order to execute critical upgrade tests on existing machine learning solutions, you need to create a basic authorization profile named ml_atf in the Basic Auth Configurations table (sys_auth_profile_basic.list). To run the tests successfully, the user attached to the ml_atf authorization profile must have the ml_admin role.

Predictive Intelligence: Classification and Similarity Solution Prediction test suite

Test	Description	Release version
PI: Presence of ML model artifacts persisted in glide	Verify all the trained ML model artifacts are persisted in glide (sys_attachments table) after model training/instance cloning so that ML prediction calls are successful.	New York
PI: Valid setup of ML user (sharedservice.worker) in glide	Validate if the ML user in glide (sharedservice.worker) is active and not logged out	New York

Predictive Intelligence: Classification and Similarity Solution Prediction test suite (continued)

Test	Description	Release version
	so that model training is successful.	
PI: Glide upgrade test for Classification solution	Validate that the classification model prediction on existing active models is producing the same class membership and confidence value results after a glide upgrade.	New York
PI: Glide upgrade test for Similarity solution	Validate that the similarity model prediction API calls on active models are successful after a glide upgrade.	New York

Problem Management

Problem Management quick start tests require activating the Problem Management Best Practice — Madrid plugin (com.snc.best_practice.problem.madrid) and the Problem Management — ATF Tests plugin (com.snc.problem.atf). For all state related test, the Problem Management State Model (com.snc.best_practice.problem.madrid.state_model) plugin needs to be active.

PRB MGMT: Problem Management test suite

Test	Description	Release version
PRB MGMT: Cancel a Problem when the state of the Problem is Assess	Verify that when a Problem in the **Assess** state is canceled, the state of the Problem changes to **Closed** with **Resolution code** as **Canceled**.	Madrid
PRB MGMT: Cancel a Problem when the state of the Problem is Root Cause Analysis	Verify that when a Problem is in the **Root Cause Analysis** state and is canceled, the state of the Problem changes to **Closed** with **Resolution code** as **Canceled**.	Madrid
PRB MGMT: Mark a Problem as Duplicate when the state of the Problem is Assess	Verify that when a Problem is in the **Assess** state and is marked as duplicate, the state of the Problem changes to **Closed** with **Resolution code** as **Duplicate**.	Madrid
PRB MGMT: Mark a Problem as Duplicate when the state of the Problem is Root Cause analysis	Verify that when a Problem is in the **Root Cause Analysis** state and is marked as duplicate, the state of the Problem changes to **Closed** with **Resolution code** as **Duplicate**.	Madrid

PRB MGMT: Problem Management test suite (continued)

Test	Description	Release version
PRB MGMT: Accept Risk of Problem (problem.acceptrisk.move_to_closed=false, Fix in Progress)	Verify that when a Problem state is **Fix in Progress** and the risk is accepted, then the Problem state changes to **Resolved** with **Resolution code** as **Risk Accepted**. **Note:** The test is valid when Problem property **Accept Risk moves the Problem to Closed state instead of Resolved state** *(problem.acceptrisk.move_to_closed)* is false.	Madrid
PRB MGMT: Accept Risk of Problem (problem.acceptrisk.move_to_closed=true, Fix in Progress)	Verify that when a Problem state is **Fix in Progress** and the risk is accepted, then the Problem state changes to **Closed** with **Resolution code** as **Risk Accepted**. **Note:** The test is valid when Problem property **Accept Risk moves the Problem to Closed state instead of Resolved state** *(problem.acceptrisk.move_to_closed)* is true.	Madrid
PRB MGMT: Accept Risk of Problem (problem.acceptrisk.move_to_closed=false, Root Cause Analysis)	Verify that when a Problem state is **Root Cause Analysis** and the risk is accepted, then the Problem state changes to **Resolved** with **Resolution code** as **Risk Accepted**. **Note:** The test is valid when Problem property **Accept Risk moves the Problem to Closed state instead of Resolved state** *(problem.acceptrisk.move_to_closed)* is false.	Madrid
PRB MGMT: Accept Risk of Problem(problem.acceptrisk.move_to_closed=true, Root Cause Analysis)	Verify that when a Problem state is **Root Cause Analysis** and the risk is accepted, then	Madrid

PRB MGMT: Problem Management test suite (continued)

Test	Description	Release version
	the Problem state changes to **Closed** with **Resolution code** as **Risk Accepted**. **Note:** The test is valid when Problem property **Accept Risk moves the Problem to Closed state instead of Resolved state** *(problem.acceptrisk.move_to_closed)* is true.	
PRB MGMT: Reanalyze Problem which is closed-Risk Accepted from state Root Cause Analysis	Verify that when a Problem is reanalyzed after it is **Closed** with the **Resolution code** as **Risk Accepted**, Problem state changes to **Root Cause Analysis**.	Madrid
PRB MGMT: Create Emergency Change from Problem	Verify the creation of Emergency Change from a Problem.	Madrid
PRB MGMT: Create Normal Change from Problem	Verify the creation of Normal Change from a Problem.	Madrid
PRB MGMT: Problem State Management	Verify problem state management.	Madrid
PRB MGMT: Reanalyze a Problem from Complete	Verify that when a Problem is reanalyzed after it is **Closed** with the **Resolution code** as **Fix Applied**, Problem state changes to **Root Cause Analysis**.	Madrid
PRB MGMT: Reanalyze a Problem which is canceled from state Assess	Verify that when a Problem is reanalyzed after it is **Closed** with the **Resolution code** as **Canceled**, Problem state changes to **Root Cause Analysis**.	Madrid
PRB MGMT: Reanalyze a Problem which is canceled from state Root Cause Analysis	Verify that when a Problem is reanalyzed after it is **Closed** with the **Resolution code** as **Canceled**, Problem state changes to **Root Cause Analysis**.	Madrid
PRB MGMT: Reanalyze Problem which is closed-Risk Accepted from state Fix in progress	Verify that when a Problem is reanalyzed after it is **Closed** with the **Resolution code** as **Risk Accepted**, Problem	Madrid

PRB MGMT: Problem Management test suite (continued)

Test	Description	Release version
	state changes to **Root Cause Analysis**.	
PRB MGMT: Create a Known Error article from Problem	Verify creation of Known Error article from a Problem.	Madrid
PRB MGMT: Risk Accept reason on Incident	Verify the **Risk Accepted reason** is copied to the Incidents which are awaiting resolution of a Problem.	Madrid
PRB MGMT: Communicate Fix	Verify the communicate fix functionality.	Madrid
PRB MGMT: Communicate Workaround	Verify the communicate workaround functionality.	Madrid
PRB MGMT: Fix information on Incident	Verify that when a Problem is resolved, the state of the Incidents that are awaiting resolution of the Problem changes to **Resolved**. The fix notes of the Problem are copied to the Incidents.	Madrid
PRB MGMT: Problem task (Type:General) state management	Verify Problem task state management of a general type Problem.	Madrid

To learn more about Problem Management, see Problem Management.

Project Portfolio Management

Project Portfolio Management quick start tests require activating the PPM Standard - ATF Tests plugin (com.snc.financial_planning_pmo.atf).

PMO: Financial Tests for verifying cost rollups and demand to project conversion test suite

Test	Description	Release version
PMO: Verify cost plan roll up to project/demand and program	Validate the total planned cost rollup from project and demand to program.	Madrid
PMO: Verify cost plan roll up to project/demand, program and portfolio	Validate the total planned cost rollup from project and demand to portfolio.	Madrid
PMO: Verify financials of Project created from Demand - Simple Financials	Validate the financial tab fields of a project created from a demand.	Madrid
PMO: Verify financials of Project created from Demand	Validate the budget, cost plan, and benefit plan of a project created from a demand.	Madrid

PMO: Financial Tests for verifying cost rollups and demand to project conversion test suite (continued)

Test	Description	Release version
- With budget, cost plans, benefit plans		
PMO: Verify ETC/EAC at cost plan breakdown and project level	Validate the EAC and ETC values at cost plan breakdown and project level.	Tokyo

PMO: Innovation Management Tests for verifying idea life cycle

Test	Description	Release version
Validate state changes of Idea	Validate that the state of idea is changed when an idea is accepted, rejected, or any other task is created from an idea.	San Diego

PMO: Project Management tests for validating basic life cycle and project rollups test suite

Test	Description	Release version
Validate PPM Cycle from Ideation to demand to project closure	Validate the flow of creating an idea, converting the idea to a demand, and then converting the demand to a project. **Note:** This test fails if the PPM Standard Multicurrency (com.snc.ppm_multicurrency) plugin is active.	Madrid
Validation of State and Date Rollup for Automatic Project	Validate the date and state rollup from tasks for a project of type Automatic.	Madrid
Validation of State and Date rollup for Manual Project	Validate the date and state rollup from tasks for a project of type Manual.	Madrid
Validation of project percent complete when all tasks are Closed Incomplete	Validate the project percent complete when all the tasks are closed as Closed Incomplete.	Orlando
Validate Project is not 100 percent complete if it has atleast one task as closed incomplete	Validate the project percent complete is not 100% when at least one of the tasks is closed as Closed Incomplete or Closed Skipped with task % complete less than 100%.	Orlando

PMO: Project Management tests for validating basic life cycle and project rollups test suite (continued)

Test	Description	Release version
Validate waterfall project does not show Agile Planning Board	Validate that the waterfall projects cannot use the following: • Add stories or epics • Add agile phase • Access Agile board from the project	Orlando
Validate dates are rolled up from existing projects to program	Validate that the start and end dates of the project are rolled up to the program to which the project belongs.	Paris
Validate dates are rolled up from new projects to program	Validate that the start and end dates of a new project are rolled up to the program to which the project belongs.	Paris
Add projects and demands with risks or issues to program	Validate that the projects and demands with risks or issue records associated with them are added to the program.	Paris
Add projects and demands with benefit plans to program	Validate that the projects and demands with benefit plans associated with them are added to the program.	Paris
Add projects and demands with cost plans to program	Validate that the projects and demands with cost plans associated with them are added to the program.	Paris
Validate program dates on addition of existing demands	Validate that the start and end date of the program are adjusted on addition of an existing demand.	Paris
Validate program dates on addition of new demands	Validate that the start and end date of the program are adjusted on addition of a new demand.	Paris
Validate program state rollup	Validate that the program state is rolled up from state of all the projects in the program.	Paris
Verify Demand task due date column field value empty	Validate that the **Due date** field is empty for a new demand task.	Rome
Verify baseline is created on Project & Demand when demand is converted to project	Validate that a project and demand baseline is created when a demand is converted to a project.	Rome
Verify timecard financial appears on Demand when time card submitted against demand task	Validate that the actual cost of the demand is updated when a time card is processed for a demand task.	Rome
Validate demand approved date	Validate that the approved dates for demand and the project created from the demand are the same.	Tokyo

PMO: Project Management tests for validating basic life cycle and project rollups test suite (continued)

Test	Description	Release version
Validate project preference "close project milestone tasks when they change to work state"	Validate that the milestone tasks are closed when their state is changed to Work in Progress after setting the project preference to "close project milestone tasks when they change to work state".	Tokyo
Validate project preference "Enable move project for WIP projects"	Validate that the project start date is changed appropriately for a project in WIP state when the project start date is changed after setting the project preference to "Enable move project for WIP projects".	Tokyo
Validate project preference "Rollup project start date from tasks"	Validate that the start date of a project task does not roll up to the project when the project planned dates are different than the project task start date after deselecting the project preference "Rollup project start date from tasks".	Tokyo

Child Test Suite: Validation of Move Project Action

Test	Description	Release version
Validate Planned start date of a project can be shifted by using the Move project action	Validate that the Planned start date of a project in Planning or Open state can be updated to a later or earlier date than the current planned start date using the Move project related link.	Orlando
Validate Move Project is disabled when Project is selected for execution	Validate that the Move Project option is not available if the Project is in Execution phase.	Orlando
Validate Move Project functionality with sprint dates populated for an agile phase	Validate that the sprint start and end dates are cleared when the project is moved using the Move Project related link. **Note:** This test is available only when Agile Development 2.0 plugin (com.snc.sdlc.agile.2.0) is activated.	Orlando
Validate Move Project functionality with external dependencies and related entities	Validate that the external dependencies and related entities are also shifted and redrawn when the project is moved using the Move Project related link.	Orlando

Child Test Suite: Validation of Move Project Action (continued)

Test	Description	Release version
Validate Move Project functionality with different project states	Validate that the Move Project does not work when the project is in Work In Progress or Closed Complete state.	Orlando

Child Test Suite: Verify RIDAC flow of a Project

Test	Description	Release version
Verify RIDAC flow for Risk	Validate the RIDAC flow for a risk associated with a project.	Quebec
Verify RIDAC flow for Issue	Validate the RIDAC flow for an issue associated with a project.	Quebec
Verify RIDAC flow for Decision	Validate the RIDAC flow for a decision associated with a project.	Quebec
Verify RIDAC flow for Action	Validate the RIDAC flow for an action associated with a project.	Quebec
Verify changes in fields of risk form	Validate that any change is the Risk form fields such as Risk rank, Risk value, and Probability is updated successfully upon submission.	Quebec

Child Test Suite: Verify RIDAC flow of a Demand

Test	Description	Release version
Verify RIDAC flow for Risk	Validate the RIDAC flow for a risk associated with a demand.	Quebec
Verify RIDAC flow for Issue	Validate the RIDAC flow for an issue associated with a demand.	Quebec
Verify RIDAC flow for Decision	Validate the RIDAC flow for a decision associated with a demand.	Quebec
Verify RIDAC flow for Action	Validate the RIDAC flow for an action associated with a demand.	Quebec
Verify changes in fields of risk form	Validate that any change is the Risk form fields such as Risk rank, Risk value, and Probability is	Quebec

Child Test Suite: Verify RIDAC flow of a Demand (continued)

Test	Description	Release version
	updated successfully upon submission.	

PMO: Resource Management tests for verifying the resource plan flows test suite

Test	Description	Release version
Verify user resource plan flow from Planned to Canceled state	Validate that the resource plan of a project can be moved to canceled state from planned state.	Madrid
Verify group resource plan flow from Planned to Complete state	Validate that the resource plan of a project can be moved to complete state from planned state.	Madrid
Verify role resource plan flow from Planned to Allocated state	Validate that the resource plan of a project can be moved to allocated state from planned state.	Madrid
Verify aggregated cost of all resource plans roll up to the corresponding project or demand fields	Validate that the aggregated cost of all resource plans on a project or demand roll up to the Planned Cost and Allocated Cost fields and the Resource Cost section of respective projects and demands.	Orlando
Verify Copy Resource plan option	Validate that the Copy Resource plan option creates an exact copy of the source resource plan in the Planning state	Orlando
Verify resource plan aggregate roll up from project/ demand to program	Validate that the aggregated cost of all resource plans on a project or demand roll up to the total planned cost of the associated program.	Orlando
Verify records on completion of a resource plan	Validate the changes in a resource plan on completion: • The state of the resource plan is updated to Completed. • If the completion date is earlier than the resource plan end date, the end date of the resource plan is updated with the completion date. If the completion date entered is later than the resource plan end date, the resource plan end date is retained. • All the requested and allocation records for the resource plan for the period after the completion date are deleted. If there are any actual hours logged against an allocation, that allocation is not deleted. For those allocation records,	Orlando

PMO: Resource Management tests for verifying the resource plan flows test suite (continued)

Test	Description	Release version
	the allocated hours become zero and the actual hours are retained. • The available and allocated hours for resources are updated in the aggregate tables.	
Verify records on completion of a resource plan with Planned Duration as allocation type	Validate the following on completion of a resource plan with Planned Duration as allocation type: • The state of the resource plan is updated to Completed. • Allocations are not deleted. • End date of the allocation is updated to the completion date.	Orlando
Verify the RP replan Capability	Validate that when a cancelled resource plan is re-planned, the state of the resource plan changes to Planning.	Orlando
Verify whether change in resource plan is reflected in corresponding cost plan	Validate that when a resource plan is updated, the corresponding cost plan is updated accordingly. For example, if the total planned cost is 500 USD, and the planned hours is 10, and you change the planned hours to 20, the total planned cost is updated to 1000 USD.	Paris
Resource-Test the default population of resource plan start & end date	Validate the following on creating a user or group resource plan from the related list of a demand: • If a demand is created without a start date and end date, the user or group resource plan has task as demand and no start and end date. • If a demand is created with a start date and end date, the user resource plan has task as demand and the start date and end date as added for the demand.	Paris
Validate that actual hours in operational resource plan and time card are equal	Validate that when a time card category is mapped with an operational work type, on submitting the time card for the operational resource plan associated with that work type, the actual hours in the resource plan and the time card are equal.	Quebec
Verify Resource plan auto population for Operational plans	Validate that the operational resource plans associated with a time card are automatically retrieved on the time card when time is logged.	Rome
Verify resource plan auto population for non-operational resource plans	Validate that the resource plans associated with a project, project task, or demand for a time card are automatically retrieved on the time card when time is logged.	Rome

To learn more about Project Portfolio Management, see Project Portfolio Management.

Project Currency test suite

Project currency quick start tests require activating the PPM Standard Multicurrency – ATF Tests plugin (com.snc.ppm_multicurrency.atf).

Product currency test suite tests

Test	Description	Release version
Verify cost in project currency on cost plan	Validate the calculation of cost line breakdown with budget reference rate and verify roll up to cost plan and also for the project in project currency.	Orlando
Verify benefit in project currency on benefit plan	Validate the calculation of benefit line breakdown with budget reference rate and verify roll up to benefit plan and also for the project in project currency.	Orlando

To learn more about PPM Standard, see PPM Standard.

Reporting

The Reporting quick start test Automated Test Framework - Reporting plugin (com.glide.automated_testing_impl.report) is active by default or instance reboot.

Note:
Reporting quick start tests do not test report access from dashboards. To test dashboards, see Quick start tests for Dashboards.

Reporting quick start tests

Test	Description	Release version
Report Visibility	Confirm whether reports are still visible to users whom they are shared with.	Madrid

Software Asset Management Foundation plugin Software Asset Management

Software Asset Management Foundation plugin Software Asset Management quick start tests require activating the Software Asset Management Professional plugin (com.snc.samp). Some quick start tests require activating the following additional plugins.

- Software Asset Management - Spend Detection (com.sn_sam_spend)
- Software Asset Management Professional for Microsoft (com.snc.samp.microsoft)
- Software Asset Management Professional for SAP (com.sn_samp_sap)
- Software Asset Management Professional for Oracle (com.snc.samp.oracle)
- Software Asset Management - SaaS License Management Integrations (sn_sam_saas_int)

Software Asset Management test suite

Test	Description	Release version
SAM - Mapping Custom PPN/ DMAP to newly published PPN and Content	Validates the replacement of a custom publisher part number (PPN) with a new Software Asset Management Content Service PPN.	San Diego
SAM - Oracle PaaS BYOL	• Validates the addition of the new Serverless Hardware [cmdb_ci_serverless_hardware] table, which stores information about PaaS devices. • Validates the license compliance of Oracle Database servers in Amazon Web Services (AWS) PaaS environments. **Note:** Requires the Software Asset Management Professional for Oracle (com.snc.samp.oracle) plugin and the CMDB CI Class Models store application.	Rome
SAM - Software Product Lifecycles records on Software Model	Validates that the Software Lifecycle tab on the Software Model form is showing records. **Note:** Requires demo data and the Software Asset Management Professional for Microsoft (com.snc.samp.microsoft) plugin.	Quebec
SAM - BYOL	• Validates the purchase date on the Software Entitlement form • Validates the addition of newly added column legacy_license on the License Metric Results [samp_license_metric_result]	Quebec

Software Asset Management test suite (continued)

Test	Description	Release version
	and License Position Report [samp_license_position_report] tables • Validates the addition of newly added columns, cloud_license_type and cloud_license _type_source in the Software Installations [cmdb_sam_sw_install] table **Note:** Requires the Software Asset Management Professional for Micorosft (com.snc.samp.microsoft) plugin.	
SAM - Validate CIS Suites	Validates reconciliation of Core Infrastructure Server (CIS) suites along with downgrade rights. **Note:** Requires demo data and the Software Asset Management Professional for Microsoft (com.snc.samp.microsoft) plugin.	Paris
SAM - PerCoreForMSCluster	Verifies the reconciliation functionality for Microsoft per core with cluster. **Note:** Requires the Software Asset Management Professional for Microsoft (com.snc.samp.microsoft) plugin.	Paris
SAM - Validate upgrade/ downgrade during Reconciliation for Microsoft publisher	Validates upgrade and downgrade rights during reconciliation for Microsoft products.	Paris

Software Asset Management test suite (continued)

Test	Description	Release version
	Note: Requires demo data and the Software Asset Management Professional for Microsoft (com.snc.samp.microsoft) plugin.	
SAM - Generate demand to consolidate SaaS applications	Validates generation and submission of a demand on SaaS applications. **Note:** Requires the Software Asset Management - Spend Detection (com.sn_sam_spend) plugin and the PPM standard (com.snc.financial_planning_pmo) plugin.	Paris
SAM - Software Model and Software Entitlement checks for SAP Engines	Verifies that the Software Model and Software Entitlement forms change when the product is an SAP engine. **Note:** Requires the Software Asset Management Professional for SAP (com.sn_samp_sap) plugin.	Paris
SAM - Downgrade Rights on Software Model	Validates that the downgrade rights pushed from the content service are correctly populated on the Downgrade Rights related list on the software model form.	Orlando
SAM - Multi-core pack validation on Software Entitlement	Validates the functionality of new fields for a multi-core pack on software entitlements.	Orlando

Software Asset Management test suite (continued)

Test	Description	Release version
	Note: Requires the Software Asset Management Professional for Microsoft (com.snc.samp.microsoft) plugin.	
SAM - Downgrade Rights on Software Entitlement	Validates that the downgrade rights pushed from the content service are correctly populated on the Downgrade Rights related list on the software entitlement form.	Orlando
SAM - Software Spend Transaction	Validates the creation of a Software Spend Transaction. **Note:** Requires the Software Asset Management - Spend Detection (com.sn_sam_spend) plugin.	Orlando
SAM - Software Model and Software Entitlement	Tests that a user can create a software model and software entitlement and validates those records.	New York
SAM - Software Installation and Discovery Model	Tests that a user can create a software installation and discovery model and validates those records.	New York
SAM - Software Entitlement Creation Using Custom PPN	Creates a custom software product, a custom DMAP for the custom product, a custom Part Number for the custom DMAP, a software entitlement using the custom Part Number, and verifies that a software model is automatically created.	New York
SAM - Software Model Checks for SAP Named Users	Tests that the software model form changes when the publisher is SAP and the product is Named Users.	New York

Software Asset Management test suite (continued)

Test	Description	Release version
	Note: Requires the Software Asset Management Professional for SAP (com.sn_samp_sap) plugin.	
SAM - Software Model Checks for SaaS	Tests that the Software Model form changes when a SaaS product is selected. **Note:** Requires the Software Asset Management - SaaS License Management Integrations (sn_sam_saas_int) plugin.	New York
SAM - Validate Fields on SaaS Software Products	Tests that the **Subscription software** and **Ignore installs** fields are present on the Software Product form. **Note:** Requires the Software Asset Management - SaaS License Management Integrations (sn_sam_saas_int) plugin.	New York

To learn more about Software Asset Management, see Software Asset Management.

Security Incident Response

Security Incident Response quick start tests require activating Security Incident Response plugin (com.snc.security_incident) and loading the demo data.

Security Incident Response tests

Test	Description	Release version
SIR: Create Security Incident	Determine whether a user can successfully create a security incident from the security incident form.	Xanadu

Security Incident Response tests (continued)

Test	Description	Release version
SIR: Create Security Incident via Security Incident Catalog	Determine whether a user can successfully create a security incident from the catalog.	Xanadu
SIR: Security Incident life cycle	Validate the response tasks of the Policy Violation workflow.	Xanadu
SIR: Threat Lookup	Validates the Threat Lookup capability.	Xanadu
SIR: PIR Assessments OOTB configuration	Use this test to validate PIR assessments and base system configurations.	Xanadu
SIR: PIR Assessments conditional configuration	Verify that security incidents matching the mandatory conditional rule are not closed without completing the post incident assessment. Verify that the security incidents matching the optional conditional rule can be closed without completing the post incident assessment. Verify that assessments are not generated for the security incidents that do not match any rule.	Xanadu
SIR: PIR run time verification	Verify that PIR reports are configured and attached to the security incidents as per the new design.	Xanadu
SIR: PIR design time setup verification	Verify that the security incident is mapped with the report template based on the administrator configuration.	Xanadu
SIR: Link Security Incident to a existing Major Security Incident	Link a Security Incident to an existing Major Security Incident and validate data from Security Incident rolled up to Major Security Incident.	Xanadu
SIR: Promote Security Incident as Major Security Incident	Promote a Security Incident as Major Security Incident and validate data from Security Incident rolled up to Major Security Incident.	Xanadu
SIR: Propose Security Incident as Major Security Incident	Propose a Security Incident as Major Security Incident and validate data from Security	Xanadu

Security Incident Response tests (continued)

Test	Description	Release version
	Incident rolled up to Major Security Incident.	
Verify that only Allowed Members can access the security incident once Enforce Restriction is ON	Verify that only the allowed members can access the security incident once the Enforce Restriction is enabled.	Xanadu
Verify that only Allowed Groups can access the security incident once Enforce Restriction is ON	Verify that only the allowed groups can access the security incident once the Enforce Restriction is enabled.	Xanadu
Validate Read Access	Validate the view access.	Xanadu
Validate Write Access	Validate the edit access.	Xanadu

To learn more about Security Incident Response, see Security Incident Response.

Service Level Management

Service Level Management quick start tests require activating the Service Level Management - ATF Tests plugin (com.snc.service_level_management.atf).

Service Level Management quick start tests

Test	Description	Release version
SLM: Service Level Management Task SLA completed workflow	Tests that a user can create a task SLA and complete the workflow.	Orlando
SLM: Service Level Management Task SLA cancelled workflow	Tests that a user can create a task SLA and cancel the workflow.	Orlando
SLM: Service Level Management Task SLA timer REST API	Tests that the SLA Timer API response matches data expected by SLA Timer Seismic component.	Paris

To learn more about Service Level Management, see Service Level Management.

Service Mapping

Service Mapping quick start tests require activating the Service Mapping (com.snc.service-mapping) plugin and loading the demo data.

Service Mapping quick start tests

Test	Description	Release version
SM OOTB: Tests SM application visibility by roles	Validate the visibility of Service Mapping applications and modules	Madrid

Service Mapping quick start tests (continued)

Test	Description	Release version
	for different roles. For example, the test verifies that a user logged in with the service_mapping_user role cannot access the Administration module under Service Mapping.	
SM OOTB: Service map verification	Use this test template to create custom tests for verifying that the topology of the most significant services is unchanged. Configure values under Test Run Data Sets, to identify the name of the service to test and the nodes that you expect to find in this service. For the node name values, enter the node attribute exactly as it appears on the map, for example, "Apache server." If the attribute name for a node is truncated or shows that a node is a CI cluster, configure this node name value to reflect the way it appears on the map, for example, "11x ExchangeF" for a group of 11 Exchange FrontEnd servers. **Note:** You cannot use this test to verify the service content beyond the top, unexpanded level.	Orlando, updated Paris
SM OOTB: Check UI accessibility after an upgrade	Run this test to check that the Service Mapping UI is fully functional after an upgrade.	Orlando

To learn more about Service Mapping, see Service Mapping.

Service Portfolio Management Premium

Service Portfolio Management Premium quick start tests require activating the Service Portfolio Management Premium plugin (com.snc.spm).

Service Portfolio Management Premium - ATF Tests test suite

Test	Description	Release version
Portfolio Editor: Not Portfolio Owner, Read Only Taxonomy Access	Ensure a portfolio editor can only read associated non-owned portfolio taxonomies.	Orlando
Portfolio Editor: Cannot create new Portfolios	Ensure a portfolio editor cannot create new portfolios.	Orlando
Portfolio Editor: Valid Portfolio Owner Taxonomy Access	Ensure a portfolio owner has access to taxonomies within owned portfolios.	Orlando
Service Editor: Access	Ensure a service editor can only edit owned services and offerings.	Orlando
Portfolio Editor: Can Modify Owned Portfolios	Ensure a portfolio editor can modify and update owned portfolios.	Orlando
Create a Portfolio	Ensure a portfolio admin can create a new portfolio.	Orlando
Portfolio Editor: Cannot Modify Non-Owned Portfolios	Ensure a portfolio editor cannot modify non-owned portfolios.	Orlando
Service Workflow	Verify that a service cannot move forward to Catalog phase without a service portfolio, taxonomy node, and service offering attached to it. Verify a service cannot move backward from the Catalog phase to the Pipeline phase.	Orlando
Service Portfolio (Normal)	Create a service portfolio, taxonomy layer, and taxonomy nodes.	Orlando
Create a Portfolio + 3 Taxonomy Layers	Create a service portfolio with three taxonomy layers.	Orlando
Service Portfolio (Exception) - Taxonomy Layer Definition Set 01	Create a service portfolio, taxonomy layer, and taxonomy nodes.	Orlando
SPM: Create a Portfolio	Create a service portfolio.	Paris
SPM: Create a Portfolio + 3 Taxonomy Layers	Create a service portfolio, with three taxonomy layers.	Paris
SPM: Service Portfolio (Normal)	Create a service portfolio, taxonomy layer, and taxonomy nodes.	Paris

Service Portfolio Management Premium - ATF Tests test suite (continued)

Test	Description	Release version
SPM: Service Portfolio (Exception) - Taxonomy Layer Definition Set 01	Create a service portfolio, taxonomy layer, and taxonomy nodes.	Paris
SPM: Portfolio Editor: Can Modify Owned Portfolios	Ensure a portfolio editor can modify portfolios that they own.	Paris
SPM: Portfolio Editor: Cannot Modify Non-Owned Portfolios	Ensure a portfolio editor cannot modify portfolios that they do not own.	Paris
SPM: Portfolio Editor: Cannot create new Portfolios	Ensure a portfolio editor cannot create new Portfolios.	Paris
SPM: Portfolio Editor: Valid Portfolio Owner Taxonomy Access	Ensure portfolio owners have access to taxonomies that they own.	Paris
SPM: Portfolio Editor: Not Portfolio Owner, Read Only Taxonomy Access	Ensure a portfolio editor can only read the taxonomies of portfolios they do not own.	Paris
SPM: Service Editor: Access	Ensure a service editor can only edit services and offerings that they own or are a delegate of.	Paris
SPM: Service Viewer: Access	Ensure a service viewer has access to view services.	Paris
SPM: Service Workflow	Verify a service cannot move forward to Catalog phase without a service portfolio, taxonomy node, and service offering attached to it. Verify a service cannot move backward from Catalog to Pipeline phase.	Paris

To learn more about Service Portfolio Management Premium, see Service Portfolio Management Premium.

Skills Management

Skills Management quick start tests require activating the Skills Management plugin (com.snc.skills_management).

Skills Management test suite

Test	Description	Release version
Skills MGMT: User skill level inheritance when user is part of multiple groups	Verify that the user is assigned the highest skill level when the user belongs to multiple groups that have been assigned the same skills with different skill levels.	New York
Skills MGMT: Add skills to lowest level category	Verify that skills can be added to the lowest level category.	New York
Skills MGMT: Create a child category under a parent category	Verify that a lower-level category can be created when the flag for **Add skills** is unchecked in the parent category.	New York
Skills MGMT: Create a skill category	Verify that a skill category can be created on the skill category form.	New York
Skills MGMT: Create skill level type and skill levels	Define the skill level type and different skill levels for the type.	New York
Skill MGMT: Skill level inheritance from group to user	Verify that skill levels can be inherited from a group to the users of the group and that the **Inherited** and **Skill level inherited** fields are set to true.	New York
Skills MGMT: Create a skill from Manage IT Skills user interface.	Verify that you can create a skill from the Manage IT Skills user interface.	Orlando
Skills MGMT: Add skills and skill levels to users in the Manage IT Skills user interface.	Verify that you can add skills and associated skill levels to users in the Manage IT Skills user interface.	Orlando
Skills MGMT: Select a skill and add users to the skill in the Manage IT Skills user interface.	Verify that you can select a skill and add the skill and associated skill levels to one or more users in the Manage IT Skills user interface.	Orlando
Skills MGMT: Select a skill that does not have a skill level and add users to that skill in the Manage IT Skills user interface.	Verify that you can select a skill that does not have a skill level and add the skill to one or more users in the Manage IT skills user interface.	Orlando

To learn more about Skills Management, see Skills Management.

Test Management 2.0

Test Management 2.0 quick start tests require activating the Test Management 2.0 plugin (com.snc.test_management.2.0). and the Test Management 2.0 - ATF Tests plugin (com.snc.test_management.2.0.atf).

Test Management 2.0: Test version test suite

Test	Description	Release version
Create test version should create test	Validate test creation and version.	Madrid
Should be able to mark test version as ready when it contains verification steps	Validate test state when test has verification steps.	Madrid
Should not able to mark test version as ready when it does not contain verification step	Validate test state when test does not have verification steps.	Madrid
Marking a test version as ready should retire other test version in ready state	Validate test state when marking test ready.	Madrid

Test Management 2.0: Test results rollup test suite

Test	Description	Release version
When test run closed, should update execution suite progress	Validate execution state progress.	Madrid
Should not be able to assign a test not in ready state	Validate test assignment.	Madrid
Test progress should roll up for test plan and test cycle	Validate test progress for test plan and test cycle.	Madrid

To learn more about Test Management 2.0, see Test Management 2.0.

Universal Request

Universal Request quick start tests require activating the Universal Request (com.snc.universal_request), Universal Request: Integration for Incident management (com.snc.incident.universal_request), and Human Resources Scoped App: Core (com.sn_hr_core) plugins.

Universal Request quick start tests

Test	Description	Release version
UR: Transferring an HR case to an Incident	Validate if an HR case is transferred to an incident and an incident is created.	Quebec
UR: Restrict or Unrestrict universal request	Validates the following: • The fields are restricted and hidden when a routing agent restricts a UR. • Only agents with `sensitiveinfo_agent` role are allowed to unrestrict the request.	Xanadu

Universal Request quick start tests (continued)

Test	Description	Release version
	• And, after the request is unrestricted all fields are visible. • sys-audit log access is available for agents.	
UR: Universal Request creation with RITM	Verifies a catalog request for any item from self-service can be created when Universal Request Certified is enabled.	San Diego

Vendor Management Workspace

Vendor Management Workspace quick start tests require activating the Vendor Manager Workspace plugin (com.snc.vlm.vmw) and loading demo data.

Vendor Management Workspace - Tests test suite

Test	Description	Release version
VLM: Create a Vendor	Track problems with the Vendor Manager Workspace plugin after upgrade. Create a new vendor.	New York

To learn more about Vendor Management Workspace, see Vendor Management Workspace.

Vendor Manager Workspace and Third-party Risk Management

GRC: Vendor Manager Workspace and Third-party Risk Management quick start tests require activating the Vendor Manager Workspace and Third-party Risk Management plugin (com.sn_vdr_risk_asmt) and loading demo data.

GRC: Vendor Risk Management and Third-party Risk Management Quick Start Tests

Test	Description
GRC: Create Engagement Risk Assessment	Creates and submits an engagement risk assessment to an engagement.
GRC: Vendor Risk Scoring - Cancel assessment for engagement	Verifies a request to recalculate a risk rating is automatically created on an Engagement and Third party after one assessment for the Engagement is cancelled.
GRC: Vendor Issue ATF	Creates and submits a third-party risk issue form and third-party risk task form.
GRC: Create Vendor Risk Assessment	Creates and submits a vendor risk assessment to a vendor.

GRC: Vendor Risk Management and Third-party Risk Management Quick Start Tests (continued)

Test	Description
GRC: Vendor Portal - Answer and Return Assessment	Vendor contact answers and submits assessment in the Service Vendor Portal.
GRC: Vendor Tiering Assessment	Selects and submits an assessment to respective assessors after changing the duration.

Verify that TPRM still works after you make configuration changes such as applying an upgrade or developing an application. Copy and customize the quick-start tests to pass when using your instance-specific data.

Vulnerability Response

Vulnerability Response quick start tests require activating the Vulnerability Response application (sn_vul) and loading the demo data.

Vulnerability Response tests

Test	Description	Release version
VR: Create Remediation Target Rule	Create a Remediation Target Rule.	Madrid
VR: Create Vulnerability Group Rule	Create a Vulnerability Group Rule.	Madrid
VR: Create Vulnerable Item via Form	Determine whether a user can successfully create a vulnerable item from the Vulnerable Item form.	Madrid
VR: Vulnerability Group Life Cycle	Determine whether a user can successfully resolve a vulnerability group.	Madrid
VR: Vulnerable Item life cycle	Determine whether a user can successfully move a vulnerable item through its life cycle, and also determine whether a closed vulnerable item can be reopened.	Madrid
VR: Rollup Calculator	Determine whether the rollup risk calculator can provide an overall risk score for an entire group of vulnerable items using the scores for all the vulnerable items in a vulnerability group.	New York
VR: Vulnerability Response Assignment Rules	Determine whether a sample set of assignment rules can successfully auto-assign vulnerable items to	New York

Vulnerability Response tests (continued)

Test	Description	Release version
	an assignment group for remediation.	
VR: Vulnerability Calculators	Test the vulnerability calculators.	New York
VR: CI Lookup - Qualys	Create a new lookup rule with method "field_matching" called "Lookup By Network Adapter" for Qualys. Determine whether a configuration item is successfully matched in the Discovered Item table by network adapter and IP address with the new lookup rule.	Orlando
VR: Create Normal and Emergency Change Request	Determine whether the user can successfully create normal and emergency change requests from a vulnerability group.	Orlando
VR: Split Vulnerability Group	Determine whether the user can successfully split a vulnerability group.	Orlando
VR: Update VG state when a CHG is cancelled.	Determine whether the State field on a vulnerability group successfully transitions when a change request that is associated with the vulnerability group is cancelled.	Orlando
VR: Update VG state when a CHG transitions to Review.	Determine whether the State field on a vulnerability group successfully transitions when a change request that is associated with it moves to the Review state.	Orlando
VR: CI Lookup - Rapid7	Test CI lookup using the existing Rapid7 Vulnerability Integration lookup rule, **IP Address**.	Orlando
VR: CI lookup - Qualys	Test CI lookup by creating a new lookup rule for the Qualys Vulnerability Integration	Orlando
VR: Exception Approval Workflow for VI	Create an exception request and verify that the approval process is working.	Orlando

Vulnerability Response tests (continued)

Test	Description	Release version
VR: False Positive Approval Workflow for VI	Create a false positive exception request and verify that the approval process is working.	Orlando
VR: Application Vulnerability Response (AVR)	Determine whether your rules and calculators are working correctly. Verify that updates are working.	Orlando
Remediation target rules: VI import test	Tests VR remediation target rules during import.	Paris
VR: Classification Rule	A sample classification rule that automatically classifies a vulnerability.	Tokyo

To learn more about Vulnerability Response, see Vulnerability Response.

Walk-up Experience

Walk-up Experience quick start tests require activating the Walk-up Experience plugin (com.snc.walkup) and loading demo data.

Walk-up Experience - Tests test suite

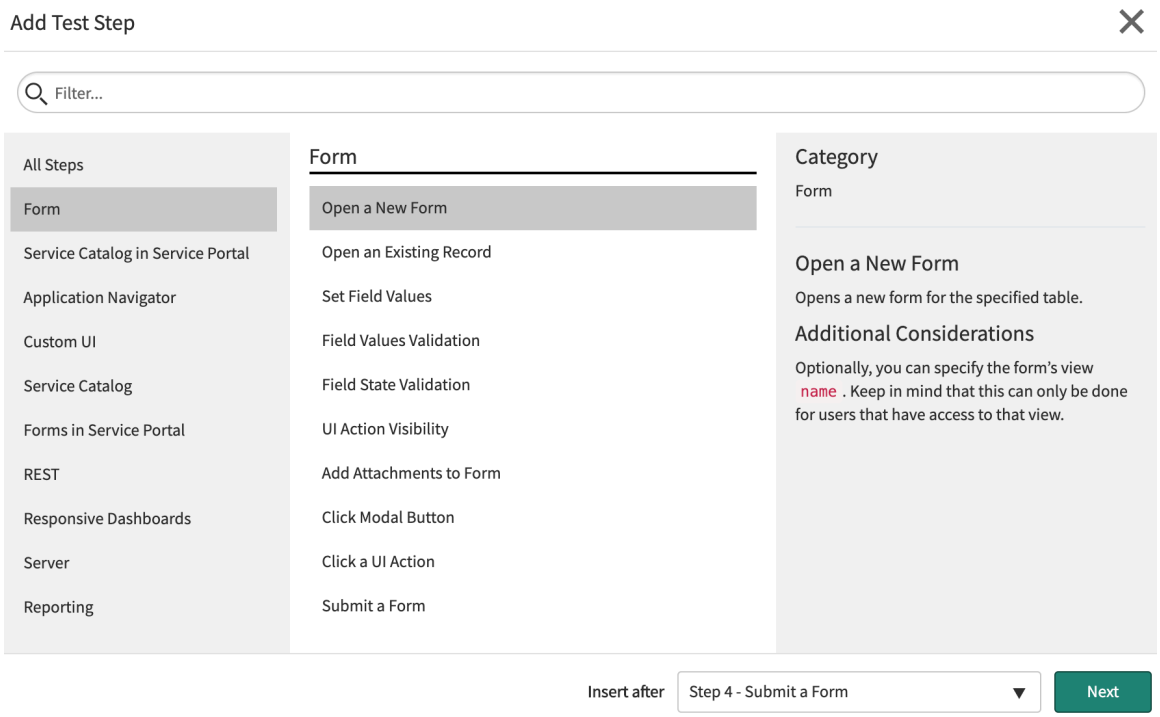
Test	Description	Release version
Create a location	Ensure users with the Walk-up administrator [sn_walkup.walkup_admin] role can access all existing walk-up queues, create new queue locations, and configure queues appropriately.	Orlando
Onsite checkin (ITIL User)	Verify that users with the ITIL role can check into an onsite queue location.	Orlando
Onsite checkin (ESS User)	Verify that users with the ESS role can check into an onsite queue location.	Orlando
Onsite checkin (Guest)	Verify that guest users can check into an onsite queue location.	Orlando

To learn more about Walk-up Experience, see Walk-up Experience.

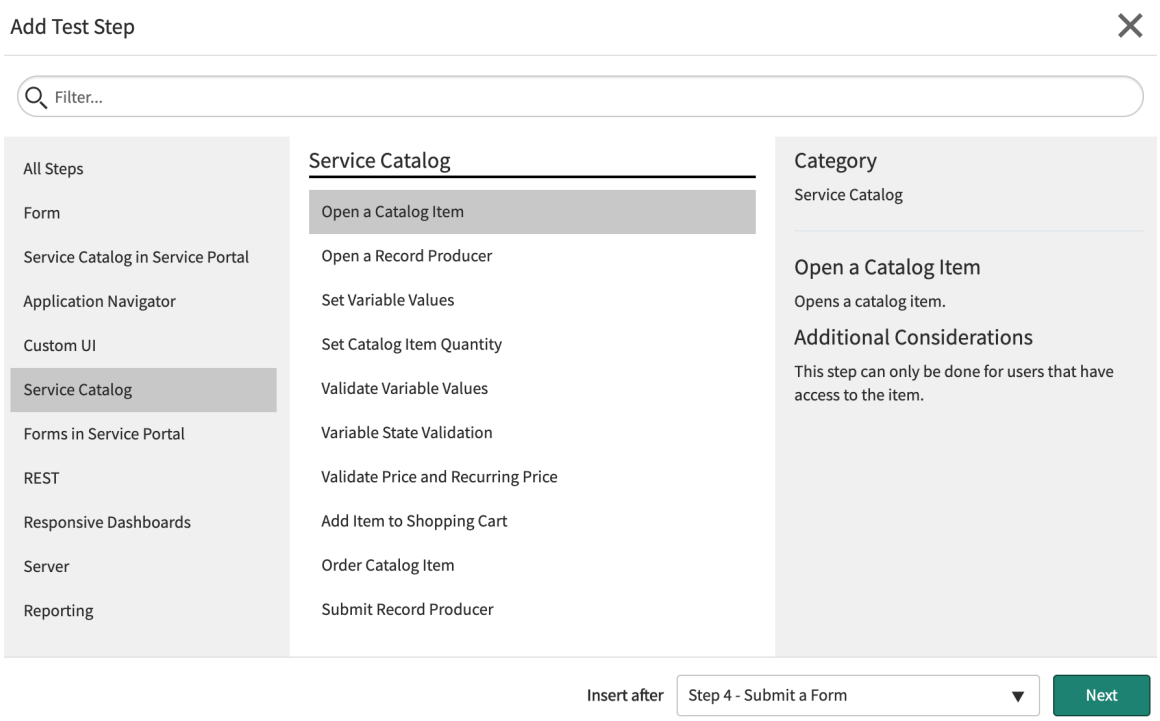
Test step categories

Find test steps for a particular user interface or ServiceNow AI Platform feature.

The Add Test Step panel lists test categories in the left pane. You can directly search for a specific test step by its name in the search field at the top of the panel. You can also select **All Steps** in the left pane to list all available test steps in the middle pane. A description of the selected step appears in the right pane.



You can select a specific test category to list only the test steps available for that test category in the middle panel. A description of the selected step appears in the right panel.



Service Catalog in Service Portal category

Validate catalog item transactions and requester flows from Service Portal.

Activation of the Automated Test Framework for Service Catalog in Service Portal

These ATF test steps require activation of the Automated Test Framework Service Catalog Service Portal (com.glide.automated_testing_impl.service_catalog_portal) plugin, which is active by default on new instances. Administrators may need to activate the plugin on instances upgraded from earlier versions.

Support for parametrized tests

Service Catalog in Service Portal step configurations support parametrized tests. For more information on parametrized tests, refer to Parameterized tests.

Open a Record Producer (SP)

Open a record producer in the Service Portal.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Portal	Portal for which you want to test this step.
Page	Service Catalog page associated with the test step.
Record Producer	Record producer that you want to open. **Note:** You should have access to the record producer.
Query Parameters	URL query parameters for the page, such as *sys_id*.

Open a Catalog Item (SP)

Open a catalog item in the Service Portal.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Portal	Portal for which you want to test this step.
Page	Service Catalog page associated with the test step.
Catalog Item	Catalog item that you want to open. **Note:** You should have access to this catalog item.
Query Parameters	URL query parameters for the page, such as *sys_id*.

Open an Order Guide (SP)

Open an order guide in the Service Portal.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.

Inputs (continued)

Field	Description
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Portal	Portal for which you want to test this step.
Page	Service Catalog page associated with the test step.
Order Guide	Order guide that you want to open. **Note:** You should have access to this order guide.
Query Parameters	URL query parameters for the page, such as *sys_id*.

Add row to multi-row variable set (SP)

Add a row to a multi-row variable set included in the current catalog item in Service Portal. You can use this step configuration only when the current catalog item contains a multi-row variable set.

Use this step after the Open a Catalog Item(SP) step, Open a Record Producer(SP) step, or Open an Order Guide (SP) step. If a contextual value has been used for the Open a Catalog Item(SP) step, Open a Record Producer(SP) step, or Open an Order Guide (SP) step, set the catalog item in this step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Notes	Notes about the test step.

Inputs (continued)

Field	Description
Catalog Item	Catalog item whose multi-row variable set requires an addition of a row. If an item is not already selected, you can either search for the item, or insert a reference to the contextual value of the item from a list of available parameters.
Multi-Row Variable Set	Multi-row variable set for which a row should be added.

Save current row of multi-row variable set (SP)

Save the current row of a multi-row variable set included in the current catalog item in Service Portal. You can use this step configuration only when the current catalog item contains a multi-row variable set. Use this step after the Add row to multi-row variable set (SP) step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Notes	Notes about the test step.
Assert Type	Criteria for the test to pass. **Successfully saved row to a multi-row variable set** Test passes only if the current row of the multi-row variable is saved. **Cannot save a row to multi-row variable set** Test passes only if the current row of the multi-row variable is not saved.

Set Variable Values (SP)

Set variable values for a catalog item or record producer in the Service Portal. For a catalog item, use this step after using the Open a Catalog Item (SP) step, and before using the Order Catalog Item (SP) step.

For a record producer, use this step after using the Open a Record Producer (SP) step, and before using the Submit Record Producer (SP) step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Item	Catalog item or record producer for which you want to set variable values.
Multi-Row Variable Set	Multi-row variable set for which variable values should be set. **Note:** Use the Add row to multi-row variable set (SP) step configuration prior to the current step configuration.
Variable Values	List of variables and the values that you want to set for them. **Note:** You can set the value for multiple variables.

Note:
Custom variables and custom variable with labels are not supported for Set Variable Values step configuration.

Validate Variable Values (SP)

Validates variable values of a catalog item or record producer in Service Portal. For a catalog item, use this step after using the Open a Catalog Item (SP) step, and before using the Order Catalog Item (SP) step.

For a record producer, use this step after using the Open a Record Producer (SP) step, and before using the Submit Record Producer (SP) step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Item	Catalog item or record producer whose variables should be validated.
Multi-Row Variable Set	Multi-row variable set for which variable values should be validated. **Note:** Use the Add row to multi-row variable set (SP) step configuration prior to the current step configuration.
Catalog Conditions	Conditions for variable validation. If the conditions are met, the test passes. **Note:** The label of a variable associated with a variable set reflects the variable set name. The format is *`variable_set_name » variable_name`*.

Note:
Custom variables and custom variable with labels are not supported for Validate Variable Values step configuration.

Variable State Validation (SP)

Validates the state of variables in Service Portal. Possible variable states are mandatory, not mandatory, read only, not read only, visible, and not visible.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Item	Catalog item or record producer whose variables should be validated.
Multi-Row Variable Set	Multi-row variable set for which variable states should be validated. **Note:** Use the Add row to multi-row variable set (SP) step configuration prior to the current step configuration.
Visible	List of the catalog item variables that must be visible for the step to pass.
Not visible	List of the catalog item variables that must be hidden for the step to pass.
Read only	List of the catalog item variables that must be read-only for the step to pass.
Not read only	List of the catalog item variables that must not be read-only for the step to pass.
Mandatory	List of the catalog item variables that must be mandatory for the step to pass.
Not mandatory	List of the catalog item variables that must not be mandatory for the step to pass.

Note:
Custom variables and custom variable with labels are not supported for Variable State Validation step configuration.

Validate Price and Recurring Price (SP)

Validate the price and recurring price of a catalog item in Service Portal. Use this step after using the Open a Catalog Item (SP) step, and before using the Order Catalog Item (SP) step. This step is not applicable for a record producer.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Price	Price of the catalog item for the step to pass.
Recurring price	Recurring price of the catalog item for the step to pass.
Recurring price frequency	Recurring price frequency of the catalog item for the step to pass.

Navigate within Order Guide (SP)

Navigate within an order guide.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of

Inputs (continued)

Field	Description
	the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Guide Step	Order guide step to which you want to navigate: • **Describe Needs** • **Choose Options** • **Summary**
Assert Type	Criteria for the test to pass. **Navigation Successful** Test passes only if the navigation is successful. **Navigation Failed** Test passes only if the navigation fails.

Set Catalog Item Quantity (SP)

Set the quantity for a catalog item in Service Portal. This step is not applicable for a record producer. Use this step after using the Open a Catalog Item (SP) step, and before using the Order Catalog Item (SP) step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Quantity	Quantity of the catalog item that you want to order.

Validate Order Guide Items (SP)

Validate items included in the order guide.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Catalog Items	Catalog items that you want to validate. **Note:** You should have access to these catalog items.

Review Order Guide Summary (SP)

Review the order guide summary in the Service Portal.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.

Inputs (continued)

Field	Description
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Catalog Items	Catalog items that you want to review. **Note:** You should have access to these catalog items.
Price	Price of the catalog item for the step to pass.

Review Item in Order Guide (SP)

Review individual items in the order guide and choose whether or not to include the item.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of

Inputs (continued)

Field	Description
	the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Catalog Item	Catalog item that you want to review. **Note:** You should have access to this catalog item.
Included	Selected if the catalog item should be included in the order guide, otherwise unselected.

Add Item to Shopping Cart (SP)

Add the current catalog item to the shopping cart in Service Portal. Use this step after using the Open a Catalog Item (SP) step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Assert Type	Criteria for the test to pass. **Successfully added item to Shopping Cart** Test passes only if the catalog item is successfully added to the shopping cart. **Cannot add item to Shopping Cart** Test passes only if the catalog item cannot be added to the shopping cart.

Outputs

Field	Description
cart_item_id	The sys_id of the added catalog item.

Add Order Guide to Shopping Cart (SP)

Add an order guide to the shopping cart.

Input

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Assert Type	Criteria for the test to pass. **Cannot add order guide to shopping cart** Test passes only if the order guide cannot be added to the shopping cart. **Successfully added order guide to shopping cart** Test passes only if the order guide is successfully added to the shopping cart.

Order a Catalog Item (SP)

Click **Order Now** for the current catalog item in the Service Portal. Use this step after using the Open a Catalog Item (SP) step.

After this step, you cannot use any other steps on the catalog item. If the two-step checkout is false, a request is generated for the catalog item. If the two-step checkout is true, you are redirected to the cart preview page.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Assert type	Criteria for the test to pass. **Successfully ordered Catalog Item** Test passes only if the catalog item is successfully ordered. **Cannot order Catalog Item** Test passes only if the catalog item cannot be ordered.

Outputs

Field	Description
table	The table to which the submitted request belongs.
record_id	The sys_id of the submitted request.

Submit an Order Guide (SP)

Click **Order Now** to order an order guide. Do not add more than one record producer to the order guide.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Assert Type	Criteria for the test to pass. **Cannot order the Order Guide** Test passes only if the order guide cannot be ordered. **Successfully ordered the Order Guide** Test passes only if the order guide is successfully ordered.

Outputs

Field	Description
table	The table containing the submitted order guide.
record_id	The sys_id of the submitted order guide.

Submit Record Producer (SP)

Submit the current record producer in the Service Portal. Use this step after using the Open a Record producer (SP) step. After this step, you cannot use any other steps on the record producer.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Assert Type	Criteria for the test to pass. **Successfully submitted Record Producer** Test passes only if the record producer is submitted successfully. **Cannot submit Record Producer** Test passes only if the record producer cannot be submitted.

Outputs

Field	Description
table	The table containing target record of the record producer.

Application Navigator category

Verify the functionality of menus and modules in the application navigator.

Application Menu Visibility

Verifies the visibility, or lack thereof, of selected application menus in the application navigator (left navigation bar). For example, you create a test that first impersonates a user, then verifies that specified application menus (such as Self-Service and Reports) are visible, or are not visible, to that user.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.

Inputs (continued)

Field	Description
Active	Option to activate this test step for use.
Application	The application scope in which the system runs this test or test suite.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Navigator	Navigator version to assert against • Core UI (UI16): If you are creating new steps, you will have Core UI by default. • Next Experience: If you have Next Experience enabled, Next Experience is the default navigator. If it is disabled, Core UI is the default navigator.
Visible assert type	Specifies how application menus selected in the **Visible application menus** field should be tested for visibility in the application navigator. • **At least these application menus are visible**: At minimum, all the selected application menus are visible in the application navigator. • **Only these application menus are visible**: Only the selected application menus are visible in the application navigator.
Visible application menus	Application menus whose visibility in the application navigator is being verified.
Not visible assert type	Specifies how application menus selected in the **Not visible application menus** field should be tested for lack of visibility in the application navigator. • **At least these application menus are not visible**: At minimum, all the selected application menus are not visible in the application navigator. • **Only these application menus are not visible**: Only the selected application menus are not visible in the application navigator.
Not visible application menus	Application menus whose lack of visibility in the application navigator is being verified.

Related topics

Create an application menu

Create an application menu

Application menus define the main content that users can access in the application navigator. You can configure which applications appear in the application navigator.

Before you begin

Role required: admin

About this task

When creating an application menu, consider grouping like modules into a consolidated application menu. When editing an existing menu, add more useful modules to the application menu, and remove unneeded ones.

Procedure

1. Navigate to **All** > **System Definition** > **Application Menus**.
2. Click **New**.
3. Complete the form.

Field	Description
Title	Defines the display name of the application menu.
Roles	Restricts access to the specified roles. All users can view the application menu when it is active.
Category	Specifies the menu category that defines the navigation menu style (default value is **Custom Applications**).
Hint	Defines the text that appears in a tooltip when a user points to this application menu.
Active	Select the check box to activate the application menu. Only active application menus appear in the application navigator.
Description	Provide a more detailed explanation of what this application does.
Other fields	
Order	Defines the relative position of the application menu in the application navigator. If you do not specify an order, the default order of the menu category is used.
Default device type	This field is not used. You can define application menus for mobile devices in a separate table.

Note:
You may need to configure the form to see all fields.

4. Click **Submit**.
5. Create modules to appear in the application menu.
   Only application menus that contain modules appear in the application navigator.

Create a module

Modules are the children, or the second tier navigation options to the applications in the application navigator. Modules often link to other pages or records in the platform. You can configure which modules appear in the application navigator using Application Menus module.

Watch this five-minute video to learn about adding application menus and modules to the application navigator. Shows how to add application menus and modules to the application navigator.

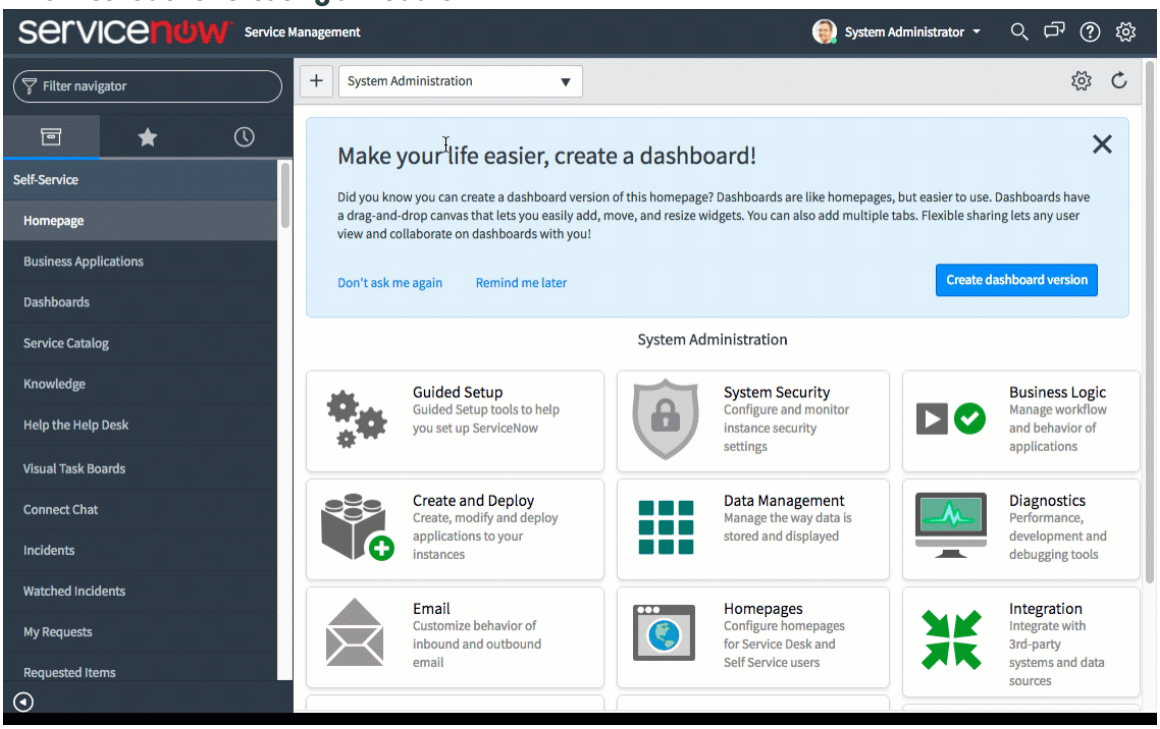
Before you begin

Role required: admin

Procedure

1. Open the application menu record using one of the following methods.
   - Navigate to **System Definition** > **Application Menus** and select the application menu from the list.
   - Point to the application menu and click the edit application (pencil) icon.

Two methods for creating a module



2. Scroll down to the **Modules** related list and click **New**.
3. Define the module by completing the fields on the Module form.

Module form

Field	Description
Title	Defines the module name. Choose a title that clearly identifies the module.
Application menu	Specifies the name of the application menu under which the module appears.
Hint	Defines the tooltip that appears when a user points to the module name. **Note:** Module Hints are deprecated in Core UI
Order	The order in which the module displays relative to other modules.

4. On the **Visibility** tab, complete the fields.

Visibility tab

Field	Description
Roles	Restricts module access to the specified roles. If this field is left blank, the module is visible to all users who have access to the application menu.
Active	Defines whether the module appears in the application navigator.
Override application menu roles	Allows users to access this module even if they do not have permission to view the containing application menu. Users must still meet the role requirements for this module.

5. On the **List Type** tab, complete the fields.

   The fields displayed depend on the **Link type** you choose. All module URIs must be encoded. If you supply arguments to the module URI, either you or ServiceNow. For more information about encoding module URIs, see Encoding module URIs.

List Type tab

Field	Description
Link type	Specifies what type of link this module opens. You must specify additional information based on the link type. See Module link types.
Table	Specifies the table used by the module. **Note:** The list shows only tables and database views that are in the same scope as the module.
Filter	Conditions for the items presented in the module, for example, **Active is true**.
Argument	String appended to the URI to create the module URI. Can be a sysparm_query. These values must be encoded either by you or ServiceNow. For more information about encoding module URIs, see Encoding module URIs.
Order	Specifies the order in which the modules appear under the application.

Module link types

The **Link type** field on the Module form specifies what type of link the module opens.

Module link types

Link Type	Description
Assessment	Links to the assessment-based survey you select in the **Assessment** reference field. See Create a survey module.
Content Page	Displays the content page you select in the **Content page** reference field. See Create a content page.

Module link types (continued)

Link Type	Description
Documentation Link	Links to a documentation page and opens in a new tab or window. This link type is used with embedded metadata in documentation topics. To open an internal document from a module, use the **URL (from Arguments)** module link type.
Homepage	Displays the homepage you select in the **Homepage** reference field.
HTML (from Arguments)	Places HTML in the application navigator. This link type is used for more complicated links, where a flat URL is not customizable enough. **Note:** • The **HTML (from Arguments)** link type is supported in the legacy UI15 and UI11 interfaces only. In Core UI, use the **URL (from Arguments)** link type instead. • Enter a value for the **Arguments** field.
List Filter	Displays an unpopulated list view for the table you select in the **Table** field. Allows users to specify a filter without loading the list first. Use the **Filter** field to define the default filter for the list. Use the **View name** field to specify a View management.
List of Records	Displays the list view for the table you select in the **Table** field. Use the **Filter** field to define the default filter for the list. Use the **View name** field to specify a view.
Map Page	Displays the map page you select in the **Map page** reference field.
New Record	Displays a form for creating a record in the table you select in the **Table** field. • Use the **View name** field to specify a view. • Use the **Arguments** field to apply a template. See Create a module for a template.
Run a Report	Runs the saved report you select in the **Report** field.
Script (from Arguments)	Runs a script, as defined in the **Arguments** field. **Note:** Enter a value for the **Arguments** field.
Search Screen	Link that displays a blank form for searching records in the table. Use the **View name** field to specify a view. **Note:** Use the parameter *&sysparm_result_view=view_name* to define the view the results are rendered in. All searches use a **[starts with]** query to search for matching text. Other query types are not supported in search screens.
Separator	Creates a division between modules. Enter a name in the **Title** field to add a section name that users can collapse or expand.

Module link types (continued)

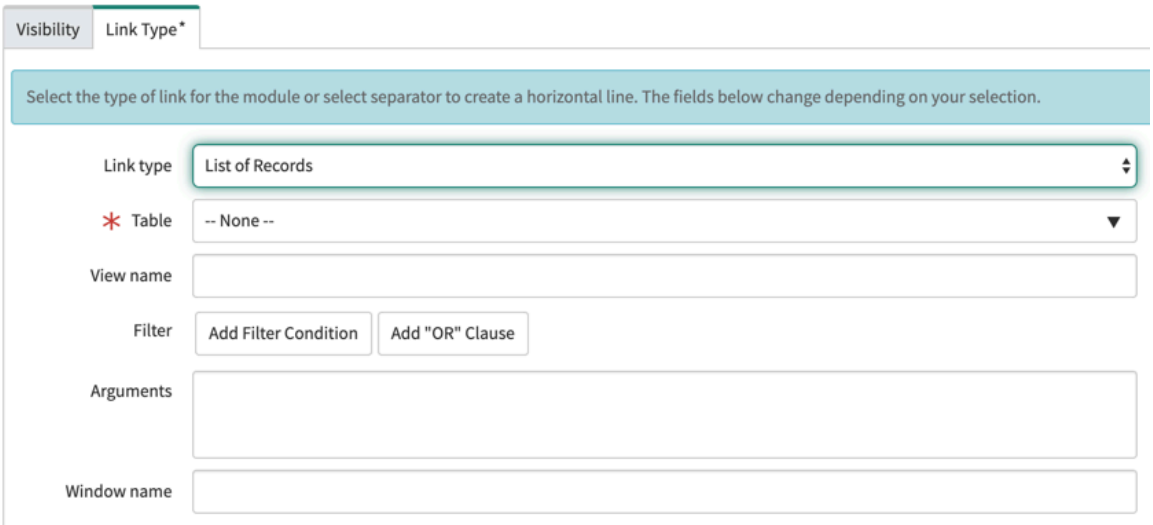
Link Type	Description
Single Record	Displays a form for a single record on the table. Use the **View name** field to specify a view.
Survey	Links to the legacy survey you select in the **Survey** reference field. Use the **Survey overwrite** check box to determine whether the survey can be taken multiple times. **Note:** The **Survey** link type is for use with legacy surveys only, which assessment-based surveys replace. Select the **Assessment** link type to link the module to an assessment-based survey.
Timeline Page	Displays the timeline page you select in the **Timeline Page** reference field. See Timeline pages.
URL (from Arguments)	Opens any URL, as defined in the **Arguments** field. [Optional] Use the **Window name** field to define a link that opens in a new window. **Note:** • For internal links, always use a relative link such as `./catalog_home.do?sysparm_view=catalog_default` or `catalog_home.do?sysparm_view=catalog_default`. Do not use an absolute link to a ServiceNow instance. It creates problems when you move an update set from a development instance to a production instance because the URL still references the development instance. • Enter a value for the **Arguments** field.

Encoding module URIs

Clicking a module name in the navigation pane executes a URI that opens the module's page in the content pane. All the characters in module URIs must be URL-encoded or the link breaks.

Note:
If you're upgrading to the New York release or later from a pre-New-York release, your module UIs may break if they do not follow the conventions presented in this topic.

When you create modules, you have the option of adding arguments and filter conditions that sort and/or reduce the number of results displayed in the content pane. When you click a module name in **System Definitions** > **Application Definitions**, you can see those conditions and arguments on the **Link Type** tab.



The argument definition in **Arguments** and filter conditions defined in **Filter** become part of the module's URI and must be URL-encoded. ServiceNow automatically URL-encodes filter conditions and appends them to the module URI using sysparm_query. For example, adding the filter condition, **Active is true** appends `sysparm_query=active%3Dtrue` to the module's URI; %3D is the URL-encoding for the equals sign (=).

The following table shows when you must URL-encode the argument in the **Arguments** field and when ServiceNow URL-encodes the argument.

Rules for encoding arguments

Has a filter condition?	Argument definition starts with	Who encodes the argument?	How argument is handled
No	^	ServiceNow	Removes the caret (^) from the argument, encodes it and uses sysparm_query to append it to the module URI.
No	&	You	Removes the ampersand (&) from the argument and appends it to the module URI.
No	Anything else	ServiceNow	Encodes the argument and uses sysparm_query to append it to the module URI.
Yes	^	ServiceNow	URL-encodes the filter definition and the argument and uses sysparm_query to append the combination to the module URI.
Yes	Anything else	You	URL-encodes the filter definition and uses sysparm_query to append it and the (unaltered) arguments to the module URI.

You can turn on (the default) and off the URL-encoding requirement for module UIs using the *`glide.ui.encode_module_uri`* property.

Examples

The following examples demonstrate when you have to URL-encode the argument definition in **Arguments**:

- There are no filter conditions and the argument definition in **Arguments** starts with an ampersand, for example,`&sysparm_fixed_query=assigned_to=javascript:gs.user_id()`.

  This argument breaks the module URI because the equals sign and the colon are not URL-encoded, and the ampersand prevents ServiceNow from URL-encoding the argument. URL-encode the argument: `&sysparm_fixed_query=assigned_to%3Djavascript%3Ags.user_id()`.

- There are filter conditions and the argument definition in **Arguments** does not start with a caret (^), for example, `sysparm_name=Barnes & Noble's`.

  This argument breaks the module URI because the ampersand and spaces are not URL-encoded. URL-encode the argument: `sysparm_name=Barnes%20%26%20Nobel's`

Module Visibility

Verify the visibility, or lack thereof, of selected modules in the application navigator (left navigation bar). For example, create a test that first impersonates a user, then verifies that specified modules (such as Homepage and My Requests) are visible, or are not visible, to that user.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	The application scope in which the system runs this test or test suite.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Navigator	Navigator version to assert against • Core UI (UI16): If you are creating new steps, you will have Core UI by default. • Next Experience: If you have Next Experience enabled, Next Experience is the default navigator. If it is disabled, Core UI is the default navigator.
Visible assert type	Specifies how modules selected in the **Visible modules** field should be tested for visibility in the application navigator. • **At least these modules are visible**: At minimum, the modules selected in the **Visible modules** field are visible in the application navigator. • **Only these modules are visible**: Only the specific modules selected in the **Visible modules** field are visible in the application navigator.

Inputs (continued)

Field	Description
Visible modules	Modules whose visibility in the application navigator is being verified.
Not visible assert type	Specifies how modules selected in the **Not visible modules** field should be tested for lack of visibility in the application navigator. • **At least these modules are not visible**: At minimum, the modules selected in the **Not visible modules** field are not visible in the application navigator. • **Only these modules are not visible**: Only the specific modules selected in the **Not visible modules** field are not visible in the application navigator.
Not visible modules	Modules whose lack of visibility in the application navigator is being verified.

Related topics

Create a module

Navigate to Module

Open a module from the application navigator, as if a user had clicked it. The module must be visible to the currently executing user to navigate to it.

Note:
Not all pages are currently testable. Wherever the module takes you is your responsibility.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Module	Module that should be opened. To navigate to the selected module, the module must be visible to the currently executing user in the application navigator. The following modules are not supported and cannot be tested:

Inputs (continued)

Field	Description
	• Modules that are separators • Modules that do not link to a specific page, but instead execute client-side JavaScript (such as Studio and the Script Debugger) • Modules that link to external websites, such as the ServiceNow documentation site (servicenow.com/docs) • Modules that reload or redirect the entire page

Related topics

Create a module

Custom UI category

Validate the behavior of page components on custom user interfaces.

Set Component Values (Custom UI)

Set component values on a custom UI page.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Component values	Page components to be tested and the value each page component should have for the step to succeed.

Inputs (continued)

Field	Description
	Note: The **Value** field defaults to the last retrieved value of the selected component.

Assert Text on Page (Custom UI)

Assert that the specified text is or is not on a custom UI page.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Text	Text to be compared with the text on the page.

Note:

- The text to be searched is case-sensitive.
- Starting with the Rome release, this test step also works for Workspace for any new tests.
- The Assert Text on Page test step also accepts text containing white spaces.

Component Value Validation (Custom UI)

Validate a component value on a custom UI page.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Component values	Page components to be tested and the value each page component should have for the step to succeed. **Note:** The **Value** field defaults to the last retrieved value of the selected component.

Click Component (Custom UI)

Click a component on a custom UI page.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You

Inputs (continued)

Field	Description
	can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Component	Component to be tested in this step.

Component State Validation (Custom UI)

Validate the state of a specified component on a custom UI page.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Component	Component to be tested in this step.

Inputs (continued)

Field	Description
Assert type	Type of assert: • **Disabled** • **Enabled**

Open Service Portal Page

Open a portal page. Test designers must first open a page in a portal before testing UI components on the page.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Portal	Select a portal.
Page	Select the page to open.
Query parameters	Add any required query parameters for the page. For example, to open a record in the form page, enter the table and sys_id parameters. For more information about Service Portal query parameters, see Page navigation by URL.

Form category

Validate the functionality of fields and UI actions on a form.

Note:
Test steps that include the **Form UI** field give you the option to select an available UI. For any available workspace, navigation between tabs is not supported. Use the **Open a New Form** or **Open an Existing Record** step to reopen a form.

It is to be noted that Agent Workspace has been removed from the Platform. If you have any Agent Workspace tests or test suites, they won't work anymore.

Open a New Form

Open a form to a new record in the specified table and **Form UI**.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step
Form UI	Option to select an available UI. Apart from the Standard UI, you have other workspace selections available. Depending on the selected workspace, the UI might vary. **Note:** Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
Table	Name of the table for the new form.
View	Name of the view in which you want this form to open. The testing user must have access to that view. If the name is not a valid form view, the form opens in its default view.

Inputs (continued)

Field	Description
	Note: This field appears when **Standard UI** is chosen from **Form UI**.

Open an Existing Record

Open a form to an existing record in the specified table and **Form UI**.

Note: Using an existing record may cause unexpected behavior for this test. See Automated Test Framework design considerations for more information.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step
Form UI	Option to select an available UI. Apart from the Standard UI, you have other workspace selections available. Depending on the selected workspace, the UI might vary. **Note:** Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
Table	Name of the table for the new form.

Inputs (continued)

Field	Description
Record	Record ID of the record that you want to open and name of the document that you want to open.
View	Name of the view in which you want this form to open. The testing user must have access to that view. If the name is not a valid form view, the form opens in its default view. **Note:** This field appears when **Standard UI** is chosen from **Form UI**.

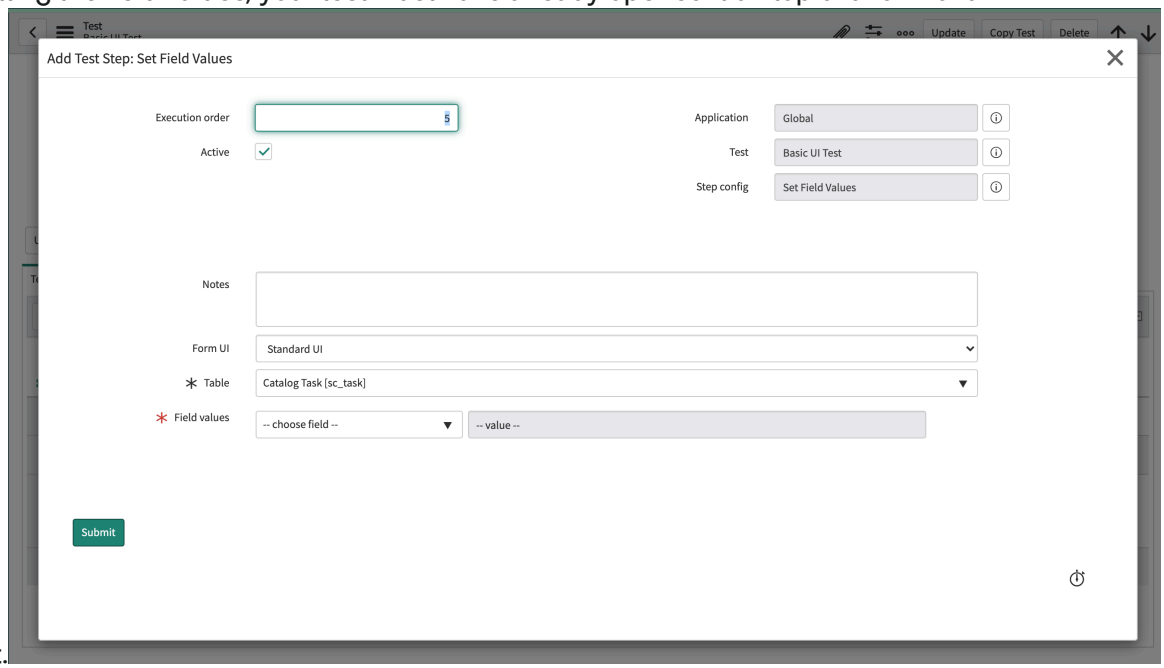
Set Field Values

Set the fields on the current form to the specified values.

To run this step, your test must have already opened a form using either the **Open a New Form** or **Open an Existing Record** step. It is recommended to not run this step directly after a **Submit a Form** or **Click a UI Action** step. This is because they can redirect your test to a different page based on the navigation stack configuration on your instance or the script defined in the clicked UI action. Unless you are certain that the UI action will take you to a specific page, you should explicitly use an **Open a New Form** step after **Submit a Form** or **Click a UI Action** to ensure that the test is on the form as expected. Ensure that the test keeps passing consistently when added to a suite.

The **Field Values Validation**, **Set Field Values**, **Field State Validation**, and **UI Action Visibility** steps can appear in any order.

Note:
This step waits for the form to load before setting field values. This step doesn't support reference qualifiers, neither at test design time nor at test runtime. A modal form appears either on top of another form or a list. To submit a modal form after setting the field values, your test must have already opened it on top of a form or a list.



Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step
Form UI	Option to select an available UI. Apart from the Standard UI, you have other workspace

Inputs (continued)

Field	Description
	selections available. Depending on the selected workspace, the UI might vary. **Note:** Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
Table	Name of the table for the new form.
Set field value	Assigns a value to a field on an open form.

Field Values Validation

Validate field values on the current form.

To run this step, your test must have already opened a form using either the **Open a New Form** or **Open an Existing Record** step. It is recommended to not run this step directly after a **Submit a Form** or **Click a UI Action** step. This is because they can redirect your test to a different page based on the navigation stack configuration on your instance or the script defined in the clicked UI action. Unless you are certain that the UI action will take you to a specific page, you should explicitly use an **Open a New Form** step after **Submit a Form** or **Click a UI Action** to ensure that the test is on the form as expected. Ensure that the test keeps passing consistently when added to a suite.

The **Field Values Validation**, **Set Field Values**, **Field State Validation**, and **UI Action Visibility** steps can appear in any order.

For the **Field Values Validation** step, specify the values that you want to test using the standard conditions builder. You can test several conditions against the same field. This step passes if the overall condition is satisfied and fails if the condition is not satisfied. The **Conditions** field is case-sensitive and requires to have the exact value as on the form. To test the values of individual fields independently of each other, include a separate **Field Values Validation** step for each value that you test.

Note:
The **Field Values Validation** step works only with fields that belong to the record for the open form. For example, with the incident table, this step is not able to validate the **Additional comments**, **Approval history**, **Comments**, or **Work notes** fields because these UI controls are not actual fields on the incident record. These UI controls make it convenient to work with related tables. To validate these cases, use the Server test step, **Record Validation**, instead.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You

Inputs (continued)

Field	Description
	can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Form UI	Option to select an available UI. Apart from the Standard UI, you have other workspace selections available. Depending on the selected workspace, the UI might vary. **Note:** Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
Table	Name of the table for the new form.
Conditions	Fields and values to be validated. Includes only fields that are visible on the open form. This field is case-sensitive.

Field State Validation

Validate the state of specified fields. States validated can include mandatory, non-mandatory, read-only, non-read-only, visible, and non-visible.

You can specify a maximum time to wait for the states of the fields to match the conditions in this step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step
Form UI	Option to select an available UI. Apart from the Standard UI, you have other workspace selections available. Depending on the selected workspace, the UI might vary. **Note:** Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
Table	Name of the table for the new form.
Visible	Validates whether the fields on this form are visible. The test fails if the fields are not visible.
Not visible	Validates whether the fields on this form are visible. The test fails if the fields are visible.
Read only	Validates whether the fields on this form are read only. The test fails if the fields are not read only.

Inputs (continued)

Field	Description
Not read only	Validates whether the fields on this form are read only. The test fails if the fields are read only.
Mandatory	Validates whether the fields on this form are mandatory. The test fails if the fields are not mandatory.
Not mandatory	Validates whether the fields on this form are mandatory. The test fails if the fields are mandatory.

UI Action Visibility

Verify if a UI action is visible on the current form. To run this step, your test must have already opened a form using either the **Open a New Form** or **Open an Existing Record** step.

The default visible UI actions vary depending on the user that you're currently impersonating.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step

Inputs (continued)

Field	Description
Form UI	Option to select an available UI. Apart from the Standard UI, you have other workspace selections available. Depending on the selected workspace, the UI might vary. **Note:** Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
Table	Name of the table for the new form.
Visible	Validates whether UI actions on this form are visible. The test fails if the UI actions are not visible.
Not visible	Validates whether UI actions on this form are visible. The test fails if the UI actions are visible.

Declarative Action Visibility

Verify if a declarative action is visible on the current form.

The default visible declarative actions vary depending on the user that you're currently impersonating.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Notes	Notes about the test step
Form UI	Option to select an available UI. Apart from the Standard UI, you have other workspace

Inputs (continued)

Field	Description
	selections available. Depending on the selected workspace, the UI might vary. **Note:** Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
Table	Name of the table for the new form.
Visible	Validates whether declarative actions on this form are visible. The test fails if the declarative actions are not visible.
Not visible	Validates whether declarative actions on this form are visible. The test fails if the declarative actions are visible.

Add Attachments to Form

Add one or more mandatory attachments to the current form. Select the attachments that the test step adds to the form from the Upload Attachments list.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Notes	Notes about the test step
Upload Attachments	Button to add one or more mandatory attachments to the form.

Note:
The Add Attachments to Form test step can't access the newly added UI workspace options.

Click Modal Button

Click a button within a modal in the specified **Form UI**.

Specify your testing by selecting either the standard platform UI or workspace UI from the **Form UI** field. If you select the standard platform UI, this test step selects the button by ID on the specified modal and validates the following conditions:

- UI page was opened in a modal.
- Button is visible and enabled.

If you select an available workspace UI, this test step selects either the Confirm or Cancel action and optionally sets the field values within the modal. This step succeeds only if a modal dialog is open on the form, and if the specified button exists on that modal dialog.

Only modals opened with the following g_modal functions are supported:

- alert
- confirm
- confirmDestroy
- showFields

Note:
Click Modal Button now supports global and scoped application modals.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds for the modal and the button to appear.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step
Form UI	Option to select an available UI.

Inputs (continued)

Field	Description
	Note: Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
UI page	The UI modal dialog to be tested. **Note:** This field appears only if **Standard UI** is selected from **Form UI**.
Button	The ID attribute of the button element. For example, the **OK**button has an ID of `OK_button` in the UI modal dialog. **Note:** This field appears only if **Standard UI** is selected from **Form UI**.
Modal values	The field values to be set in the modal. **Note:** This field appears only if a workspace is chosen as **Form UI**.
Modal action	The action to be selected in the modal. **Note:** This field appears only if a workspace is chosen as **Form UI**.
Assert type	The effect on the tests on clicking the modal button. • **Modal closed and page is reloaded or redirected**: The test passes only if the modal was closed and the page was reloaded or redirected to another page. • **Modal closed and page is not reloaded or redirected**: The test passes only if the modal was closed and the page was not reloaded or redirected to another page. • **Modal not closed**: The test passes only if the modal still exists and was not closed.
Assertion timeout	Number of seconds allowed before the assert fails. If the assert fails, the system repeats the assert until the duration of the Timeout

Inputs (continued)

Field	Description
	is reached. If the validation fails after the Timeout duration has passed, the step fails.

Note:
The Click Modal Button test step can't access the newly added UI workspace options.

Click a UI Action

Click a UI action on the current form.

When this step runs, the system performs the action normally activated by that control. The test step also validates that the current form contains the control and that the control is visible and enabled. To run this step, your test must have already opened a form using either the **Open a New Form** or **Open an Existing Record** step. It is recommended to not run this step directly after a **Submit a Form** or **Click a UI Action** step. This is because they can redirect your test to a different page based on the navigation stack configuration on your instance or the script defined in the clicked UI action. Unless you are certain that the UI action will take you to a specific page, you should explicitly use an **Open a New Form** step after **Submit a Form** or **Click a UI Action** to ensure that the test is on the form as expected. Ensure that the test keeps passing consistently when added to a suite.

In the Xanadu release, this step supports UI actions of type Form context menu.

Note:
Don't write tests that depend on the system displaying a specific page after executing a **Submit a Form** or **Click a UI Action** step. After these test steps, the system returns to the page that was open before the form was opened. The test cannot determine what that page was, so writing a test that expects a particular page can lead to unpredictable results.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of

Inputs (continued)

Field	Description
	the test step. This field appears after the test step is submitted.
Notes	Notes about the test step
Form UI	Option to select an available UI. Apart from the Standard UI, you have other workspace selections available. Depending on the selected workspace, the UI might vary. **Note:** Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
Table	Name of the table for the new form.
UI action	The UI action to click. **Note:** The declarative action and UI action buttons look exactly the same. Depending on the selected test step (either Click a UI Action or Click a Declarative Action), the type of button can be identified.
Assert type	The effect on the tests with clicking of a UI action. • **Form submission canceled in browser**: The step passes only if form submission is canceled. • **Form submitted to server**: The step passes only if the form is submitted.

Outputs

Field	Description
table	The table for the form that contains this UI action.
record	The sys_id of the record on which the action was clicked.

Click a Declarative Action

Click a declarative action on the current form.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Notes	Notes about the test step
Form UI	Option to select an available UI. Apart from the Standard UI, you have other workspace selections available. Depending on the selected workspace, the UI might vary. **Note:** Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
Table	Name of the table for the new form.
Declarative action	Option to select a declarative action from the list. **Note:** The declarative action and UI action buttons look exactly the same. Depending on the selected test step (either Click a UI Action or Click a Declarative Action), the type of button can be identified.
Assert type	The effect on the tests with clicking of a UI action. • **Form submission canceled in browser**: The step passes only if form submission is canceled. • **Form submitted to server**: The step passes only if the form is submitted.

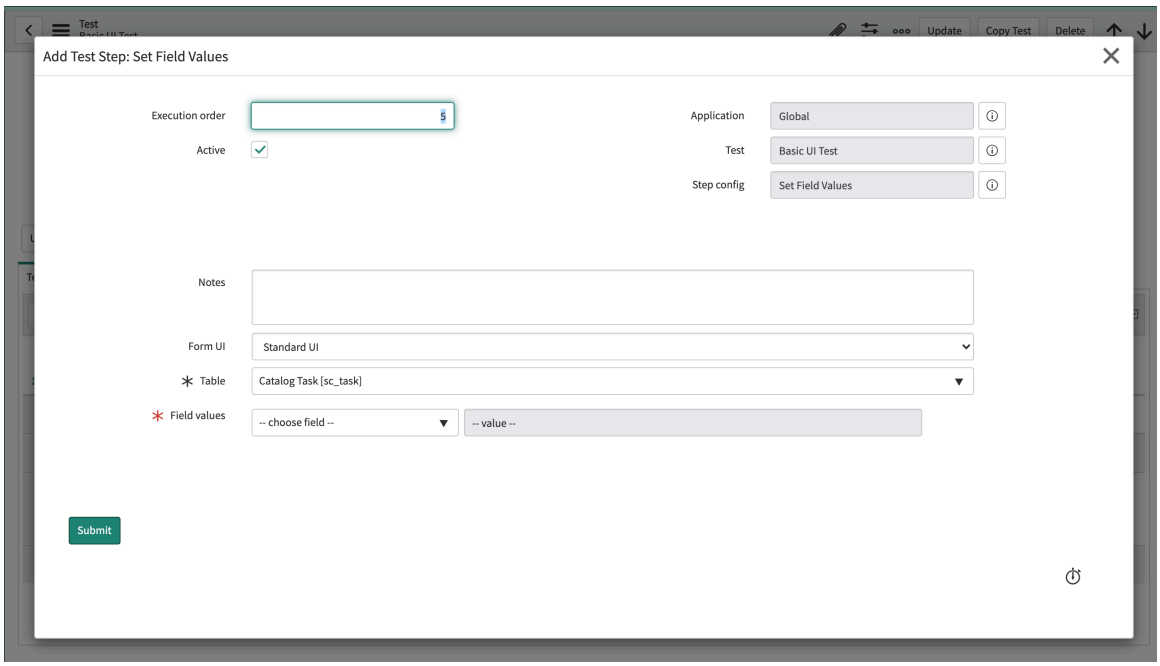
Submit a Form

Submit the current form.

To run this step, your test must have already opened a form using either the **Open a New Form** or **Open an Existing Record** step. It is recommended to not run this step directly after a **Submit a Form** or **Click a UI Action** step. This is because they can redirect your test to a different page based on the navigation stack configuration on your instance or the script defined in the clicked UI action. Unless you are certain that the UI action will take you to a specific page, you should explicitly use an **Open a New Form** step after **Submit a Form** or **Click a UI Action** to ensure that the test is on the form as expected. Ensure that the test keeps passing consistently when added to a suite.

Note:
Don't write tests that depend on the system displaying a specific page after executing a **Submit a Form** or **Click a UI Action** step. After these test steps, the system returns to the page that was open before the form was opened. The test cannot determine what that page was, so writing a test that expects a particular page can lead to unpredictable results.

A modal form appears either on top of another form or a list. To submit a modal form, your test must have already opened it on top of a form or a list.



Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.

Inputs (continued)

Field	Description
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails. **Note:** This field appears when an available workspace is chosen from **Form UI**.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step
Form UI	Option to select an available UI. Apart from the Standard UI, you have other workspace selections available. Depending on the selected workspace, the UI might vary. **Note:** Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.
Assert type	The effect on the tests on submitting a form. • **Form submitted to server**: The step passes only if the form is submitted. • **Form submission canceled in browser**: The step passes only if form submission is canceled. • **None**: Make no assertion on submitting the form. The step always passes when using this assert type regardless of the result of submitting the form.

Outputs

Field	Description
table	The table for the submitted record.

Outputs (continued)

Field	Description
record	The sys_id of the submitted record.

Service Catalog category

Validate single catalog item transactions as well as requester and fulfiller flows in Service Catalog.

Activation of the Automated Test Framework for Service Catalog

These test steps require activation of the The Automated Test Framework Service Catalog (com.glide.automated_testing_impl.service_catalog) plugin, which is active by default on new instances. Administrators may need to activate the plugin on instances upgraded from earlier versions.

Support for parametrized tests

Service Catalog step configurations support parametrized tests. For more information on parametrized tests, refer to Parameterized tests.

Variable editor support

After opening a record that supports variable editor (requested item, catalog task, or incident), you can add step configurations to set variable values, or validate variable states or values. Use the step configurations in the following order to support variable editor.

1. Step configurations to order a catalog item or record producer in the **Service Catalog** category.
2. **Open an Existing Record** step configuration in the **Form** category.
3. **Set Variable Values**, **Validate Variable Values**, or **Variable State Validation** step configuration in the **Service Catalog** category.

Note:
Custom variables and custom variable with labels are not supported for Set Variable Values, Validate Variable Values, and Variable State Validation step configurations.

Open a Catalog Item

Open a catalog item.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.

Inputs (continued)

Field	Description
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Catalog Item	Catalog item that you want to open. **Note:** You should have access to this catalog item.

Open a Record Producer

Open a record producer.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Record Producer	Record producer that you want to open. **Note:** You should have access to the record producer.

Set Variable Values

Set variable values for the current catalog item or the record producer.

For a catalog item, use this step after opening a catalog item page using the **Open a Catalog Item** step, and before using the **Order Catalog Item** step. For a record producer, use this step after opening a record producer page using the **Open a Record Producer** step, and before using the **Submit Record Producer** step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Item	Catalog item or record producer for which you want to set variable values.
Variable Values	List of variables and the values that you want to set for them. **Note:** You can set the value for multiple variables.

Set Catalog Item Quantity

Set the quantity for the current catalog item.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.

Inputs (continued)

Field	Description
Item	Catalog item whose quantity you want to set.
Quantity	Quantity you want to set for the catalog item.

Validate Variable Values

Validate variable values on the current catalog item or record producer.

For a catalog item, use this step after opening a catalog item page using the **Open a Catalog Item** step, and before using the **Order Catalog Item** step. For a record producer, use this step after opening a record producer page using the **Open a Record Producer** step, and before using the **Submit Record Producer** step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Item	Catalog item or record producer whose variables should be validated.
Catalog Conditions	Conditions for variable validation. If the conditions are met, the test passes. **Note:** The label of a variable associated with a variable set reflects the variable set name. The format is *`variable_set_name » variable_name`*.

Variable State Validation

Validate the state of variables. Possible variable states are mandatory, not mandatory, read only, not read only, visible, and not visible.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Catalog item	Catalog item for which you want to validate the state. **Note:** You should have access to this catalog item.
Visible	List of the catalog item variables that must be visible for the step to pass.
Not visible	List of the catalog item variables that must be hidden for the step to pass.
Read only	List of the catalog item variables that must be read-only for the step to pass.
Not read only	List of the catalog item variables that must not be read-only for the step to pass.

Inputs (continued)

Field	Description
Mandatory	List of the catalog item variables that must be mandatory for the step to pass.
Not mandatory	List of the catalog item variables that must not be mandatory for the step to pass.

Validate Price and Recurring Price

Validate price and recurring price of a catalog item. Use this step after opening a catalog item page using the **Open a Catalog Item** step, and before using the **Order Catalog Item** step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Price	Price of the catalog item for the step to pass.
Recurring price	Recurring price of the catalog item for the step to pass.
Recurring price frequency	Recurring price frequency of the catalog item for the step to pass.

Add Item to Shopping Cart

Add a catalog item to the shopping cart. Use this step after opening a catalog item page using the Open a Catalog Item step. After this step, you cannot use any other steps on the catalog item.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.

Inputs (continued)

Field	Description
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Assert Type	Criteria for the test to pass. **Successfully added item to Shopping Cart** Test passes only if the catalog item is successfully added to the shopping cart. **Cannot add item to Shopping Cart** Test passes only if the catalog item cannot be added to the shopping cart.

Outputs

Field	Description
cart_item_id	The sys_id of the added catalog item.

Order Catalog Item

Clicks **Order Now** for a catalog item. Use this step after opening a catalog item page using the Open a Catalog Item step.

After this step, you cannot use any other steps on the catalog item. If the two-step checkout is false, a request is generated for the catalog item. If the two-step checkout is true, you are redirected to the cart preview page.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.

Inputs (continued)

Field	Description
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Assert type	Criteria for the test to pass. **Successfully ordered Catalog Item** Test passes only if the catalog item is successfully ordered. **Cannot order Catalog Item** Test passes only if the catalog item cannot be ordered.

Outputs

Field	Description
request_id	The sys_id of the created catalog request.
cart	the sys_id of the cart holding the catalog item.

Submit Record Producer

Submits the current record producer. Use this step after opening the record producer page using the Open a Record producer step. After this step, you cannot use any other steps on the catalog item.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.

Inputs (continued)

Field	Description
Notes	Notes about the test step.
Assert Type	Criteria for the test to pass. **Successfully submitted Record Producer** Test passes only if the record producer is submitted successfully. **Cannot submit Record Producer** Test passes only if the record producer cannot be submitted.

Outputs

Field	Description
record_id	The sys_id of target record of the record producer.

Forms in Service Portal category

Validate the functionality of fields and UI actions in Service Portal form widgets.

Service Portal dependency

Creating automated Service Portal steps requires knowledge of the ServiceNow data model and Service Portal form and data structures.

Open a Form (SP)

Opens a form in a portal.

Use this step for the base system Form page. For custom form pages, use the Open Service Portal Page step from the Custom UI category.

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.

Field	Description
Notes	Notes about the test step.
Portal	Portal in which the defined form opens. Service Portal is the default.
Page	Page to open in the defined portal. The form page is the default.
Table	Table containing the form to open.
sys_id	Sys_id of the record to open. Default is `-1`, which opens a new record.
View	The form view to open. If blank, the system uses the default view.
Query parameters	Additional URL query parameters and values for the form.

Set Field Values (SP)

Sets the values of fields in a form. To use this step, you must have already opened a form using the **Open a Form (SP)** test step.

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Table	The table for the form on which to set field values. The value should be the table in the **Open a Form (SP)** step.
Field values	Fields for which to set values and the values to be set for those fields.

Field Values Validation (SP)

Validates field values on the current form based on defined conditions. To use this step, you must have already opened a form using the **Open a Form (SP)** test step.

Field	Description
Execution order	Integer specifying the order in which the test executes this step.

Field	Description
	As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Table	The table that contains the form on which to validate fields. The value should be the table in the **Open a Form (SP)** step.
Conditions	Conditions used to validate one or more fields on the form. If the condition evaluates to true, the step passes.

Field State Validation (SP)

Validates field states on a form in Service Portal.

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Table	The table for the form on which to validate field states. The value should be the table in the **Open a Form (SP)** step.

Field	Description
Visible	Validates whether the fields on this form are visible. The test fails if the fields are not visible.
Not visible	Validates whether the fields on this form are visible. The test fails if the fields are visible.
Read only	Validates whether the fields on this form are read only. The test fails if the fields are not read only.
Not read only	Validates whether the fields on this form are read only. The test fails if the fields are read only.
Mandatory	Validates whether the fields on this form are mandatory. The test fails if the fields are not mandatory.
Not Mandatory	Validates whether the fields on this form are mandatory. The test fails if the fields are mandatory.

Add Attachments to Form (SP)

Test the functionality of attaching a file to a Service Portal form widget.

To use this step, you must have already opened a form using the **Open a Form (SP)** test step or **Open Service Portal Page steps**. This step can't be used after a **Submit Form** step or **Click a UI Action** step has been used.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Notes	Notes about the test step.
Upload Attachments	Button to attach one or more files to the form.

UI Action Visibility Validation (SP)

Determines whether a UI action on the current Service Portal form is visible. To use this step, you must have already opened a form using the **Open a Form (SP)** test step.

Service Portal only supports server UI actions. The setRedirectURL() method and client UI actions are not supported. UI action visibility can vary depending on the currently logged in or impersonated user.

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Table	The table for the form on which to check UI action visibility. The value should be the table in the **Open a Form (SP)** step.
Visible	Fields from the UI Actions table to be checked for visibility. Includes only form-based UI actions. The test fails if the UI action is not visible on the form for the currently logged in user. **Note:** If the list contains UI actions with the same name, check the form to determine the sys_id of the element. Then filter by sys_id in the UI Action table to select the correct element in the step.
Not visible	Fields from the UI Actions table to be checked for visibility. Includes only form-based UI actions. The test fails if the UI action is visible on the form for the currently logged in user. **Note:** If the list contains UI actions with the same name, check the form to determine the sys_id of the element. Then filter by sys_id in the UI Action table to select the correct element in the step.

Click UI Action (SP)

Selects a UI action on the current Service Portal form and outputs the table and sys_id of the record on which the action was selected.

To use this step, you must have already opened a form using the **Open a Form (SP)** test step. After using this step, you cannot use any other form steps.

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the

Field	Description
	order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Table	The table for the form on which to click a UI action. The value should be the table in the **Open a Form (SP)** step.
UI action	The UI action to click, selected from the UI Actions table. Includes only form-based UI actions.
Assert type	Specifies where to check for form submission after clicking the UI action: • **--None--**: Selects the UI action without validating mandatory or other fields. • **Form submission canceled in browser**: Checks whether the form was canceled in the browser and did not reach the server due to validation or other issues. • **Form submitted to server**: Checks whether the form was submitted to the server.

Outputs

Field	Description
record_id	Sys_id of the record on which the action was clicked.
table	Table with the clicked UI action.

Submit a Form (SP)

Submits the current form in a Service Portal page and outputs the table and sys_id of the submitted record.

To use this step, you must have already opened a form using the **Open a Form (SP)** test step. After using this step, the page closes. You can't use any other steps on the current page.

Field	Description
Execution order	Integer specifying the order in which the test executes this step.

Field	Description
	As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Assert type	Specifies where to check for form submission: • **--None--**: Submits the form without validating mandatory or other fields. • **Form submitted to server**: Checks if the form was submitted to the server. • **Form submission canceled in browser**: Checks whether the form was canceled in the browser and did not reach the server due to validation or other issues.

Outputs

Field	Description
record_id	Sys_id of the submitted record.
table	Table for the submitted record.

List and Related List

Validate the functionality and visibility of records and UI actions in lists and related lists.

Validate Related List Visibility

Validate the visibility of the selected related lists on a form.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step.

Inputs (continued)

Field	Description
	As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
Table	Name of the table of the parent form where related list visibility is validated.
Visible	List of related lists to assert as visible.
Not visible	List of related lists to assert as not visible.

Apply Filter to List

Apply a filter to a list to find the required record.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
List type	Option to select the type of list. • **List** • **Related list**
Assert Type	Specifies the assertion on executing the test step: • **At least one matching record found**: The step succeeds if there is at least one matching record. • **No matching record found**: The step fails if there is any matching record. • **One matching record found**: The step succeeds if there is exactly one matching record.

Inputs (continued)

Field	Description
Table	If the **List type** is **List**, this field is the table of the opened list. If the **List type** is **Related list**, this field states the name of the table of the parent form where the list belongs.
Related List	The related list to apply a filter to. **Note:** This field is available when **Related list** is selected from **List type**.
List filter	Filter conditions to apply to the list.

Outputs

Field	Description
first_record	The first record found in the list after applying the indicated filter.

Validate Record Present in List

Validate the presence of a record in a list. A valid form must be open and the list containing the record must be visible to proceed.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Step config	Name of the step.
Notes	Notes about the test step.
List type	Option to select the type of list. • **List** • **Related list**
Assert type	Specifies the assertion on executing the test step:

Inputs (continued)

Field	Description
	• **Record is present in the list** • **Record is not present in the list**
Table	Name of the parent table where the list belongs.
Related list	The related list which has the record to validate. **Note:** This field is available when **Related list** is selected from **List type**.
Record	The record whose presence is validated.

Open a Record in List

Open a specific record in a list.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
List type	Option to select the type of list. • **List** • **Related list**
Table	Name of the parent table where the list belongs.
Related List	The related list which has the record to open. **Note:** This field is available when **Related list** is selected from **List type**.
Record	The record to be opened.

Validate List UI Action Visibility

Validate that a UI action is visible in a list. If you're impersonating a user, the visibility of a UI action can change depending on the user being impersonated.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
List type	Option to select the type of list. • **List** • **Related list**
Table	Name of the table of the parent form.
Related List	The related list which has the UI actions. **Note:** This field is available when **Related list** is selected from **List type**.
Visible	List of UI actions to assert as visible.
Not visible	List of UI actions to assert as not visible.

Click a List UI Action

Select a list UI action in a list on a form.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
List type	Option to select the type of list.

Inputs (continued)

Field	Description
	• **List** • **Related list**
Table	Name of the table where the UI action belongs.
Related list	The related list which has the UI actions. **Note:** This field is available when **Related list** is selected from **List type**.
List action	The list UI action to be clicked.
Action type	The type of UI action to be clicked.
Apply to	The record on which the UI action is applied.
Assert type	The assertion made by the step when executed. • **None**: Click a UI action and continue without making an assertion. • **Page reloaded or redirected**: Click a UI action, and assert that the page was reloaded or redirected. This assert type doesn't assert form submission.
Record	The record to which the UI action is applied. **Note:** This field appears when you choose Single record in the **Apply to** field.

REST category

Verify the functionality of REST calls.

Send REST Request - Inbound - REST API Explorer

This test step begins with the REST API Explorer. Use the REST API Explorer to create and specify the HTTP method, path, query parameters, request headers, and body of a REST request, and then send the REST request to the current instance.

When you have tested the request, the **Create Automated Test Step** button appears. Click **Create Automated Test Step** to create the test step. This button does not appear until after the request has been sent. You cannot create a test step when the request payload is larger than the maximum request payload size property.

This test step creates the same test record as the **Send REST Request - Inbound** test step. After the test step is created, you cannot go back and use the REST API Explorer to update the test. All changes must be made on the **Send REST Request - Inbound** test step form.

No HTTP response validation is performed as part of this step. The step fails if the response payload size is too big, the request parameters are invalid, or the request could not be sent. Use the assert steps to validate the response.

You cannot use this step to send a request to another instance or third party/remote address.

These inputs are for the REST API Explorer. The fields you see depend upon the API selected. For more information on using REST APIs on your instance, see REST APIs.

Inputs

Field	Description
Namespace	Namespace for the request. Select from the list.
API Name	API to be used. Select from the list.
API Version	API version to be used. Select the version available on your instance from the list.
Path parameters	The part of the path after the API name. Path parameters are generally name-value pairs where the allowable values are in a list.
Query parameters	Name-value pairs of query parameters added to the URI after the path. The REST API Explorer encodes the URI, so it is not necessary to encode query parameters and values.
Request headers	Name-value pairs contained in the request header. The authentication header is set to **Send as me** to use the current user's credentials. To use the test step in production, you may need to change the **Authentication Type** field in the **Send REST - Inbound** test step. Do not encode the name or value.
Request Body	The request content. Some requests do not have a body.

Send REST Request - Inbound

Create a test step to send a REST request to the current instance. Specify the HTTP method, path, query parameters, request headers, and body of a REST request.

No HTTP response validation is performed as part of this step. The step fails if the response payload size is too big, the request parameters are invalid, or the request could not be sent. Use the assert steps to validate the response.

You cannot use this step to send a request to another instance or third party/remote address.

For more information on using REST APIs, see the REST APIs.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step.

Inputs (continued)

Field	Description
	As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Authentication Type	The type of authentication to use. For public APIs, select **None**. To configure basic or mutual authentication, users need the atf_ws_designer role. For more information, see Automated Test Framework roles.
Basic authentication	The basic authentication profile to use when doing the test. You must create or select a basic authentication profile to assign to test steps to avoid authentication issues when running the test. For more information, see Create a basic auth profile using the Automated Test Framework.
Mutual authentication	An X.509 certificate for mutual authentication. You must create or select a client certificate to assign to test steps to avoid authentication issues when running the test. For more information, see Set up Certificate-based authentication.
Method	The HTTP method to be used: • **GET** • **POST** • **PUT**

Inputs (continued)

Field	Description
	• **DELETE** • **PATCH**
Path	The path to be used. This field accepts only the portion of the URI after the instance name. If you use `https://<instance name>`, you get an error.
Query Parameters	Query parameter names and values. Do not encode the parameter names or values.
Headers	Header names and values. Do not encode the header names or values.
Body	The body of the request.

Assert Status Code

Assert that the HTTP response status code has the specified relationship to the specified value. You specify a numeric value of the status code and the relationship.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.

Inputs (continued)

Field	Description
Notes	Notes about the test step.
Operation	Comparison to be performed between values: • **is** • **is not** • **less than** • **greater than** • **less than or is** • **greater than or is**
Status code	Status code to be tested against the response code.

Assert Status Code Name

Assert that the HTTP response status code name has the specified relationship to the specified value. You specify a value of the status code name, and the relationship.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.

Inputs (continued)

Field	Description
Notes	Notes about the test step.
Operation	Comparison to be performed between values: • **contains** • **does not contain** • **is** • **is not**
Status code name	Status code name to be tested.

Assert Response Time

Assert that the HTTP response time has the specified relationship to the specified value. You specify a value of the response time and the relationship.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Operation	Comparison to be performed between **Response time** entered and actual response time:

Inputs (continued)

Field	Description
	• **less than** • **greater than**
Response time (ms)	Time in milliseconds to be compared to the actual response time.

Assert Response Header

Assert the HTTP response header exists, or the header has the specified relationship to the specified value.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Header	Header name.
Operation	Comparison to be performed between values: • **contains** • **does not contain** • **is**

Inputs (continued)

Field	Description
	• **is not** • **is not empty**
Value	Element value to be used in the test. Not shown if the **Operation** is **is not empty**.

Assert Response JSON Payload is Valid

Assert that the response payload is in valid JSON format.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.

Assert Response XML Payload is Well-Formed

Assert that the response payload is well-formed XML.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.

Assert XML Payload Element

Assert the XML response payload element exists, or has the specified relationship to the specified value.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.

Inputs (continued)

Field	Description
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Element path	XML path to the element to be evaluated. For example, `/result/short_description` for `{ "result": { "number": "INC0020001", "short_description": "test" } }`
Operation	Comparison to be performed between values: • **contains** • **does not contain** • **is** • **is not** • **is not empty**
Value	Element value to be used in the test. Not shown if the **Operation** is **is not empty**.

Assert JSON Response Payload Element

Assert the JSON response payload element exists, or has the specified relationship to the specified value.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value.

Inputs (continued)

Field	Description
	This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Element path	SNC path to the element to be evaluated. For example, `/result/short_description` for `{ "result": { "number": "INC0020001", "short_description": "test" } }` See Importing JSON files for more information.
Operation	Comparison to be performed between values: • **contains** • **does not contain** • **is** • **is not** • **is not empty**
Value	Element value to be used in the test. Not shown if the **Operation** is **is not empty**.

Assert Response Payload

Assert the HTTP response payload has the specified relationship to the specified value. You specify the value and the relationship.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps

cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.

Note:
The entire payload is used to look for a match. A large payload can affect performance.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Operation	Comparison to be performed between values: • **contains** • **does not contain** • **is** • **is not** • **is not empty**
Response body	The value of the response body to be used in the test. Must contain the name and value to be compared as it appears in the response payload. Must not contain any curly braces. Not shown if the **Operation** is **is not empty**.

To check the short description in the response payload

```
{"result":{"number":"INC0010040","short_description":"Test ATF
 Incident"}}
```

the **Response body** should contain

```
"short_description":"Test ATF Incident"
```

These formats are incorrect and the step fails.

- `{"short_description":"Test ATF Incident"}`
- `"{"short_description":"Test ATF Incident"}"`
- `short_description: Test ATF Incident`
- `short_description:"Test ATF Incident"`

Email category

Use Automated Test Framework (ATF) to test email notifications, outbound email flows, and inbound email responses.

Validate Outbound Email

Verify that a certain outbound email exists by searching for it in the Email [sys_email] table.

Use this step to test any email-generating script that isn't captured in the Validate Outbound Email Generated by Flow or Validate Outbound Email Generated by Notification test steps.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
Conditions	Conditions used to filter outbound emails. For example, to find an email that was sent to user@example.com, set the condition to **[Recipients] [is] [user@example.com]**.
Table	Table to be queried. By default, this step queries only the Email [sys_email] table.

Note:
During testing, this step may take longer than expected to execute. The step times out after two minutes by default.

Validate Outbound Email Generated by Flow

Verify that a certain outbound email exists by searching for it in the Email [sys_email] table. Use this step to test that a flow is triggered as expected.

Note:
This step searches only for emails that are created by a flow Send Email action. To find an email that was sent after a notification was triggered in a flow, use the Validate Outbound Email Generated by Notification step instead. To find an email that was created in any other flow action, such as a custom scripted action, use the Validate Outbound Email step instead.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
Source Flow	Flow that the outbound email was created from.
Conditions	Conditions used to filter outbound emails. For example, to find an email that was sent to user@example.com, set the condition to **[Recipients] [is] [user@example.com]**.
Table	Table to be queried. By default, this step queries only the Email [sys_email] table.

Note:
During testing, this step may take longer than expected to execute. The step times out after two minutes by default.

Validate Outbound Email Generated by Notification

Verify that a certain outbound email exists by searching for it in the Email [sys_email] table. Use this step to test that an email notification is triggered as expected.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.

Inputs (continued)

Field	Description
Notes	Notes about the test step.
Source Notification	Notification that the outbound email was created from. This field references the Notification [sysevent_email_action] table.
Conditions	Conditions used to filter outbound emails. For example, to find an email that was sent to user@example.com, set the condition to **[Recipients] [is] [user@example.com]**.
Table	Table to be queried. By default, this step queries only the Email [sys_email] table.

Note:
During testing, this step may take longer than expected to execute. The step times out after two minutes by default.

Generate Inbound Email

Create an incoming email record to test an inbound email flow or an inbound email action.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
From	Address of the email sender. You can manually enter an email address or reference an email address from a user record. If you manually enter an email address, the system matches the address to an existing user record during testing.
To	Address of the email recipient. You can manually enter an email address or reference an email address from a user record. If you manually enter an email address, the system matches the address to an existing user record during testing.
Subject	Subject of the email. You can enter text or reference a string output from a previous test step.
Body	Content of the message body. You can enter text or reference a string output from a previous test step.

Output

Field	Description
output_email_record	Record in the Email [sys_email] table. The **Receive type** is **New** and the **Type** is **send - ready**. For more information on what these fields mean, see System email log and mailboxes.

Generate Inbound Reply email

Create a reply email record to test how the system handles a user response to an email notification.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
Target Table	Table of the target record.
Target Record	Record that the reply email updates. Selecting a target record also applies a watermark to the reply email.
From	Address of the email sender. You can manually enter an email address or reference an email address from a user record. If you manually enter an email address, the system matches the address to an existing user record during testing.
To	Address of the email recipient. You can manually enter an email address or reference an email address from a user record. If you manually enter an email address, the system matches the address to an existing user record during testing.
Subject	Subject of the email. You can enter text or reference a string output from a previous test step.
Body	Content of the message body. You can enter text or reference a string output from a previous test step.

Output

Field	Description
output_reply_email_record	Record in the Email [sys_email] table. The **Receive type** is **Reply** and the **Type** is **send - ready**. For more information on what these fields mean, see System email log and mailboxes.

Generate Random String

Generate a string of random alphanumeric characters that you can use as test data for another step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
Length	Number of characters in the generated string. The maximum length is 10,000 characters. If you leave the field blank, the string length is 10 characters by default.

Output

Field	Description
random_string	String of random alphanumeric characters.

Server category

Perform server-side operations. For example, query and update a record, impersonate a user, or run a server-side script.

Create a User

Create a user with specified roles and groups for the test. The user record gets rolled back after the test completes.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
First name	First name of the user.
Last name	Last name of the user.
Roles	Assigned roles of the user.
Groups	Assigned groups of the user.
Impersonate this user	Option to impersonate the new user.

Outputs

Field	Description
user	The user ID of the user impersonated.

Impersonate

Impersonate the specified user for the test.

Impersonate specifies a user for executing subsequent steps in this test. It works for both server-side and browser-side steps and stays in effect until changed with another **Impersonate** step or until the test ends. The impersonation automatically ends when the test is over.

Note:

- Do not impersonate a user with the test author role. Doing so can lead to conflicts that interfere with executing the test.
- Tests which involve impersonated users which no longer exist fail.

  Tip:
  It is recommended to create a new user to avoid data dependencies. See Create a User, for more information.

- Do not rely on user IDs being consistent across different instances. The system dynamically assigns users IDs, so the ID for a particular user often differs from one instance to the next.
- When exporting and importing automated tests, keep in mind that update sets do not update the user field.
- Tests can impersonate users with the snc_external role, which allows testing users who do not have login access. See Explicit Roles for requirements of the snc_external role.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
User	The user ID for the test to impersonate.

Outputs

Field	Description
user	The user ID of the user impersonated.

Search for a Catalog Item

Searches for a catalog item or record producer in the specified catalog and category. You can perform this step both in Platform and Service Portal.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.

Inputs (continued)

Field	Description
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Search in Portal only	Selected if the search is restricted to the Service Portal only. Otherwise, not selected.
Search term	Term used to search for a catalog item.
Catalog	Catalog in which to search for the catalog item.
Category	Category in which to search for the catalog item.
Assert item	Catalog items that should be available in the search results.
Assert Type	Specifies how searching the catalog item affects the test: • **Assert Item present in search result**: Test passes only if the assert item is present in the search result. • **Assert Item not present in search result**: Test passes only if the assert item is not present in the search result.

Outputs

Field	Description
catalog_item_id	The sys_id of the first catalog item found that the user can view.

Record Query

Query the database to verify that a record exists matching the conditions set in this step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.

Inputs (continued)

Field	Description
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Enforce security	Selected to enforce ACLs. Otherwise, not selected.
Notes	Notes about the test step. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Assert type	Specifies how querying the record affects the test: • **There is at least one record matching the query**: The test fails if there are no records matching the query. • **No records match the query**: The test fails if any records match the query.
Table	The table to be queried.
Conditions	Conditions used to run the query.

Outputs

Field	Description
table	The table queried.
first_record	The first record resulting from the query.

Note:
If you don't update your record query test step, the original record query test step still functions the same way as before, irrespective of it being termed as **(Deprecated)**.

Record Insert

Inserts a record into a table with the field values you specify.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.

Inputs (continued)

Field	Description
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Assert type	Specifies how inserting the record affects the test: • **Record successfully inserted**: Test fails if the record was not successfully inserted. • **Record was not inserted**: Test fails if the record was successfully inserted.
Enforce security	Selected to enforce ACLs and the read-only role. Otherwise, not selected.
Table	The table into which the record should be inserted.
Conditions	Specific field values to be set when the test runs this step.

Outputs

Field	Description
table	The table to which the new record belongs.
record_id	The sys_id of the new record.

Record Update

Changes field values on a record on the server.

Note:
To ensure that the changes were applied, follow this step with a **Record Validation** step.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.

Inputs (continued)

Field	Description
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Assert type	Specifies how updating the record affects the test: • **Record successfully updated**: Test fails if the record was not successfully updated. • **Record was not updated**: Test fails if the record was successfully updated.
Enforce security	Selected to enforce ACLs and the read-only role. Otherwise, not selected.
Table	The table containing the record to be updated.
Record	ID of the record to be updated.
Field values	Fields for which you want to set values and the values you want to set for those fields. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.

Note: Record Update step succeeds even if a field on the record is blocked by ACL. Use the Record Validation step after Record Update to check whether a particular field was modified, or use the Form steps to evaluate ACL conditions for individual fields on a record.

Record Delete

Deletes a specified record in a table.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step.

Inputs (continued)

Field	Description
	As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Assert type	Specifies how updating the record affects the test: • **Record successfully deleted**: Test fails if the record was not successfully deleted. • **Record was not deleted**: Test fails if the record was successfully deleted.
Enforce security	Selected to enforce ACLs and the read-only role. Otherwise, not selected.
Table	The table containing the record to be deleted.
Record	ID of the record to be deleted.

Record Validation

Validates that a record meets the specified conditions on the server side.

For the **Record Validation** step, specify the values you want to test using the standard conditions builder. You can apply several conditions to the same field.

This step passes if the overall condition is satisfied and fails if it is not. If you need to test the values of individual fields independently of each other, include a separate **Record Validation** step for each value to be tested.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.

Inputs (continued)

Field	Description
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step. **Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.
Assert type	Specifies how validating the record affects the test: • **Record successfully validated**: The test fails if the record does not match the conditions. • **Record not found**: Test fails if the record is found.
Table	The table that contains the field to be validated.
Record	The record that contains the field to be validated.
Field values	Specific fields to be validated when the test runs this step.

Run Server Side Script

Executes a script on the server.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Jasmine version	The version of the Jasmine testing framework to use for running the server-side script. Any new scripts you create use Jasmine version 3.1. Your existing scripts

Inputs (continued)

Field	Description
	can continue to use Jasmine version 1.3, or you can upgrade them to Jasmine version 3.1.
Test script	The javascript for the server to execute. Supports the Jasmine testing framework. **Note:** steps(SYS_ID) can be defined as a function to retrieve Output variable data from a step that executed earlier in the test. The Run Server Side Script test step now supports parameters as step inputs.

Outputs

Field	Description
record_id	The sys_id output by the server-side script.
table	The table output by the server-side script.

Note:
If the script creates data, the system rolls back that data after all steps in the test finish. The output for the Run Server Side Script test step now indicates the line and the line number for the cause of failure.

- Test script

```
//  Test step 1 - add data
var now_GR = new GlideRecord('sc_task');
//  this sample step's Step config has Output variables named
 table and record_id
outputs.table = 'sc_task';
outputs.record_id = gr.insert();
//  Test step 2 - access added data and validate
//  check that the record exists (or that business logic
 changed it)
var now_GR = new GlideRecord("sc_task");
gr.get(steps(PREVIOUS_STEP_SYS_ID).record_id);
assertEqual({name: "task gr exists", shouldbe: true, value:
 gr.isValidRecord()});
stepResult.setOutputMessage: Log a message to step results
 after step executes.
                            Can only be called once or will
 overwrite previous message
```

- Create a suite of test scripts

```
var now_GR = new GlideRecord('sc_task');
gr.setValue('short_description', 'verify task can be
 inserted');
var grSysId = gr.insert();
var justCreatedGR = new GlideRecord('sc_task');
if (justCreatedGR.get(grSysId)) {
stepResult.setOutputMessage("Successfully inserted task
 record");
```

```
return true; // pass the step
} else {
stepResult.setOutputMessage("Failed to insert task record");
return false; // fail the step
}
```

- Jasmine test

```
describe('my suite of script tests', function() {
it('should meet expectations', function() {
expect(true).not.toBe(false);
});
});
//  make sure to uncomment jasmine.getEnv().execute(); outside
 the function body
assertEqual: A function used to compare that assertion.shouldbe
 == assertion.value;
in case of failure it throws an Error and logs that the
 assertion by name has failed
```

Note:
`describe` is only supported in Global scope. Use `describe` to create a suite of test scripts and `it` to define test expectations.

- Logs message to test step output

```
var testAssertion = {
name: "my test assertion",
shouldbe: "expected value"
value: "actual value",
};
assertEqual(testAssertion); // throws Error, logs message to
 test step output
```

- See Step Execution Scripts for Run Server Side script example.

Replay Request Item

Get the item and requester from an existing request item, add the item to a new cart for that user, and place an order.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.

Inputs (continued)

Field	Description
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Original Request Item	The request item to be replayed.

Outputs

Field	Description
table	The table to which the replayed request item belongs.
request	The replayed request item.

Related topics

Automated Test Framework use case: test a Service Catalog request

Log

Logs a message and stores it as a step result.

The log message can contain variables and other information pertaining to the test. The message is stored as a step result.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
Log	The message to be logged. To include the value of an output variable from a previous step, click the input value icon () and follow the procedure to Pass values from one automated test step to another.

Add Attachments to Existing Record

Add one or more mandatory attachments to the specified record. Use **Upload Attachments** to select from the attachments the test step adds to the record.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the **Execution order** values.
Application	Application scope in which the system runs this step.
Active	Option to activate this test step for use.
Test	Name of the test that you're adding the step to.
Step config	Name of the step.
Notes	Notes about the test step.
Table	Valid table selection from the list.
Record	Pre-existing record either from before the test or inserted as a part of the test.
Upload Attachments	Button to add one or more mandatory attachments to the record.

Checkout Shopping Cart

Submits the cart and generates a request. You can perform this step both in the ServiceNow AI Platform and Service Portal.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Timeout	Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.

Inputs (continued)

Field	Description
Assert Type	Criteria for the test to pass. **Empty cart** Test fails if the cart is not empty. **Successfully Checkout cart** Test fails if the cart is not successfully checked out.
Requested For	User for whom the request is generated.
Delivery Address	Delivery address for the request.
Special Instructions	Special instructions for the request.

Outputs

Field	Description
request_id	The sys_id of the submitted request.

Custom Scripted StepConfig

Provides an example of scripts for a custom step configuration.

This example checks if the user name provided starts with the letter A. This step is useful primarily to users with the [atf_test_admin] role. Users with the [atf_test_admin] role can view the example scripts by opening the record for this step in Step configurations.

Inputs

Field	Description
Execution order	Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the **Execution order** values.
Active	Option to activate this test step for use.
Application	Application scope in which the system runs this step.
Test	Read-only name of the test that you're adding the step to.
Step config	Read-only name of the step.
Description	Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.
Notes	Notes about the test step.
User	The user whose name the system checks to see if it starts with the letter **A**. To include the value of an output variable from a previous step, click the input value

Inputs (continued)

Field	Description
	icon ( ) and follow the procedure to Pass values from one automated test step to another.

Outputs

Field	Description
value	The name of the user.

Automated Test Framework reference

Reference information for the Automated Test Framework.

Watch https://players.brightcove.net/6274575390001/nUx4EKfUz_default/index.html?videoId=6286204365001 for some helpful tips to use ATF features.

Tables excluded from rollback after running an automated test

The Automated Test Framework tracks data created by running tests and rolls back changes after testing. The system excludes certain tables from being tracked during testing.

The system excludes certain tables from being tracked or rolled back:

- The History [sys_history_line] table
- The ECC Queue table [ecc_queue].
- The Email [sys_email] Email Log [sys_email_log] tables
- The Report Executions [report_executions] and ReportStats [report_stats] tables.
- The Execution Tracker [sys_execution_tracker] tables
- The Progress Worker [sys_progress_worker] table
- The Schema Change [sys_schema_change]
- The Upgrade History [sys_upgrade_history] and Upgrade History Log [sys_upgrade_history_log] tables
- The Mutex [sys_mutex] table
- The Plugin Log [sys_plugin_log] table
- The Status [sys_status] table
- The Number Counter [sys_number_counter] table
- The AMB Channel Presence [sys_amb_channel_presence] table
- Any table that extends an excluded table.
- Any table starting with the following prefixes are also excluded:

- syslog
- sys_amb_message
- sys_cluster
- cmdb_metric
- ts_
- v_
- sys_delete_recovery

If your test run changes (inserts/updates/deletes) any record on these excluded tables, the system does not roll back the change after testing.

Tests

The Tests module opens the Test table. From here, you can add, edit, and run tests. By opening an individual test record, you can view and edit the steps comprising that test.

Related topics

Building and running automated test suites

Test record form

In the Test record form, you view and edit values of fields for the test record.

Fields

Field / UI Element	Description
Name	Test name.
Description	Test description.
Active	If this test is active, **true**. Otherwise, **false**.
Application	Application scope in which the system runs this test or test suite.
Test steps related list	The steps that this test executes.
Test results related list	The results from individual executions of this test.
Fail on server error	The errors detected while performing UI steps on the server that occur and fail the test.

UI Actions

Name	Description
Update	Click to update the test record.
Run test	Click to run test.
Copy test	Click to copy test.
Delete	Click to delete this test.

Suites

The Suites module opens the Test Suites table. You can create, edit, and run test suites from this table.

Related topics

Building and running automated test suites

Test suite form

The Test Suite form contains information about one test suite.

Fields

Field / Element	Description
Name	The name of the test suite.
Active	To make this test suite active, check this field.
Description	(Optional) Enter a description to identify the purpose of this test suite.
Application	Application scope in which the system runs this test or test suite.
Parent Suite	To make this test suite a child of another test suite, enter the name of the parent test suite here.
Test Suite Tests (related list)	The tests included in this test suite.
Child Test Suites (related list)	Any test suites that are children of this test suite.
Test Suite Results (related list)	Results from executing this test suite.
Test Suite Schedules (related list)	Any test suite schedules that include this test suite.

Test results

Each time you run a test, the automated test framework creates a record of the test results. Use the Test Results module to view details about the results of individual tests and individual steps within a test. If the test generated screenshots, they appear as attachments on the test results record.

Each Test Results record displays detailed results information about one test execution, and contains links to detailed step results and test logs. Step results records display information about one step in a test result, while test log (test results item) records contain detailed console logging and test execution information.

By default, the system deletes test and test suite results data 30 days after creation. You can modify this default retention policy as needed in the Table Cleanup module.

Table Cleanup module

Test results record

A Test Results record contains detailed results information about one test execution. Client Error Details and Failure Details sections appear when a test fails due to error conditions, and include detailed error information you can use for troubleshooting purposes.

Field	Description
Test	Name of the test.
Status	Result of the Test execution: **Success** Test passed. **Failure** Test failed. **Success with warning(s)** Test run passed but encountered client error(s) that were allowed as warnings in the Allowed Client Error table. **Waiting** Test waiting to start. **Running** Test is running. **Skipped** Occurs if an earlier test in the suite failed and **Abort on failure** is set to **true**. **Error** An error occurred in the test framework. For example, the test runner halted, or the server encountered an unintended scenario. The error message appears in the Summary field of the steps results record for the step that threw the error. **Cancelled** User canceled the Test.
Retain indefinitely	Check box to keep this record even after the specified data retention period has passed. For more information, see Table Cleanup.
Start time	Date and time of day at which this test started executing.
End time	Date and time of day at which this test finished executing.
Duration	Elapsed time it took to execute this test.
Previous test result	Results of the previous test execution, indicating if the test passed or failed. Only appears if this test result is for a re-run of a failed test and you are logged on with the admin, atf_test_admin, or atf_test_designer role. Click the information icon (ⓘ) to navigate to the original test result. 
Note:
If this test created screenshots, they appear as attachments in **Manage attachments**.

Client Error Details

This section only displays when a test fails due to a client error.

Field	Description
Failing step	Reference to the first test step result that failed during this test. Click the information icon ( ) to view detailed step results and error information in the Step Results form.
Summary	The following text indicates that a client error occurred at this step, and includes the detailed error message: `This step failed because the client error 'DETAILED ERROR MESSAGE' was detected on the page being tested. See failing Test Logs. To ignore these errors in the next test run, use 'Add all client errors to warning/ ignored list' links.` Test designers and developers should always investigate client errors to determine if there are issues with your business process. For more details, see Identify and resolve client errors.
First failing client error	Reference to the first client error that failed during the test. Click the information icon ( ) to view detailed test results and error information in the Test Logs form. **Note:** For details on how to allow client errors as ignored or warning entries, refer to Allowed client errors
Failing step screenshot	Screenshot of the step that failed. Click to download the screenshot.

Failure Details

This section only displays when a test fails due to a cause other than a client error.

Field	Description
Failing step	Reference to the first step result that failed during this test. Click to download the screenshot.
Summary	Output of the step that failed.
Failing screenshot	Screenshot of the step that failed.

Additional information

This section is visible for all test results.

Field	Description
Output	Output generated for the test step. • Test result (often `Passed` or `Failed`). • For failed tests, includes the same error message detail displayed in the Summary field for the first test step that failed. See Client Error Details above.
Browsers involved	User agent strings returned by browsers that ran the test.

Related lists

Related list	Description
Step Results	Record for each step result and log entry for this test.
Test Log	Record for each test log related to this test results record.
Test Transactions	Record for each transaction (from the system transaction log [syslog_transaction] related to this record. To view the step results associated with a transaction, click the appropriate link in the **Step Results** column. To view the transaction logs associated with a transaction, click the appropriate link in the **Transaction** column. **Note:** The system may not be able to log some transactions with short durations.
Warnings	List of test logs containing client errors with a warning status. The Warnings related list only appears on test results with warnings.

Step results record

The Step Results record contains information about one step in a test result. You access specific step results from the Step Results related list in the Test Results record.

Field	Description
Status	Result of the step: **Success** Test step passed.

Field	Description
	Failure Test step failed. **Success with warning(s)** Test step passed but encountered client error(s) that were allowed as warnings in the Allowed Client Error table. **Skipped** Occurs if an earlier test in the suite failed and **Abort on failure** is set to **true**. **Error** An error occurred in the test framework. For example, the test runner halted or the server encountered an unintended scenario. **Cancelled** User canceled the test or suite.
Type	Type of test result item: Step Result
Summary	Summarized version of the Output field. If an error occurred in the test step, the following text indicates that a client error occurred at this step, and includes a detailed exception/error message. `This step failed because the client error 'DETAILED ERROR MESSAGE' was detected on the page being tested. See failing Test Logs. To ignore these errors in the next test run, use 'Add all client errors to warning/ignored list' links.` Test designers and developers should always investigate client errors to determine if there are issues with your business process. For more details, see Identify and resolve client errors. For a Send REST Request - Inbound step, the URL for the request endpoint, and a response code. For example: `The HTTP request has been sent to the endpoint 'https://demonightlyus.service-now.com/api/now/table/kb_knowledge'`
Output	Generated output for the test step. • For a step result, the outputs from the step, including any explanation why a step failed or was skipped. • For a Send REST Request - Inbound step, the REST request and response including the response body. The output field is truncated at 4096 characters. ○ The REST request and response headers are filtered to prevent sensitive information from being added to the log. A filtered header text is replaced with the text "Header redacted for security." ○ See Filter REST request and response headers for information on how to add a list of REST request and response headers to be filtered. For additional console logging and test execution information for a test step, see the Test Logs record.

Field	Description
Step	Name of the step executed.
Test Result	Reference to the test result associated with this step result. Click the information icon ( ) to view detailed test results information.
Description	Description of the specific actions performed (for example, Open Create Incident Report Producer, Validate that the form matches the following condition) for this test step. For a client log, blank.
Start Time	Date and time of day at which this step or log entry started.
End Time	Date and time of day at which this step or log entry ended.
Duration	Elapsed time it took to execute this test.
Step Transactions (related list)	Record for each transaction (from the system transaction log [syslog_transaction] related to this step result.

Test logs record

The Test Results Item (test log) record contains console logging and test execution information.

During test execution, any information reported to the environment is recorded in the Test Log (sys_atf_test_result_item) table. This information can include browser console logging, results, and error messages recorded by step environments. You access specific test logs from the Test Log related list in the Test Results form.

Field	Description
Status	The result of the test log: **Success** Test step run passed. **Failure** Test step run failed. **Success with warning(s)** Test step passed but encountered client error(s) that were allowed as warnings in the Allowed Client Error table. **Ignored** Client error that has been allowed with a report level of Ignored. **Warning** Client error that has been allowed with a report level of Warning. **Waiting** Test or suite waiting to start.

Field	Description
	Running Test or suite is running. **Skipped** Occurs if an earlier test in the suite failed and **Abort on failure** is set to **true**. **Error** An error occurred in the test framework. For example, the test runner halted or the server encountered an unintended scenario. The error message appears in the Summary field of the Steps Results record for the step that threw the error. **Cancelled** User canceled the test or suite.
Type	Type of test log: • Step Result • Client Log • Client Error **Note:** If a Client Error, you can optionally add it as an ignored or warning entry in the Allowed Client Errors. Doing so prevents the allowed client errors from affecting ATF test executions when they recur in future test runs. For more details, refer to Allowed client errors.
Output	Output generated for the test log. • For a step result, the console logging and test execution outputs from the step, including any explanation why a step failed or was skipped. • For a client log, the log entry text. • For a client error, the actual client error is displayed.
Step	Name of the step executed. This field may be blank for a client log.
Test Result	Reference to the test result associated with this step result. Click to view detailed test result information.
Description	For a step result, the actions performed in this test step. For a client log, blank. For a client, this message displays: `This client error occurred on the page in Browser Type Browser Version` (for example, Chrome 62.0.3202.62).
Start time	Time at which this test step started executing.
End time	Time at which this test step finished executing.
Duration	Time duration it took to execute this test step.
Recorded at	Time at which this step or log entry was recorded.

Field	Description
Allow listed client error	Reference to the Allowed Client Error record (if any). Click ⓘ to view the Allowed Client Error record for this client error.

Suite results

The Suites Results module opens the Suites Results table.

You can drill down to the Test results record to view details about the results of individual test suites, the individual tests within those test suites, any child test suites, and so on.

Related topics

- Building and running automated test suites

Test suite results record

The Test Suite Results record displays information about the results of one execution of one test suite.

Fields

Field / Element	Description
Start Time	(Appears in list of records, but not on default record form). The time this test suite started.
Test Suite	The test suite that was run.
Number	Unique ID for this test suite results record.
Base Test Suite Result	If this test suite is a child in a hierarchy of test suites, the base test suite result is the unique ID of the result record for the suite at the top-most level of the hierarchy. For more information, see Example: Base test suite result.
Parent	If this test suite has a parent, this is the test result record for the parent suite. For more information, see Example: Parent test suite results.
Status	Result of the test or test suite execution: • Canceled – user canceled the test or test suite run. • Error – an error occurred in the test framework. For example, the test runner halted or the server encountered an unintended scenario. The error message appears in the summary field of the Step Results form for the test step that contains the error. • Failure – test, test suite run, or test step failed due to an error. • Ignored – test step passed but contains client-side JavaScript errors entered into the Allowed Browser Error table with report level of Ignored. • Running – test or test suite is running.

Fields (continued)

Field / Element	Description
	• Skipped – occurs if an earlier test in the suite failed and **Abort on failure** is set to **true**. • Success – test, test suite, or test step run passed. • Success with warning(s) – test or test suite run passed but contains a test step with client-side JavaScript errors entered into the Allowed Browser Error table with report level of Warning. • Waiting – test or suite run is waited to start. • Warning – test or suite contains client-side JavaScript errors entered into the Allowed Browser Error table with report level of Warning.
Run time	The duration it took to execute this test suite.
Retain indefinitely	Check box to keep this record even after the specified data retention period has passed. For more information, see Table Cleanup.
Rolled up test success count	How many tests were successful. The tests counted as part of the roll up are all tests included in this suite, plus all others included in suites that are descendents of this one. For more information, see Rolled up counts for test suites results.
Rolled up test failure count	How many tests failed. The tests counted as part of the roll up are all tests included in this suite, plus all others included in suites that are descendents of this one. For more information, see Rolled up counts for test suites results.
Rolled up test error count	How many tests resulted in an error. The tests counted as part of the roll up are all tests included in this suite, plus all others included in suites that are descendents of this one. For more information, see Rolled up counts for test suites results.
Rolled up test skip account	How many tests were skipped. The tests counted as part of the roll up are all tests included in this suite, plus all others included in suites that are descendents of this one. For more information, see Rolled up counts for test suites results.
Test Results (related list)	Results of the individual tests included in this test suite.
Child Test Suites Results (related list)	The results of any test suites that are children of this test suite.
All Test Suite Results (related list)	Results from this test suite and all descendent test suites.
Failed Tests in Suite	Results from any failed tests included in this test suite.

Fields (continued)

Field / Element	Description
(related list)	
Previous suite result	Only appears if this suite result is for a re-run of failed tests and you are logged on with the atf_test_admin, atf_test_designer, or admin role. Click the information icon to navigate to the "original" suite result record. 
Related topics

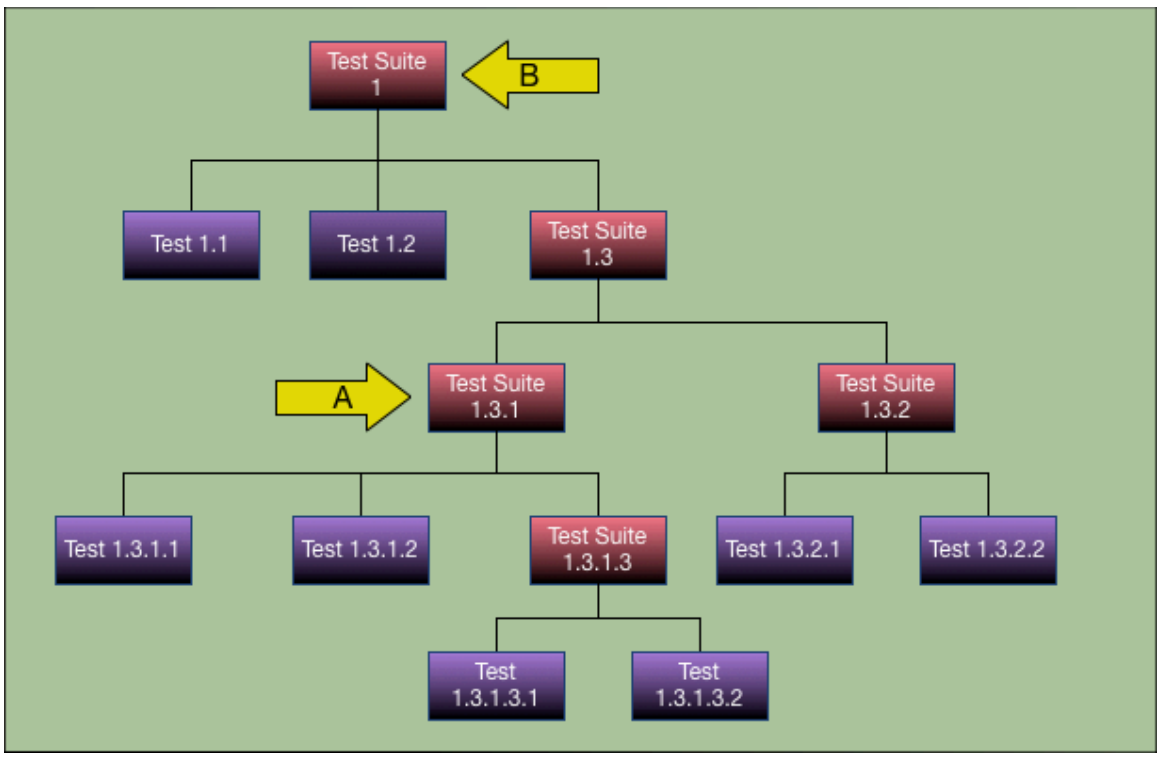
Test results

Test suite results examples

Examples of relationship terms and how aggregated results roll up for test suites.

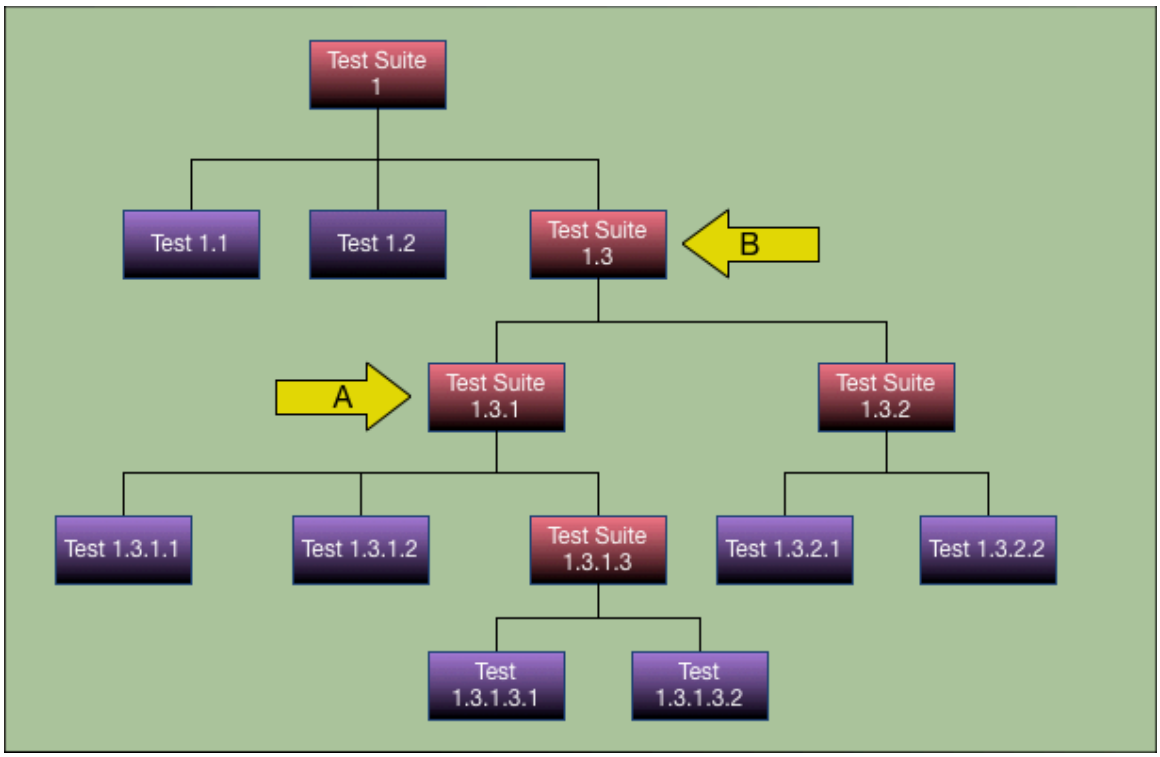
Example: Base test suite result

The base test suite is the top-level test suite in the hierarchy. For example, if you are viewing the test suite results record for (A) Test Suite 1.3.1, the **base test suite result** field links to the test suite results record for (B) Test Suite 1.



Example: Parent test suite results

The parent test suite is the test suite immediately above the one you are currently viewing. For example, ff you are viewing the test suite results record for (A) Test Suite 1.3.1, the **parent** field links to the test suite results record for (B) Test Suite 1.3.

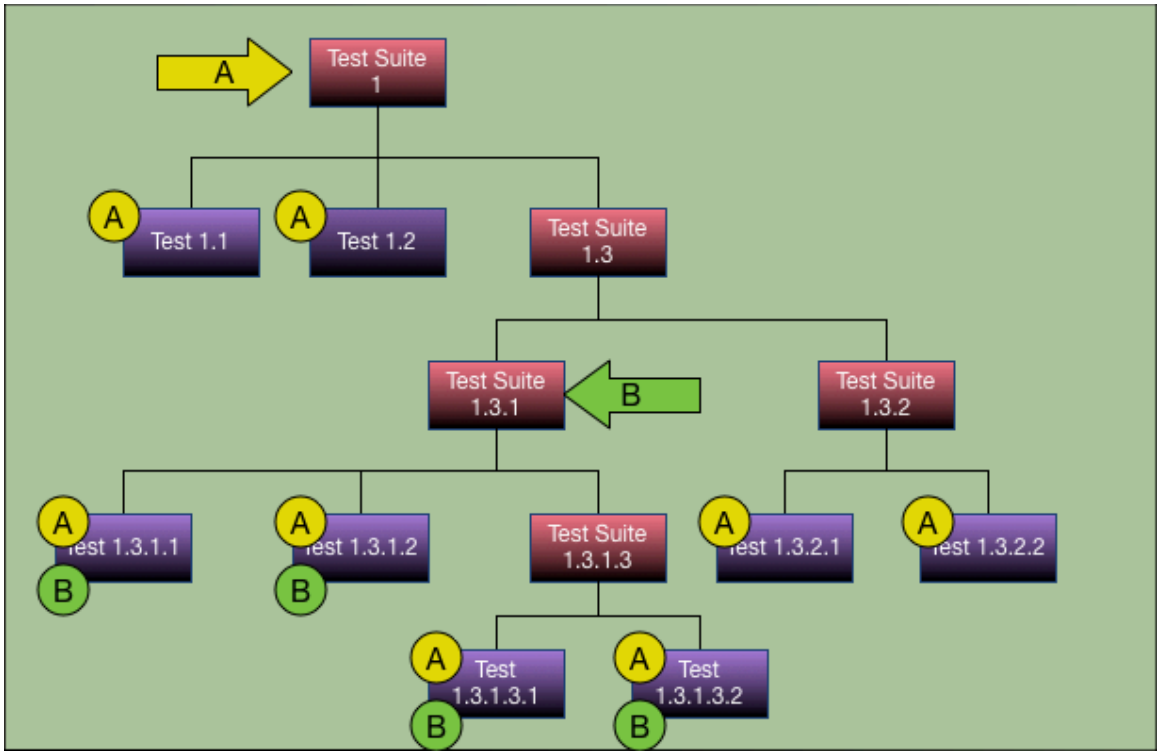


Rolled up counts for test suites results

You can view rolled up counts for a test suite for four metrics: test successes, failures, errors, and skips. Each of these sum data from all tests in the test suite plus all tests in the test suite's descendents.

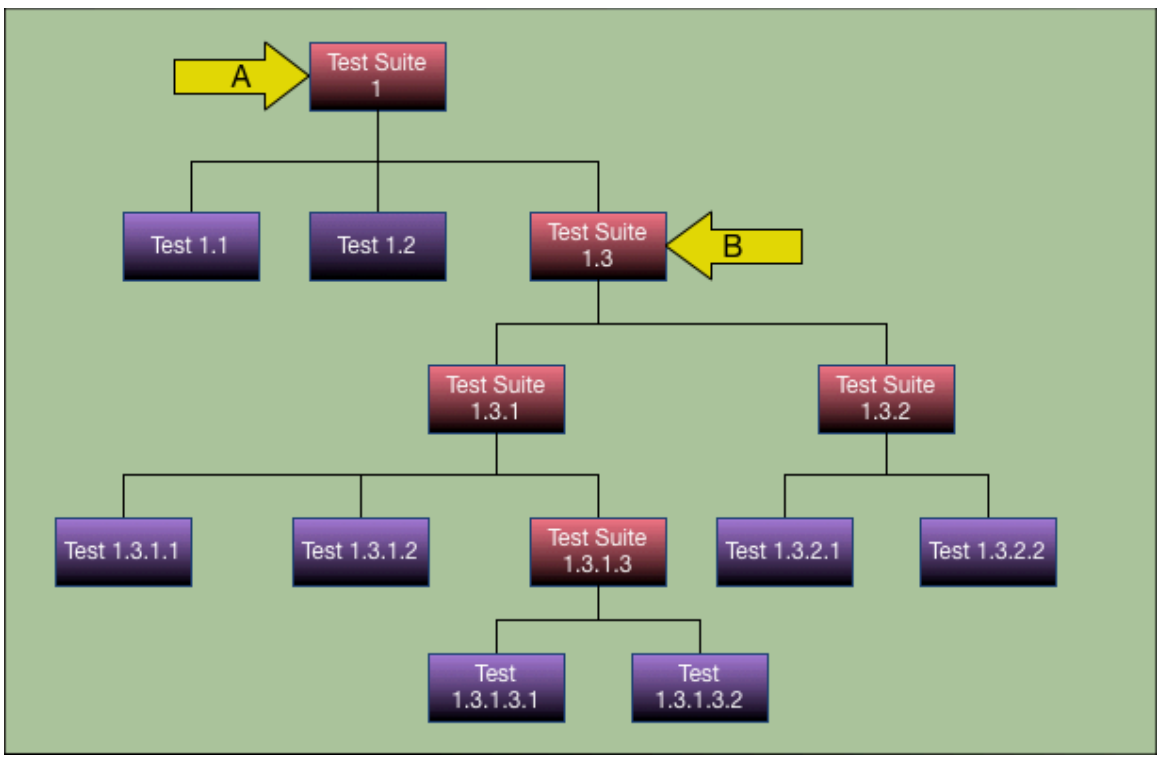
For example, if you are viewing the test suite results record for (A) Test Suite 1.3.1, the **Rolled up test success count** field shows the total number of successes counting results from all the tests represented by boxes labeled A.

If you are viewing the test suite results record for (B) Test Suite 1.3.1, the **Rolled up test success count** field shows the total number of successes counting results from all the tests represented by boxes labeled B.



Child Test Suites Results

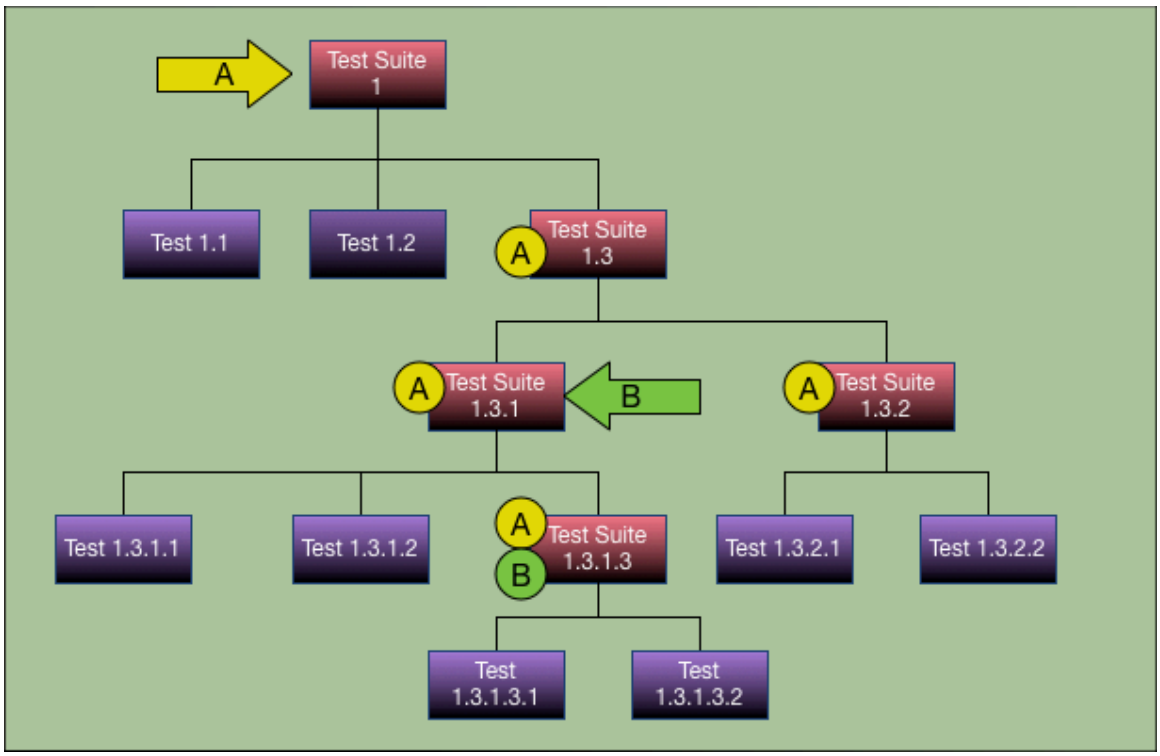
If you are viewing the test suite results record for (A) Test Suite 1, the **Child Test Suites Results** related list shows result records for Test Suite 1.3 (B).



All Test Suites Results

If you are viewing the test suite results record for (A) Test Suite 1, the **All Suites Results** related list shows result records for all Test Suites represented by boxes labeled A

If you are viewing the test suite results record for (B) Test Suite 1.3, the **All Suites Results** related list shows result records for all Test Suite 1.3.1 only (represented by the box labeled B)



Suite schedules

Open the Suites Schedules table. You can drill down to see details about the results of individual schedules or create a new schedule.

Related topics

Building and running automated test suites

Suite schedule record

The Suite Results record displays information about one test suite schedule.

Fields

Field / Element	Description
Name	A name for this test suite schedule.
Description	A description for this test suite schedule.
Active	If this schedule is active **true**. Otherwise, **false**.
Application	The application scope for this test suite schedule.
Run	The frequency with which the system runs test suites belonging to this schedule.
Run as tz	The timezone used for the **Time** field.
Time	The time of day at which the system runs test suites belonging to this schedule.

Fields (continued)

Field / Element	Description
Day	If **Run** is set to Weekly, the day of the week on which the system runs test suites belonging to this schedule. If **Run** is set to monthly, the day of the month.
Repeat interval	If Run is set to **Periodically,**the number of days and hours that constitute the repeat interval for running suites in this schedule.
Conditional	Check to enable a script to define conditions under which the system should run the test suites in this schedule.
Condition	If **Conditional** is checked, the script to execute for determining the conditions under which the system should run the test suites in this schedule.
Scheduled Suite Runs (related list)	The test suites the system should run on this schedule.

Related topics

Schedule an automated test suite

Scheduled suite run record

A Scheduled Suite Run record associates a Suite Schedule record with a Test Suite.

Fields

Field / Element	Description
Schedule	The schedule to use.
Test Suite	The test suite to run.
Application	The application scope for this scheduled suite run.
Watch list	Users the system notifies when this scheduled suite run completes.
Browser name	If the test suite has UI components, the browser that must be used. If no client test runner is available with this browser, the system does not run the suite.
Browser version starts with	If the test suite has UI components, the browser version for the client test runner must start with this string. If no client test runner is available with this browser version, the system does not run the suite.
OS name	If the test suite has UI components, the client test runner must run under this OS. If no client test runner is available with this OS, the system does not run the suite.
OS version starts with	If the test suite has UI components, the OS version for the client test runner must start with this string. If no client test runner is available with this OS version, the system does not run the suite.
Test Suite Results (related list)	All test suite results from this scheduled run.

To determine the browser name and version of a browser you want to use, start a scheduled test runner with that browser, then inspect that runner's record in the Active Scheduled Test Runners Module.

Related topics

Schedule an automated test suite

Run

Start a client test runner and view information about test runners and test runs.

For information on how to work with test runners, see Working with client test runners.

Client test runner

The Client Test Runner opens a browser window or tab for running manually-started client automated tests.

You can toggle a client test runner to act as either a manual or scheduled client test runner. For more information about scheduling test suites, see Schedule an automated test suite.

Fields on the Client Runner Test window

Field / UI Element	Description
Form preferences icon ()	Click to display the form preferences panel.
Form preferences panel: Screenshots mode	Choose among: • Enable for all steps • Enable for failed steps • Disable for all steps For additional information, see Set the system property to control when the Automated Test Framework captures screenshots
Form preferences panel: Run scheduled tests only	Click to toggle between: • On (green): Use this client test runner to run only scheduled tests and suites. • Off (gray): Use this client test runner to run only manually-started tests and suites.

Scheduled client test runner

The Scheduled Client Test Run opens a browser window for running scheduled client automated tests.

For information about scheduling automated tests, see Schedule an automated test suite and Working with scheduled test suites. You can toggle a client test runner to act as either a manual or scheduled client test runner.

Fields on the Client Runner Test window

Field / UI Element	Description
Form preferences icon ( )	Click to display the form preferences panel.
Form preferences panel: Screenshots mode	Choose among: • Enable for all steps • Enable for failed steps • Disable for all steps For additional information, see Set the system property to control when the Automated Test Framework captures screenshots
Form preferences panel: Run scheduled tests only	Click to toggle between: • On (green): Use this client test runner to run only scheduled tests and suites. • Off (gray): Use this client test runner to run only manually-started tests and suites.

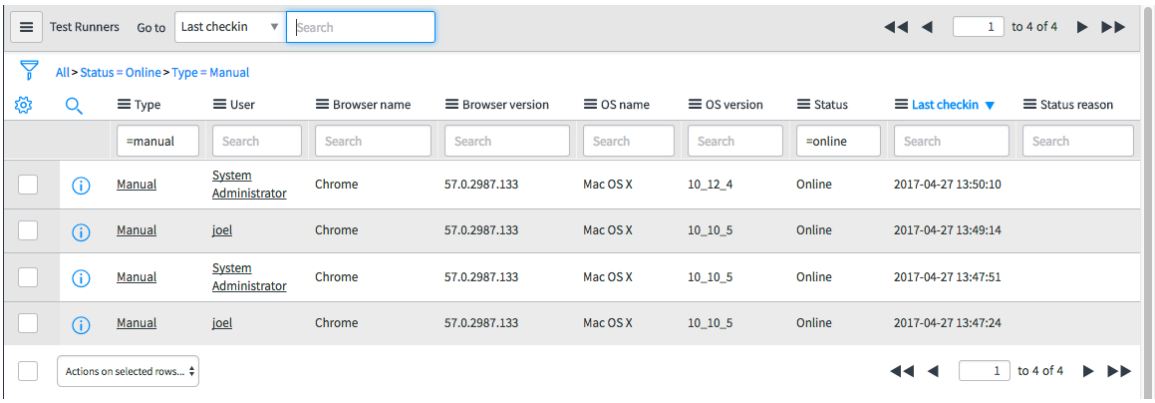
Active manual test runners

View the client test runners table filtered to show only those runners available to run manually-started tests.

When you start a manual client test runner, the system registers that runner in the Test Runners table as active.

The data in this table is transient. While the runner is active, it reports in to the system at a specified interval. If the runner does not report in at the expected time, the system marks the runner as inactive. After a period of time the system deletes the runner. You can modify these intervals on the Automated Test Framework properties page.

Example Active Manual Client Runner Test table



Fields on the Client Runner Test table

Field / UI Element	Description
Type	Whether this test runner is for manual or scheduled tests. In the Active Manual Test Runners module, Type is always **Manual**.
User	The user logged into the browser session.
Browser name	The browser name.
Browser version	The browser version.
OS name	The name of the operating system running the browser.
OS version	The version of the operating system running the browser.
Status	Whether this runner is currently online or offline. In the Active Manual Test Runners module, Status is always **Online**.
Last checkin	The time/date this runner most recently reported in to the system.
Status reason	If the Status is Offline, the reason why. In the Active Manual Test Runners module, Status reason is always empty.

Active scheduled test runners

View the client test runners table filtered to show only those runners available to run tests to be started by a schedule.

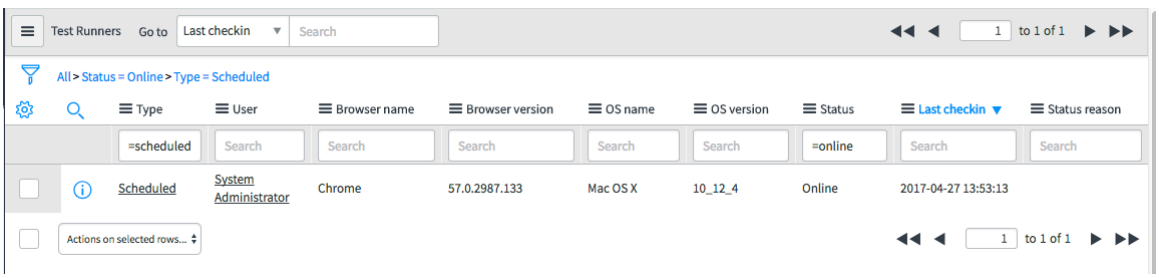
When you start a scheduled client test runner, the system registers that runner in the Active Scheduled Test Runners table.

The Active Scheduled Test Runner module is useful when you create a scheduled suite run. For scheduled suite runs, you can specify the browser to use. To determine the name and version of a browser you want to use, start a scheduled test runner with that browser, then inspect that runner's record in the Active Scheduled Test Runners module.

The data in this table is transient. While the runner is active, it reports in to the system at a specified interval. If the runner does not report in at the expected time, the system marks the runner as inactive. After a period of time the system deletes the runner.

You can modify these intervals on the Automated Test Framework properties page.

Example Scheduled Client Runner Test table



Fields on the Client Runner Test table

Field / UI Element	Description
Type	Whether this test runner is for manual or scheduled tests. In the Active Scheduled Test Runners module, Type is always **Scheduled**.
User	The user logged into the browser session.
Browser name	The browser name.
Browser version	The browser version.
OS name	The name of the operating system running the browser.
OS version	The version of the operating system running the browser.
Status	Whether this runner is currently online or offline. In the Active Manual Test Runners module, Status is always Online.
Last checkin	The time/date this runner most recently reported in to the system.
Status reason	If the Status is Offline, the reason why. In the Active Scheduled Test Runners module, Status reason is always empty.

Waiting/running test runs

The Waiting/Running Test Run module opens a list of records showing the tests waiting to be run.

Note:
To prevent conflicts, the system allows only one test to run at a given time. This is true even if you have multiple client test runner windows open. If you submit tests to run when another test is already running, the system holds the new tests in a queue to run later. If a test remains in the queue for more than ten minutes, the system cancels the test.

You can cancel execution of a waiting automated test.

Waiting/running suite runs

The Waiting/Running Suite Runs module opens a list of records showing the test suites waiting to be run.

Allowed client error records

Review the list of existing Allowed Client Error [sys_atf_whitelist] records to see which client errors produce warnings and which are ignored. Modify existing Allowed Client Error records as needed or create new ones.

Allowed Client Error form

Field	Description
Report level	Report action to take when the client error is encountered. Options include:

Allowed Client Error form (continued)

Field	Description
	• **Warning – Step & Test will report Success with Warning(s)**: Test steps containing the allowed client error report a status of `Success with warning(s)`. The error message appears in the test result output, and is recorded in the test logs with the status `Warning`. • **Ignored – Step & Test will report Success**: Test steps containing the allowed client error report a status of `Success`. The error is recorded in the test logs with an `Ignored` status.
Active	Check box to enable or disable allowing of a client error.
Error message	Message of the client error you want to allow.
Description	Description of the error you want to allow. If this client error was allowed from a test result, step result, or a test log, the test log description is copied into this field.

Related topics

Allowed client errors

Reported client errors

The Reported Client Error module lists test logs across all tests that are client errors and have failed. You can review individual test log records, and allowed client errors as needed to prevent them from adversely impacting future test executions.

Field	Description
Start time	Time at which this test step started executing.
Step	Name of the step executed.
Status	The result of the test log. Failure: Test step run failed.
Output	Output generated for the test log. For a client error, the actual client error is displayed.
Duration	Time duration it took to execute this test step.
Type	Type of test log. Client Error **Note:** You can optionally add client errors as an ignored or warning entry in the Allowed Client Errors. Doing so prevents the allowed client errors from affecting ATF test executions when they recur in future test runs. For more details, see Allowed client errors.
Recorded at	Time at which this step or log entry was recorded.

Administration

The Administration module contains forms for configuring and managing the automated test framework.

Properties

On the Properties form, you can set parameters that control how the system executes automated tests and test suites.

Test/Test Suite Properties

Field / Element	Description
Enable test/test suite execution *sn_atf.runner.enabled*	If checked, enables running tests and test suites on this instance. This setting is unchecked by default to prevent users from unintentionally running tests on production instances.
Enable scheduled test suite execution sn_atf.schedule.enabled	If checked, enables scheduling test suites on this instance.

Test Debugging Properties

Field / Element	Description
Enable additional debugging functionality *sn_atf.debug*	Enables additional debugging functionality, including adding a debugging tab on the client Test Runner UI page and saving UI Test Result JSON to the test result record.

Screenshot Properties

Field / Element	Description
Enable or disable screenshot capture during test execution. *sn_atf.screenshots.mode* **Note:** For additional information, see Set the system property to control when the Automated Test Framework captures screenshots	• To capture screenshots for all steps, select **Enable for all steps**. • To capture screenshots only for failed steps, select **Enable for all failed steps**. • To capture no screenshots, select **Disable for all steps**.
Enable the GlideScreenshot feature *sn_atf.screenshots.use_glide_screenshot*	Improves the fidelity of screenshots on Workspaces and other interfaces. **Note:** IE and Safari don't support this property. If this property is disabled or your current browser doesn't support it, html2canvas is used to take screenshots. If you are upgrading to a new release version, this property is set to false by default.
Enable capturing the full page when taking a screenshot *sn_atf.screenshots.capture_full_page*	Enables dynamic resizing of the test frame and capturing the full page while taking a screenshot.

Screenshot Properties (continued)

Field / Element	Description
	Note: By default, the property is set to false because it can significantly slow test execution time If the property is disabled, only the portion of the page that is visible in the test frame is captured.
Screenshot timeout *sn_atf.atf_test_runner.screenshot_timeout*	Skips a screenshot capture attempt in the Client Test Runner if it exceeds this value in seconds. Users should review performance settings and browser caches on affected client systems before increasing this value.
Number of pixels for screenshot height *sn_atf.atf_test_runner.testframe.min_height*	Numeric value representing the number of pixels for the screenshot height. Default value: 600
Number of pixels for screenshot width *sn_atf.atf_test_runner.testframe.min_width*	Numeric value representing the number of pixels for the screenshot width. Default value: 800

Custom UI Page Data Capture Properties

Field / Element	Description
Enable tests with Custom UI steps to capture page data each time they are run. *sn_atf.page_data_capture.enabled*	When true, Custom UI test steps retrieve page data every time the test runs. Set this property to true when developing custom UI pages to always run tests on the most recent page version. When false, Custom UI test steps do not retrieve page data unless the test designer manually selects **Retrieve Components** during test design. Set this property to false when UI development is complete to enable faster test runs.

Test Runner Properties

Field / Element	Description
Test runner timeout *sn_atf.runner.heartbeat.timeout*	If there is no heartbeat from the test runner within this period of time in seconds, the status changes from online to offline. The value of this property should be between 120 and 1800. Default value: 120
Test runner heartbeat interval *sn_atf.runner.heartbeat.interval*	Time interval in seconds for sending a heartbeat from the test runner to the server.
Offline test runner retention interval *sn_atf.runner.offline_retention.timeout*	If an offline test runner does not communicate with the system for this period of days, the system deletes that test runner.

Test Suite Report Properties

Field / Element	Description
Test suite report properties *sn_atf.schedule.reports.suite.aging_threshold*	The number of test suite results to display in the test suite aging report.

Email Properties

Field / Element	Description
Boolean value for results displayed in scheduled suite result emails. *sn_atf.schedule.suite_result_email.only_show_failed_results*	When true, the scheduled suite test result emails only show results that failed. When false, displays all results.
Maximum number of test results to be displayed in scheduled suite result emails. *sn_atf.schedule.suite_result_email.max_test_history*	Maximum number of test results to be displayed in scheduled suite result emails.

Email Properties (continued)

Field / Element	Description
Maximum depth when printing suite results in suite result emails. *sn_atf.schedule.suite_result_email.max_depth*	Maximum depth when printing suite results in suite result emails.
Color to indicate an ATF test failed in scheduled suite result emails. *sn_atf.schedule.suite_result_email.fail_color*	Hexadecimal code for color to indicate an ATF test failed in scheduled suite result emails.
Color to indicate an ATF test errored in scheduled suite result emails. *sn_atf.schedule.suite_result_email.error_color*	Hexadecimal code for color to indicate an ATF test errored in scheduled suite result emails.
Color to indicate an ATF test passed in scheduled suite result emails. *sn_atf.schedule.suite_result_email.pass_color*	Hexadecimal code for color to indicate an ATF test passed in scheduled suite result emails.
Color to indicate an ATF test was skipped in scheduled suite result emails. *sn_atf.schedule.suite_result_email.skip_color*	Hexadecimal code for color to indicate an ATF test was skipped in scheduled suite result emails.
Color to indicate an ATF test was canceled in scheduled suite result emails. *sn_atf.schedule.suite_result_email.cancel_color*	Hexadecimal code for color to indicate an ATF test was canceled in scheduled

Email Properties (continued)

Field / Element	Description
	suite result emails.

Step configurations

Step configuration records define how each type of step behaves.

Automated Test Framework Step Config record

The step config record controls how a test step of this type behaves.

Fields

Field / Element	Description
Name	The name for this test step configuration.
Active	**True** if this step configuration is active. Otherwise, **false**.
Step Environment	The step environment in which a step with this configuration can run.
Category	The category assigned to a step with this configuration.
Application	The application scope in which the system runs steps with this configuration.
Batch order constraint	Constrains where a step with this configuration can appear in a test: • **None**: A step based on this configuration can appear at any point in a test. • **Start Batch Execution**: If a test includes this a step based on this configuration, it must be the first step in the test. • **Run in the middle of an execution**: If a test includes a step based on this configuration, it cannot be the first or last step. • **Stop Execution**: If a test includes a step based on this configuration, it must be the last step in the test.
Class type	For custom step configurations, this field is always **Script**.
Order	An integer specifying where steps with this configuration appear in the step list on the Add Test Step dialog. For more information, see the example using the Order field.
Template reminder	The instructions that appear when a step with this configuration is included in a test as part of a template. For more information, see theexample of using the Template reminder field.
HTML description	The text that appears when the cursor highlights a step with this configuration on the Create New Step dialog. For more information, see the example using the HTML description field.
Description generation script	Generates the text that describes a step when a test includes it. For more information, see the example using the description generation script.

Fields (continued)

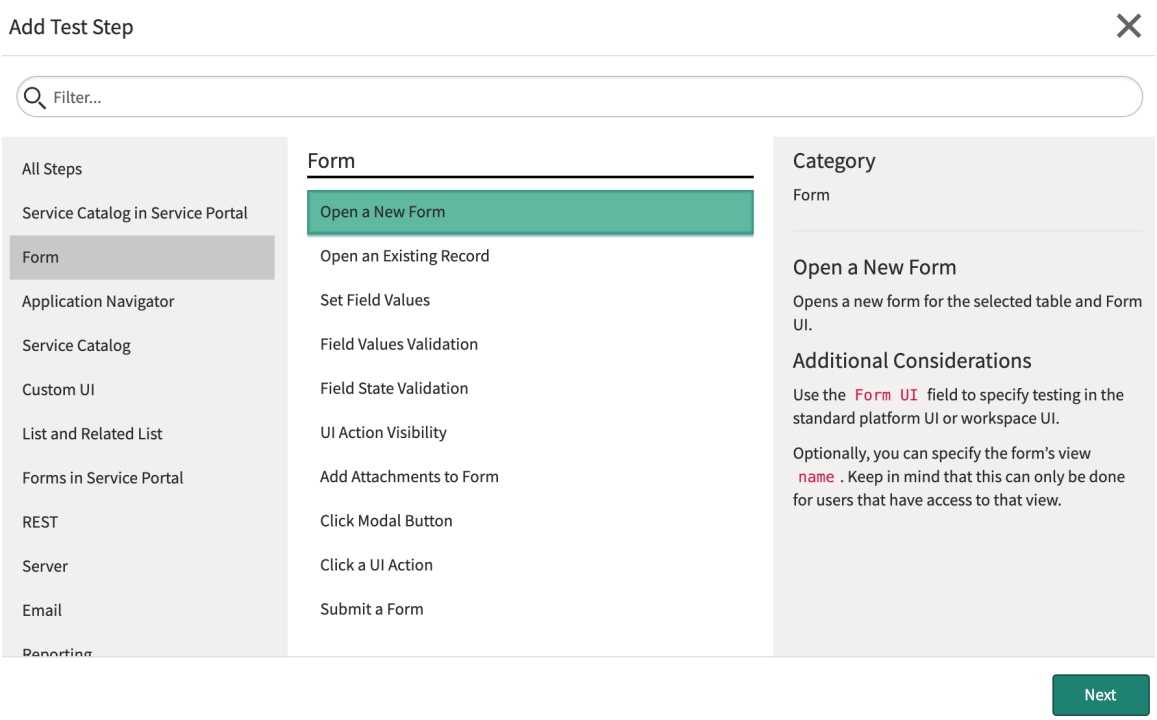
Field / Element	Description
Step execution script	Script (javascript) that runs when a step with this config runs.
Input Variables related list	The variables that act as inputs for a step with this config.
Output variables related list	The variables that act as outputs for a step with this config.

Examples of step config field values

Examples of where the system displays values assigned to some of the step config fields.

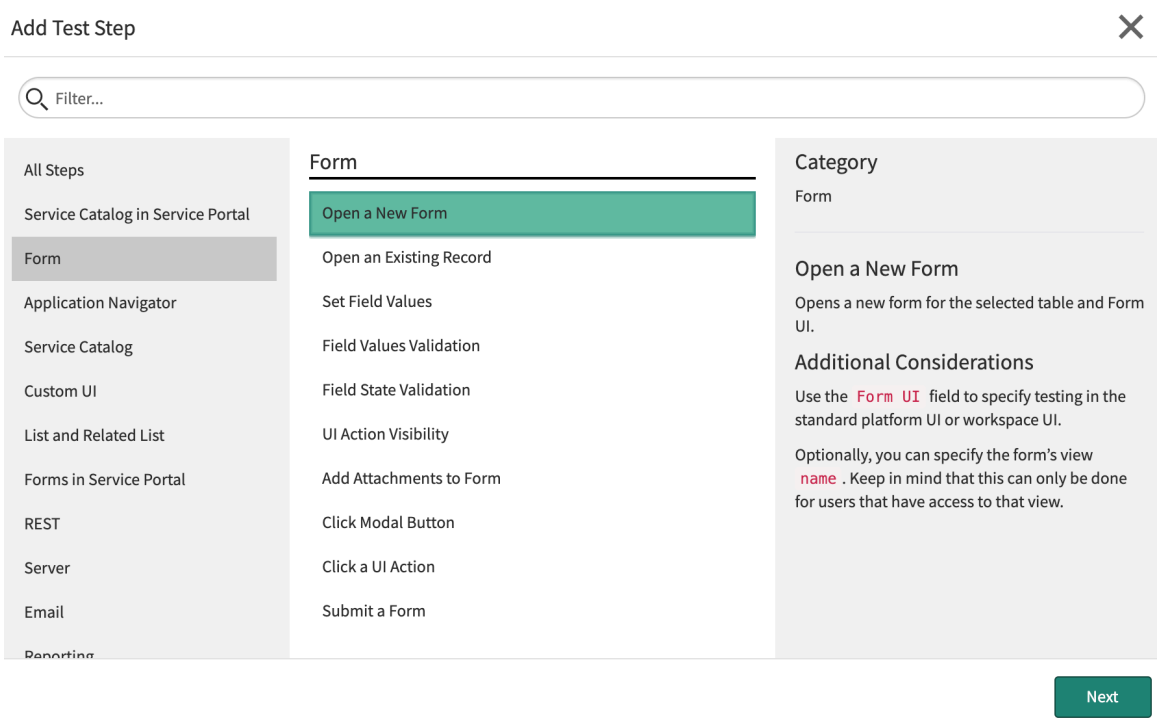
Order field example

The steps in the middle column are sorted according to the values of the **Order** field.



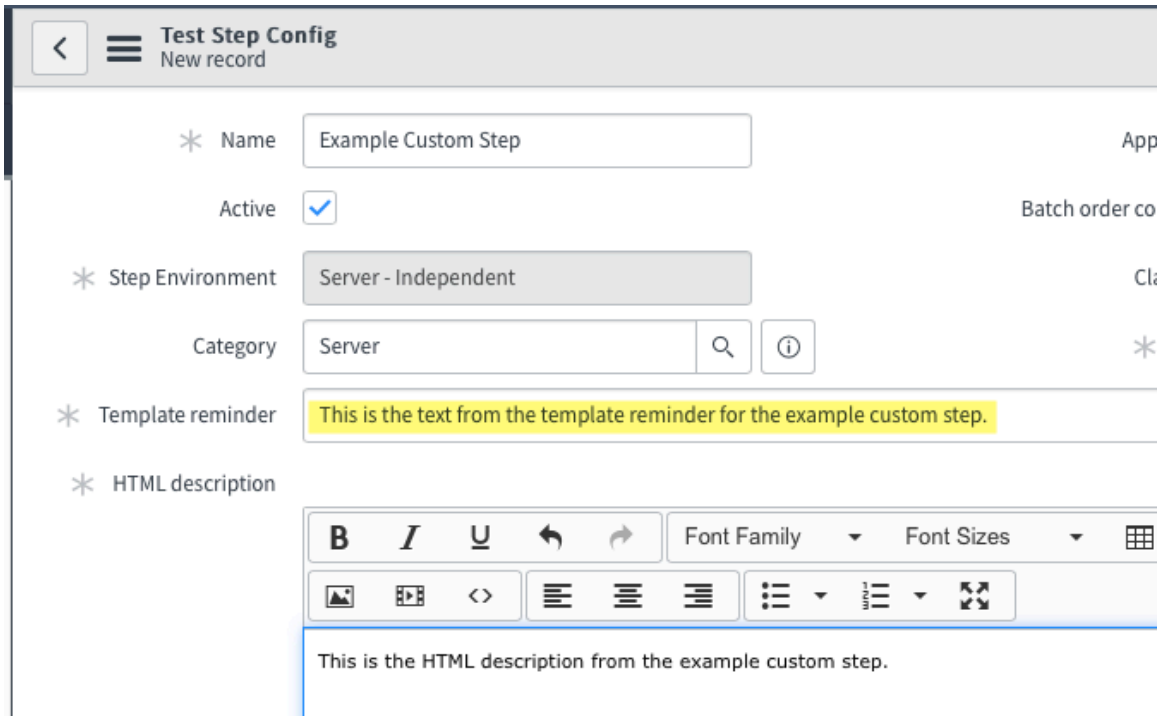
Category field example

The labels in the left column show the categories for available steps. You can filter the list in the middle column, by selecting a category in the left column.

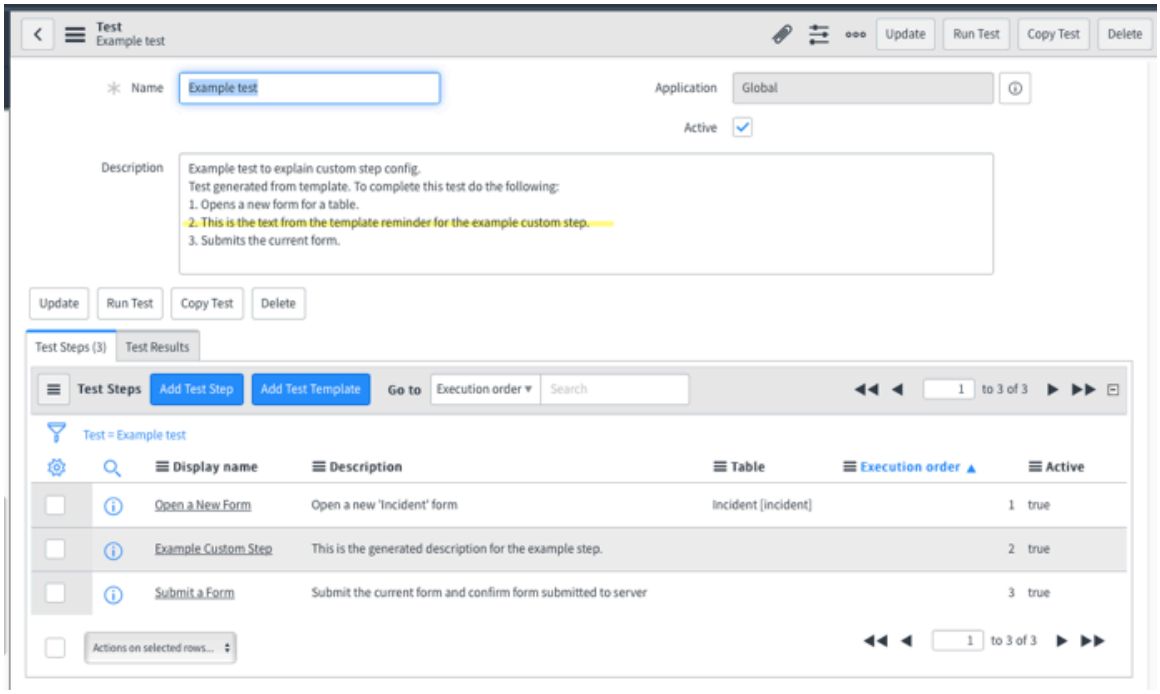


Template reminder example

Here is a portion of the new record form for a test step config for Example Custom Step.

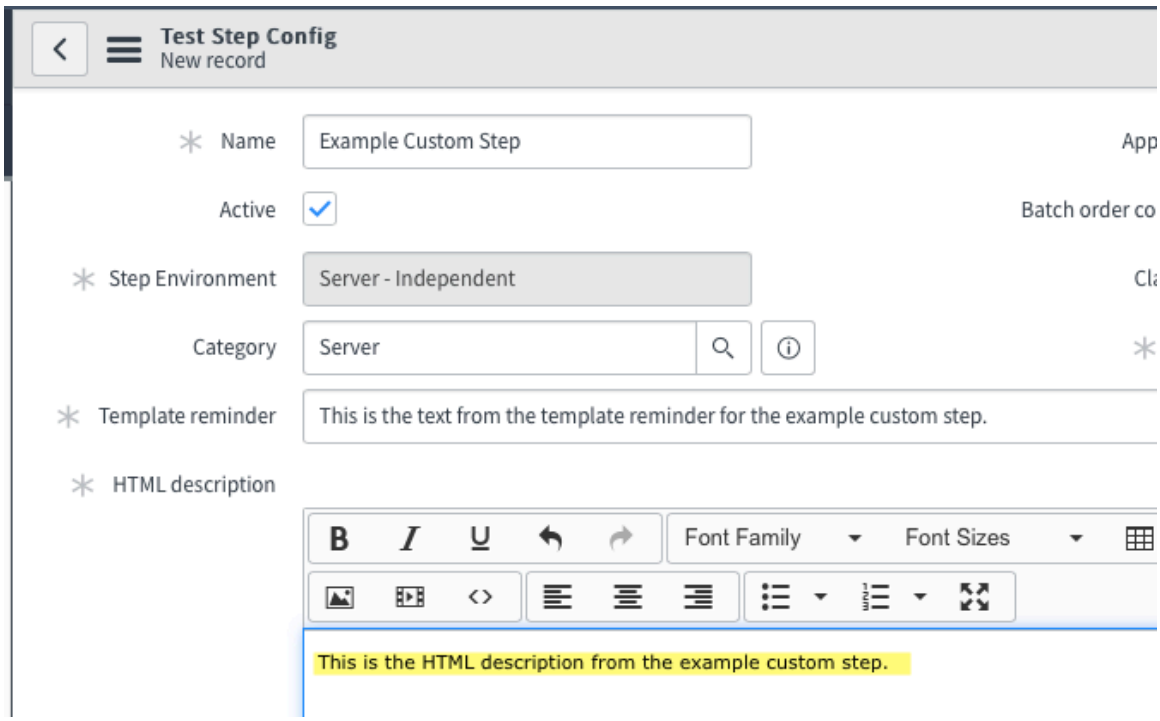


When you add a template to a test, the system generates a set of instructions for completing the template steps and saves them in the test **Description** field. The text in the step config's **Template reminder field** appears as the instructions for the corresponding step.

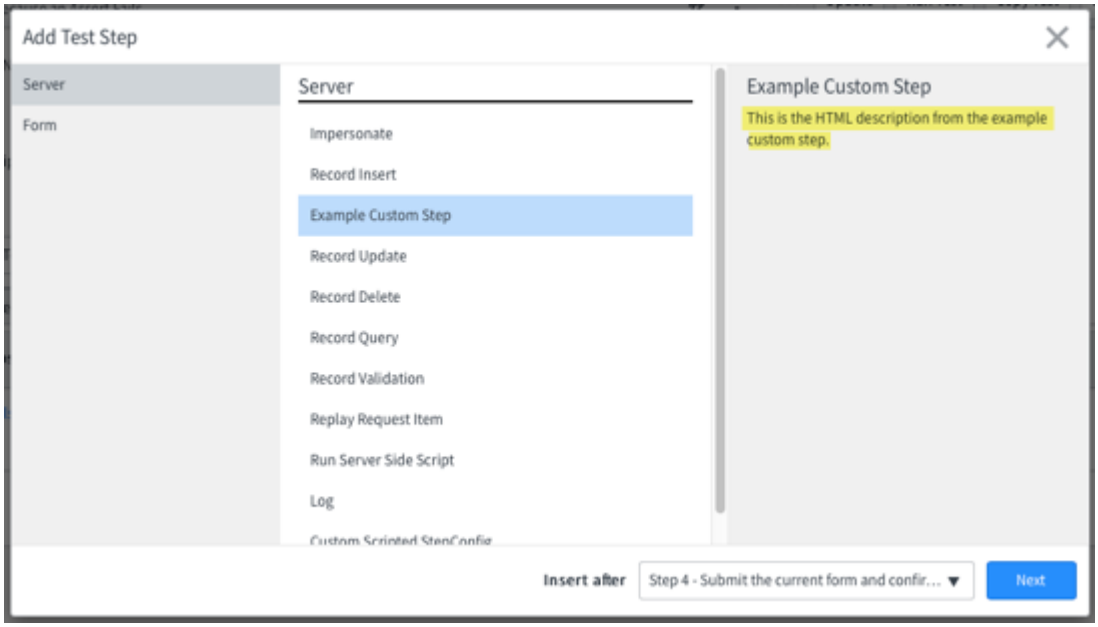


HTML description example

Here is a portion of the new record form for a custom step named Example Custom Step.

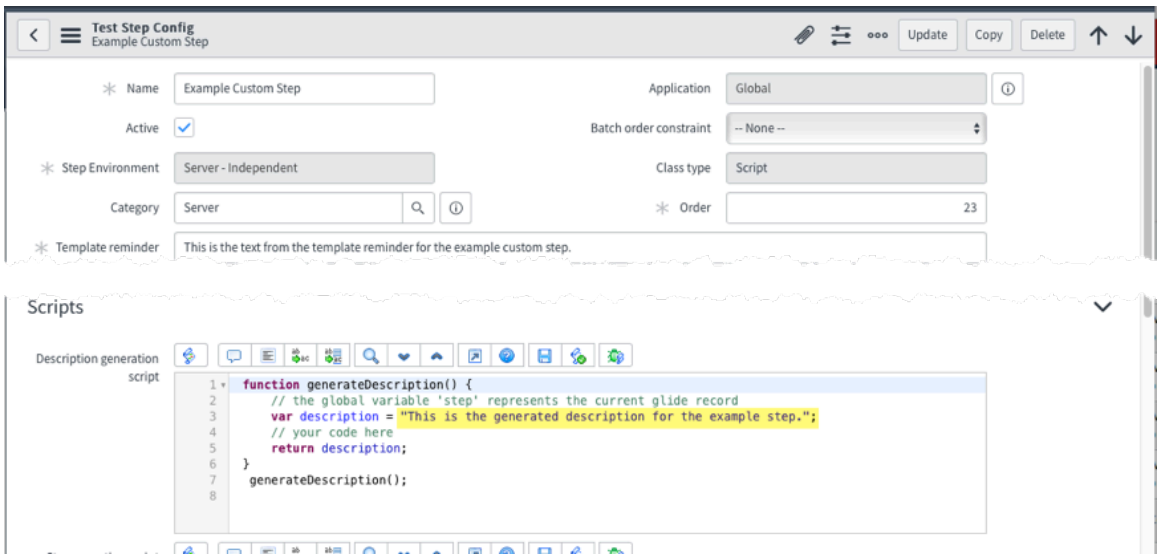


Here is how the step appears in the Add Test Step dialog.

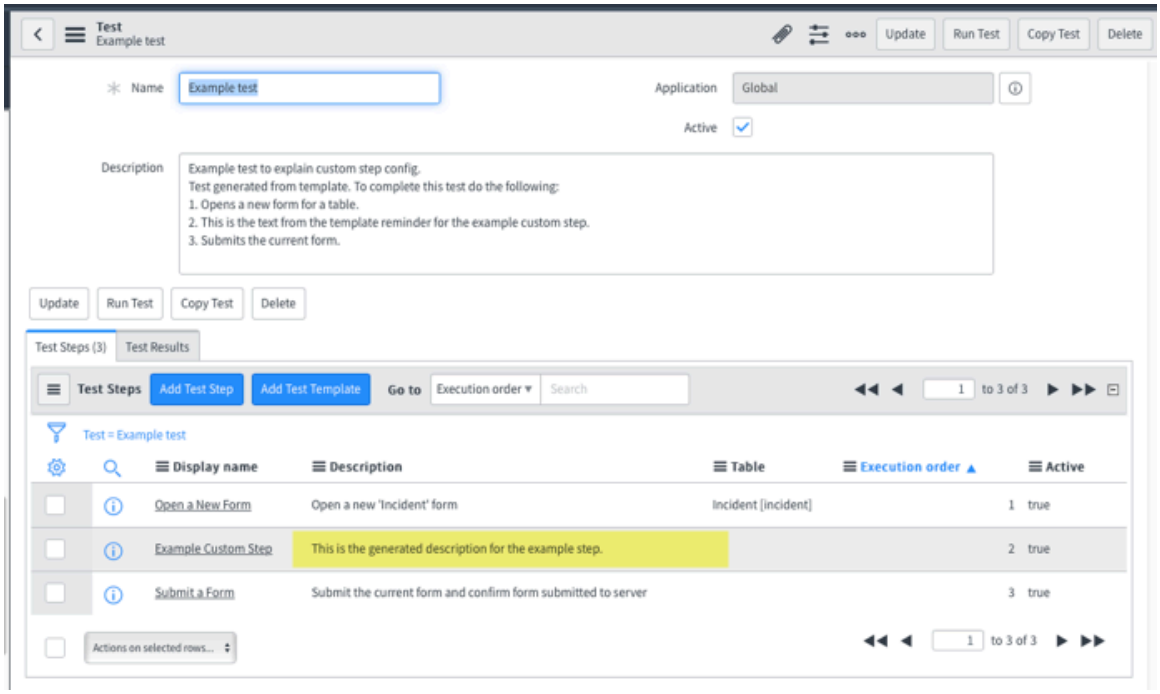


Description generation script example

Here is a portion of the new record form for a custom step named Example Custom Step.



When a step of this type is included in a test, the generated description appears in the Test Steps related list.



Step execution scripts

In a step configuration record, the step execution script field determines what a step with this configuration does when it runs.

Step inputs

The input variables to a step are determined by the inputs related list in the step configuration record. The *`inputs`* parameter to `executeScript()` gives the script access to these variables. For example, if the inputs related list contains two records, *`var1`* and *`var2`*, the script can reference *`var1`* with the expression `inputs.var1` and can reference *`var2`* with `inputs.var2`.

Step outputs

The output variables to a step are determined by the outputs related list in the step configuration record. The *`outputs`* parameter to `executeScript()` gives the script access to these variables. For example, if the outputs related list contains two records, *`out1`* and *`out2`*, the script can reference *`out1`* with the expression `outputs.out1` and can reference *`out2`* with `outputs.out2`.

Step result

The *`stepResult`* parameter provides access to an API that controls whether the step passes or fails. It also determines the message the step writes to the log.

The method `stepResult.setSuccess()` causes the step to succeed. The method `stepResult.setFailed()` causes the step to fail.

The method `stepResult.setOutputMessage()` sets the message to write to the log when the step succeeds or fails. It takes one parameter: the string to write to the log. If the script calls `stepResult.setOutputMessage()` more than once, the most recent value set overwrites any previous value.

Example: Record Query step execution script

```
   (function executeStep(inputs, outputs, stepResult) {
        if (gs.nil(inputs.table)) {
           stepResult.setOutputMessage(gs.getMessage("The '{0}'
input variable was not specified",
               'table'));
        stepResult.setFailed();
         return;
   }
   var query = new GlideRecord(inputs.table);
   query.addEncodedQuery(inputs.field_values);
   query.query();
   if (!query.next()) {
        stepResult.setOutputMessage(gs.getMessage("No records
matching query:\n{0}",
            inputs.field_values));
         stepResult.setFailed();
   } else {
        stepResult.setSuccess();
        outputs.table = inputs.table;
        outputs.first_record = query.getUniqueValue();
        stepResult.setOutputMessage(gs.getMessage("Found {0}
{1} records matching query:\n{2}",

[query.getRowCount(),
                                                inputs.table,

inputs.field_values]));
   }
   }(inputs, outputs, stepResult));
```

Example: Custom scripted step configs

```
   ((function executeStep(inputs, outputs, stepResult, timeout)
{
// Waits up to the timeout for some asynchronous logic to
finish
// This script checks for completion once a second for up to 60
seconds
var counter = 1;
// Try for up to 60 seconds
while (counter <= timeout) {
 // If the asynchronous logic is finished, return "true" to
pass the step
 // isMyAsyncLogicFinished() can be replaced with any
asynchronous event that needs to be tested
 if (isMyAsyncLogicFinished()) {
  stepResult.setOutputMessage("Success!");
  stepResult.setSuccess();
  return;
 }
 // Wait one second, and log the total number of seconds waited
```

```
 gs.info("Waited " + counter + " seconds for asynchronous logic
to finish");
 sn_atf.AutomatedTestingFramework.waitOneSecond();
 counter++;
}
// If this point is reached, the retry loop ran out of tries;
return false to fail the step
stepResult.setOutputMessage("FAILURE: Timed out after waiting
for " + timeout + " seconds");
stepResult.setFailed();
}(inputs, outputs, stepResult, timeout));
```

Note:
The above example can also be used for Run Server Side script by replacing `stepResult.setSuccess()"` and `stepResult.setFailed()` with `return true` and `return false`.

Step description generation script

In a step configuration record, the step description generation script field determines the step description that the system generates when a step of this type is added to a test.

For an example showing how where the description generated by this script appears, see Description generation script example.

Step

The *step* parameter to `generateDescription()` gives the script access to the step object, which it turn gives access to the input variables as defined in the step configuration record. (Input variables are defined in a related list.)

For example, if – in a step config record – the inputs related list contains two records: *var1* and *var2*, the script can reference *var1* with the expression `step.inputs.var1` and can reference *var2* with `step.inputs.var2`.

Example: Record Query description generation script

```
   (function generateDescription(step) {
   var td = GlideTableDescriptor.get(step.inputs.table);
   if (!td) {
        gs.log("Invalid table name in test step: " +
step.inputs.table);
        return gs.getMessage("Set field values");
   }
   var descriptionGenerator = new
ATFStepDescriptionGenerator();
   var description = gs.getMessage("There should be at least
one record in '{0}' matching " +
                   "a query of\n{1}",
                   [step.inputs.table.getDisplayValue(),

descriptionGenerator.getConditionDescription(step.inputs.table,
step.inputs.field_values)]);

   return description;
```

```
})(step);
```

Add output variables to scripted steps

Execute the following steps to add additional outputs in Run Server Side Script and Custom Scripted StepConfig test steps.

Adding outputs in Run Server Side Script test step

Modify the test scripts of Run Server Side Script test step to create additional outputs of your choice.

Before you begin

Role required: admin or atf_test_admin

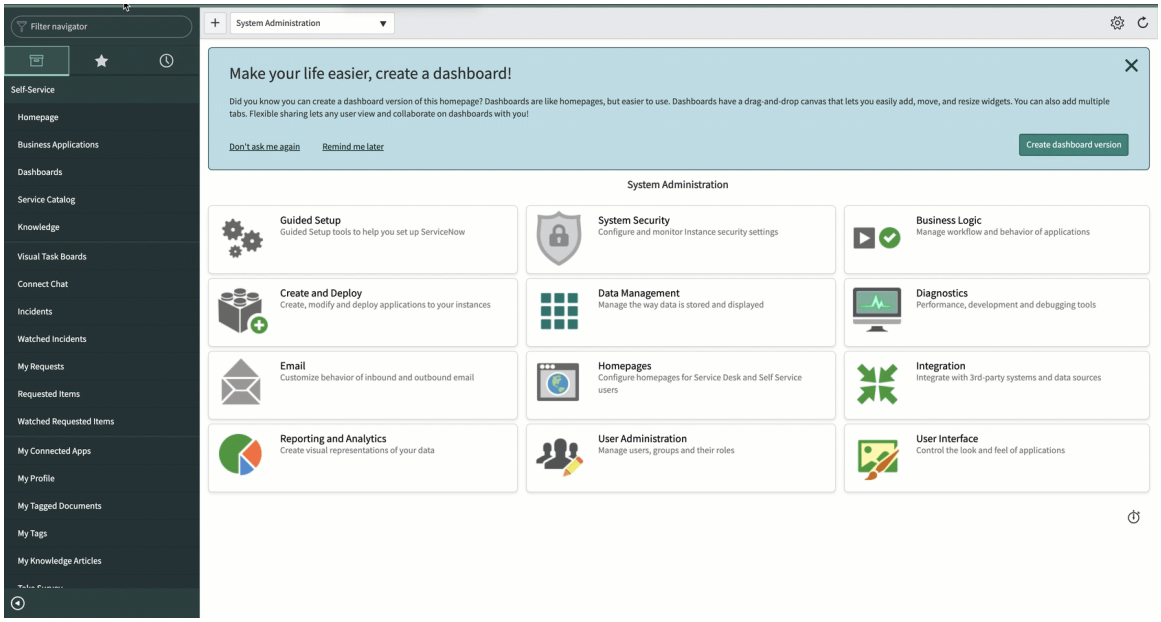
Procedure

1. Navigate to **All** > **Automated Test Framework (ATF)** > **Administration** > **Step Configurations**.
2. Search and select Run Server Side Script.
   The read-only Test Step Config form shows up.

   Note:
   Although the form is read-only, new output variables can be created.

3. Scroll down to the Output Variables related list.
   The list of default output variables shows up.
4. Click **New** to create a new output variable.

Field	Input Value
Type	Type of output variable
Application	Scope of the user
Label	User-facing name of the output variable
Column name	Variable name used in the script
Max length	Length of the data type. **Note:** This field doesn't show up for all data types.



The new output variable gets added to the Output Variable related list.

5. Navigate to **Automated Test Framework (ATF)** > **Tests**.
6. Select the test where you want to implement the new output variable.
7. Click **Add Test Step**.
8. Search and select Run Server Side Script test step.
9. Follow the instructions to change outputs mentioned in the **Test script**.

```
outputs.<column_name> = "<desired value>";
```

10. Click **Submit**.
    The newly created output variables are now ready to be used in any subsequent steps of the test.

Adding outputs in Custom Scripted StepConfig test step

Copy the Custom Scripted StepConfig test step and customize the copied version by adding additional outputs.

Before you begin

Role required: admin or atf_test_admin

Procedure

1. Navigate to **All** > **Automated Test Framework (ATF)** > **Administration** > **Step Configurations**.
2. Search and select Custom Scripted StepConfig.
   The read-only Test Step Config form shows up.

> **Note:**
> Since the form is read-only, you must copy the test step to customize it to add more output variables.

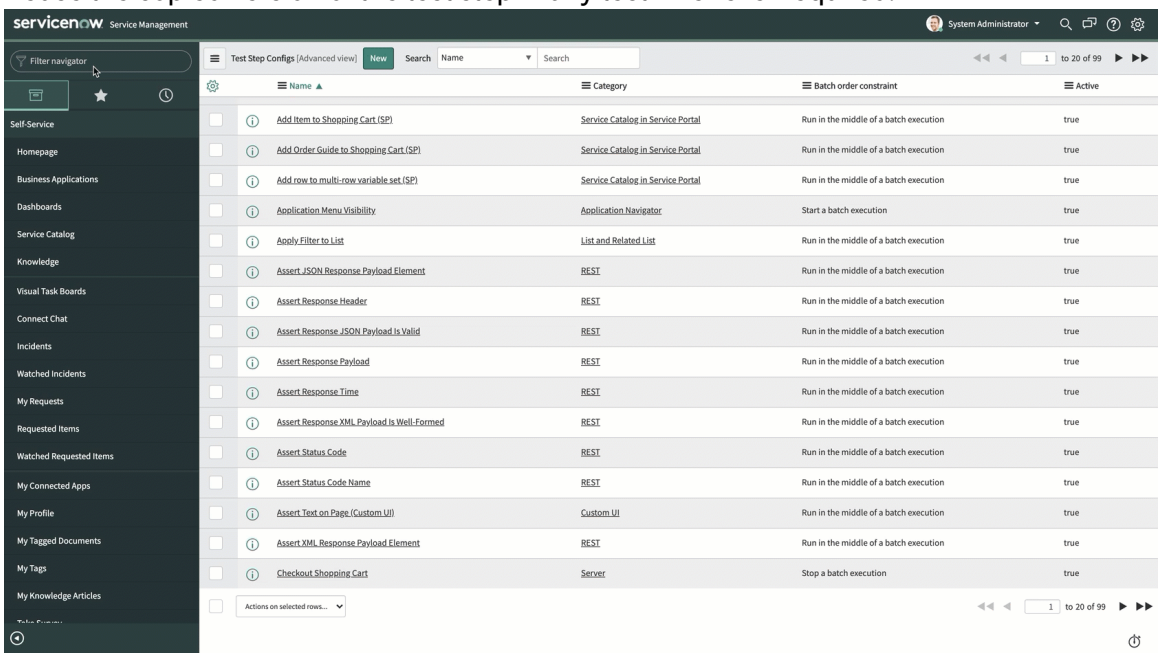
3. Select **Copy** to have a copied version of the test step.

> **Note:**
> The copied version is no longer read-only.

4. Add additional output variables in the copied version by implementing the following steps:
   a. Select **New** under Output Variables related list.
   b. Modify **Step execution script** to add more output variables.
   See Adding outputs in Run Server Side Script test step to add more output variables.

> **Note:**
> You can use these steps to customize the test step only in the copied version.

5. Reuse the copied version of the test step in any test whenever required.



Test templates

The Test Templates module opens a list of available templates. From this module, you create, view, and edit test templates.

To view or edit a test template, click the row for the template you want. For more information, see Edit automated test steps template.

For information how to add a new template, see Create an automated test steps template. For information on how to use a template when creating a test, see Add a predefined list of steps (template) to an automated test.

Automated Test Template record

The Test Template record contains information about one test template.

Fields

Field / Element	Description
Name	The name of this test template.
Application	Application scope in which the system runs this test or test suite.
Test Template	The tests to include in this template.
Description	(Optional) Enter a description to identify the purpose of this test template.

Step configuration categories

The Step Configuration Categories module opens a list of records specifying the step categories on the Add Step dialog. From this module, you can add, delete, and edit these categories.

Categories are used for filtering the step list in the Add Step dialog. For more information, see Category field example.

Test step config category form

On the Test Step Config Category form, you specify a retention policy for a set of records on a given test results table.

Fields

Field / Element	Description
Name	The name for this step config category.
Step Environment	The step environment for this step config category.
Display name	The category name that appears in the middle column of the Add Test Step dialog when this category is selected. See an example in Step Config Category Display name.
Application scope	The application scope to which this policy applies.

Table cleanup

The Table Cleanup module opens a list of records specifying the retention policies for test result and test suite result tables and the records within them. From this module, you can view and modify these policies.

By default, the system deletes system records related to test results and test suite results 30 days after creation. To modify the retention policies for a table and its records, click the table for which you want to modify policies. For more information, see Modify data retention policy for ATF test results.

Note:
Table cleanup policies are platform-specific policies. See Table cleaner for more information.

Autoflush form

On the Auto Flush form, you specify a retention policy for a set of records on a given test results table.

Fields

Field / Element	Description
Tablename	The table containing the records to which the policy applies.
Matchfield	The field for which the system monitors duration.
Age in seconds	The amount of time (in seconds) the system wait before deleting the records.

Fields (continued)

Field / Element	Description
Active	**True** if this policy is active. Otherwise, **false**.
Application scope	The application scope to which this policy applies.
Cascade delete	If checked, the system deletes all matching records plus any records referring to them. If unchecked, the system deletes matching records, but not records referring to them.
Conditions	The filter conditions defining the records in this table to which the policy applies.

Note:
Table cleanup policies are platform-specific policies. See Table cleaner for more information.

Step environments

A test step environment specifies where the step executes (for example, server versus browser). In this release, custom step configs can use only the Server-Independent environment.

In this release, you cannot add custom test step environments.

Deploying applications

Deliver your application to users by publishing it to a live production environment.

Deploying applications on the Next Experience

Managing application deployments using Pipelines and Deployments

Use Pipelines and Deployments to review and publish applications built in App Engine Studio.

Manage deployments using AEMC

Use App Engine Management Center (AEMC) dashboard to view multiple pipelines and manage applications at all stages of deployment.

Managing app deployments using Pipelines and Deployments

Use Pipelines and Deployments to review and publish applications built in App Engine Studio.

Managing deployments using pipelines in AEMC

Use App Engine Management Center (AEMC) dashboard to view multiple pipelines and manage applications at all stages of deployment.

Deploying applications in the Core UI

ServiceNow application repository

The ServiceNow Application Repository is a central location for all scoped applications that are published by all ServiceNow customers. After you develop and test a custom application, you can make the application available to company instances by publishing it to this repository.

System update sets

An update set is a group of configuration changes that can be moved from one instance to another. This feature enables administrators to group a series of changes into a named set and then move them as a unit to other systems for testing or deployment.

ServiceNow application repository

The ServiceNow Application Repository is a central location for all scoped applications that are published by all ServiceNow customers. After you develop and test a custom application, you can make the application available to company instances by publishing it to this repository.

System update sets

An update set is a group of configuration changes that can be moved from one instance to another. This feature enables administrators to group a series of changes into a named set and then move them as a unit to other systems for testing or deployment.

System update sets

An update set is a group of configuration changes that can be moved from one instance to another. This feature allows administrators to group a series of changes into a named set and then move them as a unit to other systems for testing or deployment.

Note:
When an update set is backed out, there is an OOB business rule that will delete sys_upgrade_state record on customer update deletion. This is an expected behavior.

An update set is an XML file that contains:

- A set of record details that uniquely identify the update set.
- A list of configuration changes.
- A state that determines whether another instance can retrieve and apply configuration changes.

Update sets track changes to applications and system platform features. This allows developers to create new functionality on a non-production instance and promote the changes to another instance.

Warning:
Update sets allow moving changes between instances that may be running different family release versions and different features. You can always load an update set created on an older family release on an instance running a newer family release. Loading an update set created on a newer family release on an instance running an older family release requires additional testing to determine compatibility. Updates from newer family releases may not produce the same functionality when moved to older family releases. In extreme cases, newer family release updates may cause outages or data loss on an older family release instance. Where possible, avoid moving updates from newer family releases to older family releases. Similar constraints apply to moving updates between instances running different versions of ServiceNow Store apps.

System properties

Administrators can exclude system properties from update sets by making them private. Keeping system properties private prevents settings in one instance from overwriting values in another instance. For example, you may not want a system property in a production instance to use a particular value from a development instance. See Add a system property.

Applications

Application developers have additional options with update sets such as:

- Create an update set for a specific version of an application.
- Specify which application tables to track in update sets.

Update set tables

Each update set is stored in the Update Set `[sys_update_set]` table, and the customizations that are associated with the update set, which are entries in the Customer Update `[sys_update_xml]` table, appear as a related list on the update set record.

When a tracked object is customized, a corresponding record is added or updated in the Customer Update `[sys_update_xml]` table and is associated with the user current update set. The associated application file properties are tracked and transferred along with the customized object in a single update record. A corresponding record is also added to the Versions `[sys_update_version]` table.

The Customer Update table contains one record per customized object, per update set. The Versions table contains one record per change to a customized object.

- Administrators can compare two versions and revert to a specific version of an object.
- Administrators can suppress versions for specific tables.
- Administrators can specify fields on tracked tables that you can change without skipping updates to the rest of the record (exclude the field from the update).

Note:
Do not directly modify Customer Updates `[sys_update_xml]` records.

Customizations tracked by update sets

Update sets can track customizations to application tables, fields, and records.

Update sets track customizations under these conditions:

- Where the table has an *update_synch* dictionary attribute.
- Where there is a special handler to track changes to multiple tables.
- Where the administrator has not excluded a field from updates.

In general, update sets capture configuration information but not task or process data. For example, update sets track service catalog item definitions and related configuration data like variables and variable choices. However, if you test the service catalog by placing orders, update sets do not track order requests, items, and catalog tasks.

Update sets have a limited capacity to transfer data as application files. For larger data transfers, export data and import it with an import set or web service.

Do not combine the usage of both Update Sets and the Application Repository for scoped app development. This will result in numerous issues, including skipped changes, commit errors, and more. Once you have installed an application from the Application Repository, you must continue to develop and publish to the Application Repository for all future development. If you decide to develop an application using update sets, you must continue to use that method exclusively.

update_synch attribute

To see the list of tables where customizations are tracked, navigate to **System Definition** > **Dictionary** and filter on *attributes CONTAINS update_synch*.

> **⚠ Warning:**
> Do not add the `update_synch` attribute to a dictionary record. When improperly used, this attribute can cause major performance issues or cause the instance to become unavailable. Because of this, the `update_synch` attribute is not accessible to customers.

A default rule blocks the use of the `update_synch` attribute on a table for which it is not predefined to avoid the following issues:

- Some core tables require special update handling because they represent information on multiple tables. When the `update_synch` attribute is added to these tables, duplicate update records are created, causing major conflicts that are difficult to troubleshoot and repair.
- Using the update_synch attribute to migrate data records between instances can cause performance issues, because it is not intended for this purpose. To migrate data, use an instance-to-instance import.

  See Import sets.

Special handlers

Some changes require special handlers because they represent information on multiple tables. These changes are packaged into one update set entry so that all records are properly updated when the customization is committed. The following changes are tracked with special handlers:

- Workflows
- Form sections
- Lists
- Related lists
- Choice lists
- System dictionary entries
- Field labels

Warning:
The form sections, lists, related lists, choice lists, and field labels special handlers delete and reinsert records. This might cause unexpected results and data loss if there are fields referencing the tables.

Choice lists

Update sets store both new and updated choice options as separate records in the Update Version `[sys_update_version]` and Customer Update `[sys_update_xml]` tables. For example, you create a new Activity `[u_activity]` table that extends the Task table. You then add a new choice option to the Task state field that is only visible for your extended table (for example, *My State*).

When you publish these changes as an update set, the update only contains update and version records for the choice you added to the u_activity table. The choice options in the task table are unaffected.

Warning:
Do not use large choice lists in update sets. Doing so leads to excessively long update set commits.

Dictionary changes

Usually, using update sets prevent you from applying dictionary changes that result in data loss. Blocked dictionary changes include:

- Removing tables
- Changing a column data type

Update sets do not track the removal of tables from the system dictionary. Instead, customers must manually remove tables from the target instance. While update sets track data type changes, the target instance skips any change that results in data loss and instead adds a log message about the action. Customers can use the log to manually make data type changes on the target instance.

Note:
Update set previews do not check for type mismatch problems since the target instance skips changes resulting in data loss. Also, using update sets to delete a column from a table can cause data loss in certain circumstances. If there is data in the column on the target instance, that data is deleted, as well as the column itself, when the update set is committed. A warning message appears if you attempt to commit an update set that deletes a column. The message states that there are one or more delete updates that cause the data to be deleted, and it specifies what delete updates there are.

Homepages and content pages

Homepages and content pages are not added to update sets by default. Add pages to the current update set by unloading them.

Important:

The functionality found in homepages, arranging information from your instance to tell a story about your data, is found in dashboards on new instances. On upgraded instances with Next Experience enabled, users can view existing homepages if they have a direct URL, but they can't create or edit them. Responsive dashboards and Analytics Center dashboards take over homepage functionality.

Use the Homepage deprecation help tool to convert the homepages on your instance to responsive dashboards.

For more information, see:

- Dashboards in the Analytics Center.
- Working with responsive dashboards.

Application changes

The system creates a separate update set for each application that only contains changes associated with the application. This ensures that access settings for each application are properly evaluated and applied when committing update set changes.

Default update set

Only one update set can be the default set for any application scope.

To set an update set to be the default set, you set the **Default set** field to true. When you set *Default set = true*, the following actions occur:

- The update set becomes the default update set for its scope.
- The system sets *Default set = false* for all other update sets with the same scope. This ensures that there is only one default update set for each scope.

Global default set

Use the global default update set to make changes to an instance without adding the changes to any user-created update sets. The global default update set is the set where *Default set = true* and application scope is *global*. The global default set (regardless of the *Name* of the set) provides system functionality and should not be changed, deleted, or moved between systems. Use this update set to make changes to an instance without adding the changes to any user-created update sets.

Auto-generated default set

At all times, to ensure that no updates to an instance are lost, the system ensures that there is a default set for the user's current scope. If the system finds that a default update set does not exist (or is marked **Ignored** or **Completed**) for the current scope, then the system auto-generates an update set and sets **Default set = true**.

These are some common cases where the system auto-generates a default update set.

- The very first time that an admin logs in, the system sets the system's global default update set as the administrator's update set. In addition, the application picker sets the administrator's application scope to global.

  If a global default update set does not exist (or is marked **Ignored** or **Completed**), the system creates a new update set for the global application scope and performs the following actions:

- The system sets *Default set* = *true* for the new set.
- The system sets the name of the new set to start with the name of the former default set and appends the next numeral (in the sequence SetName, SetName 1, SetName 2, …, SetName n).
- The system sets the newly created set as the administrator's update set.

- When a user marks the default set for a scope as **Ignored** or **Completed** (not a recommended practice), the system immediately auto-generates a new default set for the scope.
- The system auto-generates a new default update set for a scope when all the following conditions occur:
  - You change application scope.
  - Your preferred update set is **Complete** or **Ignored**.
  - There is no In-Progress default update set for the new scope.

Get started with update sets

Because update sets make changes to an instance, review this information to avoid errors and performance issues. Learn how to plan the update process and avoid common mistakes.

When to use update sets

Deployment option	Good for	Future considerations
Update Sets	Storing changes to a base system or installed application. Storing and applying a particular version of an application. Producing a file for export.	You can manually create update sets to store a particular application version. Use update sets to deploy patches or changes to installed applications. **Note:** Don't use update sets to install applications. Instead, use the application repository or the ServiceNow Store to install applications.
Application Repository	Installing and updating applications on all company instances. Automatically managing application update sets. Restricting access to applications to the same company. Deploying completed applications to end users.	Consider uploading an application to the ServiceNow Store to share it with other users. Allows installation of and update to the latest application version only. Use update sets to store prior application versions. **Note:** If used with team development, publish applications only from a parent instance.

Plan the update process

Before working with update sets, create a standard process for moving customizations from instance to instance using this check list:

1. Check that both instances are on the same version. Customizations may not work if they rely on code that has changed between versions.
2. Determine the changes to make in a single update set. Complete your update sets as you finish small to medium-sized tasks. As update sets get larger, it becomes harder to review them, takes longer to identify changes within them, increases the risk of conflicts with other update sets, and takes more time to preview and commit them. This is especially true if the update sets contain schema changes or revisions to large workflows or if the set has to be backed out.
3. Confirm that all base system records have matching sys_id fields. Some base system records are created on an instance after provisioning and don't match between different instances, leading to problems with update sets. The best way to avoid this issue is to:
   - Provision production and non-production instances.
   - Clone the production instance onto the non-production instance.
4. Identify a common path for update sets to move from instance to instance and maintain that model. Never migrate the same update set from multiple sources. Move update sets from dev to test and then from test to production.
5. Plan for when to commit the update sets to production. Avoid committing an update set to a production instance during business hours. The instance may perform more slowly while the update set applies. Rest assured, this slower performance is temporary.
6. Make sure update set names are clear. Create a naming convention to coordinate changes from multiple developers and to reference when committing the changes to another instance.
   - If update sets are being generated as fixes for problems, consider including the problem ticket in the name (for example, **PR10005 - Duplicate Email Issues Fix**).
   - If you need more than one update set to address a problem, include a sequence number in the naming convention. Doing so helps ensure that update sets are applied in the order that they were created (for example, **PR10005 - Duplicate Email Issues Fix** and **PR10005.2 - Duplicate Email Issues Fix**).
7. Understand the following about update sets:
   - What records are generated.
   - Which customizations are tracked.
   - Which dictionary changes are valid.
   - Which customizations can be backed out (reversed) after applied.
8. Before making any customizations, double-check that the correct update set is selected.

Working with update sets

Review this information to avoid errors and performance issues.

- Don't delete update sets. If an update set is deleted, any updated records may be overwritten in the next update.
- Don't include the **system_id** field from the ldap_server_config record in an update set. An update set from a working configuration points to the wrong system_id node for the target instance and doesn't work.
- Don't back out the Default update set. This action damages the system.
- Never change the **Update Set** field value (update_set) in a Customer Update record (sys_update_xml). If a customization is made in the wrong update set, take the following action:

1. Switch to the desired update set.
2. Modify the object (record) that was originally changed. You can make a trivial change, such as adding a field.
3. Save the record.
4. Back out the change just performed, and then save the record again.

   This action ensures that the latest version of the object is included in the desired update set and prevents duplicate updates for the same object in a single update set.

- Don't mark an update set as **Complete** until it's ready to migrate. After an update set is complete, don't change it back to **In progress**. Instead, create another update set for the rest of the changes, and make sure to commit them together in the order that they were created. Naming conventions may help in this case (for example, Performance Enhancements and Performance Enhancements 2).
- Don't manually merge updates into an update set. Use the Merge Update Sets module. This tool compares duplicate files between update sets and selects the newest version.
- If a committed update set has a problem in the test instance, build the fix in another update set in the development instance. Commit this set to the test instance, and then make sure both sets are migrated to the production instance and committed in the order they were made.
- Always preview an update set before committing it.
- Set completed update set on the production instance to **Ignore**. This state ensures the update set isn't reapplied when cloning the instance.
- Keep a to-do list of manual changes and data loads that must be completed after an update set is applied.
- Don't make too many changes at one time. Verify that the correct changes have been made incrementally.
- You can't change a single update to update across multiple domains (that is, global and TOP domains). This function isn't supported in the ServiceNow AI Platform.

To create an update set see Create and select an update set as the current set.

Update set administration

Manage how update sets store, retrieve, preview, and apply configuration changes between instances.

Administrators have the following options with update sets.

- Create an update set to store local changes.
- Select the current update set to store local changes.
- Commit an update set to prepare it for distribution.
- Report on the contents of update sets.
- Compare update sets to determine what differences they contains.
- Merge separate update sets into a single update set.
- Create an external file from an update set.
- Retrieve update sets from remote instances.
- Apply retrieved update sets.

- Back out changes applied from an update set.
- Set system properties related to update sets

Grant access to the update set picker

The update set picker allows users to choose an update set for making and tracking customizations. By default, only administrators can use the update set picker. You can grant access to additional users.

Automatically preview retrieved update sets

By default, the system automatically previews update sets as soon as it has retrieved them. To turn off this behavior, set the system property **glide.update_set.auto_preview** to **false**: in the navigator filter, type **sys_properties.list** then navigate to the **glide.update_set.auto_preview** property and edit the **value** field.

Track an application table

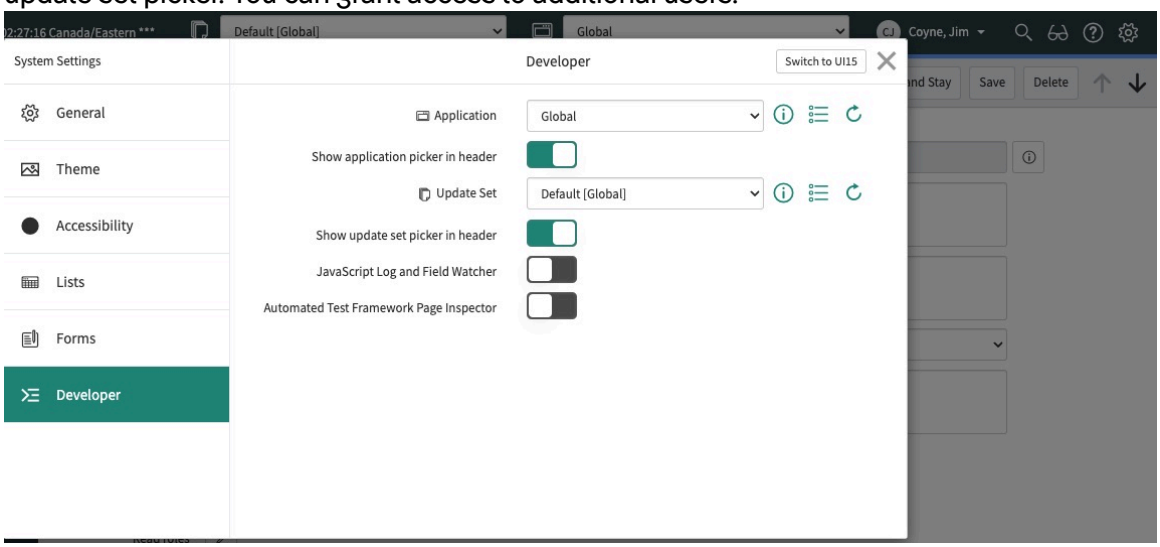
Application developers can track application changes in an update set to save or distribute a particular version of an application. During table creation, set **Extends Table** to Application File [sys_metadata].

Grant access to the update set picker

Enable a non-administrative user to use the update set picker.

Before you begin
Role required: admin

About this task
The update set picker appears on the Settings panel. The picker allows users to choose an update set for making and tracking customizations. By default, only administrators can use the update set picker. You can grant access to additional users.



Procedure

1. Grant the user role read access to the Update Set table [sys_update_set].
2. Enable users to see the update set picker on the Settings panel.

a. Add a system property *glide.ui.update_set_picker.role* to the System Properties table.

b. Set the value of *glide.ui.update_set_picker.role* to the role for which you want to give access.

Overwrite customizations during an upgrade

Specify which customized objects you want to replace during the next upgrade. By default, the upgrade process skips changes to customized objects.

About this task

The systems tracks the configuration changes you make such as modifying the dictionary record for a table or field. Each configuration change you make has a corresponding record in the Customer Update `[sys_update_xml]` table where the **Replace on upgrade** field is set to false. You may want to overwrite your customizations with the next software version. For example, you may change a script to implement a temporary workaround for a problem that is fixed in the next version. You would want to overwrite your workaround when upgrading to the next version to ensure that you receive any future enhancements to the script.

Procedure

1. Open the customized object (for example, the *ArrayUtil* script include).
2. Right-click the header and select **Show Latest Update**.
3. Configure the form to add the **Replace on upgrade** field, if necessary.
4. Select the **Replace on upgrade** check box and click **Update**.
   The customized object will be replaced on the next upgrade.

Creating, testing, and moving customizations

Use these procedures to create, test, and move customizations from a development system to a production system.

Three-step import process

A common process for developing customizations with update sets involves moving changes from development, to test, to production instances.

1. Create an update set on the development instance.
2. Make customizations and changes on the development instance.
3. Mark the update set as Complete.
4. Log in to the test instance and retrieve the completed update set from the development instance.
5. Commit the update set on the test instance, and test customizations thoroughly.
6. If the update set has problems in the test instance, repeat steps 1 - 5 to develop the fix on the development instance with another update set.
7. Identify a common path for update sets to move from instance to instance and maintain that model. Never migrate the same update set from multiple sources. Move update sets from dev to test and then from test to production.
8. Commit the update set on production. If the update set required a fix, commit both update sets in the order they were made.

Two-step import process

If your development environment consists of only two instances, you can combine your development and testing instances into a single staging instance.

1. Create an update set on the staging instance.
2. Make customizations and changes on the staging instance.
3. Mark the update set as Complete.
4. Test customizations thoroughly on the staging instance.
5. If the update set has problems, repeat steps 1 - 4 to develop the fix on the staging instance with another update set.
6. Log in to the production instance and retrieve the completed update set from the staging instance. If the update set required a fix, retrieve both update sets.
7. Commit the update set on production. If the update set required a fix, commit both update sets in the order they were made.

Update set use

These procedures help you manage your customizations and resolve potential collisions before you move them to another instance.

Before using update sets, review Get started with update sets to learn when to use and when not to use update sets, and how to plan the update process and avoid common mistakes. Then, create an update set and use it to make changes on a development instance. You can report on updates, merge update sets, and compare update sets to ensure the desired changes are ready to move.

When the update set is completed, you can transfer the update set to another instance according to your test process. See Update set transfers for details.

Create and select an update set as the current set

Create an update set to store customization changes and select it as the current set.

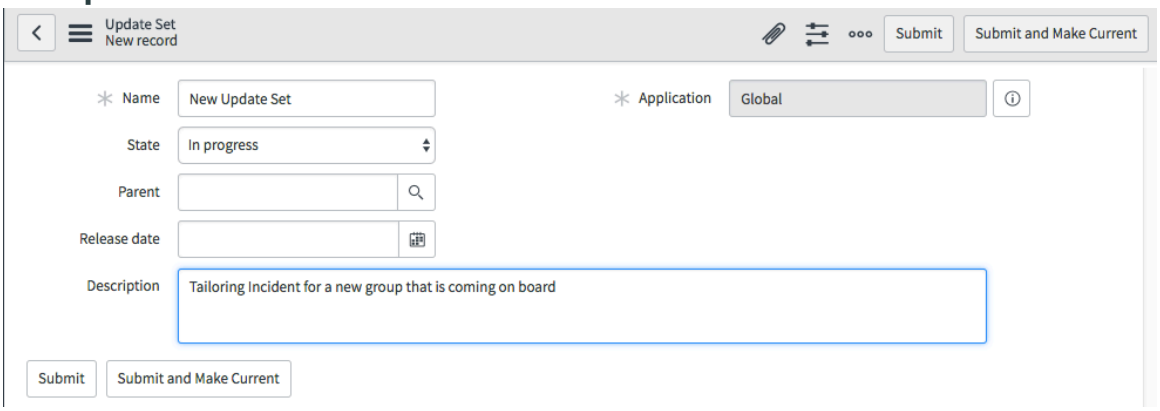
Before you begin
Role required: admin.

About this task
You can select an update set as the current set when you create it, or you can select it later from the Settings panel.

Procedure

1. Navigate to **All** > **System Update Sets** > **Local Update Sets** and click **New**.
2. Complete the form from the fields in the table.
3. Click **Submit** to create the update set.
4. If the picker is enabled and the update set is in the *In progress* state, click **Submit and Make Current** to select the new update set as the target for configuration changes.

New update set



Update Set Fields

Field	Description
Name	Enter a unique name for the update set. You can use naming conventions to organize update sets. For example, add the problem number to the name of the update that fixes it, identify the application scope, or use sequence numbers to keep track of the order in which update sets need to be committed.
State	Select **In progress** for a new update set. Selecting an *In progress* update set tracks customizations in the update set. The update set picker only displays *In progress* update sets. Select **Completed** only when you are certain that the update set is complete. After it is marked *Completed*, do not set it back to *In progress*. Instead, create a new update set with further customizations, and make sure to commit the update sets in the order that they were marked *Completed*. Use *Completed* update sets to transfer changes from one instance to another. Select **Ignore** when you are no longer working on an update set but do not want it to be transferred to another instance. You should always set *Completed* update sets on the production instance to *Ignore*. This state ensures the update set is not committed again when cloning the instance. Update set picker only displays *In progress* update sets. See Select the current update set in Unified Navigation. Select **Completed** only when you are certain that the update set is complete. After it is marked *Completed*, do not set it back to *In progress*. Instead, create a new update set with further customizations, and make sure to commit the update sets in the order that they were marked *Completed*. Use *Completed* update sets to transfer changes from one instance to another. Select **Ignore** when you are no longer working on an update set but do not want it to be transferred to another instance. You should always set *Completed* update sets on the production instance to *Ignore*. This state ensures the update set is not committed again when cloning the instance.
Release date	Enter the date on which you plan to release the update set.
Application	Populates the application scope that is currently selected in the Application picker. All changes in the update set apply only to the current scope.
Description	Enter a description of the update set.

Select the current update set in Unified Navigation

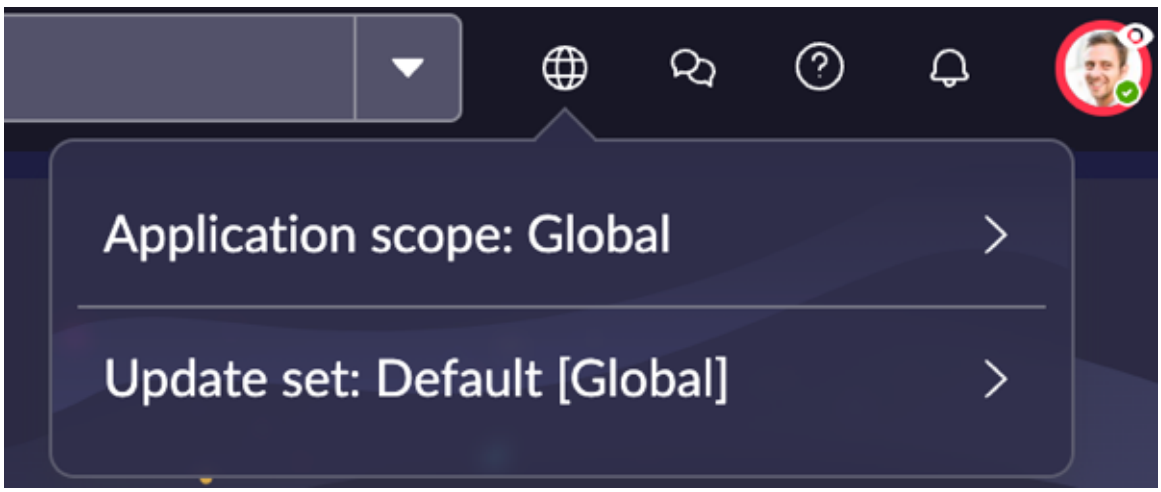
You can change the current update set at any time, using the update set picker in Unified Navigation.

Before you begin
Role required: admin.

About this task
When you change your application scope, the system automatically switches the current update set to be the application's default update set. However, you can choose a different update set.

Procedure

1. Select the Application scope icon ( ) in Unified Navigation.



2. Select the update set you want to make current from the list available in the **Update set** field, using **Filter** if needed.

The update set you selected is confirmed with a check mark icon.

3. **Optional:** If the update set you want isn't in the list, you can create an update set by selecting the plus icon (+).

What to do next

The update set picker is part of the Next Experience picker. For more information, see Exploring Next Experience pickers.

For more information about application scoping, see Application scope.

View customizations and compare with current version

View the customizations that make up an update set and compare the update to the current version.

Before you begin

Role required: admin

About this task

The Customer Update *[sys_update_xml]* table contains one record per customized object.

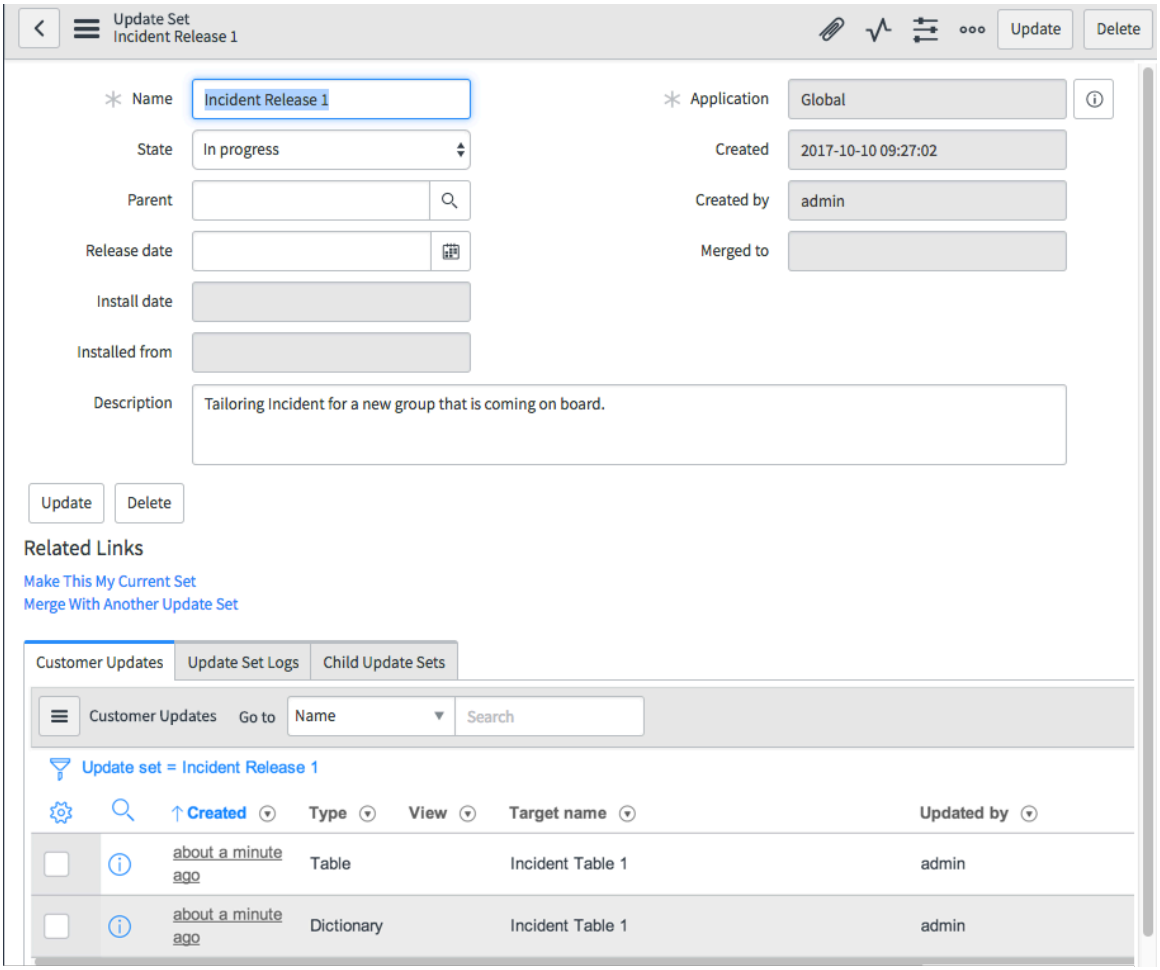
The customer update record specifies:

- The update set containing the customized object.
- The type of action applied to the customized object.
  - INSERT
  - INSERT_OR_UPDATE
  - UPDATE
  - DELETE
- The type of object customized.
- The target object of the update.
- The sys_id of the customized object (if it is a change to a particular record).
- The user who customized the object.
- The date and time the object was customized.

Procedure

1. Navigate to **All** > **System Update Sets** > **Local Update Sets**.
2. Click the update set name.
3. View the *Customer Updates* related list.

You can compare any update to the current version. Right-click the update record and select **Compare to Current**.



Related topics

- Compare two versions of an article
- Resolve conflicts for an individual record

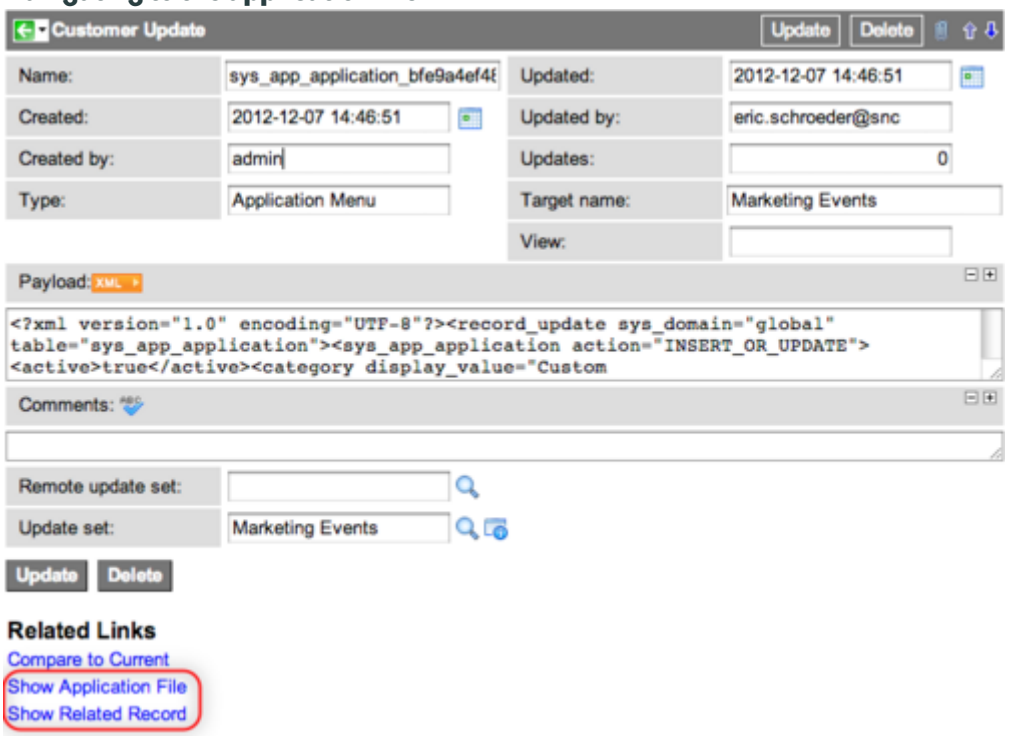
Navigation between records

You can navigate between a customer update record and the customized object or the application file for the object.

Navigate from an update record to:

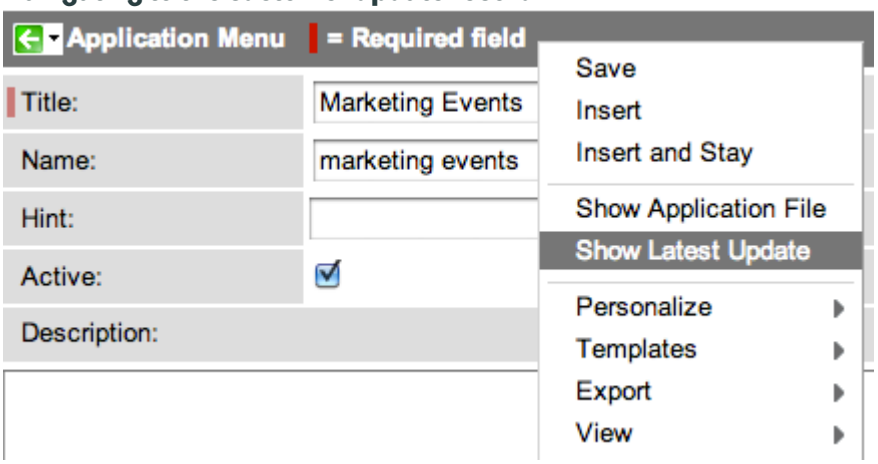
- The customized object, such as the application menu record: Click the **Show Related Record** related link.
- The application file record for the object: Click the **Show Application File** related link.

Navigating to the application file



To navigate from a customized object or an application file to the current customer update record: Click the form header and selecting **Show latest Update**.

Navigating to the customer update record



View a report on customizations and configuration changes

The base system provides reports for changes to the Incident table and changes by the current user.

Procedure

1. Navigate to **All** > **Reports** > **View / Run** and locate the *Customer Update* section.
2. Run any of the available reports or create a new report.

The following reports are available:

- *Application Changes (Incident)*: Displays all changes made to the Incident table. Select a different table and run the report again to view all changes to another application.
- *My Changes*: Displays all changes created or updated by the current user, grouped by table name.

Merge update sets

You can merge multiple update sets into a single update set. This capability is supported for backward compatibility with earlier releases of the ServiceNow® platform. The newer batch update sets feature accomplishes the same outcome with a more predictable and robust solution.

Before you begin

Note:
You cannot "unmerge" update sets once they have been merged. To learn more, see Update set batching.

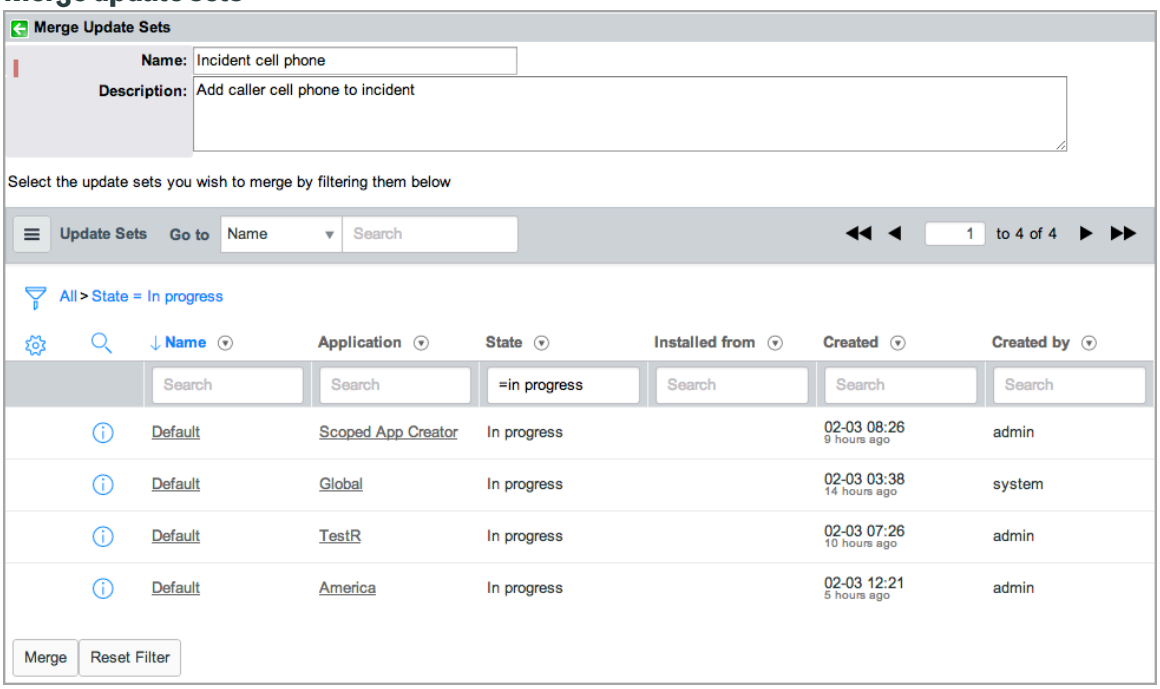
Procedure

1. Navigate to **All** > **System Update Sets** > **Merge Update Sets**.
   By default, the list is filtered to only show update sets that are *In progress*.

   Alternatively, navigate to **System Update Sets** > **Merge Completed Sets**. By default, the list is filtered to only show update sets that are in the *Complete* state. For example, you may want to use this filter after pushing changes or transferring update set from a development to a test instance.

2. Filter the list to show only the update set that you want to merge.
   You can only merge update sets that belong to the same application.

Merge update sets



3. Enter a **Name** for the new update set.
   Updates are moved to this new update set during the merge process.

4. **Optional:** Enter a **Description** for the update set.
5. Click **Merge**.
6. In the confirmation dialog box, click **OK**.
   - The new update set is created.
   - The most recent change for each object is moved from the original sets to the new set. Only changes that are not merged into the new set remain in the original sets. A message indicates how many updates were moved and how many were skipped. For example, if both update sets modify the Incident form, only the most recent change is moved to the new update set. The other modification remains in its original update set to provide a record of the changes that were not moved.

   Note:
   The system determines which record is the most recent by comparing the **Updated** field for the records, NOT the **sys_updated_on** value in the payload.

7. Verify that the correct changes were moved to the new set by scrolling down to the *Merged Update Sets* related list and opening the old update set records.
8. Delete or empty the original update sets to avoid committing an older change by mistake. The system does not remove updates that were not merged into the new set. Do not move updates "left behind" in old sets into the new set.

Compare local update sets

Administrators can preview local and remote (retrieved) update sets and compare the sets with one another to resolve conflicting changes.

About this task

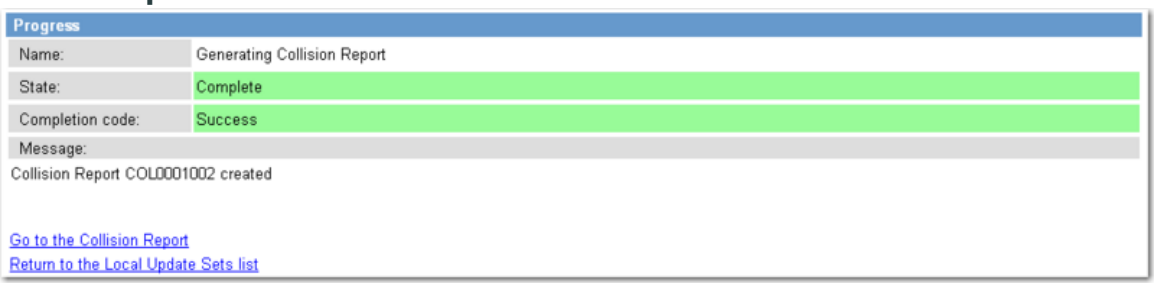
Compare local update sets to identify collisions and ensure that the proper changes are being committed. Resolve all conflicts before moving an update set between instances.

Procedure

1. Navigate to **All** > **System Update Sets** > **Local Update Sets**.
2. Select the check boxes beside the update sets to compare.
3. In the *Action* choice list, select **Compare Update Sets**.

   The progress screen appears as ServiceNow generates the collision report.

Collision report

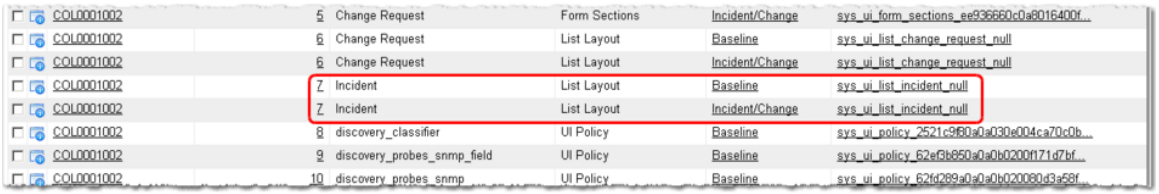


4. Click **Go to the Collision Report** when the report is complete.

   The Update Set Collisions list appears, showing all the changes in the selected sets.

5. Inspect the list for collisions by locating duplicate *Collision Numbers* that show the same change in separate update sets.

Update set collisions



COL0001002	5	Change Request	Form Sections	Incident/Change	sys_ui_form_sections_ee936660c0a8016400f...
COL0001002	6	Change Request	List Layout	Baseline	sys_ui_list_change_request_null
COL0001002	6	Change Request	List Layout	Incident/Change	sys_ui_list_change_request_null
COL0001002	7	Incident	List Layout	Baseline	sys_ui_list_incident_null
COL0001002	7	Incident	List Layout	Incident/Change	sys_ui_list_incident_null
COL0001002	8	discovery_classifier	UI Policy	Baseline	sys_ui_policy_2521c9f80a0a030e004ca70c0b...
COL0001002	9	discovery_probes_snmp_field	UI Policy	Baseline	sys_ui_policy_62ef3b850a0a0b0200f171d7bf...
COL0001002	10	discovery_probes_snmp	UI Policy	Baseline	sys_ui_policy_62fd289a0a0a0b020080d3a58f...

6. Resolve the collision by deleting the unwanted update record from one of the update sets.
   a. Click the link in the *Sys update* column for the unwanted update (`sys_ui_list_incident_null` in the example).
   b. Click **Delete**.

> **Note:**
> You must open the update record to delete the record. You cannot delete the update by selecting the check box for the entry in the Update Set Collisions list and using the *Delete* action. When you delete the update record, the customization is not backed out of the instance. Only the record of the customization is deleted.

Remote update set:
Update set: Default
Update | Delete

7. Run the comparison again to make sure all collisions have been resolved.

Update set collision resolution

A collision is an update that has a newer local update.

The platform detects collisions by comparing the values in the *Name* and *Updated* fields of the customer update record from each update set. If the name matches but there are different update date values, then there is a collision.

When a customer update is moved from one instance to another, it may be re-written to match the target instance. The re-write can involve changing the update name of the customer update and one or more `sys_ids` within the update. The re-writes are done when the record or the

reference field is for a table that uses a coalesce strategy. This ensures that the customer update will be applied to the correct record. For example, if the `sys_dictionary` record for `tablename.fieldname` has `sys_id` `123456789` on instance A and `sys_id` `987654321` on instance B, when a customer update that refers to that record is retrieved from instance A and recorded in the sys_update_xml table on instance B, references to `123456789` are updated to read `987654321`.

Coalesce strategies

Update sets can detect collisions between identical records that you independently create on separate instances. To detect such collisions, the record must have a coalesce strategy based on coalescing columns. Because collision detection depends on uniqueness of tables, the tables must be unique when the coalescing columns are combined. Records that are not listed here will not collide if the same record is created separately on different instances.

Type	Coalescing Columns
atf_input_variable	name, element
atf_output_variable	name, element
dp_data_pattern	source_sys_id
dynamic_attribute	namespaced_name
dynamic_category	namespaced_name
dynamic_category_member	category, attribute
dynamic_choice_override	choice, category, attribute
dynamic_namespace	name
sys_analytics_bucket	sys_scope, bucket_document_id, bucket_table_name
sys_attachment	(uses custom matching logic)
sys_choice_set	name, element
sys_collection	collection, name, join_field
sys_db_object	name
sys_df_data_dictionary	name, element
sys_dictionary	name, element
sys_documentation	name, element, language
sys_index	logical_table_name, col_name_string
sys_module	path
sys_notification_category	name
sys_package	source
sys_package_dependency_m2m	dependency, sys_package
sys_properties	name
sys_report_chart_color	name, element, value
sys_scope_script_access	source_scope, target_scope, script_name
sys_scope_table_access	source_scope, target_scope, table_name

Type	Coalescing Columns
sys_script_validator	internal_type, ui_type
sys_translated	name, element, value, language
sys_translated_text	tablename, fieldname, documentkey, language
sys_ui_form	name, view, sys_domain
sys_ui_list	name, view, sys_domain, element, relationship, parent
sys_ui_message	key, language, code
sys_ui_related_list	name, view, related_list, sys_domain
sys_ui_section	name, view, caption, sys_domain
sys_ui_view	name
sys_user_group	name
sys_user_role	name
sys_wizard	name
ua_table_licensing_config	name

How customer update record names affect collisions

To understand coalescing, it helps to understand how records that do not coalesce work. For most record types, when a customer update is moved to a new instance, the system does not detect collisions for the following reason:

- When you create a record, it receives a unique sys_id. For most record types, the sys_id becomes part of the customer update record name. For example: `sysevent_email_template_9e1998c078b71100a92ecacd80df1d39`.
- Creating an identical record in the same table on another instance produces a customer update record name with a different sys_id. For example: `sysevent_email_template_10b958c8653311005840134572f8e020`

As a result, even though the records might be otherwise identical, the records have different names so the system does not detect the collision.

Coalescing records, in contrast, use the following approach to naming records and determining collisions: The following customer update record types use some or all of their coalescing columns instead of the sys_id in their names.

- sys_dictionary
- sys_documentation
- sys_choice_set
- sys_ui_list
- sys_ui_related_list

The resulting identical record name in each instance helps the system to identify collisions even if the records have different sys_ids.

When a customer update is moved from one instance to another, it may be re-written to match the target instance. The re-write can involve changing the update name of the customer update and one or more sys_ids within the update. The re-writes are done when the record or the reference field is for a table that uses a coalesce strategy. This ensures that the customer

update will be applied to the correct record. For example, if the sys_dictionary record for tablename.fieldname has sys_id "123456789" on instance A and sys_id "987654321" on instance B, when a customer update that refers to that record is retrieved from instance A and recorded in the sys_update_xml table on instance B, references to "123456789" are updated to read "987654321".

Preventing duplicate records

- Transfer data with update sets rather than recreating it on separate instances to ensure the records have the same sys_id.
- Export and import records as XML files to ensure the records have the same sys_id. See Export and import XML files.
- Enable a unique index for the table from the system dictionary. See Table administration.

Note:
The default records included in the baseline system will always have the same Sys ID because the instance imports the records as XML files during instance provisioning.

Mark an update set complete

When you have completed the customizations and compared local update sets to resolve conflicts, mark the update set as *Complete*.

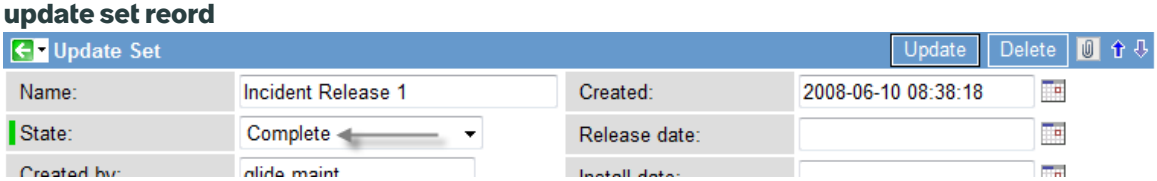
About this task

Mark an update set as *Complete* only when it is ready to migrate. Once an update set is complete, do not change it back to *In progress*. Instead, create another update set for the rest of the changes, and be sure to commit them together in the order that they were created. Naming conventions may help in this case (for example, Performance Enhancements and Performance Enhancements 2).

Procedure

1. Open the update set record.
2. Change the *State* of the update set from *In progress* to *Complete*.
   - The update set is available for other instances to retrieve.
   - No additional customizations are tracked in the update set.

update set reord



Save an update set as a local XML file

Administrators can export an update set as an XML file to save a specific version of an application or set of changes.

Before you begin

Role required: admin

About this task

Typically you create an XML file of an update set when one of the following conditions apply:

- The two instances do not have network connectivity so you cannot retrieve update sets from the remote instance nor create a data source to pull, or import, data directly from the source instance.
- You do not want to provide administrator credentials to the source instance (for example, you do not want to share an administrator password with people outside your company) so you cannot retrieve update sets nor create a data source.
- You want to back up important customizations locally.

The ability to export and import customizations as an XML file is provided by the following UI Actions:

- **Export to XML** on the Update Set [sys_update_set] table.
- **Export to XML** on the Retrieved Update Set [sys_remote_update_set] table.
- **Import Update Set from XML** on the Retrieved Update Set [sys_remote_update_set] table.

The **Export to XML** UI Action on Update Set [sys_update_set] table calls a processor called `UnloadRetrievedUpdateSet`, which transforms a local update set into a retrieved update set, exports the retrieved update set with its related list, and then deletes the temporary update set, if necessary.

Both **Export to XML** UI actions depend on the script include `ExportWithRelatedLists`, which exports a record and manually defined related lists to a single XML file.

Procedure

1. Navigate to **System Update Sets** and click either **Local Update Sets** or **Retrieved Update Sets**.

   Note:
   Retrieved Update Sets must be in a loaded state to be exported.

2. Select an update set that is in the **Complete** state.
3. On the Update Set form, click the **Export to XML** Related Link.
4. Save the XML file.
   An XML file is created. When the file is uploaded to another instance, it appears as a retrieved update set regardless of whether it is local or retrieved on the instance where it is created.

Load customizations from a single XML file

Administrators can load an update set XML file to apply a specific version of an application or set of changes.

Before you begin

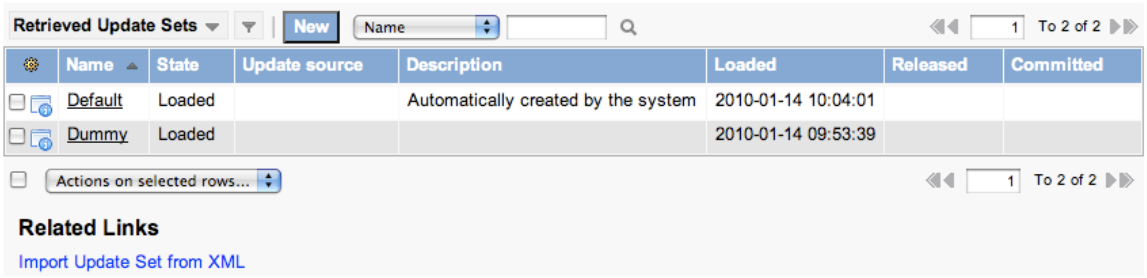
Roles required: admin

Procedure

1. Elevate privileges to the security_admin role.
2. Navigate to **System Update Sets** > **Retrieved Update Sets**.
3. Click the link **Import Update Set from XML**.
4. Click **Choose File** and select an XML file.
5. Click **Upload**.
   The customization is now available as a retrieved update set with state *Loaded*.

6. Follow standard procedure to commit the update set.

Retrieved update sets



Update set transfers

When an update set is completed, you can transfer it between instances to move customizations from development, through testing, and into production.

Warning:
Update sets allow moving changes between instances that may be running different family release versions and different features. You can always load an update set created on an older family release on an instance running a newer family release. Loading an update set created on a newer family release on an instance running an older family release requires additional testing to determine compatibility. Updates from newer family releases may not produce the same functionality when moved to older family releases. In extreme cases, newer family release updates may cause outages or data loss on an older family release instance. Where possible, avoid moving updates from newer family releases to older family releases. Similar constraints apply to moving updates between instances running different versions of ServiceNow Store apps.

Transferring with IP access control

If IP address access control is enabled on the source instance or the source instance resides in a different datacenter than the target instance, complete these tasks before transferring an update set:

1. Contact Customer Service and Support to find out the IP addresses of all application nodes supporting your instance.
2. On the source instance, navigate to System SecurityIP Address Access Control.Add the IP address from step one as an exception.

Transferring with basic authentication

If the source instance has basic authentication turned on for SOAP requests, you must use valid credentials to retrieve update sets.

Transferring with an XML file

You can unload an update set as an XML file and then transfer it to another instance. See Save an update set as a local XML file for details.

Retrieve an update set

Retrieve completed update sets from another instance.

About this task

Warning:
Update sets allow moving changes between instances that may be running different family release versions and different features. You can always load an update set created on an older family release on an instance running a newer family release. Loading an update set created on a newer family release on an instance running an older family release requires additional testing to determine compatibility. Updates from newer family releases may not produce the same functionality when moved to older family releases. In extreme cases, newer family release updates may cause outages or data loss on an older family release instance. Where possible, avoid moving updates from newer family releases to older family releases. Similar constraints apply to moving updates between instances running different versions of ServiceNow Store apps.

Procedure

1. If IP address access control is enabled on the source instance, set up the target instance as an exception.
2. On the target instance, navigate to **System Update Sets** > **Update Sources** and click **New**.
3. Specify the connection settings as described in the table.

Field	Description
Name	Enter a unique name for the instance.
Type	Specify whether the remote instance is a development, test, or UAT instance.
Active	Specify whether the local instance can transfer update sets to the remote instance. You can transfer update sets only to active remote instances.
URL	Specify the URL of the remote instance using the appropriate transfer protocol. Each remote instance record should have a unique URL. Creating duplicate records with the same URL can cause errors. The remote instance must be on the same release family as the local instance. **Note:** You cannot change the URL after the system verifies the connection. Use the *Active* field to deactivate unwanted remote instances.
Username	Enter the user on the remote instance who authorizes transferring update sets to this the instance. This user account must have the admin user role on the remote instance.
Password	Enter the password of the authorizing user.
Short description	[Optional] Enter any other relevant information about the remote instance.

4. Click **Test Connection**.
   - If the connection is successful, a confirmation message appears.
   - If the connection fails, a warning message identifies the cause of the failure.
5. If the connection fails, modify the settings to establish connectivity.

- You must establish connectivity before you can save the connection settings.
- You may want to modify the source instance (for example, change the password).

6. Right-click the form header and select **Save**.
7. Under **Related Links**, click **Retrieve Completed Update Sets**.
   - Any update sets marked as **Completed** are transferred from the source instance to the target instance. Update sets that already exist on the target instance are skipped.
   - The confirmation page provides detailed messages about how many update sets were transferred and how many were skipped.
   - To view retrieved update set, navigate to **System Update Sets** > **Retrieved Update Sets**.

What to do next

If the system property **glide.update_set.auto_preview** is set to **true**, the system automatically starts the preview process after the update set is retrieved. If this property is **false**, you must start the process manually. For more information on the preview process, see Preview a remote update set.

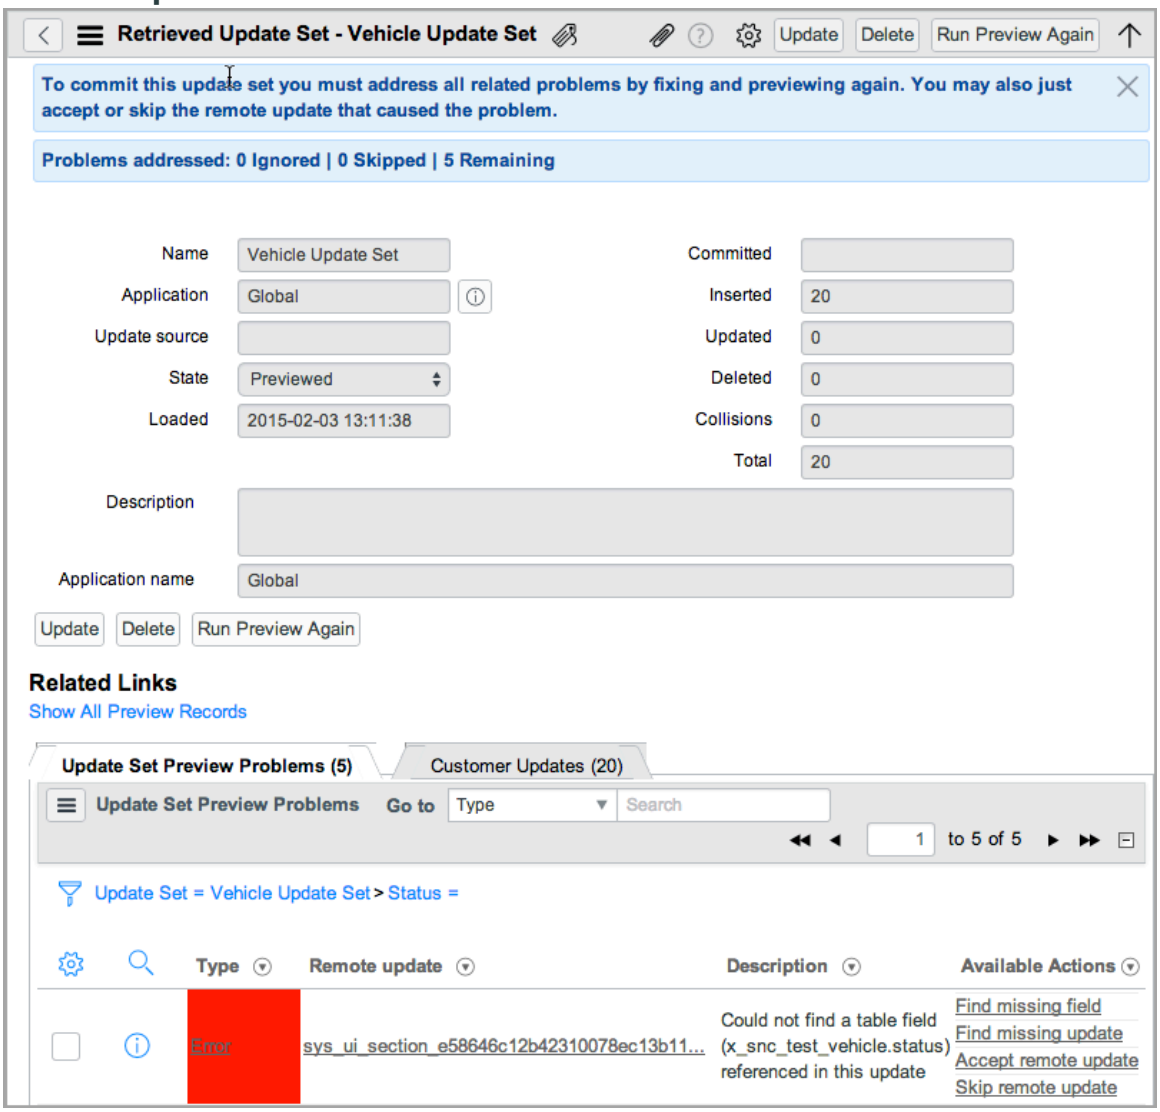
Preview a remote update set

Previewing compares an update set retrieved from a remote instance to updates on the local instance to detect potential problems. You must preview an update set and address all problems before you can commit the update set.

Procedure

1. If the system property **glide.update_set.auto_preview** is set to **true**, the system automatically starts the preview process after the update set is retrieved.
   If this property is **false**, the preview process must be started manually.
   a. Navigate to **System Update Sets** > **Retrieved Update Sets**.
   b. Click **Preview Update Set**.
   For large update sets, the preview process may require a significant amount of time. If necessary, you can cancel the preview process by clicking the **Cancel** button on the progress dialog box.
   The Update Set Preview page shows results and lists problems. Read the information and click **Close**.
2. On the Retrieved Update Set form, make a selection.

Retrieved Update Set form



3. **Optional:** Preview the records.
   a. Open the update set record and click **Show All Preview Records** to make sure the correct updates are being committed.
   b. Open the update set record and click **Run Preview Again** to run the comparisons again.
   c. Review the **Update Set Preview Problems** related list to ensure that the correct updates are being committed.

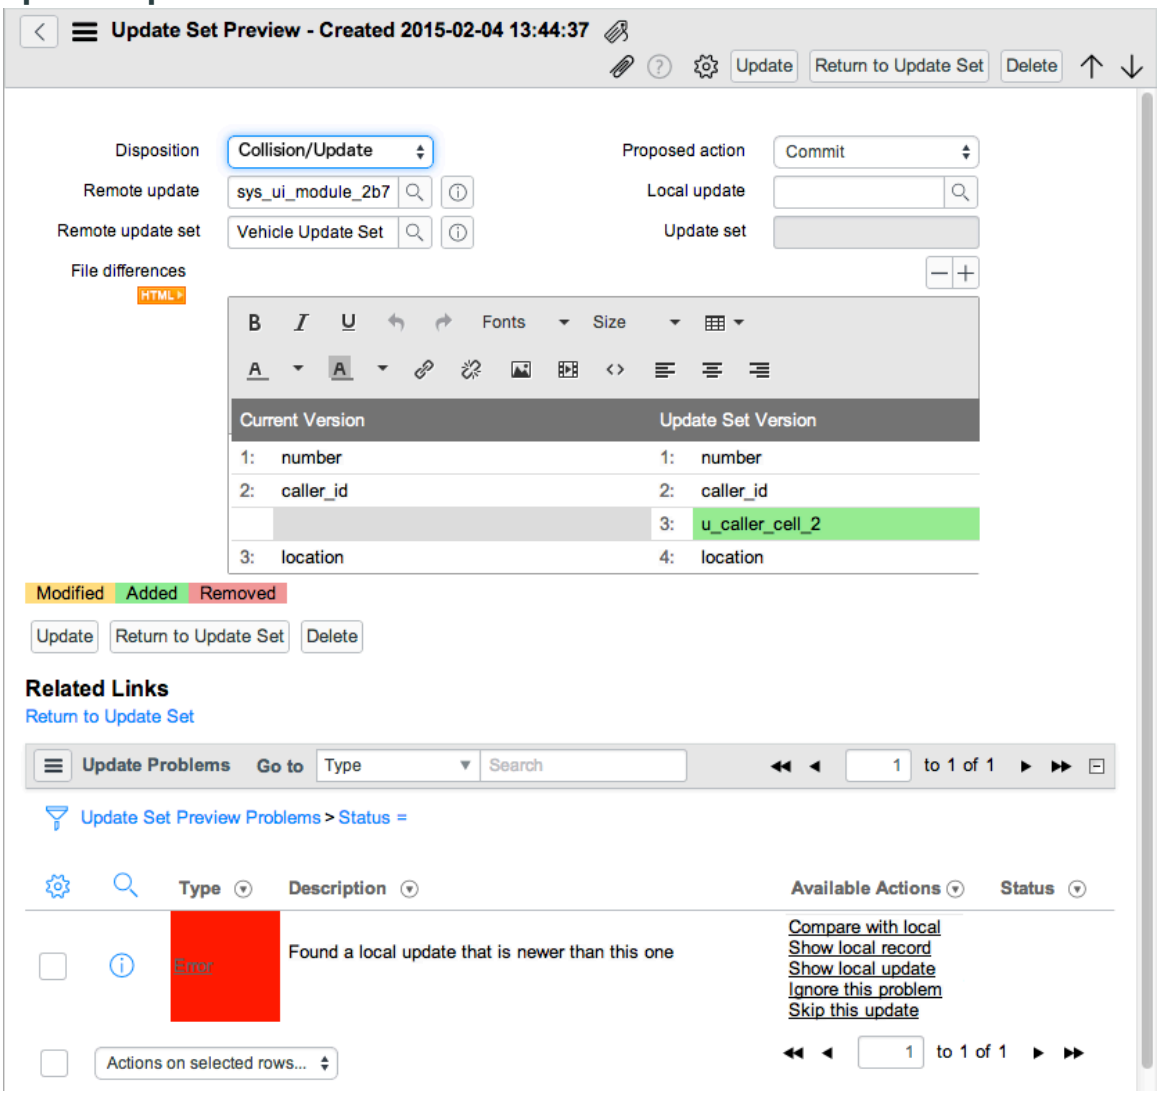
Review a preview record for an update set

The process of previewing an update set creates a preview record for each update. You can review the preview records to make sure that the correct updates are being committed.

Procedure

1. Open the Update Set record and preview the update set.
2. Click the **Show All Preview Records** related link.
3. Click the **Disposition** to open a preview record and then review the information (see table).
4. Fill in the fields on the form, as appropriate.

Update set preview



Field	Description
Disposition	Indicates when a collision is detected: ○ **Collision/Update**, **Collision/Insert**, or **Collision/Delete:** the change is older than a change to the same object on the local instance. ○ **Update**, **Insert**, or **Delete:** the change does not conflict with a change on the local instance.
File differences	Compares the most recent version of the object on the local instance with the version in the update set. Differences are marked with a color key. Deletions are highlighted in red, additions in green, and modifications in yellow.
Proposed action	Indicates how to handle the change when the update set is committed. ○ **Commit:** Accept the change in the remote update. The default proposed action for every preview record is Commit, even if a newer update exists on the instance. ○ **Skip:** Reject the change.

5. If necessary, resolve any problems listed in the **Update Problems** related list.

6. In the Proposed action field, select the action to take when committing the update set.
7. Click **Update** to save the action.
8. Repeat the process for every preview record.

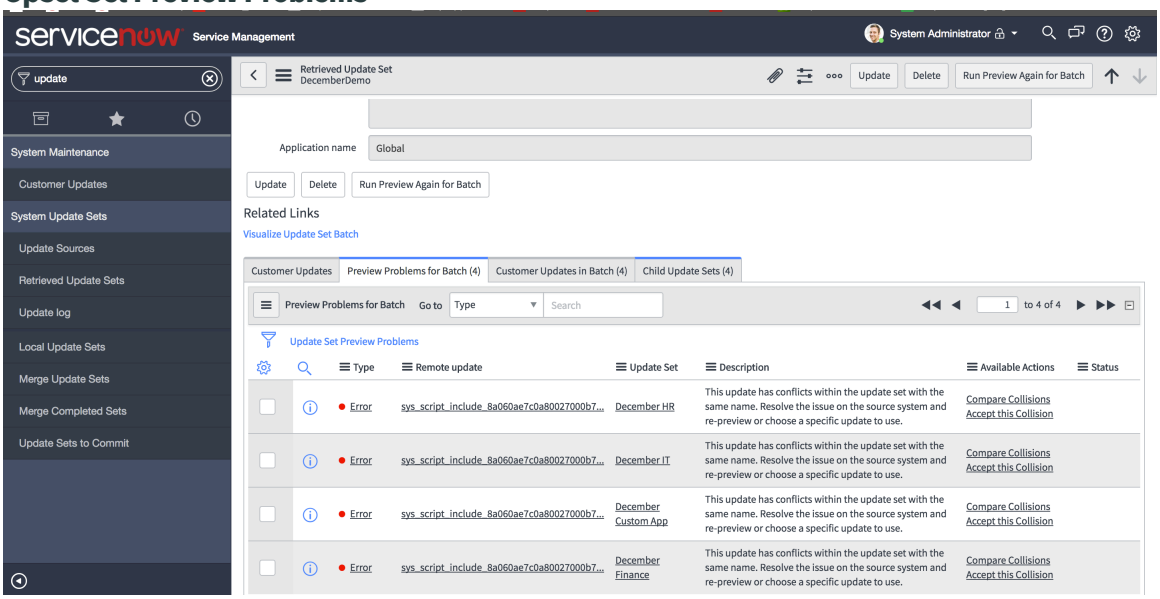
Resolve a preview problem in an update set

Preview an update set to detect and resolve problems that may occur if you commit the updates on the local instance.

Procedure

1. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**.
2. Open the update set record and scroll to the **Update Set Preview Problems** related list.

Upset Set Preview Problems



3. Review each problem description to determine the cause and resolve the problem.
   Update Set Preview Problems

   Missing Object

   Example problem text: `Could not find a record in sys_ui_policy referenced in this update.`

   Description: The object or a referenced object does not exist on the target instance. For example:

   - An update modifies the form layout for a table that has not been created in the local instance.
   - A UI policy action is included in the update set, but the parent UI policy is not.
   - Resolution: Create another update set on the source instance to transfer the missing object to the local instance, or create the object on the local instance. Use these **Available Actions** to assist in problem resolution:
     - **Find missing field** or **Find missing record**: Opens a new window and searches the source instance for the missing field (dictionary entry) or record.
     - **Find missing update**: Opens a new window and searches the source instance for the update record that corresponds to the missing field or record.

Collision

Example problem text: `Found a local update that is newer than this one`

Description: A change in the update set is older than a change to the same object on the local instance.

Resolution: Compare the two updates and determine which version to use. To use the version on the local instance, select **Skip remote update**. To use the version in the update set, select **Accept remote update**. Use these **Available Actions** to assist in problem resolution:

- **Compare with local**: opens the preview record, which provides a comparison of the differences between the local version and the version in the update set.
- **Show local field** or **Show local record**
- **Show local update**

Uncommitted update

Example problem text: `Could not find a table field (u_case.u_reference) referenced in this update, but did find it in another uncommitted update set`

Description: The object exists in another remote update set that has not been committed.

Resolution: Commit the other remote update set first or move this update to the other update set. Use these **Available Actions** to assist in problem resolution:

- **Show uncommitted update**: opens the update record in the other remote update set.
- **Show uncommitted Update Set**: open the other remote update set record.

Table to be deleted has data

Example problem text: `Found a row in the table that is going to be deleted`

Description: One difference between table deletes and other metadata deletes is that the table data is lost when the table is deleted. (If the table is empty (no rows), then no problem is generated.)

Resolution: The problem must be ignored (delete will happen) or skipped (delete will not happen) before the update set can be committed. You can restore the table, but the restore does not bring back the data.

You are not allowed to delete system tables (ServiceNow tables) or tables outside your application scope.

Application scope validation issue

Description: The previewer identifies the following combination of states as a problem:

- The scope for the update set is not Global and
- The application is not found on the target instance and
- The application is not included with the update set and
- The application is not found on the ServiceNow Store.

Resolution: Transfer the update set only to instances that include the application scope or ensure that the update set includes the application.

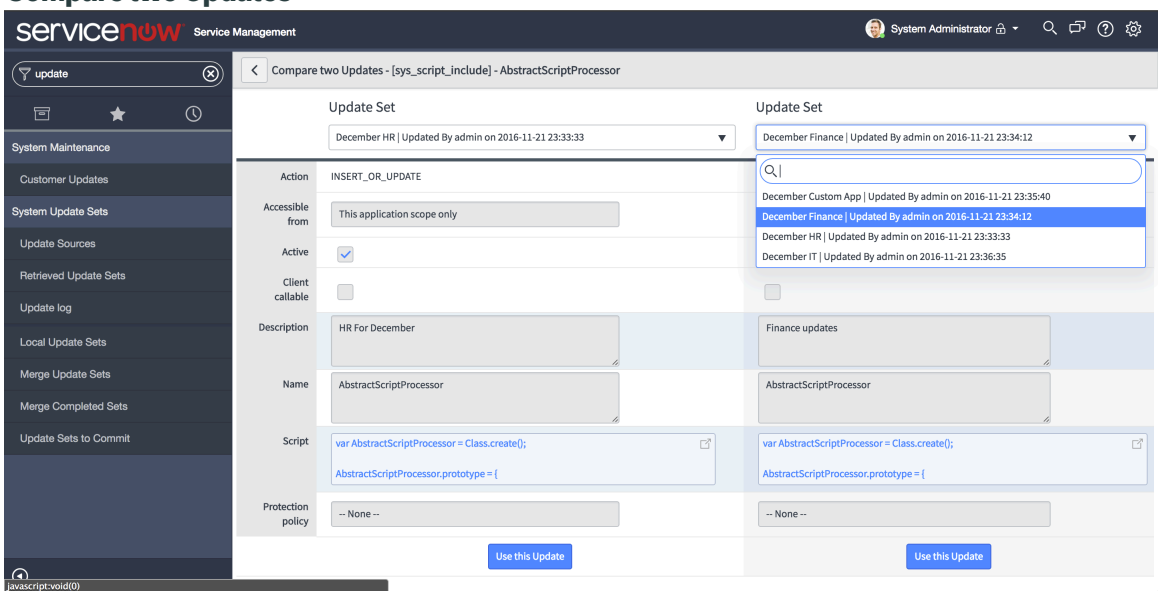
Conflict within a single batch

Example problem text: `This update has conflicts within the update set with the same name. Resolve the issue on the source system and re-preview or choose a specific update to use.`

Description: Two or more update sets within the same batch have conflicting changes. The **Update Set Preview Problems**list contains a record for each update set with a conflicting change.

Resolution: Compare the conflicting update sets and determine which version to use. If you know which update set is the correct one to use, select the row for that set and click **Accept this collision.** Otherwise, click **Compare Collisions** to compare the conflicting update sets.

Compare two Updates



From this screen, you can compare any two of the conflicting update sets and choose the update set to commit.

Commit an update set

When you have previewed an update set and have resolved any issues, commit the update set. Committing an update set applies all changes to the instance and creates a local copy of the update set that contains an update record for every change.

Procedure

1. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets** and open the update set.
2. Resolve any problems.
   You cannot commit an update set until all problems are resolved.
3. Click **Commit Update Set**.

- Click **Cancel** to return to the preview and reevaluate the change. None of the updates are committed.
- Click **OK** to skip the change and continue committing the changes that are marked as **Commit**.

If the update set contains one or more DELETEs for schema, the system displays a warning. The warning lists up to five updates that may contain problems. If more than five updates have potential problems, the system provides a link.

When the system successfully commits an update set, it displays a completion page.

4. Click **Commit log** on the confirmation page, or navigate to **System Update Sets** > **Update log** and filter for the update set name.
   - Look for warnings that contain the text **unsafe edit**. The system automatically skips any changes that results in data loss, such as changing the type of a field that contains data. You must manually make any of these changes, if necessary. Use caution when making changes that affect production data.
   - Look for errors that indicate which records failed to commit and why. Create a new update set to address those failures, if necessary.
5. When you are no longer working on the update set but do not want it transferred to another instance, navigate to **System Update Sets** > **Local Update Sets** and open the local update set record.
   Change the State to **Ignore**.

What to do next
For completed update set on the production instance, you should always change the state to **Ignore**. This state ensures that the update set is not committed again when cloning the instance.

Back out an update set

You can back out changes to existing records for any committed update set.

Before you begin
Role required: admin

About this task
Backing out an update set creates delete updates in the current update set. If you commit, back out, and then reapply a remote update set, errors appear in the previewer because the deleted updates are considered more recent changes and cause collisions.

> **Warning:**
> Do not back out the **Default** update set. This action can damage the configuration of the instance.

The back out process reverses both record-level updates and changes to the dictionary. Some changes caused by a back-out can result in data loss. These are the expected results of the back-out process:

Customer Update	Result of the back out action
A new table	The table is dropped from the database, deleting any data from it.
A new field	The field is dropped from the database, deleting any data from it.
A deleted field	The field is restored to the database, but the original data is lost.

Customer Update	Result of the back out action
A resized field	The field resize is reversed. If the field has been increased, data is truncated first to avoid errors.
A configured form	The form is reverted to its previous state.
A record is inserted	The record is deleted. (See **Note** below)
A record is deleted	The record is restored with its original data.

Warning:
Backing out an update set that belongs to an update set batch may affect other update sets in the batch. For more information, see Back out batched update set.

- If the sys_package is global, it is deleted.
- If the sys_package is not global, and it has a value, a warning displays that there is no deletion. Rather, the sys_update_xml is put into the default update set and the record is left in place.

Procedure

1. Navigate to **All** > **System Update Sets** > **Local Update Sets**.
2. Open the update set record.
   Make sure it is complete and a date is set on the **Release date** field.

   Note:
   The currently selected application affects what options are available for the update set. Make sure you select the application, such as Global, that matches the contents of the update set.

3. Carefully review the contents of the update set and consider whether there will be problems if it is backed out.
   If backing out an update set is not sufficient or will cause issues, then, instead, create and commit a new update set to reverse the customizations.
4. Click **Back Out**.
   A Progress page displays actions, progress, and problems. Problems are changes in more recent update sets that affect the update set that is being backed out. The backout preview process generates a warning for each problem.
5. Resolve each problem before proceeding with the back out.
   - To keep the latest version, click **Decide to Keep Current**.
   - To back out to the previous version, click **Decide to Use Previous**.

   All changes are reversed as described in the table. The current update set tracks all of the new changes that occur.

The update set and all associated update records are deleted. If needed, you can still navigate to the retrieved update set, preview it, and commit it again.

Note:
If you commit, back out, and then reapply a remote update set, errors appear in the previewer because backing out an update set creates delete updates in the current update set. The deletes are considered more recent changes and cause collisions.

Cautions about deleting update sets

Deleting an update set is a bad practice. To revert a customization, back out the update set rather than deleting it.

Administrators can delete an update set only when it is not the current update set and it is empty (no `sys_update_xml` entries are associated with it). For example, after merging update sets, you might want to delete the original sets. This function is restricted by an access control rule (ACL) on the Update Set [sys_update_set] table.

Do not delete `sys_update_xml` entries, because this action:

- Does not undo the updates.
- Removes any record of who applied the customizations.
- Removes the `sys_update_xml` entries associated with the update set, so customizations are overwritten when the instance is upgraded.

When you try to delete an update entry, a warning message appears. Click **OK** to confirm the deletion.

Update set batching

Batch update sets enable you to group update sets together so you can preview and commit them in bulk.

Dealing with multiple update sets can lead to problems, including committing update sets in the wrong order or inadvertently leaving out one or more sets. You can avoid these problems by grouping completed update sets into a batch.

Note:
To preserve the update set batch hierarchy while cloning, set only the parent update set to 'Ignore' status and leave all other update sets as 'Complete'. This will prevent batch sets from cloning and preserves the batch update set hierarchy.

The system organizes update set batches into a hierarchy. One update set can act as the parent for multiple child update sets. A given set can be both a child and parent, enabling multiple-level hierarchies. One update set at the top level of the hierarchy acts as the base update set.

When you preview or commit the base update set, you preview or commit the entire batch. The system determines the processing order, and checks for collisions, based on the dates the changes were recorded, and on their sequential ancestry. Their ancestries are the specific instances in which the changes in the update sets took place.

Note:
For more details, see Compare local update sets and View customizations and compare with current version.

Example of batched update sets

The list of update set records reflects the batch hierarchy in the **Parent** and**Batch Base** columns.

List of batched update sets

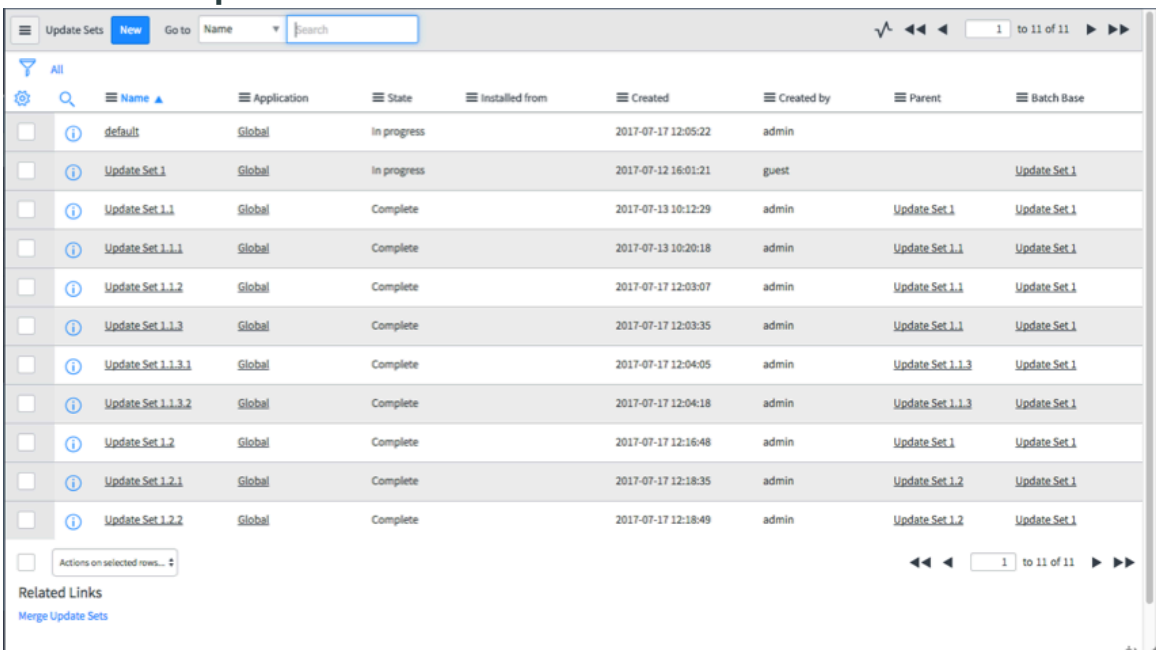


Diagram of batched update set hierarchy

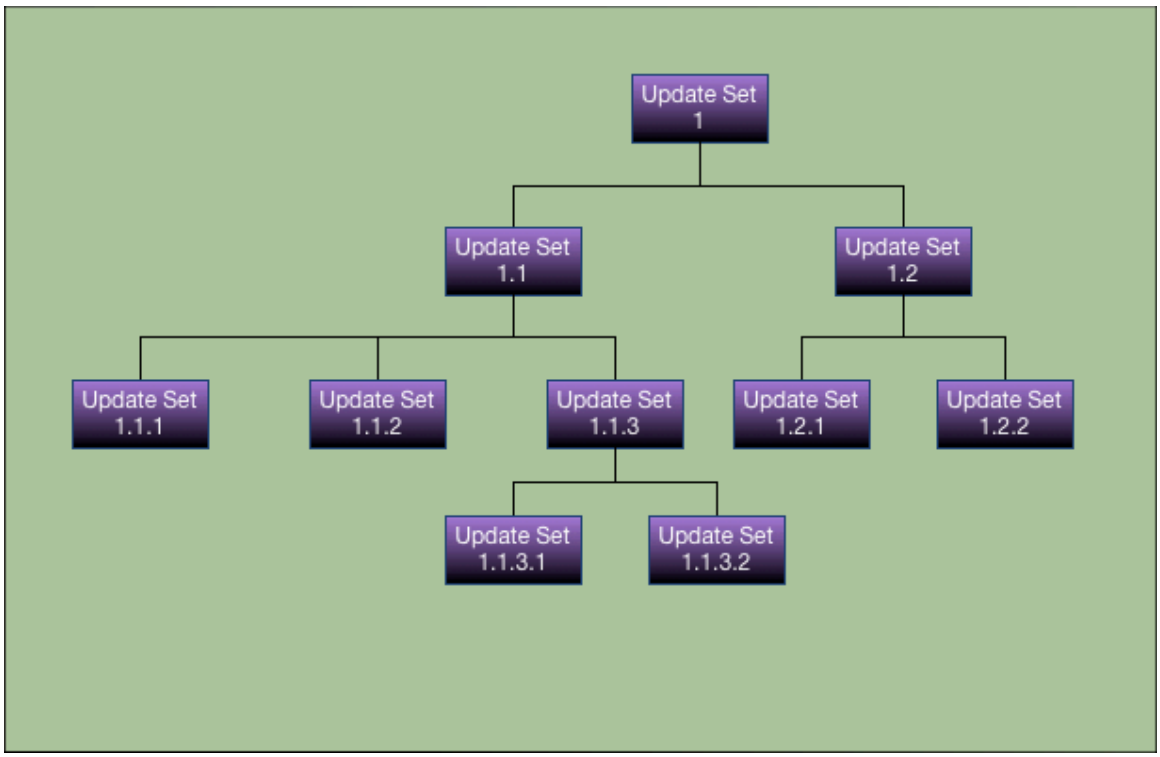


Create a batch update set

You include an update set in a batch by specifying another update set as its parent.

Before you begin

Role required: admin

Adding a WIP update set to a completed batch resets the batch base to WIP.

Procedure

1. Navigate to **All** > **System Update Sets** > **Local Update Sets**.
2. Select the record for an update set that you want to include as a child in the batch.
3. On the Update Set record, navigate to the **Parent** field and select the update set to act as the parent.
4. Click **Update**.
   The system returns to the list of Update Sets. If the **Parent** column is visible, it shows the parent for the newly-created child.

Retrieve batched update sets

You retrieve a batch of update sets using the same process you would as for any individual update set.

Before you begin

Role required: admin

Procedure

To retrieve a batch of update sets, follow the same process for the batch base as you would for any individual update set.
The system will process the entire batch at once. For details, see Retrieve an update set.

Preview a batch of update sets

You can preview at once all the update sets belonging to a batch.

Before you begin

Role required: admin
You must have retrieved the update sets from the source instance.

Procedure

1. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**
2. From the list of retrieved update sets, select the batch base for the batch you want to preview.
   You cannot separately preview an update set that is a child in a batch. You must preview the entire batch by previewing the batch base. If necessary, you can remove the child update set from the batch by editing its record's **parent** field.
3. Click **Preview Update Set Batch**.
4. If the system found problems, preview the problems.
   a. Click the **Preview Problems for Batch** and resolve the problems as you normally would for any update set.
   b. When you have resolved all the problems, click **Run Preview Again for Batch**.

Commit a batch of update sets

You can commit at once all the update sets belonging to a batch.

Before you begin

Role required: admin
Before committing, you must have previewed the update sets from the source instance and resolved any collisions.

Procedure

1. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**
2. From the list of retrieved update sets, select the batch base for the batch you want to preview. You cannot separately commit an update set that is a child in a batch. You must commit the entire batch by committing the batch base. If necessary, you can remove the child update set from the batch by editing its record's **parent** field.
3. Click **Commit All Update Sets**.

Reorganize a batch of update sets

You can remove an individual update set from the batch or change its parent.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Update Sets** > **Local Update Sets**.
2. Select the record for an update set that you want to move or remove as a child in the batch.
3. On the update set record, navigate to the **Parent** field and select the new update set to act as the parent.
4. To remove the update set from the batch, delete any text from the **Parent** field and leave it blank.
5. Click **Update**.
   The system returns to the list of update sets. If the **Batch Base** column is visible, it shows the parent for the newly-created child.

What to do next

If the system property **glide.update_set.auto_preview** is set to **true**, the system automatically starts the preview process after the record is updated with a new parent. If this property is **false**, you must start the process manually. For more information on the preview process, see Preview a batch of update sets .

Back out batched update set

Back out a batched update set by following the backout procedure for the base update set for the batch. You can also back out any child update set independently.

The following rules apply when backing out an update set that belongs to a batch:

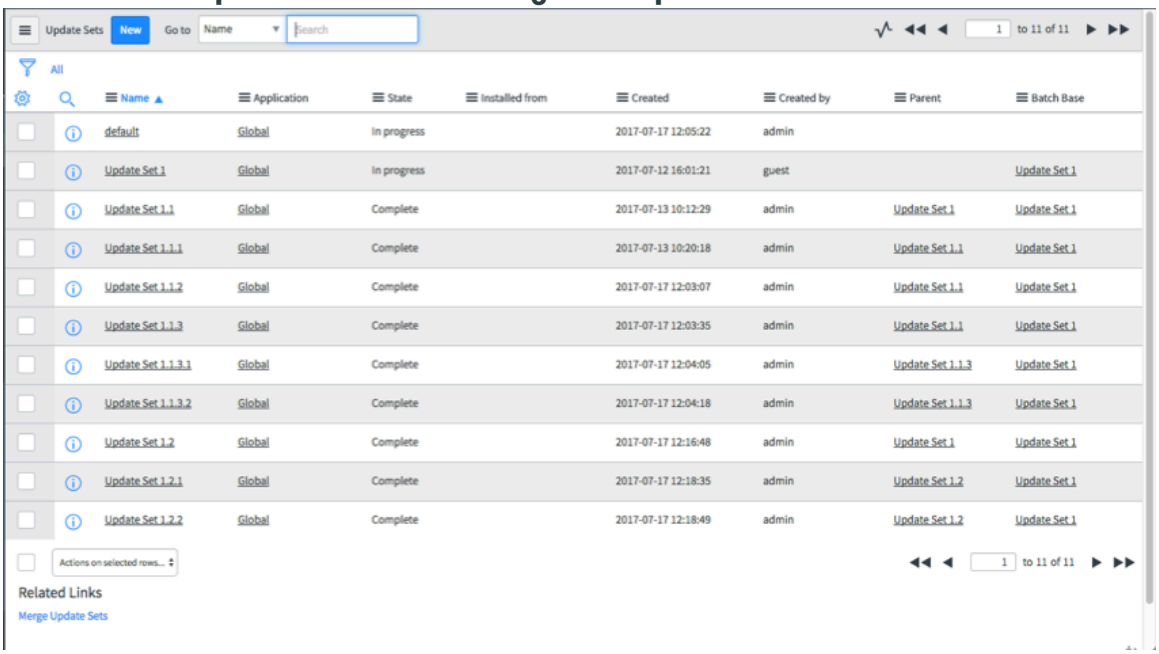
- If the update set has a parent value, the system clears the parent value and treats the update set as an independent update set, or as a new batch base if it has any children.
- The system backs out the selected update set, plus any children of the backed-out update set.

To learn more, see Back out an update set and Update set batching

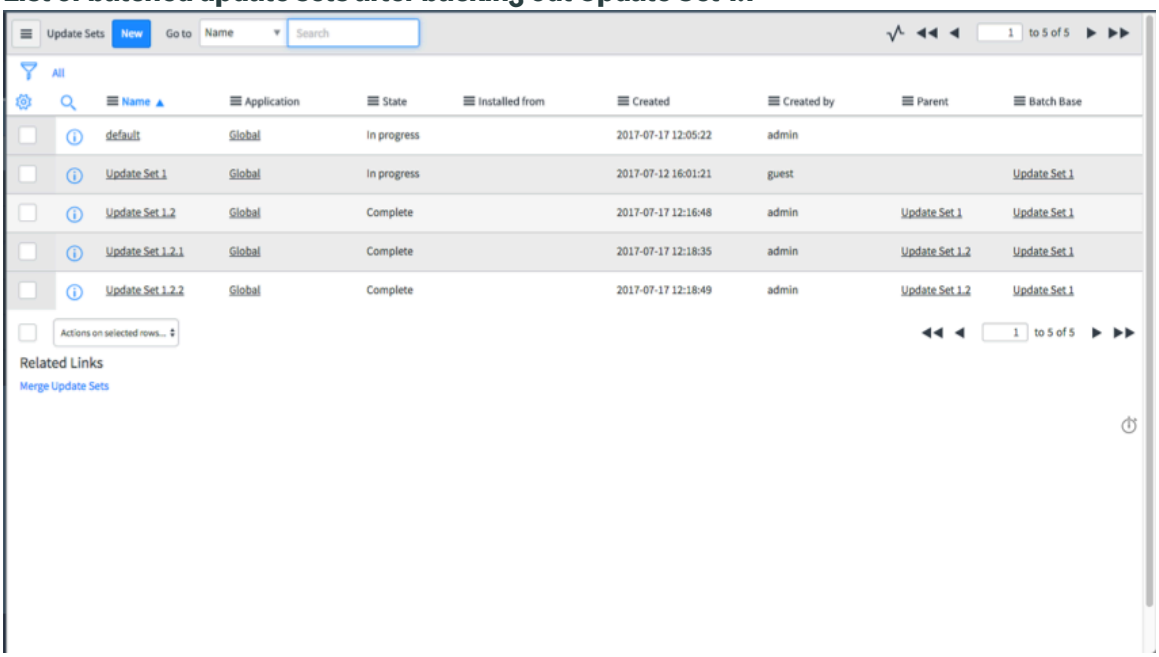
Example of backing out a batched update set

If you back out Update Set 1.1 from the batch shown in List of batched update sets before backing out an update set, the result is the batch shown in List of batched update sets after backing out Update Set 1.1.

List of batched update sets before backing out an update set

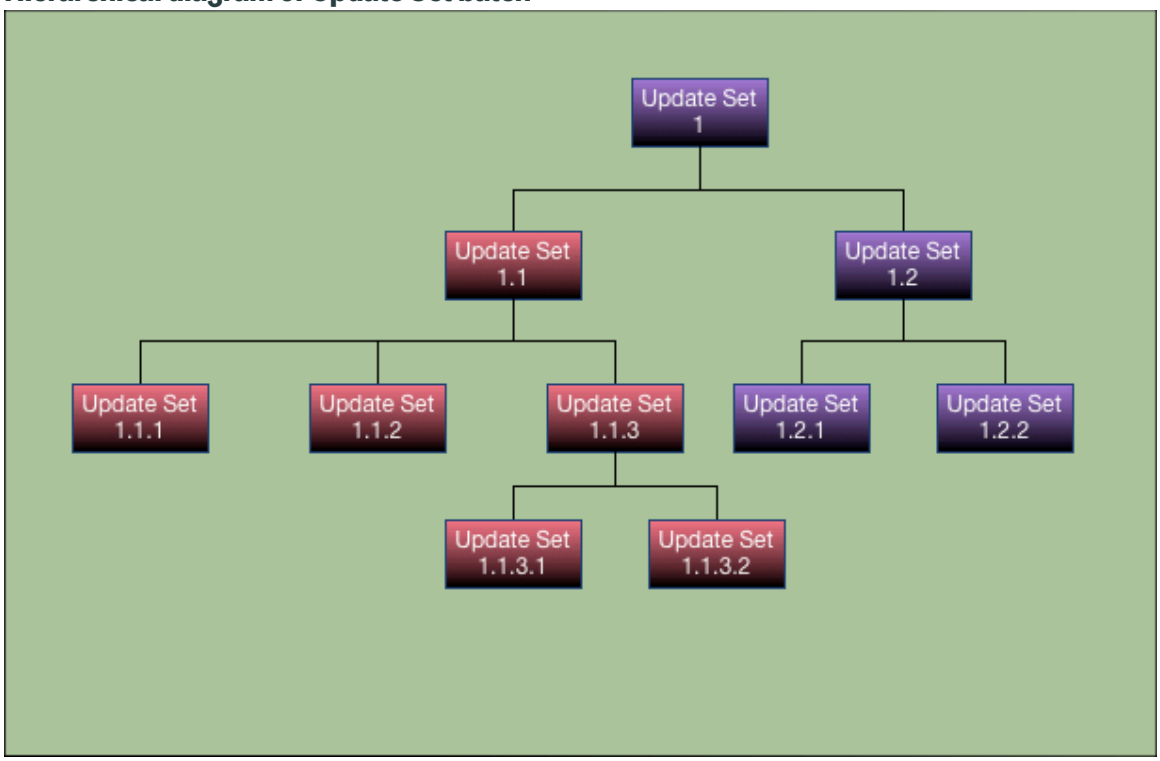


List of batched update sets after backing out Update Set 1.1



Hierarchical diagram of Update Set batch shows the hierarchy both before and after the back out. The red boxes show the update sets the system backs out if you back out Update Set 1.1.

Hierarchical diagram of Update Set batch



Administer your apps

The system offers several ways to manage applications. You must have the admin role to perform these procedures.

Legacy Application Manager

The legacy application manager provides information on how to administer your applications in your instance. For more information about installing, updating, or removing an application see Available actions.

Application Manager

A new Application Manager experience is now available. The new experience simplifies the process of managing your licensed applications by consolidating them in one convenient location, displaying all your licensed applications, plugins, installed applications, and available updates. For more information, see Application Manager.

Application sharing

Administrators can share applications that are complete and are ready for use on other instances by publishing to the application repository, publishing to the ServiceNow Store, publishing to an Update Set, or pushing to team development instances. For more information, see Application sharing.

Application sharing

Administrators can share applications that are complete and are ready for use on other instances.

Application developers can share applications using one of the following methods.

Application sharing methods

Sharing method	Makes available to	Typical use case
Publish to the application repository	All instances assigned to the same company	Transfer an application to a test or production environment.
Publish to the ServiceNow Store	All ServiceNow customers	Share or sell applications to other companies.
Publish to an Update Set	Any instance with access to the Update Set file	Save a version of an application for compliance or backup reasons.
Push to team development instances	Other instances in the team development environment	Push developer changes to the parent instance.

Note:

"Tracking schema": Deleting a table or a column in a scoped application is enabled by default for freshly zBooted instances. This is done by having the system property `com.glide.apps.include_my_schema` set to "true".

For upgraded instances, if you have no custom applications installed or in development, "tracking schema deletes" is enabled by default. Otherwise the property is set to "false" so that customers get the same experience for schema deletes in their applications as in previous releases before Paris. To learn more see the New York and Scoped Applications New Features article on the ServiceNow Community site.

Custom licensing for ISV applications

For applications that you are sharing, you can create a definition to track usage metrics on your application. For more information, see Custom licensing for ISV applications.

ServiceNow application repository

After you develop and test a custom application, you can make the application available to company instances by publishing it to the ServiceNow application repository.

The ServiceNow application repository is a central repository for all scoped applications that are published by all ServiceNow customers.

Note:
The ServiceNow application repository isn't available for self-hosted (on premise) customers.

The application repository enables ServiceNow customers to upload and distribute applications between their instances. When you access the application repository, you can see and manage only the applications that are published by your own organization. You can't see or manage applications that are published by other organizations.

After you have designed, developed, and successfully tested a custom application, you can publish your application to the ServiceNow application repository to share it to other instances in your company.

Entitlements

An entitlement refers to permission given to an instance to install a scoped application from the application repository. An instance must be entitled to an application in order for you to be able to install the application on the instance.

By default, after you publish an application to the application repository, all your company instances are entitled to the application automatically. To limit which company instances are entitled to the application, access the application repository by going to https://apprepo.service-now.com, and then change the entitlement type for the application. You can also entitle an instance again if the application entitlement has already been removed. For more information, see Manage application entitlements from the application repository.

Using the application repository

You can access the application repository by going to https://apprepo.service-now.com.

Note:
Customers using the Federal Store must log in to HIWave and then select the Federal Store option at the bottom of the page. Then, under your company name, select My Repository to proceed.

After you publish an application to the application repository, you can:

- Install an application from the application repository
- Manage application entitlements from the application repository
- Delete an application from the application repository
- Release a scope from the application repository

Manage applications

Learn how to manage the applications you publish to the ServiceNow application repository.

After you have designed, developed, and successfully tested a custom application, you can publish your application to the ServiceNow application repository to share it to other instances in your company. You can see, manage and customize only the applications that are published by your own organization or scoped applications that are installed via plugins using the ServiceNow Application Repository. You can't see or manage, or customize applications that are published by other organizations.

Note:
Do not combine the usage of both Update Sets and the Application Repository for scoped app development. This will result in numerous issues, including skipped changes, commit errors, and more. Once you have installed an application from the Application Repository, you must continue to develop and publish to the Application Repository for all future development. If you decide to develop an application using update sets, you must continue to use that method exclusively.

Overview

The Application Repository is part of the ServiceNow Store. ServiceNow customer instances are connected to a particular Store instance (for example, Commercial or Regulated Market). Customer applications published to the Application Repository are stored in a multi-tenant artifact storage, but the storage is designed so that customers cannot see or access other customers' published applications.

Application Repository has a limit of 20 versions of a given application. If your team is generating more builds or versions of your application than 20 at a time, the oldest is deleted.

Application Repository has a file size limit for applications at 1GB. Applications over this file size are not accepted during the publishing process.

Manage application entitlements from the application repository

Add or remove application entitlements to limit which instances the application can be installed on.

Before you begin

You can manage only the applications that you've published to the application repository. For more information, see Publish an application to the application repository.

Role required: none

About this task

By default, after you publish an application to the application repository, all your company instances are entitled to the application automatically. To limit which company instances are entitled to the application, access the application repository by going to https://apprepo.service-now.com, and then change the entitlement type for the application. You can also entitle an instance again if the application entitlement has already been removed.

Procedure

1. Go to https://apprepo.service-now.com.
2. Log in using your HI credentials.

> **Note:**
> Customers using the Federal Store must log in to HIWave and then select the Federal Store option at the bottom of the page. Then, under your company name, select My Repository to proceed.

3. Next to the application listing, click **Select Action** and then click **Manage Entitlements**.
4. Choose an entitlement type for your application.
5. Click **OK**.

Release a scope from the application repository

Release a scope from the application repository so that the scope can be used to create new scoped applications.

Before you begin

You can release an application scope only if the scope isn't being used by any application. If your scope is being used by an application, follow the steps in Delete an application from the application repository before releasing the scope.

Role required: Primary customer admin of the account

About this task

The application repository stores the scopes of all your custom applications. You cannot create a new application using a scope that is being stored in the application repository. To release a scope means to remove the scope from the application repository so that you can create new applications using the scope.

Procedure

1. Go to https://apprepo.service-now.com.
2. Log in using your HI credentials.

> **Note:**
> Customers using the Federal Store must log in to HIWave and then select the Federal Store option at the bottom of the page. Then, under your company name, select My Repository to proceed.

3. Open the Scopes tab.
4. Next to the scope listing, click the trash icon ( ).

Publish an application to the application repository

Publish a custom application to the application repository so that it can be installed on other instances in your organization.

Before you begin

To enable a developer to publish an application to the application repository, delegate the Publish to App Repo permission to the developer. For more information, see Delegate development and deployment permissions to personnel.

Role required: admin or delegated_developer with Publish To App Repo permission enabled

Procedure

1. Navigate to **All** > **System Applications** > **My Company Applications**.
2. Open the In Development tab.
3. Open the application record that you want to publish to the application repository.
4. Select the **Publish to My Application Repository** related link.
5. Select **Submit**.

What to do next

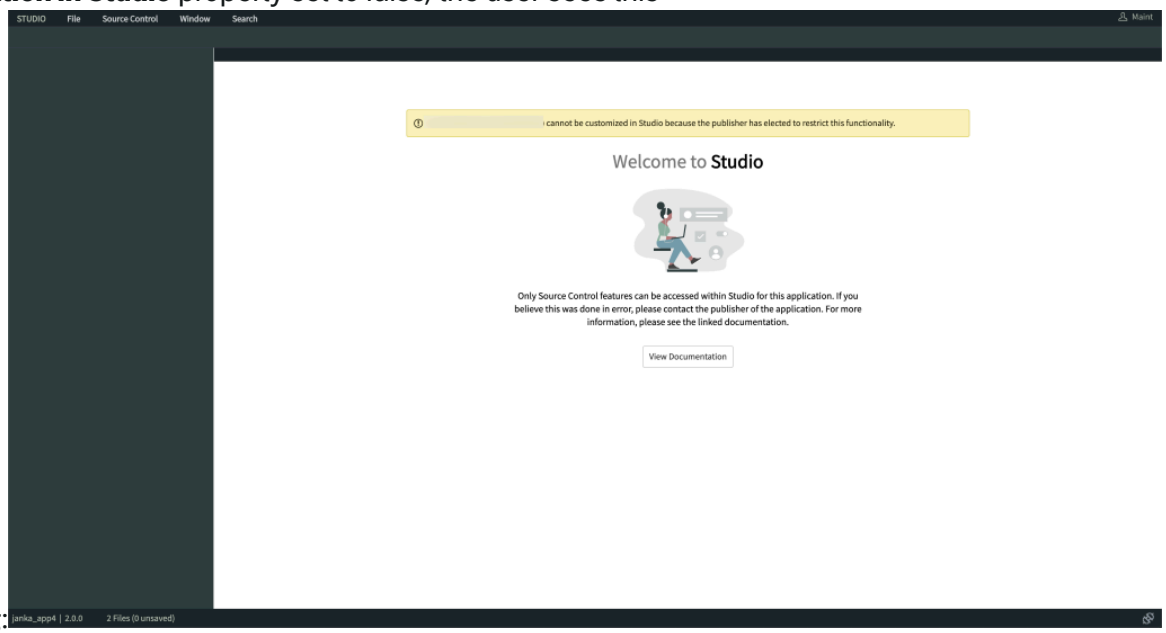
Install the application on company instances so that your organization can start using it. For more information, see Install an application from the application repository.

By default, after you publish an application to the application repository, all your company instances are entitled to the application automatically. To limit which company instances are entitled to the application, access the application repository by going to https://apprepo.service-now.com, and then change the entitlement type for the application.

Note:

The **Can Edit Application in Studio** property defaults to true for new applications, but you can set it false before publishing.

In Studio, when an application customization has the **Can Edit Application in Studio** property set to false, the user sees this warning:



For more information, see Manage application entitlements from the application repository and Legacy - Access ServiceNow Studio.

Install an application from the application repository

Install your application on an instance so that employees can start using the application that you developed.

Before you begin

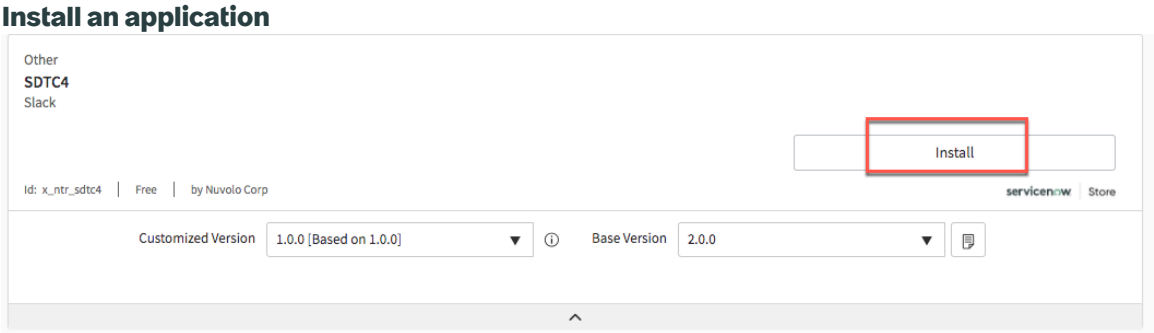
- Publish an application to the application repository.
- Check the entitlement type of the application to ensure that your instance is entitled to the application. For more information, see Manage application entitlements from the application repository.

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **My Company Applications**.
2. Find the application.
3. Next to the application listing, select a version to install.

4. Click **Install**.



Delete an application from the application repository

Delete an application from the application repository so that it's no longer available to your company instances.

Before you begin

- Publish an application to the application repository
- You can delete an application only if the application is not installed on any of your company instances. Uninstall the application on all your instances before deleting it from the application repository.

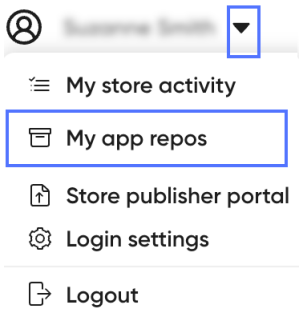
Role required: Primary customer admin of the account

Procedure

1. Go to https://apprepo.service-now.com.
2. Log in using your HI credentials.

> **Note:**
> Customers using the Federal Store must log in to HIWave and then select the Federal Store option at the bottom of the page. Then, under your company name, select My Repository to proceed.

3. Select the expand arrow next to your name and select **My app repos**.



4. Next to the application listing, click **Select Action** and then click **Flag for Deletion**.
5. On the confirmation window, click **Yes**.
   After you flag an application for deletion, the application is deleted automatically after 90 days.
6. To delete the application immediately:
   a. Open the Flagged Apps tab.
   b. Next to the application listing, click **Select Action** and then click **Delete Immediately**.

Manage customizations to applications

You can manage your company's customizations for applications that belong to other organizations or a scoped ServiceNow plug-in.

Before you begin

Role required: admin

The entitlements of your company's application-customizations are controlled solely by the entitlements of the respective store or vendor-released application. There are no separate entitlements for application-customizations, so you can't customize instances that don't have an entitlement to a base store application.

The development instance that you are using to create application-customizations should have its respective store or plugin application entitled and installed.

Note:
ISV partners who want to customize their own applications must first publish to the ServiceNow Store and install on an instance before they can use application-customizations via the Application Repository. This is the case even though all of the records are in the same scope. Installing on the instance enables ISV partners to publish a different set of capabilities for ServiceNow Store applications versus extensions used internally for their own use.

About this task

You cannot change the actual applications that belong to other organizations (purchased from the Store) or the global plugins provided in the ServiceNow base system. But you can create and manage your company's customizations for store applications or scoped applications that are installed via plugins, using the ServiceNow Application Repository.

There are two ways to create application-customizations.

- Create from ServiceNow Studio
- Create from the navigation pane

Important:
An App Customization package is intended to be authoritative and a full representation of the desired changes or customizations of the application that you're building on top of. Local customizations (typically tied to the sys_update_xml) are not honored because of this. If a specific field must be persisted (for example a MID Server) – consider using the Loader exempt attribute, see Altering tables and fields using dictionary attributes. If a specific property must be set – consider making it 'private', see Available system properties.

Procedure

1. Use these steps to create application-customizations from ServiceNow Studio.

   a. Open the Store application or the application installed via plugin from ServiceNow Studio. To learn more, see Legacy - Access ServiceNow Studio.
   The application opens in Studio.

   b. Make application changes from Studio.

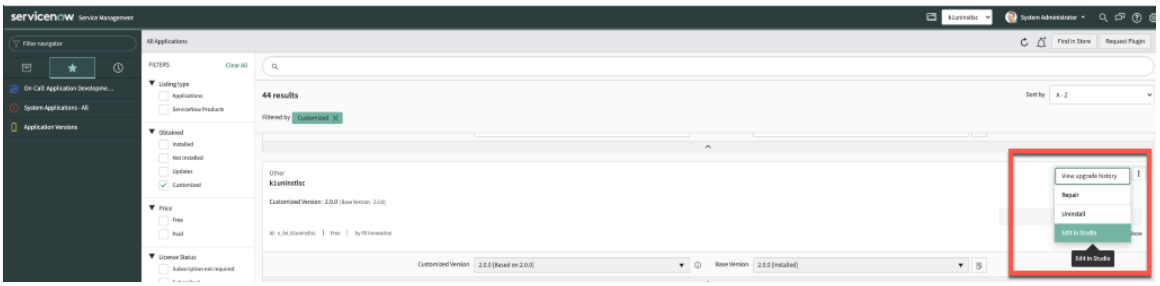
2. Use these steps to create application-customizations from the navigation pane.

a. Navigate to **System Applications >All**.

b. Search for the installed application you want to customize.

> **Note:**
> You can open the application in either Studio or select it as the current working application in the Store application record.

c. To open this application in Studio, select the stack menu, and then select **Edit in Studio**.



The application opens in Studio. You can make application changes from Studio.

d. To edit the Store application record, select the name of the application.

e. In the Related Links section of the Store application record, select **Switch to this Application**.
The application becomes the current working application in the Application picker. You can make application changes from the Store application record.

Related topics

Manage application entitlements from the application repository

Publish customizations to an application repository

After you have designed, developed, and successfully tested your customizations to a store application or a scoped plugin, you can publish it to the ServiceNow application repository to share it to other instances in your company.

Before you begin

Role required: admin, or delegated_developer with Publish To App Repo permission enabled

Only one customization can be created per vendor or customer code registered on the store and app repo.

To enable a developer to publish an application to the application repository, delegate the Publish to App Repo permission to the developer. For more information, see Delegate development and deployment permissions to personnel.

Procedure

1. Navigate to **System Applications** > **All Available Applications** > **All**.
2. Find the application by typing its name in the Filter Navigation box.

3. Open the application record for which you want to publish the customization to the application repository.
4. Click the **Publish Customizations to My App Repo** related link or in ServiceNow Studio, use the **File Publish** menu item.
5. Click **Submit**.

Convert custom applications to upgrade from the application repository

When your applications are placed in the Custom Applications table [sys_app], you can't upgrade them directly through the Application Repository. This procedure helps you do a one-time conversion when you want to migrate deploying your applications using the Application Repository.

Before you begin

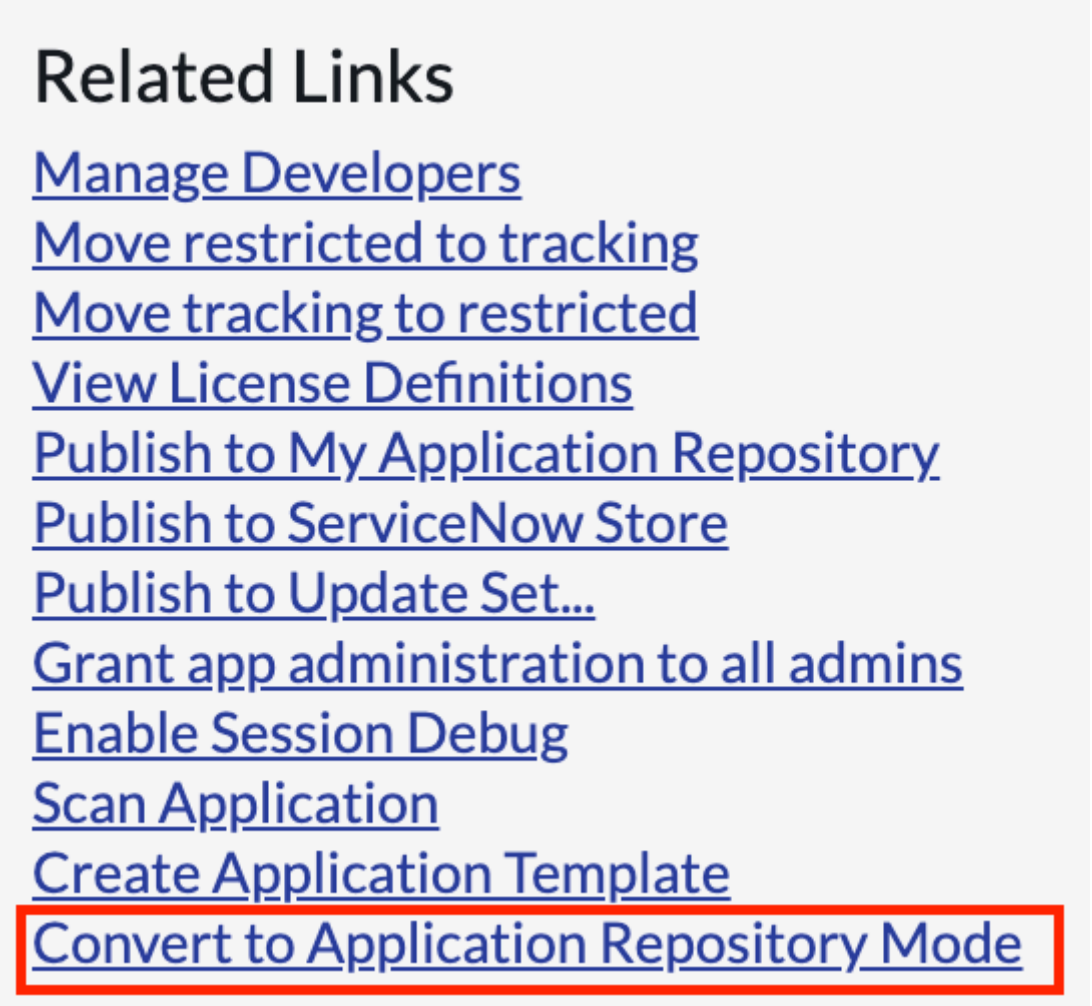
Role required: admin

When you start with Update Sets, all your applications in all your instances are placed in the Custom Applications table [sys_app]. However, if you decide to use the recommended ServiceNow® Continuous Integration/Continuous Delivery API/Spoke guidance for using the Application Repository in your CI/CD pipelines, the system doesn't allow the upgrades because the applications already exist in Custom Applications table. They are moving to the ServiceNow Store table [sys_store_app] so they can be installed from the application repository, which is why they can no longer be developed on that instance.

After you convert the application, it is no longer enabled for development on the instance where the conversion is performed. For a scoped custom application, all associated records in the Customer Updates table are deleted for this application.

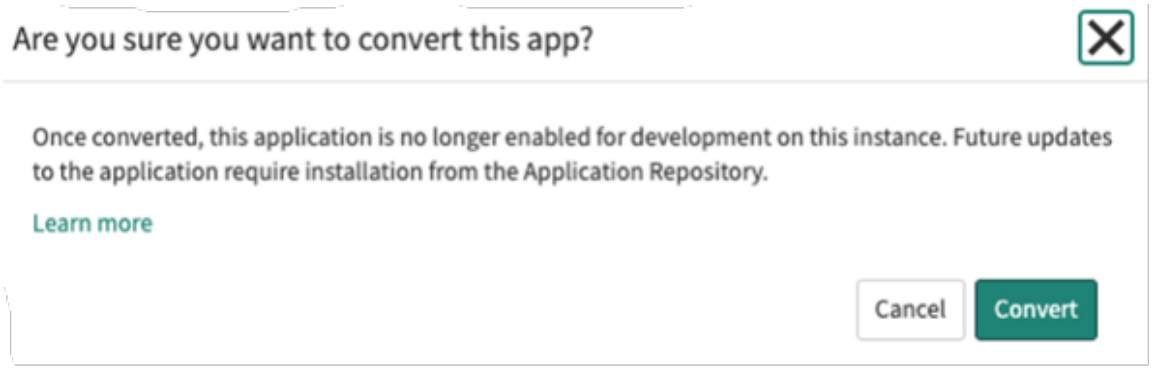
Procedure

1. Navigate to **All** > **System Applications** > **My Company Applications**.
2. Open the **In Development** tab.
3. Click the name of the application record that you want to convert.
4. Select the **Convert to Application Repository Mode** related link.

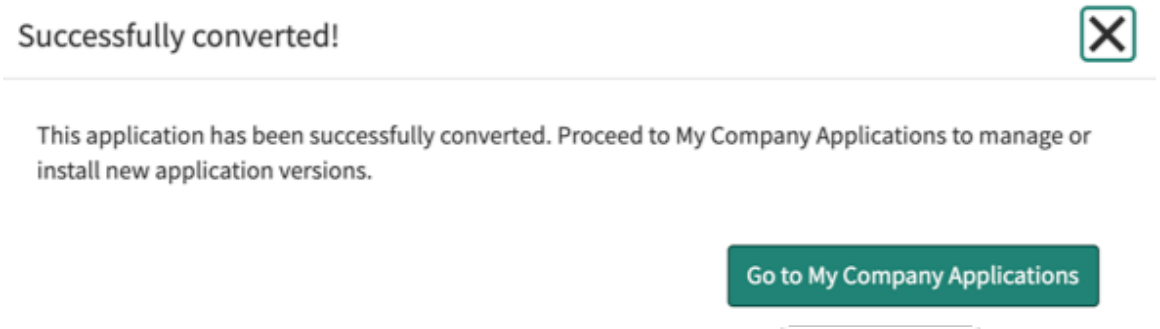


5. Select **Convert**.
   - In scoped custom applications, the following message displays.

   - In global custom applications, the following message displays.



- After the successful conversion, the following message displays.



What to do next

Go to **System Applications->My Company Applications** and update the application using the software from the application repository. See Install an application from the application repository to learn more.

Convert your installed applications to development mode

Convert the installed applications that your company owns to development mode after you install an application onto a non-production instance to use for development or clone a production instance into a non-production instance for development. With this conversion, you enable newer versions of the application to be created, committed, and published.

Before you begin

You must set the instance scope to the desired application scope. For example, if converting Agent Workspace, the application scope is set to Agent Workspace.

Role required: admin

About this task

The system properties feature [sn_appclient.store_app_convert_enabled] controls this action, which is enabled by default. You can disable this feature by setting sn_appclient.store_app_convert_enabled to false.

You can convert only the applications that your company owns. The application scope must match a key that is set in sn_appauthor.all_company_keys.

Note:
Installed global applications are eligible for conversion.

After you convert the application, it can't receive updates from the application repository on this instance. Ensure that the version of the application that is installed on the instance is the version that you intend to develop as a new version.

Note:
Applications that are installed with demo data lose their reference to this data on installation. If an application is converted, you must re-create any sys_metadata_link records to the demo data before you link the application to the source control or publish a new version.

Procedure

1. Navigate to **All** > **System Applications** > **My Company Applications**.
2. In the **Installed** tab, click the name of the application record that you want to convert.
3. Select the Convert to Development Mode related link.
4. Select **Convert**.
   - If the installed version of the application is equal to the latest version that is published to the Application Repository, you see the following dialog:

   - If the installed version of the application is lower than the latest version that is published to the Application Repository, you see the following warning:

     - If an instance is connected to a self-hosted application repository, you may see this warning regardless of the availability of a higher version in the repository. Check your repository to ensure that the development version that you require is installed in this case.
   - After the successful conversion, the following message is displayed:

     - Close the window to be redirected to the development application form.

Install customizations from an application repository

Install your customization to a store application on an instance.

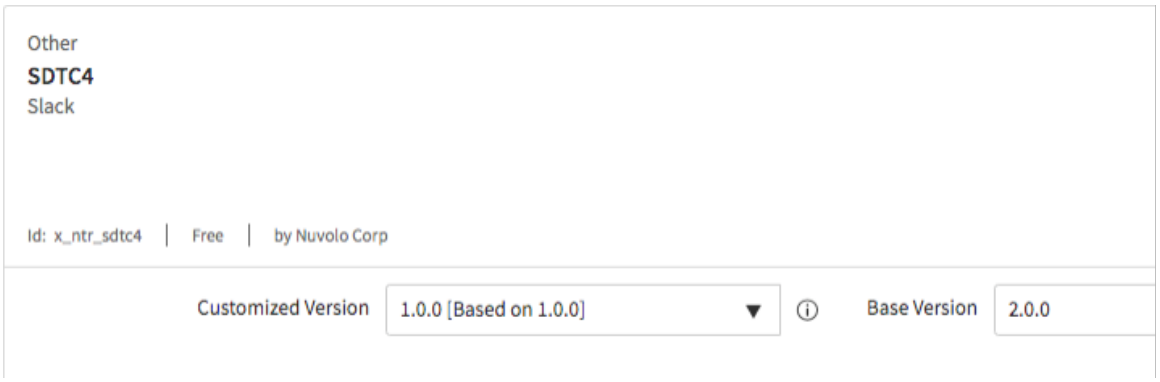
Before you begin

Role required: admin

Publish a customization of a store application to the application repository. Check the entitlement type of the application to ensure that your instance is entitled to the application.

Procedure

1. Navigate to **System Applications** > **All Available Applications** > **All**.
2. Find the application.
3. Select a customization version to install.



Note:
For scoped applications installed via plugins, the base system version is the ServiceNow release version that you are currently using (Paris, Quebec, Rome, and so on).

4. Click **Install**.

Preserve applications and customizations in development during a system clone

Manually preserve a copy of each application and customization that you currently have in development before you can clone the application version to the target (development) instance.

Before you begin

Ensure that you have write access to the application record.

Ensure that you have access to a source control repository.

Role required: admin

About this task

The cloning process does not preserve version differences for applications and app customizations in development. Instead, the system clones only the copies of the application and app customization versions that are installed on the source instance onto the target instance. If the target instance had a development version of the same application, the application is editable after the clone, but is at the version that was installed on the source instance. If the application was missing from the source instance, the cloning process deletes the application from the target instance.

Procedure

1. To preserve the application on the clone target instance, do one of these actions:

Version differences between instances

Application version state	Action to take
The application version on the clone target instance is different than the source instance version.	Export each application from the clone target instance. The choices include: ○ Link each application to a source control repository. **Note:** If the application is already linked to a source control repository, commit the latest version to it. ○ Publish each application to an update set.
The application is available only on the clone target instance.	
The application version on the clone target instance is the same as the source instance.	None. The system clone process copies this application version onto the target instance during the clone.

2. Request a system clone of the source instance to the target instance.

Example

For example, clone your production instance over your development instance.

3. After the clone process finishes, log in to the clone target instance.

4. **Note:**
   If source control is linked, then post clone, the platform will automatically retrieve applications and customized applications. If this is disabled via `glide.source_control.post_clone_import_enabled` you will need to manually retrieve by doing the following.

   If you saved each application to a source control repository, use one of these actions to retrieve them from the source control repository:

   Note:
   For what to expect after application customization post clone, see Results post cloning for application customizations.

Retrieve applications from a source control repository

Application installation state	Action to take on clone target
The application and customization were previously installed on the source instance.	Apply remote changes from the source control repository.
The application was never installed on the source instance.	Delete the repository configuration (sys_repo_config) and import the customization from the source control repository.

Remote changes after clone

Field	Description
glide.source_control.post_clone_import_enabled	To disable the apply remote changes automation, set to **False**. The default is **True**.
glide.source_control.post_clone_import_delay_time_sec	To provide a delay time, which will delay processing of the queue, provide a value. The default is zero.
glide.source_control.post_clone_import_pause_refresh_time_sec	To provide a time interval in which the refresh repository job will not run, provide a value. The default is three hours (10800).

5. If you saved each application to an update set, do one of these actions to retrieve them from the update set:

Retrieve applications from an update set

Application installation state	Action to take on clone target
The application was previously installed on the source instance.	**a.** Delete the application version that was cloned from the source instance. **b.** Load the update set that contains the current application version.
The application was never installed on the source instance.	Load the update set that contains the current application version.

Result
The applications previously in development are available for further development on the clone target instance.

Example: Preserve the Marketing Events application

Let's say that your company previously created version 1.0 of a custom application called Marketing Events. You have already published version 1.0 of the Marketing Events application to the application repository and installed it on your production instance.

Over time, users have submitted enhancement requests for the application, and you decide to develop version 2.0 of the Marketing Events application on a non-production instance to address these requests. As development nears completion, you want to update your non-production instance to the latest copy of production for some comprehensive testing.

Because you previously used a source control integration to develop version 1.0 of the Marketing Events application, you have already linked the Marketing Events application to a source control repository. You commit version 2.0 of the Marketing Events application to the source control repository.

You schedule a clone of the production instance over the development instance. After completion, you log in to the development instance and see that it has version 1.0 of the Marketing Events application, because that was the version installed on the source instance.

Because the application was already installed on the source instance, you apply the remote changes from the source control repository to receive the latest application version. The development instance now has version 2.0 of the Marketing Events application and is available for further development and testing.

Results post cloning for application customizations

The results to expect post cloning for application customization display the expected behaviors based on the state of the application, and the actions to recover your application customizations.

The following are the expectations based on the state of the application customizations, and the actions to recover your customizations.

Application Customization expectations post cloning

State of the App Customization on Source Instance	State of the App Customization in the Target (Development) instance pre-clone	State of the App Customization in Target (Development) instance post clone	Action to take to recover App Customization in the Target (development) instance post clone
Base application is not installed	Base application version 1.0 and App Customization version 1.0	Base application is not installed	Reinstall Base application and App Customization
Base application not installed	Base application version 1.0 and App Customization in Source Control	Base application is not installed, and the sys_repo_config has an empty app field.	Remove the repository configuration (sys_repo_config) record (the app field has been emptied) and import again from Source Control and install Base application.
Base application version 1.0	Base application version 1.0 App Customization version 1.0	Base application version 1.0	Reinstall App Customization
Base application version 1.0	Base application version 1.0 and App Customization in Source Control	Base application version 1.0, repo_config is retained and the App Customization version displays as none in the all apps page.	Apply the remote changes from the Git repository.
Base application version 1.0 and App	Base application version 2.0 and App	Base application version 1.0 and App	Reinstall App Customization

Application Customization expectations post cloning (continued)

State of the App Customization on Source Instance	State of the App Customization in the Target (Development) instance pre-clone	State of the App Customization in Target (Development) instance post clone	Action to take to recover App Customization in the Target (development) instance post clone
Customization version 1.0	Customization version 2.0	Customization version 1.0	version 2.0 and Base application version 2.0
Base application version 1.0 and App Customization version 1.0	Base application version 2.0 and App Customization version 2.0 in Source Control	Base application version 1.0 and App Customization version 1.0, sys_reconfig is retained	Apply the remote changes from the Git repository.
Base application version 2.0 and App Customization version 2.0	Base application version 1.0 and App Customization version 1.0	Base application version 2.0 and App Customization version 2.0 is installed.	Both Base and App Customization are at the latest versions.
Base application version 2.0 and App Customization version 2.0	Base application version 1.0 and App Customization version 1.0 in Source Control	Base application version 2.0 and App Customization version 2.0 is installed with repo_config retained, so the branch version is on 1.0	Both Base and App Customization are at the latest versions.

Application Repository for self-hosted, air-gapped customers

This application feature enables self-hosted customers to use their own internal application repository just as cloud customers do. These customers don't install the Application Repository via the ServiceNow® Store; they use an alternative method.

Overview

Customers whose instances are hosted on the ServiceNow® cloud have access to an application repository by default via the public ServiceNow® Store. However, self-hosted and air-gapped customers don't have such access, and thus can't take advantage of advanced application development features.

> **Warning:**
> Most customers install applications through their networks from the ServiceNow® Store. This topic covers customers who aren't using networked sources.

The term "air-gapped" refers to the condition when a computer or network has no network interfaces, either wired or wireless, connected to any outside networks. When you want to move data from one source to another, you must use an alternative method. To move data between sources that aren't on a network, you must use an alternative such as the one described in this topic.

The ServiceNow® Application Repository is a scoped application that can be installed on a customer instance, and enables usage of the latest application development features inside their own private network without the need to communicate with external networks.

Recommended installation

It is recommended to install the Application Repository on a dedicated instance used only for that purpose. Installing in this way reduces the load on other instances from other transactions and improves the experience of installing other Store applications. After you have successfully installed the application, other networked client instances can publish and install application artifacts to and from this instance.

Acquiring the application

Before attempting to install the application, ServiceNow self-hosted "air-gapped" customers should reach out to their account representative. They will work with Support and your team to set up the installation process. To learn more, see the Knowledge Base article, How On-Prem customers can request a Store App.

How the setup process works

Instances are authenticated with the repository via a “pairing” process that stores instance credentials on the server-side, and needs to be done only once per instance. After an instance is “paired” with the repository, it can start interacting with the repository via its various application development features.

Installing the Application Repository store app on an air-gapped instance

Because self-hosted, air-gapped customers don't allow their instances to communicate with external networks, they don’t install the Application Repository directly from the ServiceNow® Store. These customers should use the following procedure instead.

Before you begin

Note:
Customization of the Application Repository is not supported or recommended.

Role required: You will need the maint role to install and configure, and then just the admin role once the configuration is complete.

Warning:
If your instances are already connected to the public ServiceNow® Store, you should not install the Application Repository. Doing so causes these instances to lose access. This product is intended for customers who can't connect to the public store.

Note:
Install on a dedicated ServiceNow® instance separate from your other instances.

Procedure

1. Install the application repository using the instruction in the following Knowledge Base article: How On-Prem Customers Can Request a Store App.
2. After installing, complete the steps in Configure the application repository on an air-gapped instance.

Configure the application repository on an air-gapped instance

After installing the application repository, you must configure it using the following procedure.

Before you begin

Role required: You’ll need the maint role to install and configure, and then only the admin role after the configuration is complete.

Procedure

1. Pair an instance with the application repository.
   a. Log in to the instance you want to connect to the application repository.
   b. Set the system property *sn_appclient.repository_base_url* to the URL of your application repository instance.
   For example, `http://localhost:8080/`.
   c. Clear the values of the *sn_appclient.upload_base_url* and *sn_appauthor.upload_base_url* properties.
   d. Set the value of the *sn_apprepo.credential* property in a Global scope to any non-null value, such as "secret."
      i. SSH into the instance.
      ii. Change the directory to `/root/instance/instance_<portno>/conf/overrides.d` using `cd /root/instance/instance_<portno>/conf/overrides.d`.
      iii. Open / Create the `glide.properties` file.
      iv. Add the credential property to the end and save the file `[sn_apprepo.credential=<value>]`.
      v. (Shutdown.sh/Startup.sh) Restart the glide, or run `Packages.com.glide.util.GlideProperties.loadPropertyFile(new Packages.java.io.File(gs.getProperty("glide.home.dist")+"/conf/overrides.d/glide.properties"));` in background scripts to dynamically load the properties file at runtime without restarting the instance.
      vi. Verify by printing the property in a background script `gs.info(gs.getProperty("sn_apprepo.credential"));`.
   e. Add *sn_appclient.repo_auth_name* with **sn_repo.AppRepo** as its value.
   f. Set the *glide.test_instance* property to **False** on both the application repository instance and the client instance.
   g. Set the *sn_appclient.client_calls_allowed* property to **True**.

      Note:
      A scheduled job might set this property to **False** when not connected.

   h. Set the *sn_appclient.app.install.offline* property to **False** on the client instance.
   i. Select **Submit**.
2. Log in to the instance where the application repository is installed and complete the following steps.

a. Navigate to the **core_company.list** table and ensure there is a record with the **Primary** field set to **True** or create one with any user-defined name.

> **Note:**
> The details of this record are not important.

b. Access the **sn_repo_instance.do** screen and create a new instance record for the client instance that you want to connect.

i. Ensure that **State** is set to Pairing.

ii. Enter the name of the instance that you want to connect (on the **stats.do** screen on that instance) in the **Name** field.

iii. Leave all other fields empty. They're populated automatically.

c. Repeat the previous step for any additional instances that you want to connect.

3. Log back in to the instance you used in Step 1 (the instance that you want to pair with the application repository) and navigate to the **Scripts - Background** module.

a. Select **sn_appauthor scope** from the drop-down list.

b. Run the following script: `new ConfigChecker().checkForChanges()`.

4. **Optional:** To remove the instance, navigate to the Instance record (sn_repo_instance table) and change the State to **Blocked**, which temporarily restricts access to the instance, or delete the instance.
If you need the instance again, you can change the State to **Paired** again.

> **Warning:**
> If the instance name, instance ID, or credential of a paired instance changes, it must be paired again. Manually updating any of these values on the instance record isn't recommended.

What to do next

After an instance is paired, it's fully set up to use the application repository. You can test your configuration by publishing a scoped application as described in Publish an application to the application repository. After publishing, you can verify that the app was successfully published by locating it in **All** > **Application Repository** > **Artifacts** > **Internal Apps**.

Publish an application to the ServiceNow Store

Publishing an application to the ServiceNow Store makes it available to everyone.

Before you begin

To publish an application to the ServiceNow Store:

- Create an application within a private application scope.
- Join the Technology Partner Program.
- Have the application certified.

> **Note:**
> Applications in the global scope cannot be published to the ServiceNow Store.

Role required: admin, or delegated_developer with Publish To App Store permission enabled

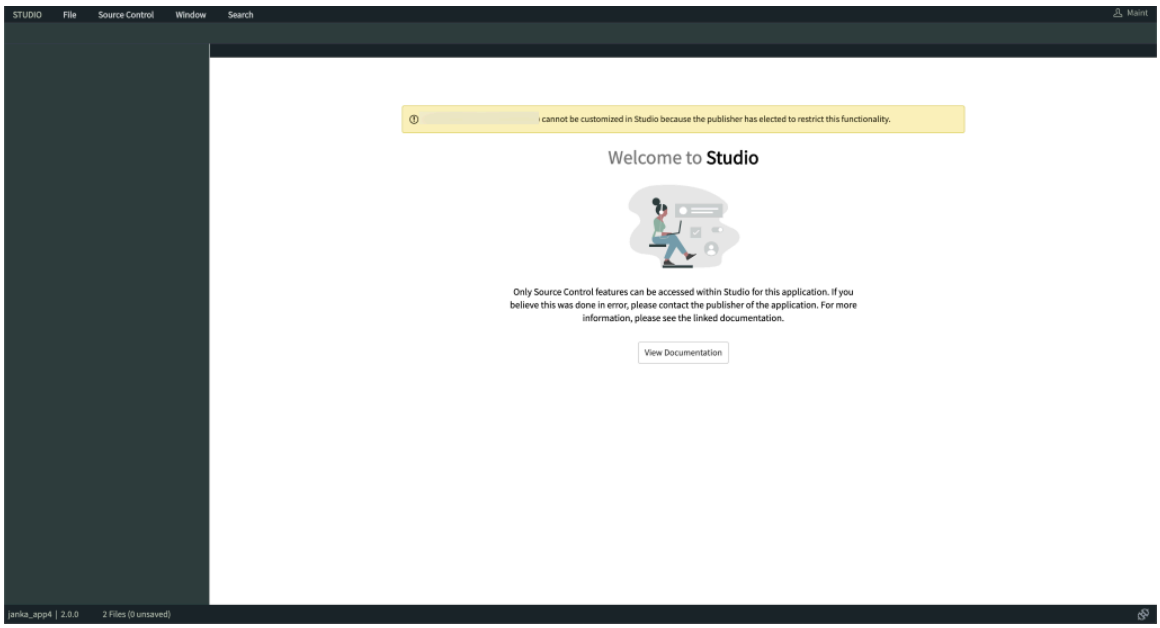
About this task

After you have met the prerequisites, you can publish the application to the ServiceNow Store

Note:

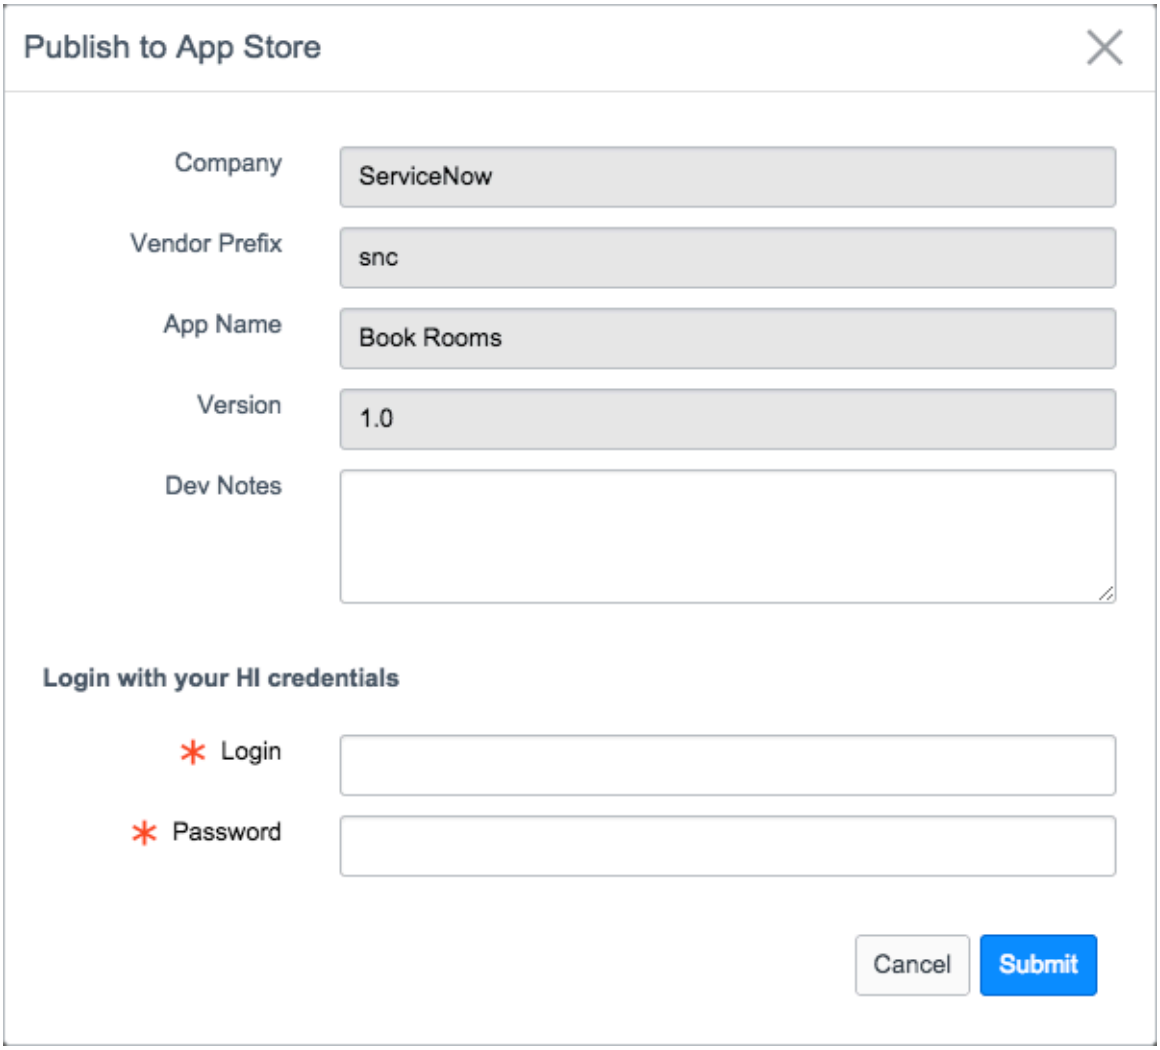
The **Can Edit Application in Studio** property defaults to true for new applications, but you can set it false before publishing.

In Studio, when an application customization has the **Can Edit Application in Studio** property set to false, the user sees this warning:



Procedure

1. Navigate to **All** > **System Applications** > **Applications**.
2. Click the **In Development** tab.
3. Open the application record you want to publish to the ServiceNow Store.
4. Click the **Publish to Store** related link.
5. **Optional:** Fill in the fields, as appropriate (see table).



6. Enter your HI credentials.
7. Click **Submit**.
   The system uploads the current version of the application to the ServiceNow Store allowing other users to download it.

Create application files to include sample data

Include sample records from an application data table when sharing a custom application.

About this task

The system can export selected records as application files that are included as part of the application update set when you share it. Including application files in an update set is not intended for the export and import of large numbers of records between instances. If you are trying to move data between instances, see Import from another instance instead.

The application data only includes the version of the records that existed when the records were shared. The system does not update this snapshot of the application data when the records change. Application designers can include data on a table by table basis.

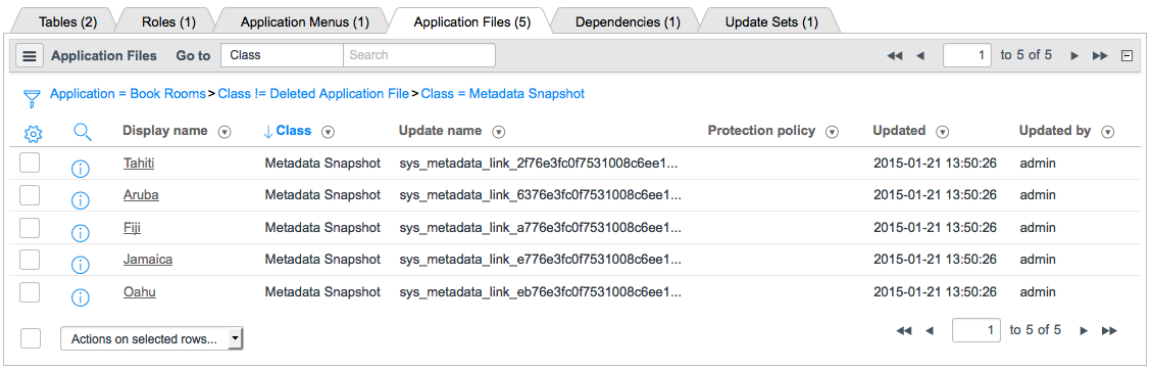
Procedure

1. Navigate to the list for an application data table.
2. Filter the list to display the records you want to include.
3. Perform the appropriate action for the list version.

4. For **Load When**, select when the application record includes application data.

Option	Description
New Install and Upgrades	Includes application data whenever the application is installed or upgraded.
New Install	Includes application data only when the application is installed.
New Install with Demo Data	Includes application data only when the application is installed with demo data.

5. Click **OK**.
   The system adds the records to the application files related list.



6. Repeat steps 1–5 for each application data table you want to include.

Publish an application to an Update Set

Publishing an application creates an update set containing the current version of all application configuration records.

Before you begin

Role required: Role required: admin, or delegated_developer with Publish To Update Set permission enabled

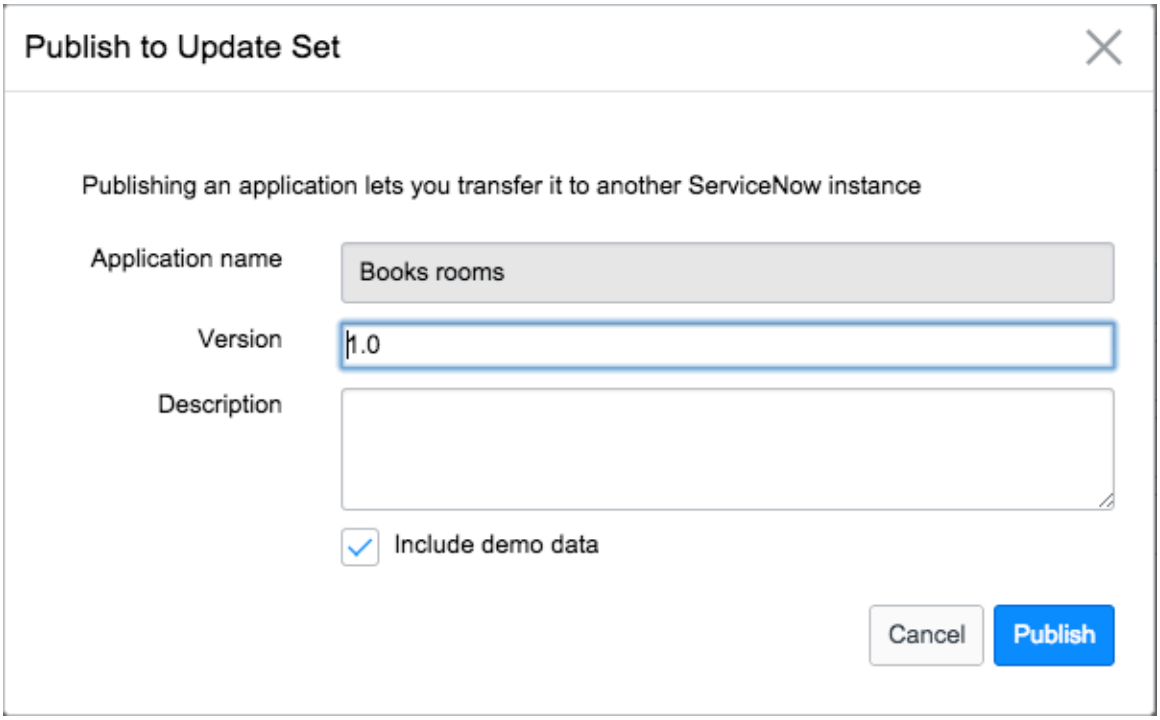
About this task

You can use this update set as a backup file for auditing purposes or to transfer the application to another instance.

Procedure

1. Navigate to **All** > **System Applications** > **My Company's Applications**.
2. Click the **In Development** tab.
3. Open the application record you want to create an update set for.
4. Click the **Publish to Update Set** related link.

5. **Optional:** Fill in the fields, as appropriate (see table).



Publish to Update Set

Field	Description
Application name	[Read-only] Displays the name of the application that you are publishing.
Version	(Optional) Enter version information to append to the Update Set name in dot-notation such as 1.2.3. The platform saves the information you enter here in the application **Version** field. The Update Set has the name <Application name> - <Version>. If you leave this field blank, the initial Update Set has the name <Application name> and subsequent Update Sets have the name <Application name> - <Sequential number>.
Description	Enter a description for the Update Set. By default, this field contains the short description of the application.
Include data	(Optional) Select the check box to include a limited number of data records from each table in the application. Use this feature to package sample data with your applications. **⚠ Warning:** (Optional) Using this feature to migrate large quantities of data records between instances can cause performance issues, as it is not intended for this purpose. To migrate data, use an instance-to-instance import. You can adjust the maximum number of data records to include with an application. See Import sets.

Field	Description
	○ If your sample data includes tables with record numbering, the current counter value is also transferred. When the update set is applied on another instance, the counter is set to the larger of the sample data or the target instance counter. ○ For translated fields, only records in English are transferred.

6. Click **Publish**.
   A new update set is created and the latest update of each application file in the application is copied into it. The update set is marked as complete.
7. Transfer the update set to another instance according to your test process.
   - Retrieve the update set from the source instance.
   - Save the update set as an XML file.
8. Run any fix scripts that are included in the application.

Queued Application Operations

CICD APIs that must obtain the update **instance wide lock / mutex** to perform the requested operations are queued instead of being rejected when the update **instance wide lock / mutex** is occupied by the other operations.

Beginning in Tokyo, the CICD APIs that require to obtain the update **instance wide lock / mutex** to perform the requested operations will be queued instead of being rejected when the update **instance wide lock / mutex** is occupied by the other operations. When a CICD request is received, the corresponding CICD service constructs an application operation NowMQ (Now Message Queue) message and insert the message to the queue using NowMQ APIs. The queued messages are then polled by the scheduled job and handled one by one or in parallel if parallel processing is enabled and the operation satisfies necessary criteria.

Application Operation NowMQ Message

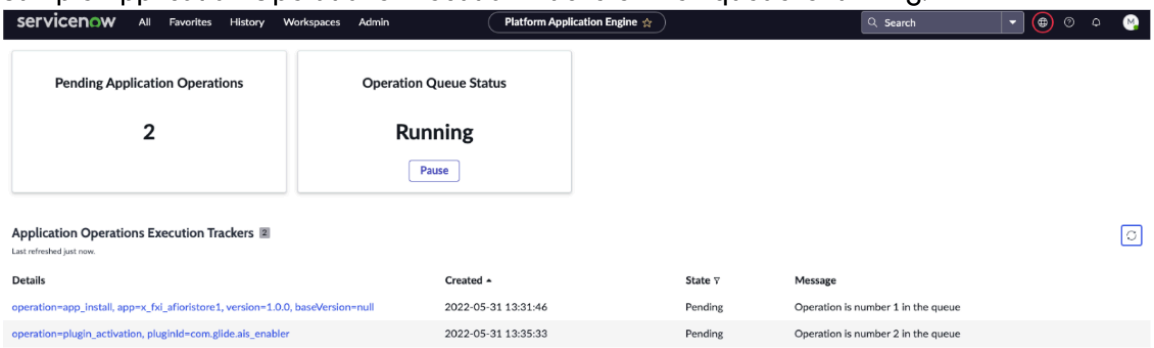
The application operation NowMQ messages have a common subject that is "sys.applifecycle.operation". The message body of the application operation NowMQ message contains a JSON object that includes the sys_id of the Execution Tracker (also refer to as the progress id returned in the CICD API response), the operation type that can be one of the following: app_install, plugin_activation, batch_install, rollback, import_app and apply_changes. It also contains the information like plugin id for plugin activation, app id or scope for application install.

Execution Tracker for Application Operation

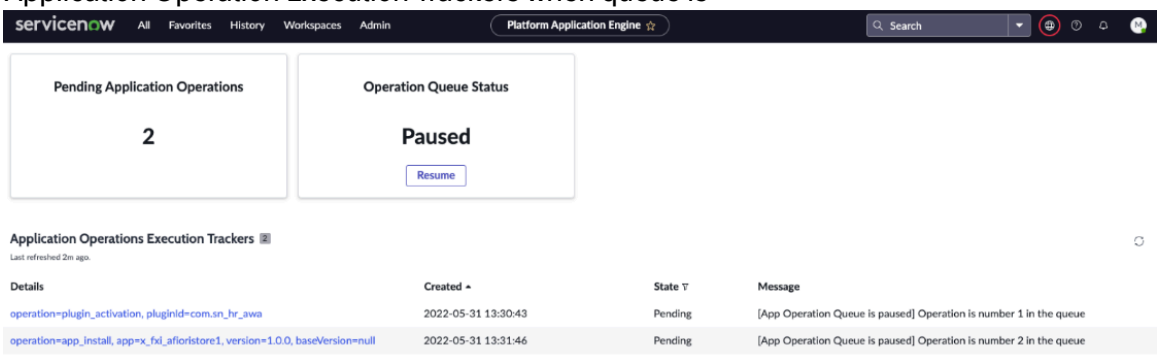
When the Application Operation NowMQ message is constructed and inserted, the Execution Tracker record for the corresponding CICD request is created and its sys_id is added into the body of the NowMQ message. The Execution Tracker is in Pending state initially. The Execution Tracker's "Details" column contains the information about the type of operation, and the

important input parameters for the CICD request. Its “Message” column contains the information about the queue position. When the queue is paused, the message is prefixed with “[App Operation Queue is paused]”.

Sample Application Operations Execution Trackers when queue is running.

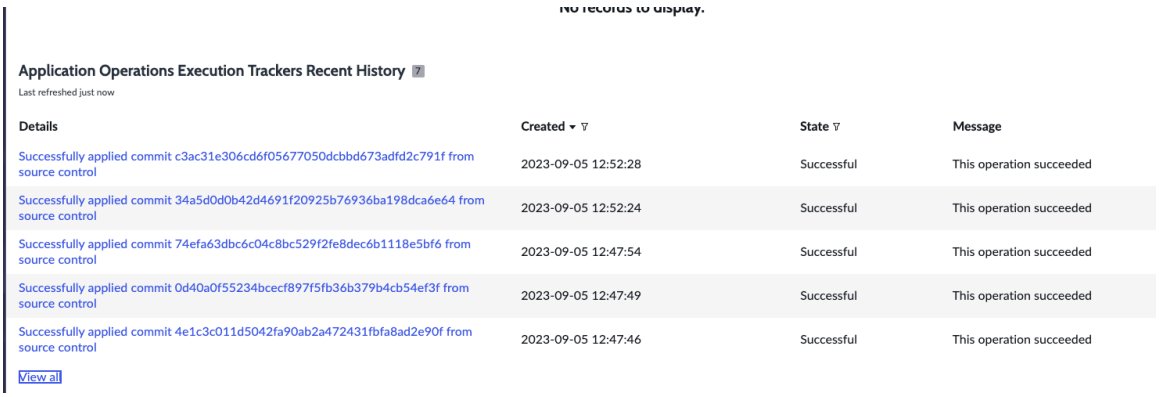


Sample Application Operation Execution Trackers when queue is paused.



Note:
Operations that are in a pending state will not display in recent history.

Sample Applications Operations Execution Trackers recent history. Recent history displays historical operations that were queued and processed in the past 24hrs.



Manage Application Operation Queue

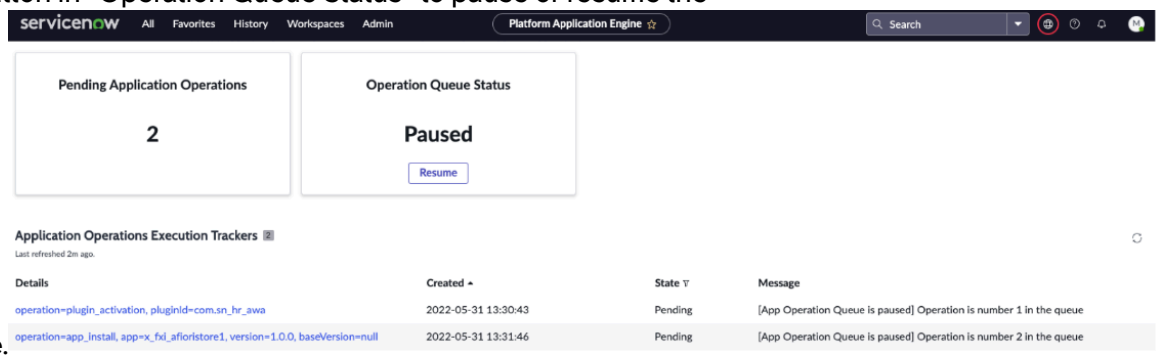
While manually installing products from All Applications is queued, manually installing an application from UI like All Applications or Application Manager isn’t queued.

Sometimes, the instance may be receiving, queueing, and handling many CICD requests which may cause the manual install from UI starving for update **instance wide lock / mutex**. When this happens, admin can temporarily pause the Application Operation Queue.

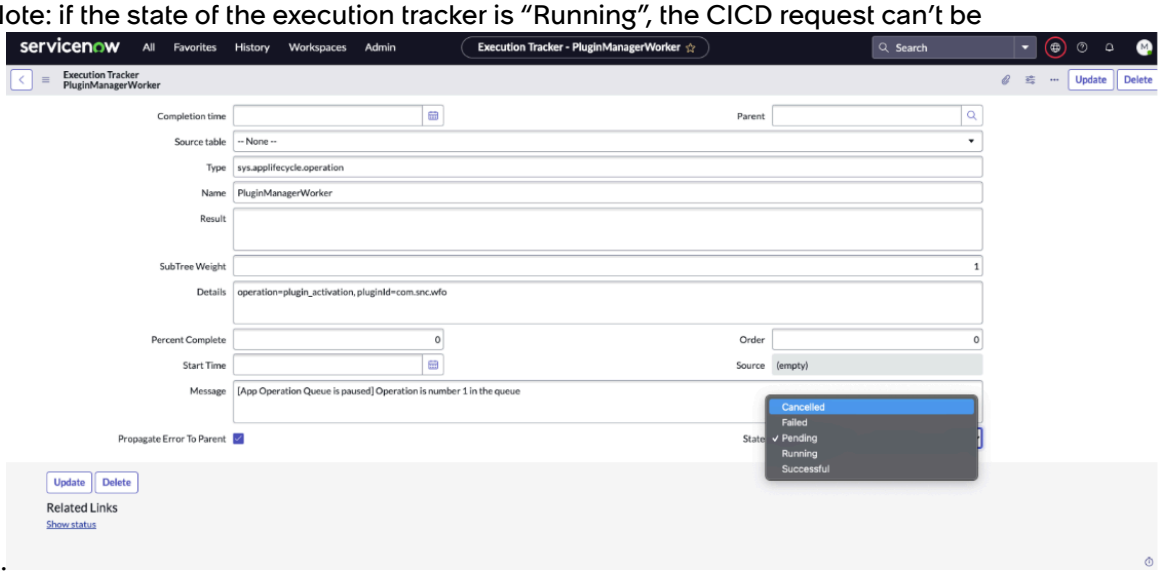
Admin can manage the Application Operation Queue through System Diagnostics->Application Operation Queue UI page. On “Operation Queue Status” panel, the admin can pause or resume the queue. Admin can also cancel the pending execution tracker, this will eventually remove the corresponding queued message from NowMQ by the App Operation Queue Health Monitor job.

Application Operation Queue UI page

Sample Application Operation Queue UI page. Admin can click the button in “Operation Queue Status” to pause or resume the queue.



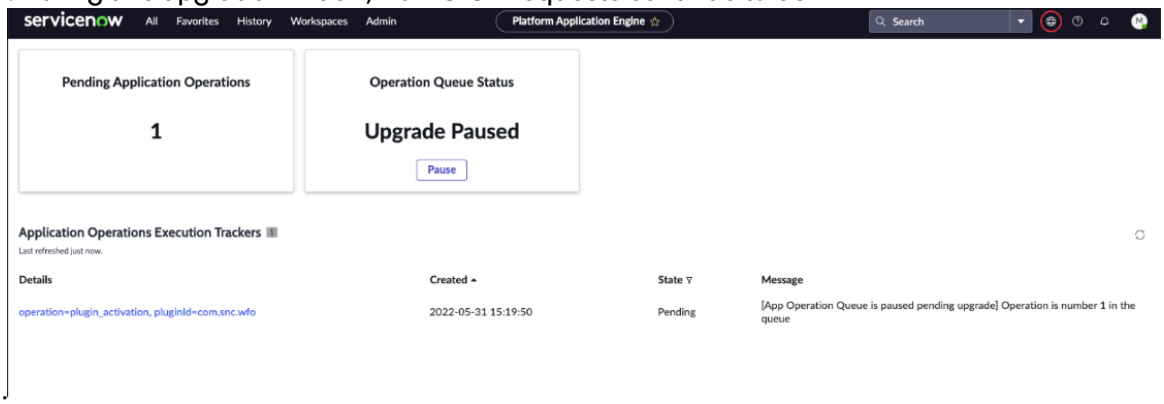
Click the “Application Operations Execution Trackers” list item, it opens the Execution Tracker form. If the queued message is pending in the queue, update the execution tracker state to “Cancelled” and save the change will cancel the corresponding queued CICD request. Note: if the state of the execution tracker is “Running”, the CICD request can’t be cancelled.



Application Operation Queue and Upgrade Window

By default, 2 hours (can be customized through sys property “com.glide.update_operation.queue_upgrade_window”) before the scheduled upgrade, Application Operation Queue stop processing queued messages.

The Application Operation Queue status is changed to “Upgrade Paused”. During this upgrade window, new CICD requests continue to be queued.



When upgrade completes, the Application Operation Queue resumes processing the queued messages automatically.

Impact to CICD Pipeline

The existing request/response contracts for the CICD APIs aren’t changed. The operation failure due to update **instance wide lock / mutex** conflicts that are observed in a pre-Tokyo release won’t be seen. The request is queued and served one by one or in parallel depending on they job type.

CICD APIs supporting queueing

The following CICD APIs are queued for processing.

- api/sn_cicd/app_repo/install
- api/sn_cicd/v1/app_repo/install
- api/sn_cicd/v2/app_repo/install
- api/sn_cicd/app_repo/rollback
- api/sn_cicd/v1/app_repo/install
- api/sn_cicd/v2/app_repo/rollback
- api/sn_cicd/sc/apply_changes
- api/sn_cicd/v1/sc/apply_changes
- api/sn_cicd/v2/sc/apply_changes
- api/sn_cicd/app/batch/install
- api/sn_cicd/sc/import
- api/sn_cicd/plugin/{plugin_id}/activate
- api/sn_cicd/plugin/{plugin_id}/rollback

Parallelize Application Installs and Plugin Activations

Starting in Tokyo, the following operations can execute in parallel with other operations.

- api/sn_cicd/app_repo/install
- api/sn_cicd/v1/app_repo/install
- api/sn_cicd/v2/app_repo/install
- api/sn_cicd/plugin/{plugin_id}/activate

All queue processing takes an **instance wide lock / mutex** and holds this mutex until any queued operation is completed. This lock is called **UpdateMutex**, and its status can be viewed in the **sys_mutex** table. During this time, operations that take this same lock (app installs, plugin activations, source control operations) are not performable via the UI. The queue can still be paused via the **Application Operation Queue** page to release the lock after currently running jobs have been completed.

Parallelization is enabled by default. It can be turned off by using the property `com.glide.update_operation.parallel_operation_enabled`, and all operations will run sequentially from the queue as in previous releases.

Limits on Parallelization

The queue processor determines if an enqueued job can run. If a job can run, it is scheduled to be picked up by an instance node at first availability. If not, it is returned to the queue, and the processor evaluates the next job in the queue for processing.

There is a limit to the maximum number of jobs that can be executed in parallel, which defaults to 2. This property can be toggled via `glide.update.app_operation_queue.parallel.max` but keep in mind that there is an upper limit of available threads to perform the install and increased parallelization takes additional memory that can slow the instance for active users.

Obtaining Resource Locks

The following plugins and applications can't be installed in parallel.

- Any two operations that share the same scope including customizations.
- Any two operations that cause schema changes.
- Any two operations containing fix scripts.

Queue processing determines if these criteria are met for enqueued operations and defers not processable jobs if necessary. The Progress ID of the job is updated to reflect if the operation is waiting for appropriate resource locks to be obtained. An executing operation maintains a list of the resources (scopes, schema, fix scripts present) in the sys_padlock table, and the insert and release of these locks can be observed in this table by the Progress ID. If a queued job is deferred due to inability to obtain necessary locks on resources, it is put on a cool-down to allow other messages to process. The cool-down period can be modified with property `com.glide.update_operation.job_cancel_timeout_minutes`. The job is still in the queue and is visible on the **Application Operation Queue** page.

If the queue is unable to download an application package or find a plugin to check for necessary resources to obtain, it logs an error against that queued operation. If the operation fails to preview its resources a determined number of times, the tracker fails, and the job is removed from the queue. The maximum number of times defaults to 3 and can be modified by the `com.glide.update_operation.max_failure_count` property.

Note:
Failing to obtain necessary locks doesn't count as a failure attempt. Only errors encountered such as failing to download an application package from AppRepo count.

Custom licensing for ISV applications

Monitor the usage of ISV applications with Subscription Management. Create a definition for your store application with the metadata you want collected. After publishing the application with the definition to the store, Usage Analytics runs and aggregates your defined metrics.

Overview

Applications that you create with the can be published to the ServiceNow Store. Monitor the usage of your applications with custom licensing.

You can use custom licensing on ISV applications that you publish to the ServiceNow Store if they meet the following criteria:

- The application is licensable.
- The application is not scoped in ServiceNow or Global.
- The application has a capacity subscription model.

Custom licensing functions through the usage analytics (com.glide.usageanalytics) and scoped app author (com.sn_appauthorr) plugins. These plugins are active by default in the App Engine. Additionally, your instance must be connected to an application repository or application store instance.

Custom license definitions

Custom licensing is achieved by creating a definition. A definition is a set of licensing metrics that you define based on what usage information you want to collect for your application. See Create a definition for your store application.

Create a definition for your store application

Create a definition for your store app to define the licensing metrics you want collected.

Before you begin
Role required: admin or developer

About this task
Create a definition for an application in development or for an application you have already published. However, if you assign a definition to a published application, you will have to re-publish it with the new definition. Additionally, you can only assign one definition to an application.

Note:
You can only create a definition for capacity subscriptions. See Types of subscriptions in Subscription Management.

Procedure

1. Navigate to **All** > **System Applications** > **My Company Applications**.
2. Select the application.
3. Under the **Subscription Management** section, set **Subscription Model** to **Capacity**.
4. Select the search icon next to **License Definition**.
   The **Application License Definitions** pop-up loads.
5. Select **New**.
6. Fill in the **Application License Definition** record.

Field	Description
Name	Name of the definition.
Description	Brief summary of the definition.

Field	Description
Metric Type	Type of collected metric.
Frequency	How often metrics are collected.
Performance Validated	Check the box if you have tested the performance of the definition.
Table	Table used to determine usage. **Note:** Only lists tables associated with the current application.
Query	Criteria to use on the table.
Aggregation	Type of aggregation. ○ Set to Count to count all records. ○ Set to Count (Distinct) to count unique records only.
Aggregation Column	Table column used for aggregation. **Note:** Column must be indexed to be aggregated.
Group By	Columns in the table to group the data by. Max of 3. **Warning:** Case sensitive.

7. Select **Submit**.
   Your new definition appears in the **Application License Definitions** pop-up.
8. Select the definition to apply it to the application.

What to do next

Create a new version of the application and publish it to the ServiceNow Store. While your application is in review, any changes to the definition may cause subsequent versions of your application to be rejected. Once the application is approved and published to the ServiceNow Store, the definition becomes read-only.

To change the definition of an application already on the ServiceNow Store, you must create a new definition, submit a new version of the application, and go through the review process.

Domain separation and Creator Workflow apps

Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Domain separation is not supported for Creator Workflow apps.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

Maintaining your application

Use your app builder tool to update and modify your application. Use your testing tool to verify that your application still functions properly.

Analytics and Dashboards

Performance Analytics Reporting  Integrate data visualization and analytics functionality into the workspace experience.	Analytics Hub  Use this exploratory view of indicators for more detailed analysis. You can see trends, predictions, breakdowns, and associated records for a specific indicator.
Analytics Center  Use the Platform Analytics Workspace with a single page for all the dashboards, visualizations, analytics answers, and insights on your instance.	Performance Analytics Dashboards  Continually visualize historical and real-time process health statistics in role-based dashboards that enable individual stakeholders to make informed decisions.

Security

Software Asset Management

Systematically track, evaluate, and manage software licenses, compliance, and optimization.

Security Operations

Bring incident data from your security tools into a structured response engine that uses intelligent workflows, automation, and a deep connection with IT to prioritize and resolve threats based on the impact they pose to your organization.

Service Mapping

Discover all application services in your organization and build a comprehensive map of all devices, applications, and configuration profiles used in these application services.

Monitoring

Monitor application health

Use the Application Service Dashboard to monitor the health state of application services. Then you can reduce the number of incomplete application services by populating them and adding any missing details.

For more information

You can either create a new workspace with an Analytics Center page in App Engine Studio or create a page from the Analytics Center page template. Either way, you have the same functions as the Analytics Center in the Platform Analytics Workspace.

Analytics Hub

In the Analytics Hub, analyze indicator scores by aggregating data, comparing scores, or viewing changes over time, and filter scores by breakdown. Enhance the Analytics Hub by adding targets, thresholds, trend lines, and useful comments for significant changes.

Monitor application health

Monitor counts indicating the health state of application services using the Application Service Dashboard. Next, reduce the number of incomplete application services by populating them and adding any missing details. To use application services effectively, ensure that application services are fully configured and populated.

Performance Analytics Dashboards

Your associates can get relevant, personalized insight by clicking a button instead of exporting data from databases and spreadsheets. You no longer manually create reports that quickly become stale and outdated.

Performance Analytics Reporting

Explore KPIs, and get answers and insights on analytics. Within the Platform Analytics Workspace, you can ask a natural language question and be shown the relevant analytics in an on-the-fly visualization, view any Next Experience dashboard that you own or has been shared with you, and create dashboards and data visualizations from your workspace runtime.

Security Operations

The ServiceNow® Security Incident Response application tracks the progress of security incidents from discovery and initial analysis, through containment, eradication, and recovery, and into the final post incident review, knowledge base article creation, and closure.

Service Mapping

Service Mapping enables IT departments of companies, organizations, and cloud companies providing platform as a service to create a service-aware view of infrastructure.

Software Asset Management

The ServiceNow® Software Asset Management (SAM) application systematically tracks, evaluates, and manages software licenses, compliance, and optimization. You can reclaim unused software rights, purchase new software rights, and manage allocations for entitlements.
