Building applications

Learn how to become an application developer using ServiceNow AI Platform low-code tools. Start with what you know and use a library of reusable components and published applications to modernize your legacy processes.

Get started

Learning about creating applications

Learn basic information about application development.

Phase 1: Planning your application

Plan how your application will work.

Phase 2: Developing your application

Add components and content to your application.

Phase 3: Testing and debugging your application

Verify that the application meets your business requirements.

Phase 4: Deploying your application

Deploy your application to your production environment.

Phase 5: Maintaining your application

Review the status of your application and make changes as needed.

What's new

Build apps smarter and deliver them faster with the new ServiceNow Studio. ServiceNow Studio empowers platform developers with a modern, unified environment for building on the ServiceNow AI Platform. ServiceNow Studio features streamlined navigation to applications and metadata, integrated low-code tools, efficient tracking and packaging of development work that accelerates development processes and enhances productivity.

App development phases

Learning about creating applications

Decide whether you want to build a new application or extend an existing application. Check the ServiceNow Store and the ServiceNow Community for existing solutions.

Before building your first application, you may want to learn some basic information about application development. This phase is optional, and you can complete it at any time while you work on other phases.

- How ServiceNow AI Platform is made up of tables and records. Learn how to convert a spreadsheet into record data.
- How to Get a development instance to practice creating applications.
- How to find out Licensing for which application features require a subscription.
- How to contact Support for developers to ask questions about application development.

Phase 1: Planning your application

The application development process starts with planning. Consider how the application will work, who will use it, and how it will improve your users' experience. Your application plan should answer the following questions:

- What are the goals, objectives, and outputs of your application?
- Who uses your application?
- Who has access to parts of the application?
- What tasks do people complete with your application?
- Where does the data come from?
- How do people interact with your application?
- What processes must the application support?
- What UI experience does the application use?
- Is there an existing application available on the ServiceNow Store or the ServiceNow Community that you can use or extend?
- What subscriptions does your application require?

Phase 2: Developing your application

During the development phase, you add the components and content of your application. Most applications consist of the following:

Data

Information is stored in your application via tables that you configure. For example, employee phone numbers or office locations.

Experience

Experiences are graphical interfaces that your users interact with. For example, you can create a portal where users find information, submit requests, or complete business tasks.

Logic and automation

Automate all the work in your application by adding logic and automation. For example, you can build a flow that sends a notification to the admin when someone makes a request.

Security

Configure roles and access controls to limit who can use your application. For example, you can restrict access to application data to users who have a specific role.

Choose a builder that matches the type of user experience that your application provides.

- See Build apps using App Engine Studio to learn about low-code development.
- See Build workflows to learn about creating automation with Workflow Studio or Playbooks.
- See Builder library to learn about specialized application resources.

Phase 3: Testing and debugging your application

Verify that the application meets your business requirements. Your testing should cover the following elements:

- Record operations, such as create, read, update, and delete.
- User interface elements, such as views and UI policies.
- Runtime operations, such as business rules and event script actions.

Phase 4: Deploying your application

After successfully testing an application, deploy it to your production environment with your builder tool.

- See Managing app development using the App Engine Management Center to learn about the App Engine Management Center
- See ServiceNow application repository to learn about the Application Repository.
- See System update sets to learn about classic deployment using update sets.

Phase 5: Maintaining your application

Use your Phase 2 builder tool to update and modify your application. Use your Phase 3 testing tool to verify that your application still functions properly.

Applications and features

- Learning about developing on the ServiceNow AI Platform
- Planning your application
- Developing your application
- Testing and debugging applications
- Deploying applications
- Maintaining your application

Learning about developing on the ServiceNow AI Platform

Using the ServiceNow Creator Workflow products, you can create intuitive experiences that run on the powerful ServiceNow AI Platform.

In this document

Use this document to discover how to:

- Find all ServiceNow developer products
- Understand low-code and pro-code development
- Understand ServiceNow licenses
- Get support as a developer
- Understand the various ServiceNow user interfaces
- Learn the basics of being a developer

Please use the reader feedback feature to suggest additional topics.

What's new

Build apps smarter and deliver them faster with the new ServiceNow Studio. ServiceNow Studio empowers platform developers with a modern, unified environment for building on the ServiceNow AI Platform. ServiceNow Studio features streamlined navigation to applications and metadata, integrated low-code tools, efficient tracking and packaging of development work that accelerates development processes and enhances productivity.

Find ServiceNow developer products quickly

Find the ServiceNow developer product that can help you build amazing products on the ServiceNow AI Platform.

Find the developer product you need

Use the following tools to find ServiceNow developer products:

- ServiceNow Widget that guides you to developer products
- ServiceNow Table that lists developer products

If you're still not sure where to start, contact your sales representative. They can help you figure out what problems you're trying to solve and how to solve them.

Finding ServiceNow developer products

Use the following widget to find ServiceNow developer products that help you create applications that run on the powerful ServiceNow AI Platform.

Find the products that help you build applications

To find the ServiceNow developer products and information that are right for you, select one of the following tiles.

I am comfortable coding

Build ServiceNow apps with custom code.

I do not code or write scripts

Build ServiceNow apps within a low code environment.

Pro-code tools: What you can do to build apps

Select an option below.

Build apps

Learn about developing on the ServiceNow platform.

Manage my apps

Customize your ServiceNow applications.

Engage with my customers

Learn how you can communicate with your customers using the ServiceNow platform.

Create reports

Create reports with your data on the ServiceNow platform.

Learn about the ServiceNow platform

See what you can do with the ServiceNow platform.

Get help

Find resources to help you with the ServiceNow platform.

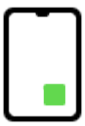
Build apps with pro-code tools

Use the ServiceNow platform to build apps.

ServiceNow Studio

Build custom applications using integrated builders and tools in one place.

Mobile App Builder



Build ServiceNow mobile applications.

VS Code Extensions

Edit your ServiceNow applications in Visual Studio Code with the help of the ServiceNow Extensions for VS Code.

AES

Build apps in a structured environment for fast development and deployment.

Manage apps with pro-code tools

Manage your ServiceNow apps.

Customize my apps

Customize your apps on the ServiceNow platform.

Automate my apps

Automate your ServiceNow applications.

Secure my apps

Secure your ServiceNow applications.

Test my apps

Test your apps on the ServiceNow platform.

Deploy my apps

Deploy your apps with the ServiceNow platform.

Maintain my apps

Maintain your apps on the ServiceNow platform.

Customize my apps with pro-code tools

Customize your ServiceNow apps.

UI Builder

Learn how to create custom experiences with the ServiceNow platform.

Table Builder

Customize your data with Table Builder.

Workspace Builder

Customize your data with Workspace Builder.

Scripts

Use custom scripts with the ServiceNow platform.

Automate apps with pro-code tools

Automate your ServiceNow apps.

Automation Discovery

Identify automation opportunities for your workflows on the ServiceNow platform.

Flows in Workflow Studio

Enables process owners to automate work with the ServiceNow platform.

Decision Builder

Enable developers to decouple decision logic from their code by creating and maintaining decision rules.

Playbooks

Enable process owners to author cross-enterprise workflows and create a single, unified process.

Business rules

Use business rules to accomplish tasks like automatically changing values in form fields when certain conditions are met.

Secure apps with pro-code tools

Secure your ServiceNow apps.

App Engine Studio roles and permissions

Control who is permitted to use or edit your apps.

Edge Encryption

Encrypt sensitive data on your company premises before sending it over the Internet.

UI Policies

Dynamically change the behavior of information on a form and control custom process flows for tasks.

Roles

Control access to features and capabilities in applications and modules.

Access Control

Control which Customer Service and Support employees can access your instance, and when.

Users and Groups

Manage the individuals who can access your instance by defining them as users in the system.

Test apps with pro-code tools

Test your ServiceNow apps.

Automated Test Framework

Create and run automated tests to confirm that your instance works after making a change.

Test Management

Streamline the management of testing processes to help you deliver software products more efficiently and with fewer errors.

Script Debugger

Debug scripts using session logs and ServiceNow AI Platform debugging tools such as a walk-through script debugger and error messages that display in the UI.

Script Tracer

Filter your debugging search to quickly narrow down script problems.

Session Log

View and download the session log for business rules, script includes, and a custom UI.

User impersonation

Impersonate other authenticated users for testing purposes and view impersonation logs.

NOW Command Line Interface (CLI)

Perform instance operations from your local system with a command-line interface.

Deploy apps with pro-code tools

Deploy your ServiceNow apps.

The Next Experience

App Engine Management Center

Track and manage your App Engine Studio (AES) requests, deployments, applications, and collaborative developers using the App Engine Management Center (AEMC) in your production instance.

Core UI Tech Stack

Application Repository

Learn about developing on the ServiceNow platform.

Cloud Provisioning and Governance

The ServiceNow® Cloud Provisioning and Governance application provides a single interface to access cloud resources, publish cloud offerings to a catalog, and manage the usage of those resources.

Maintain apps with pro-code tools

Maintain your ServiceNow apps.

The Next Experience

System Update Sets

Allow administrators to group a series of changes into a named set and then move them as a unit to other systems for testing or deployment.

Service Mapping

The ServiceNow® Service Mapping application discovers all application services in your organization and builds a comprehensive map of all devices, applications, and configuration profiles used in these application services.

Engage with customers with pro-code tools

Engage with your customers using ServiceNow apps.

Chat bot

Virtual Agent Designer

Create and manage virtual agent topics using the ServiceNow platform.

Virtual Agent Dashboard

The Conversational Analytics Dashboard helps you improve Virtual Agent interactions with users by providing deep insights into conversational data.

Artificial intelligence

Natural Language Understanding Workbench

Use the NLU Workbench to create morphological representations of human language.

Platform Analytics

Optimize processes and increase productivity with Platform Analytics, virtual agents, and machine learning.

Predictive Intelligence

Provide a layer of artificial intelligence that empowers features and capabilities across ServiceNow applications to provide better work experiences

Reporting on data from pro-code apps

Most applications that you create have some level of reporting requirements. Reports should be actionable to drive change.

"Reporting" generally refers to showing the data inside facts tables like Incident [incident]. You can also create key performance indicators (KPIs) to track changes in this data over time, through the Performance Analytics application.

Currently the ServiceNow AI Platform® is in transition between two user interfaces for showing this information:

- The older Core UI technology. This UI includes the Reporting application, which only shows data directly from tables, and PA Widgets, which show data from Performance Analytics indicators. Both reports and PA widgets can be placed on Core UI responsive dashboards. For more information, see Reporting, dashboards, and Performance Analytics in the Core UI.
- The newer Platform Analytics technology. This UI includes Data Visualizations, which let you report on data from any source. These visualizations can be placed on Platform Analytics dashboards, along with Platform Analytics filters. For more information, see Platform Analytics experience.

All Platform Analytics objects are rooted in the Next Experience UI Framework and are available to developers. However, a non-developer can still build their own objects through the Platform Analytics experience, without using UI Builder. For more information, see Platform Analytics experience.

Note:
Although "reporting" is a general term, this documentation usually uses "report" and "reporting" to refer to the Core UI Reporting application and "visualization" or "visualize" to refer to Platform Analytics data visualizations, for disambiguation.

Follow these guidelines when building reports or data visualizations:

- Creating reports or visualizations on large tables can negatively impact performance. Be sure to filter by a date range or other limiting criteria rather than showing all records on the table.
- Grouping by fields that contain many possible values can negatively impact performance.
- If loading a report or visualization gives a Long running transaction timer message, consider adding more data filters to reduce the load time.
- If you need to export a report, data visualization, or dashboard on a regular basis, schedule the export and email.

In Platform Analytics, you have several possibilities for showing multiple data visualizations on one page:

- Create the data visualizations and the dashboards entirely inside the Platform Analytics experience. This approach does not require a developer role or special technical knowledge, and probably should be explored before you try a more complex solution.
- Create data visualization components in a generic UI Builder page, along with filters and other components. This approach gives you the most freedom as a developer, but also requires the most configuration.
- Create the data visualizations and the dashboards inside the Platform Analytics experience, but then place the dashboards inside UI Builder pages using the Dashboard page template. This approach lets you use the convenience of the Platform Analytics experience to create dashboards, data visualizations, and filters in your own experiences/workspaces. It also gives you the freedom to customize the page configuration partially. For more information, see Creating Platform Analytics pages in your own workspace.
- Create a technical dashboard and populate it inside UI Builder. This approach is almost the same as creating your own UI Builder page from scratch, but the dashboard is available in the dashboard library, has dashboard details, and can be shared like other dashboards. For more information, see Technical dashboards.

Low-code and no-code tools: What you can do to build apps

When building low-code apps, you can customize them, create reports on their usage, and more.

Programming basics

Software development usually encompasses a standard set of steps. If you're new to developing applications, read on.

Your job as a developer

If you're new to developing applications, if you don't even know how to code, ServiceNow has a low-code development platform called Creator Studio that makes creating a basic request-fulfill application possible for you. Development might be new waters for you to swim in but you will find the low-code tools easy to use. So, don't be shy about developing an app!

Software developers do many things but what they have in common is solving problems using computer code. ServiceNow offers coding platforms that require no coding experience, platform coding experience, and expert coding experience. The less coding required, the more work the coding platform does for you. So, even experienced software developers will appreciate no-, low-, and platform-level coding products, such as Creator Studio and ServiceNow Studio.

Software development life cycle

The common stages of developing an application are:

1. Define the problem.
2. Plan the solution.
3. Code the solution.
4. Test the application.
5. Deploy the application.
6. Document the application.

These steps are commonly referred to as the software development life cycle. ServiceNow developer documentation is grouped according to these steps.

Do you really need to create a new application

Your first step is to determine if creating an application is necessary. Consider:

- Can you extend an existing application instead of creating a new one?
- How many people will the application serve? If not many, is it worth the effort?
- Are you willing to maintain the application as things change over time?
- How often will anyone use this application? If not often, is it worth the effort?

If creating a new application makes sense, then move forward.

Defining the problem

If you're planning to create an application, you must have some notion of what you want it to do. You might not have a detailed idea of the solution, however. At a minimum, you need to define in detail:

- Desired application output
- Data going into the application

The data going in typically comes from a table of data. You need to know the table name and the type of data in it. You can use ServiceNow tools, like Table Builder, to store and customize your data.

The desired output might be a dashboard, data stored in a table, or a piece of equipment being sent to an employee. Before you decide on the output, show a mockup of your output to a lot of people to see if they can suggest improvements to the output. Do not skip this step.

Planning the solution

There are various ways to create an algorithm that produces the output you want. The easiest methodology is to use a flowchart that starts with the input data and shows each step in the process that leads to the output. Using a flowchart enables you to focus on the big picture of what you want to do and avoid how to do it. Look at your flowchart critically to optimize the process.

You may need to get permissions to use tables of data or even permission to create an application. For example, citizen developers are granted app development permissions through App Engine Management Center.

For more information about ServiceNow planning tools, see Planning your application.

Coding the application

To code the application, you can use:

- Low-code ServiceNow tools, such as App Engine Studio.
- Platform developer ServiceNow tools, such as ServiceNow Studio.
- Pro-dev source code tools, such as ServiceNow IDE and ServiceNow SDK.

For more information about ServiceNow coding platforms, see Developing your application.

Testing your application

Testing your application requires inputting data to make sure the outcome is accurate. It is important to input a lot of data, even incorrect data, to see how well your application handles correct and incorrect inputs. Put in data that is too large or the wrong type. Put in no data at all. Try to break your application to prevent your users from doing so. Handling error conditions gracefully is critical for a good customer experience.

For more information about ServiceNow testing tools, see Testing and debugging applications.

Deploying your application

Now that you've tested your application, it's time to deploy it so customers can use it. Application deployment is done by system administrators not developers.

For information about ServiceNow deployment tools, see Deploying applications.

Maintaining your application

Maintaining the application deals with issues such as overloading a server, application errors, and feature updates. Accounting for feature updates is a developer's job. Seeing how well an application is working is a system administrator's job.

For more information about ServiceNow tools that help you maintain your application, see Maintaining your application.

Documenting your application

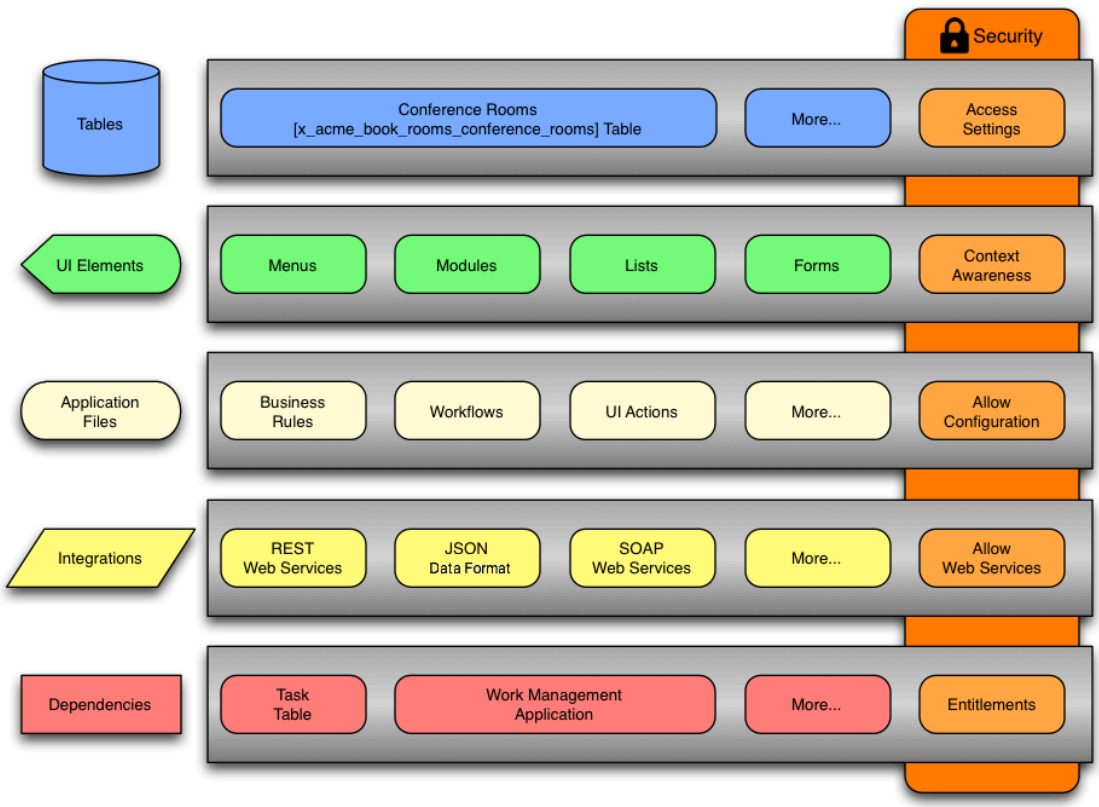
Application development is never complete until the application is documented. There are many reasons to document your application:

- Internal notes help other developers work on your application. It takes a lot of time to figure out the reasoning behind programming decisions and methodology. Documenting those helps future developers maintain your application.
- Users need to know how to use your application. As transparent as you believe the application is, you will find many people who get frustrated trying to use it. Do a usability test on your application and documentation to see where users run into problems. The broader the audience, the more important the application, the more important the documentation. Consider using an experienced technical writer to write the documentation.

Anatomy of an application

Applications consist of several types of files and records that collectively deliver a service.

Application model



Custom application record

The custom application record defines and identifies an application and all its associated artifacts.

It is similar to a system dictionary record for a table or column in that it stores the most current configuration of an application. The system automatically creates a custom application record during the application creation process. Application developers can use this record to perform the following tasks.

- Change the application name
- Change the application version

- View the scope the system uses to identify application files and configuration records
- Enable scoped administration
- Manage design and runtime access to the application
  - Select what JavaScript standards the application supports
  - Select how the system tracks runtime API operations
  - Permit or restrict access to tables from other applications
- Monitor or enforce subscriptions
- Select the default menu in which to display application modules
- Set the user role required to access the application
- Add or update a logo
- View all application files
- View resources from other applications on which the application depends
- View the run-time resource to which the application has been granted access
- View the design-time resources to which the application has been granted access

Application versions

Each installed application has a version as defined by its application developer in the custom application record.

The system uses this version information to determine whether there are updates available from the ServiceNow application repository or ServiceNow Store.

Application scope

Application scoping protects applications by identifying and restricting access to application files and data.

Administrators can specify what parts of an application are accessible to other applications from:

- The Custom application record
- Each application Table record

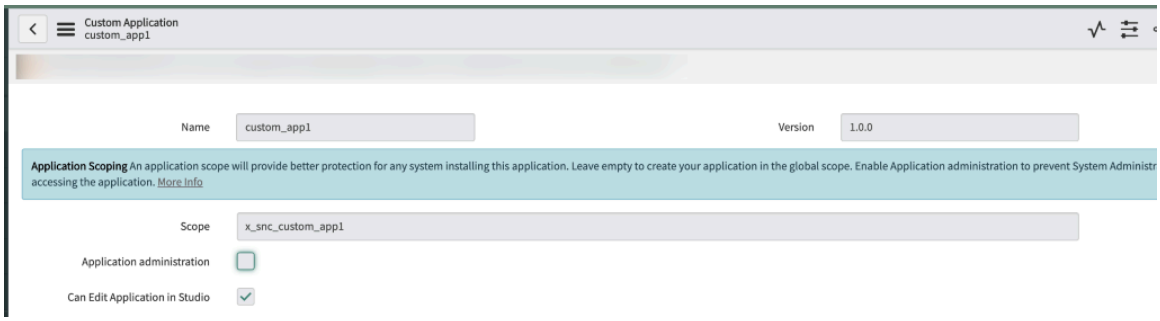
For example, suppose that you create a conference room booking application in its own application scope. By default, the application can access and change its own tables and business logic but other applications can't unless you give them explicit permission. The application scope ensures:

- The conference room booking application does not interrupt core business services.
- Other applications do not interfere with its normal functioning.

By default, all custom applications have a private scope that uniquely identifies them and their associated artifacts with a namespace identifier. The application scope prevents naming conflicts and allows the contextual development environment to determine what changes, if any, are permitted. Application developers specify an application scope when they create an application.

Tip:
Global apps can alter data that you don't intend to alter. You should leverage scoped apps to create new tables, and consider transitioning old ones to scoped apps. This allows you to split responsibilities with Delegated Development. To learn more about delegated development, see Delegated development and deployment.

Selecting the **Can Edit Application in Studio** option does not affect any custom or global applications in development on an instance. If you are the owner and choose to publish the application, you can restrict the development of customizations in Studio of. If you set **Can Edit Application in Studio** to false and then publish it, those who download the application to their own instances won't be able to edit the application in Studio. But they will have access to Legacy - Source Control integration features inside of Studio.



Related topics

Runtime access to applications tables

Global scope

The global scope is a special application scope that identifies applications developed prior to application scoping, or applications intended to be accessible to all other global applications.

Applications in the global scope do not append a unique namespace identifier to the application name. Global applications can have naming conflicts and data collisions when developers create multiple global applications with the same name.

Since all global applications are in the same scope, they bypass scope protections. Global applications allow other global applications access to their tables to

- Read records
- Run API requests
- Create configuration records

Typically, only applications provided by ServiceNow are in the global scope. However, any custom applications created before application scope was implemented are also in the global scope. Additionally, developers with the sn_g_app_creator.app_creator role can create applications in the global scope. For more information, see Allow global application development in Guided Application Creator.

Applications in the global scope are eligible for upload to the application repository, but not to the ServiceNow Store.

Publish an application to the ServiceNow Store

Namespace identifier

The system adds a namespace identifier to the front of application artifacts such as tables, scripts, and configuration records.

The identifier cannot be changed or removed from application artifacts to ensure that they are always associated to the proper application and that they have a unique name.

The system generates a namespace identifier from the following information:

Elements used to generate a namespace identifier

Element	Requirements	Sample Value
The prefix characters for a scoped application.	Scoped applications always start with an x_ prefix.	x_
The instance customer prefix (glide.appcreator.company.code)	This string is two to five characters long. ServiceNow generates this prefix for each customer. The instance stores the prefix in the *glide.appcreator.company.code* system property.	acme
The application ID	This string can be up to 40 characters long. If the string is longer than 18 characters, the system truncates the application name and appends it to prefix `x_<glide.appcreator.company.code>_`. Application developers set this ID when they create the application. The system uses the application name by default.	book_rooms

The example values generate a namespace identifier of x_acme_book_rooms.

Namespace identifier examples

The following examples illustrate generating namespace identifiers for applications, tables, and fields.

Example namespace identifiers

Action	Element generated	Explanation
1. Generate a namespace identifier for a private scope application called Book Rooms.	x_acme_book_rooms	This is a combination of the vendor prefix and applicatio
2. Generate a namespace identifier for a global scope	None	The system does not generate namespace prefixes for g applications.

Example namespace identifiers (continued)

Action	Element generated	Explanation
application called Marketing Events.		
3. Add the conference rooms table to the Book Rooms application.	x_acme_book_rooms_conference_rooms	This table is in the Book Rooms scope so begins with th namespace identifier.
4. Add a Marketing Event table to a global application.	u_marketing_event	Custom tables in the global scope always use the `u_` namespace identifier.
5. Select Book Rooms in the application picker and add the **Capacity** field on the Conference Rooms table.	capacity	The field is in the same scope as the table so it does not have its own namespace identifier. However, to dot-walk to the field in a script, you would use the full path including the table namespace identifier: `x_acme_book_rooms_conference_rooms.cap`
6. Select Book Rooms in the application picker and add the **Theme** field to the Marketing Event table.	x_acme_book_rooms_theme	The field is in a different scope from the table so it is prefixed with the `x_acme_book_rooms` namespace identifier. To dot-walk to the field in a script, you would use full path including the field namespace identifier: `u_marketing_event.x_acme_book_rooms_th` **Note:** This example assumes that the Marketing Event tab allows other application scopes to add fields.
7. Select Marketing Events in the application picker and add the **Theme** field to the Marketing Event table.	u_theme	Custom fields in the global scope use the **u_** prefix. To dot-walk to the field in a script, you would use `u_marketing_event.u_theme`.

Application tables

Application developers create tables and their associated lists and forms for users to add and update records.

An application owns its tables and determines whether other applications can access resources from them. For example, the Book Rooms application can store conference room data in the Conference Rooms [x_acme_book_rooms_conference_rooms] table and permit other applications to read this data.

The system uses standard access controls to manage user access to application data. During application creation, developers can specify an application-specific user role for these access controls. They can also use application access settings to manage runtime and design time access to application tables.

Note:
Certain ServiceNow AI Platform subscriptions include custom table entitlements. You can create custom tables for any purpose, up to the entitlement limit in the subscription. To learn more about how your usage administrator maps the custom tables that you create to subscriptions, see Map custom tables to a product subscription in Subscription Management.

Be aware of these database limitations:

- The system can only have a maximum of 1000 columns per table. Although 1000 columns is a specified limit, this limit doesn't mean you can physically have 1000 columns within a table. The number of columns within a table is defined by the database used in the ServiceNow datacenter, not by the ServiceNow AI Platform.
- Every table, regardless of storage engine, has a maximum row size of 65,535 bytes. Storage engines may place additional constraints on this limit, reducing the effective maximum row size.
- The system can't have more than 10 medium-length or longer **String** fields to a single table. Attempting to save a large number of characters in 11 or more String fields can result in the following error: Syntax Error or Access Rule Violation detected by database (Row size too large (> 8126).
- When you create fields, the u_ prefix is automatically added to the column name. If the column label that you enter contains leading numeric characters, they are replaced by the u_ prefix.

For more information on database limitations and general questions on tables in your ServiceNow instance, see KB0749585.

Related topics

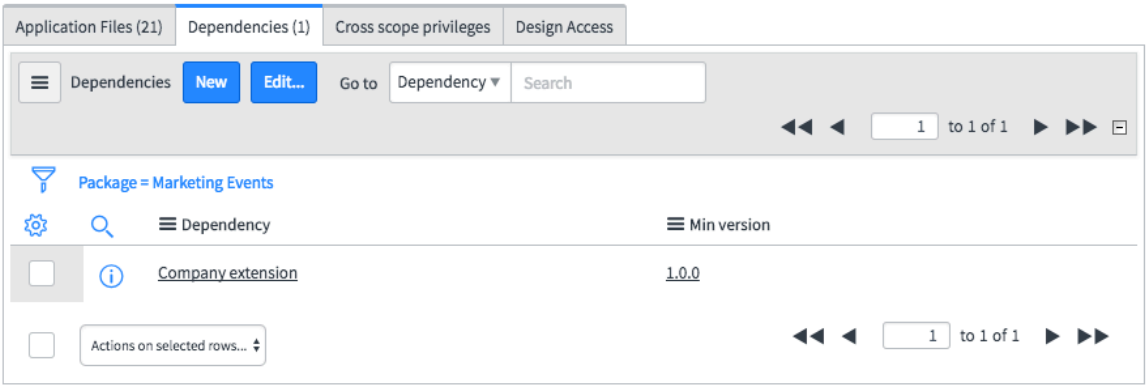
Application access settings

Dependencies for custom applications

Every custom application record includes a related list identifying its dependencies on other applications.

Administrators can review this list to determine whether an application poses any risk to existing processes or data. Application developers can use this list to ensure that their applications have the proper access to other applications.

Sample application dependencies



Application files

Application files are configuration records that allow developers to extend application functionality.

Application developers create application files when they add configuration records for application logic such as business rules, workflows, and script includes. Scoped applications do not own these tables, but they do own the records (files) within these tables. For example, adding a business rule to check for available rooms from the Conference Room table adds an application file to the Business Rule [sys_script] table. Application developers can view the complete list of application files from the custom application record.

The Application File [sys_metadata] table is the parent table for all tables that contain configuration records. It provides a series of standard fields that define the attributes for a configuration record. Tables that contain configuration records extend the Application File table. For example, the Business Rule [sys_script] table extends the Application File table.

Developers do not create application file records directly from the Application File table. Instead, they create or modify configuration records, and the system creates or modifies the associated application file record. Most configuration record tables do not display a reference field or related list for the Application File table. By default, only Applications [sys_scope] and Tables [sys_db_object] have a reference to the Application File table.

The system also tracks application file records in Update Sets. Whenever you change an application file record or its related configuration record, the system adds a corresponding record in the Customer Updates [sys_update_xml] table. The system uses a single update record, ensuring that a configuration record and its application file are kept in sync when transferring applications between instances. To avoid collision, users are warned when they edit an application file that has been previously edited in another Update Set.

Administrators can:

- View file properties for configuration records.
- Protect application files from changes during upgrades.
- View parent-child relationships between configuration records.

Related topics

Legacy - Add an application file to an application

View file properties

Administrators can view the application file properties of a single record.

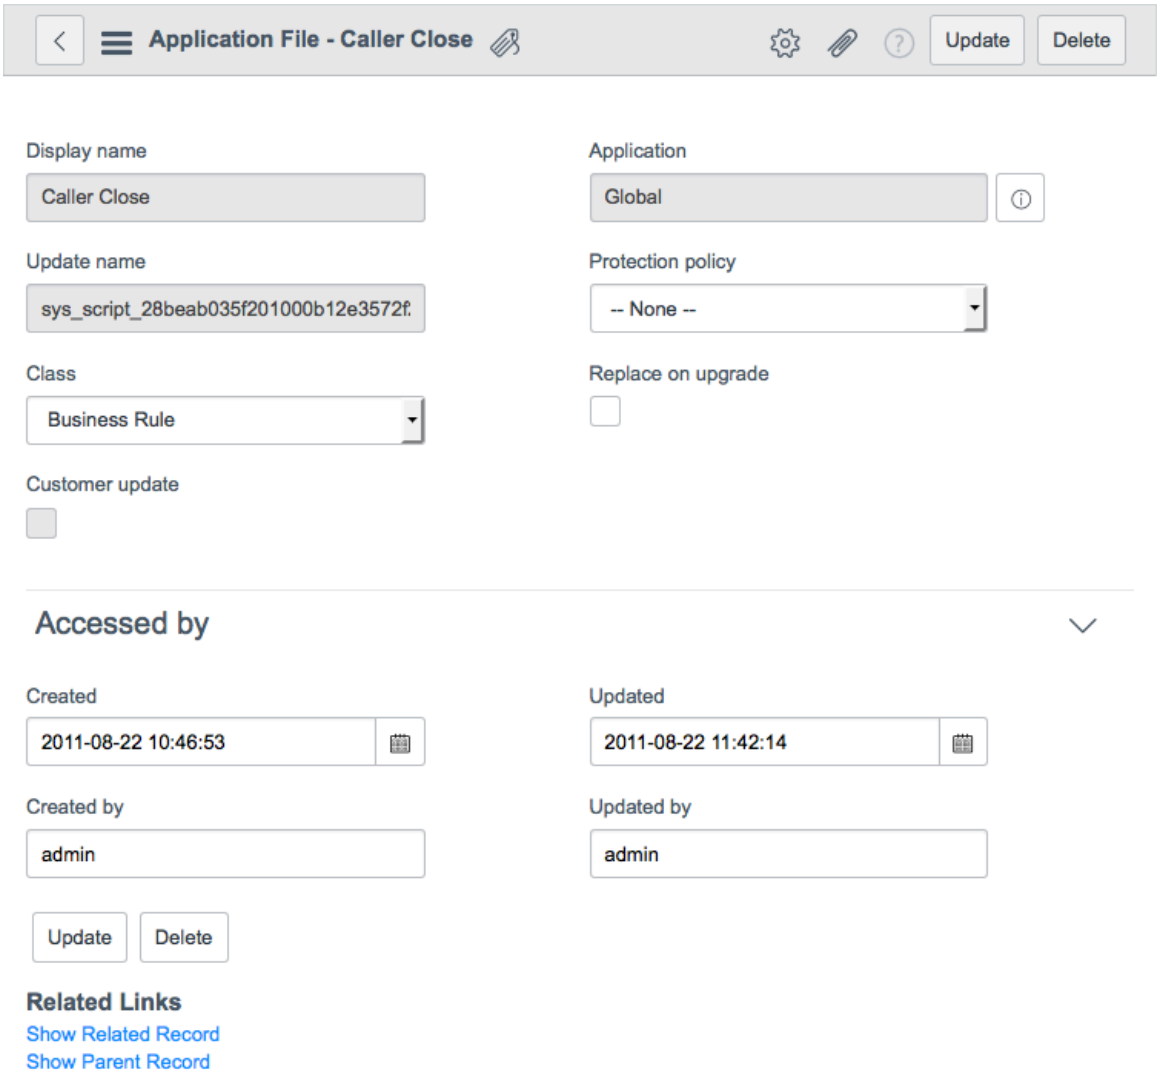
Before you begin
Role required: admin

Procedure

1. Navigate to the form view of the configuration record.
   For example, navigate to **All** > **System Definition** > **Business Rules** and select a business rule for the Incident table.
2. Right-click the form header and select **Show File Properties**.

   The Application File table provides the standard fields that define the attributes for the configuration record.

3. To return to the configuration record view, click the **Show Related Record** related link.



4. Navigate between a customer update record, the file properties view, and the configuration record view.

Option	Description
Show Related Record related link	Navigate to the configuration record
Show Parent Record related link	Navigate to the parent record of the current configuration record.
Descendants related link	View child configuration records, such as a field label translation.

Application File form

Use the Application File form to view relationships between applications and configuration records.

Application File form fields

Field	Description
Display name	Display name for the configuration record.
Update name	Unique identifier for the configuration record. This value is used to identify versions and updates of the record.
Class	Table that contains the configuration record.
Application	Application that contains the configuration record.
Protection policy	Policy that determines if the configuration record is protected from changes. See Protected Application Files.
Created	Creation date of the configuration record.
Created by	User who created the configuration record.
Updated	Last update date for the configuration record.
Updated by	User who last updated the configuration record.
Related Record Versions	Version records for the related configuration record. A version record is created every time a user changes the related record. Use this list to compare versions of the configuration record or to revert to a previous version. See Versions.
Related Record Updates	Local update records for the related configuration record. An update record is created for the most recent change to the related record in a given Update Set. See Update Sets.

Note:
You may find it useful to manually add an **Owned By** (owned_by) field to this form. It indicates, for each application, who in IT owns the application and is responsible for maintaining information about it. The Data Certification function uses this field to send certification tasks every quarter, or at any time interval that is configured. You can assign certification tasks to other users, but using this field limits configuration effort. To learn more about adding a field to a form, and about Data Certification, see Using the form designer and Data Certification.

Application file protection policy

A read-only protection policy prevents anyone from modifying an application file or its related record.

Some application code shipped with the ServiceNow system requires special protection. Only a ServiceNow employee can alter the protection policy and then modify the application file or its related record. A ServiceNow employee cannot edit protected files without changing the policy designation first.

To prevent customizations from being overwritten by system upgrades, the upgrade process automatically skips changes to customer-updated records. If you modify an application file or related record that is later designated as *Read-only* in an upgrade, the application file maintains the default protection policy of *Write*. You keep the existing modifications and can continue modifying the records.

Note:
Reverting a customized file to its baseline state causes the record to inherit the new protection policy as well. For example, a record going from a *Write* protection policy to a *Read-only* protection policy.

Relationships between configuration records

The Application File Types table defines parent-child relationships between configuration records.

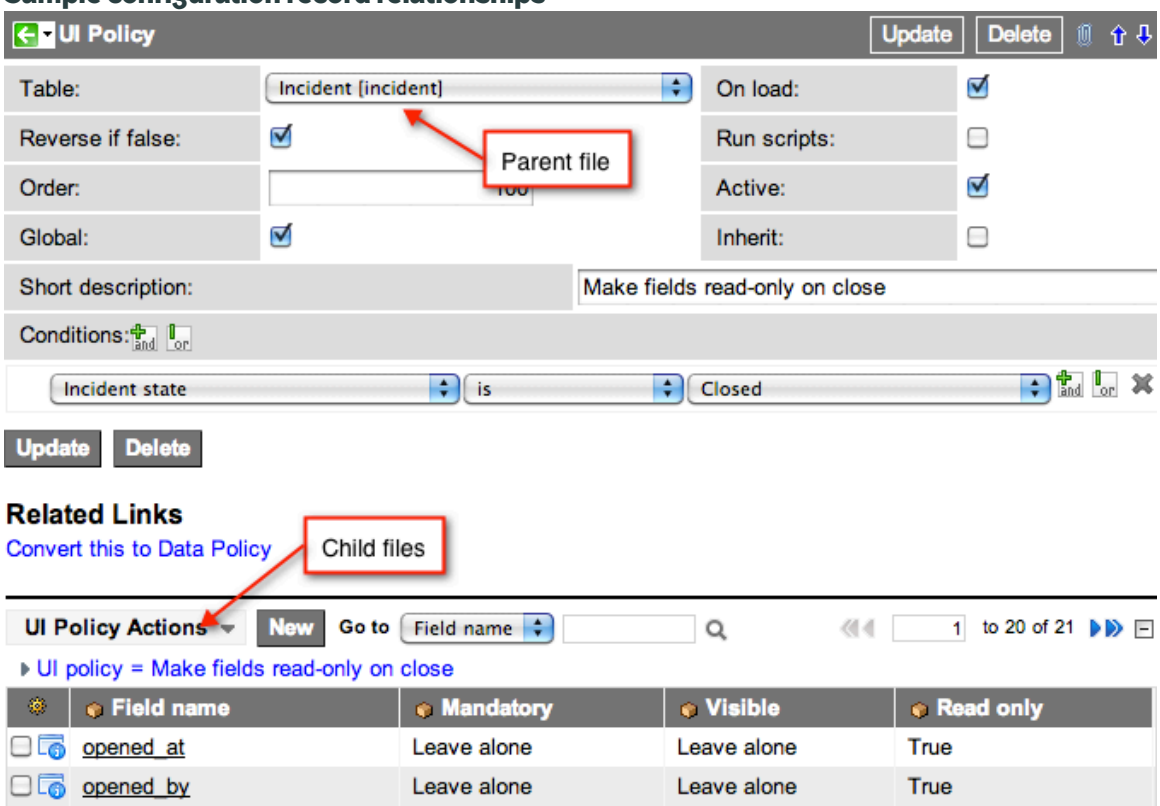
The system uses this structure to keep configuration records that normally belong together in the same application.

Note:
Do not modify the Application File Types table as it provides system functionality.

For example, consider the parent-child relationships for a UI policy.

- The UI policy is a child of the application table.
- UI policy actions are children of the UI policy.
- UI policy actions have a parent UI policy and a grandparent application table.
- The UI policy actions and the UI policy are all descendants of the application table.

Sample configuration record relationships



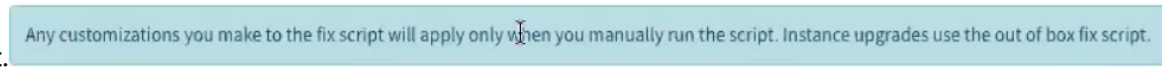
Fix scripts

A fix script is server-side JavaScript code that you run after an application is installed or upgraded.

Include fix scripts to make changes that are necessary for the data integrity or product stability of an application.

Administrators can create, manage, and run fix scripts. Users with the script_fix_admin role can create and manage fix scripts but cannot run fix scripts.

Note:
An annotation with the following message shows up when you open an existing fix script or create a new fix script.



Create a fix script

Create fix scripts to ensure the system installs or updates an application properly.

Before you begin
Role required: script_fix_admin or admin

About this task
Use fix scripts to add, update, and delete data, including rules, scripts, and property settings.

Procedure

1. Navigate to **All** > **System Definition** > **Fix Scripts**.
2. Click **New**.
3. Define the fix script by filling in the fields on the form.

Field	Description
Name	Unique, descriptive name for the fix script.
Unloadable	Option to create Customer Update records [sys_update_xml] when the fix script runs. Fix script tests enforce the Unloadable option.
Before	Option to run the fix script before installing or upgrading the application.
Record for rollback	Option to record execution of the script so that it can be reverted if needed.
Description	Description of the fix script.
Script	Code for the fix script.

4. Click **Submit**.
5. Test the fix script and make any necessary changes.

Test a fix script

Test your fix scripts to ensure they install or update applications as expected.

Before you begin
Role required: admin

About this task
Fix scripts add, update, and delete data, including rules, scripts, and property settings.

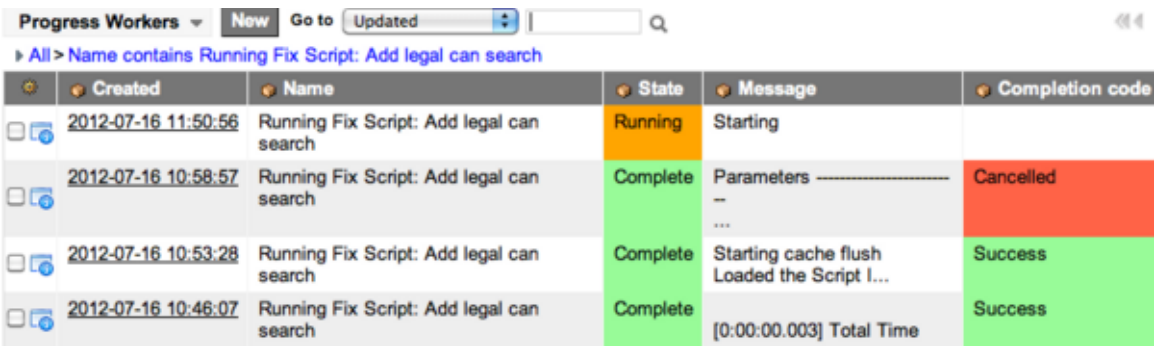
Note:
Do not test fix scripts on production instances.

Procedure

1. Open the fix script record.
2. Review the code design to ensure that it can run more than once on the same system without causing damage.
   For example, you may write a fix script that adds a role to a property by default. Design the script so that it can run multiple times on the same system without overwriting the existing data, even if it is not necessary to run the script again after the initial installation.
3. Click the **Run Fix Script** related link.
   Tests enforce the Unloadable option.
4. Confirm how to run the script.

Option	Description
Proceed in Background	Use this option for long-running scripts, or if you do not know the expected execution time.
Proceed	Use this option to run the script immediately and display the results in a confirmation win dow.

5. Review the results from the Progress Workers related list, and make any necessary changes.
6. To manually stop a running fix script:
   a. From the **Progress Workers** related list, select a worker in the `Running` state.
   b. Select the **Cancel job** related link.



Run fix scripts

Fix scripts run at the first installation or updated after they have been added to an application. However, previous fix scripts do not run on subsequent application updates, and you must manually run any necessary fix scripts.

Before you begin
Role required: admin

About this task
To run a fix script:

Procedure
1. Navigate to **All** > **System Definition** > **Fix Scripts**.
2. Edit the filter to search for your application name.
   For example, `Application | is | Book Rooms`).
3. Open the fix script record.
4. Click **Run Fix Script**.

Fulfillment tables

To enable a production instance to enforce entitled usage of your ServiceNow Store App, you configure the tables where only record owners or subscribed app users can make updates.

For any table that you, the developer, create or extend to support a custom application, you can specify that the table is a fulfillment table. In a fulfillment table, only a subscribed fulfiller user can perform a fulfiller action (typically, create/update/delete a not-own record).

In contrast, for a table that is not a fulfillment table, any user—even a user who is not subscribed —can act as a requester. The intent is to allow the usage admin to enable subscription enforcement on any production instance that implements the application.

Ownership of records in a fulfillment table

To enable the system to identify a fulfiller action, you define how to determine ownership of any record in the table. The developer of the application specifies the set of conditions that determine whether a user owns the record. For example, *`UserA`* owns a record in a task table if *`UserA`* opened the record or another resource opened the record on behalf of *`UserA`*.

For task-extended tables, time cards, and apps that require a subscription, the system sets the table as a fulfillment table by default and auto-assigns the ownership condition. For tables that you create to support your app, you can mark the table as a fulfillment table and can specify the ownership condition (for example, use the filter **[opened_by][is][currentUser] OR [caller_id][is] [currentUser]**).

System default conditions for ownership

Action	Ownership condition [owner_condition]
task extension	opened_by (read-only)
catalog request	requested_for (read-only)
other tables in apps that require a subscription	sys_created_by (read-only)
tables created by developer for app that requires a subscription	Specified by developer

Specify that a table is a fulfillment table

You configure a table as a fulfillment table to enable the system to prevent updates by users who are not subscribed to the app. For ServiceNow Store apps, you configure a table as a fulfillment table to enforce that fulfillment usage complies with your subscription use policy.

Before you begin
Role required: usage_admin, admin

Procedure

1. While working on a table, open the **Table Subscription Configuration** related list.
2. Select **Fulfillment table**.
3. Specify how the system determines ownership of records in the table so that both end users who own a record and subscribed fulfiller users can update the record: Specify the **Ownership condition**.
   For example, set the filter as **[opened_by][is][currentUser] OR [caller_id][is][currentUser]**.

Personal developer instance guide

ServiceNow® offers free personal developer instances (PDIs) to Developer Program members to learn, explore, and experiment with the ServiceNow AI Platform®.

ServiceNow® offers free personal developer instances (PDIs) to Developer Program members who want to develop applications or improve their skills on the ServiceNow AI Platform®. PDIs provide members with a sandbox environment to experiment with the ServiceNow AI Platform and build greater value for their businesses. The ServiceNow® Developer Program allows each member to have only one instance to maximize this valuable resource for all Developer Program members.

Personal Developer Instances (PDIs) can be used to test application ideas without impacting a customer or partner instance. PDIs are intended for you to use to learn, explore, and experiment with the ServiceNow AI Platform®. PDIs are not intended to be used for business or production purposes. Using a PDI for business or production is a violation of the ServiceNow® Developer Program Agreement. With a PDI, you receive admin-level access to all of the features the ServiceNow AI Platform® has to offer. Use your PDI on a continuous basis and it is yours forever.

Learn more on the ServiceNow Developer Site.

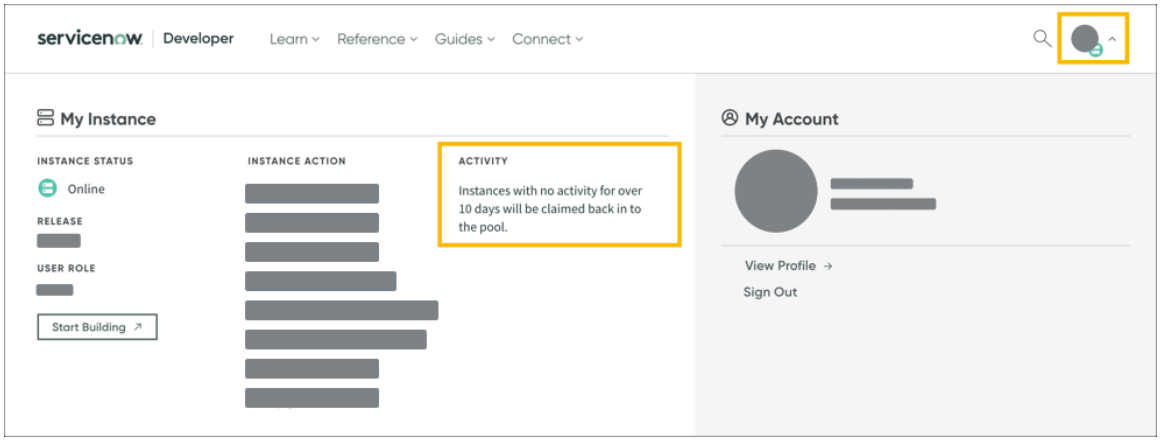
Understanding PDIs

PDIs require you to select a specific release and maintain consistent usage to avoid hibernation.

Sign in to the Developer Site to keep your PDI active. After a period of inactivity, your instance is reclaimed. Back up your work regularly to prevent data loss.

Note:
To save your work, commit your work to source control or create update sets. Work that is not saved may be lost due to instance reclamation.

When a PDI is reclaimed, the instance is unassigned from you, reset to its original state, and reassigned to another Developer Program member. Reclaiming instances allows the Developer Program to support active program members with free instances. The **Account** menu on the Developer Site header includes a reminder in the Activity section that you have ten days of inactivity.



Keep your PDI active by signing in or performing developer-type activities on your instance such as:

- Creating an application
- Creating a table
- Adding a field to a table
- Creating a Script Include

Hibernation

To keep the developer program free and provide PDIs to everyone who wants one, instances hibernate when they are idle. When a PDI hibernates, the database and application server shut down to conserve computing resources. All your data is preserved when the PDI hibernates. You can wake up a hibernating instance by signing in to the Developer Site. Waking an instance from hibernation resets the ten-day inactivity countdown.

In addition, you should also be aware of the following:

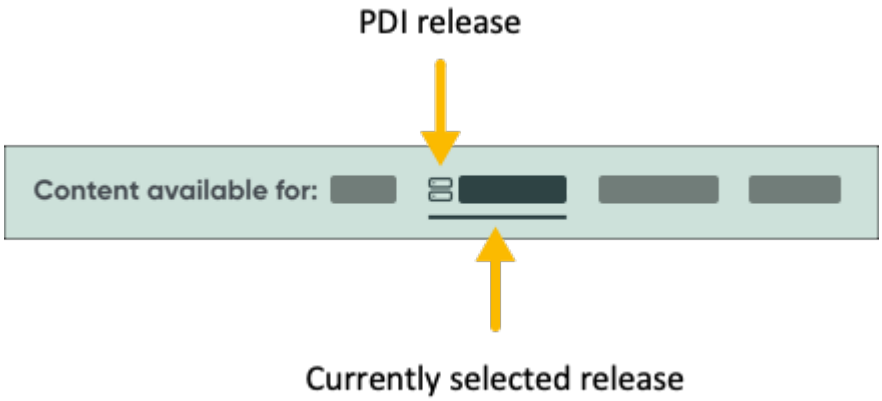
- PDIs are returned to the pool of available instances if they go unused for ten days. Duration may change due to availability.
- Availability is not guaranteed.
- PDIs cannot be clone targets or clone sources for customer or partner instances.
- PDIs cannot be linked via team development to customer or partner instances since they belong to ServiceNow®.
- PDIs cannot publish to the ServiceNow Application Repository or the ServiceNow® Store.
- PDIs cannot work with Machine Learning, Instance Data Replication, or MetricBase.
- Many ServiceNow® Store applications cannot be installed on PDIs.

Mainentance

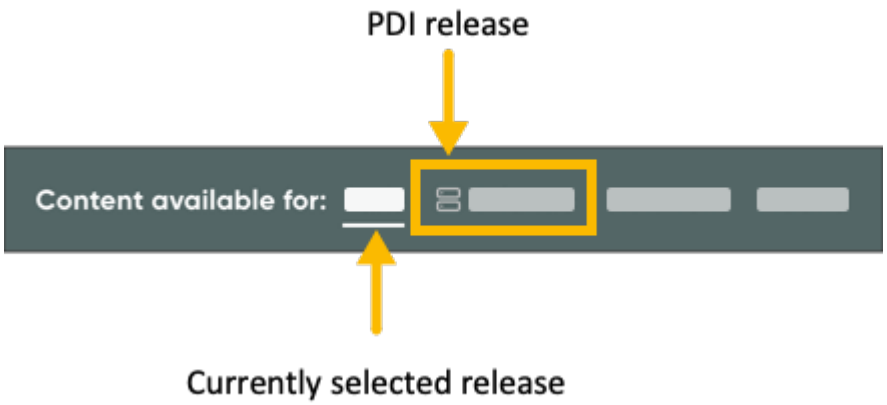
ServiceNow® occasionally needs to perform maintenance on the underlying infrastructure associated with PDIs. Maintenance includes updating and patching software, firmware, and replacing hardware. During maintenance, your PDI may not be accessible. The length of time required for maintenance depends on the type of maintenance. If available, the My Instance page indicates the expected completion time for planned maintenance. Your work and data on your PDI is unaffected by planned maintenance.

PDIs and the release selector

When content is available for different releases, use the release selector to select a release. The server icon next to the release name identifies the release of your PDI. The bar under the release name identifies the selected release. When working on your PDI, be sure the content matches your PDI.



If the content does not match your PDI release, click the release with the server icon to view the content that matches the release of your PDI.



The selector only shows releases for which the current page of content is available except when the content is not available for your PDI release. When the content is not available for your PDI release, the PDI release is grayed out and cannot be selected.

If your PDI is not on the latest release, follow the steps for upgrading your PDI to get the latest release.

Get a development instance

Request a personal development instance to build and test applications.

Before you begin
Role required: none

About this task
Get a free ServiceNow personal developer instance (PDI). Build applications within a sandbox to test application builders and deployment strategies.

Procedure

1. Navigate to the Developer Site in your browser.
2. Select **Sign In** or **Sign up and Start Building** if you do not have a ServiceNow developer account.
3. After logging into the ServiceNow Developer Site, select **Guides**.
4. Select **Guides Overview**.
5. Select **Personal Developer Instance (PDI) Guide** in the side navigation.
6. Follow the instructions to obtain your personal developer instance.

Obtaining a PDI

Get a new instance to run a PDI on the latest generally available release.

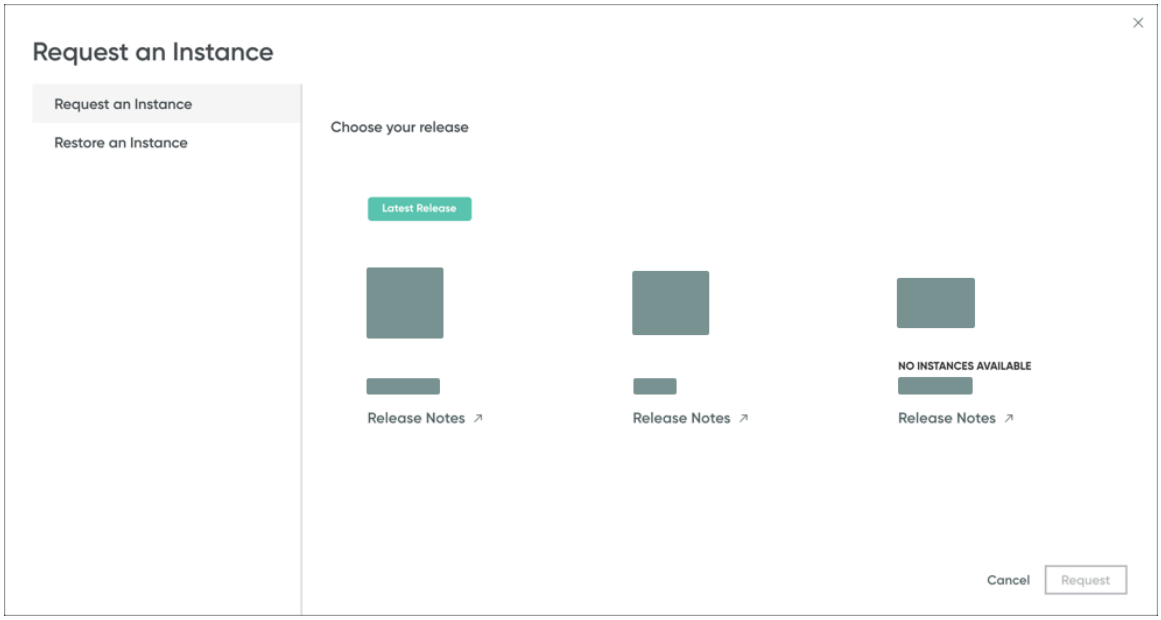
Before you begin
Role required: none

About this task
The first time you sign in to the Developer Site, you are given a PDI running the latest generally available release. You can use this PDI as long as you keep it active. If you want a PDI running an earlier release, release your PDI and request a new instance.

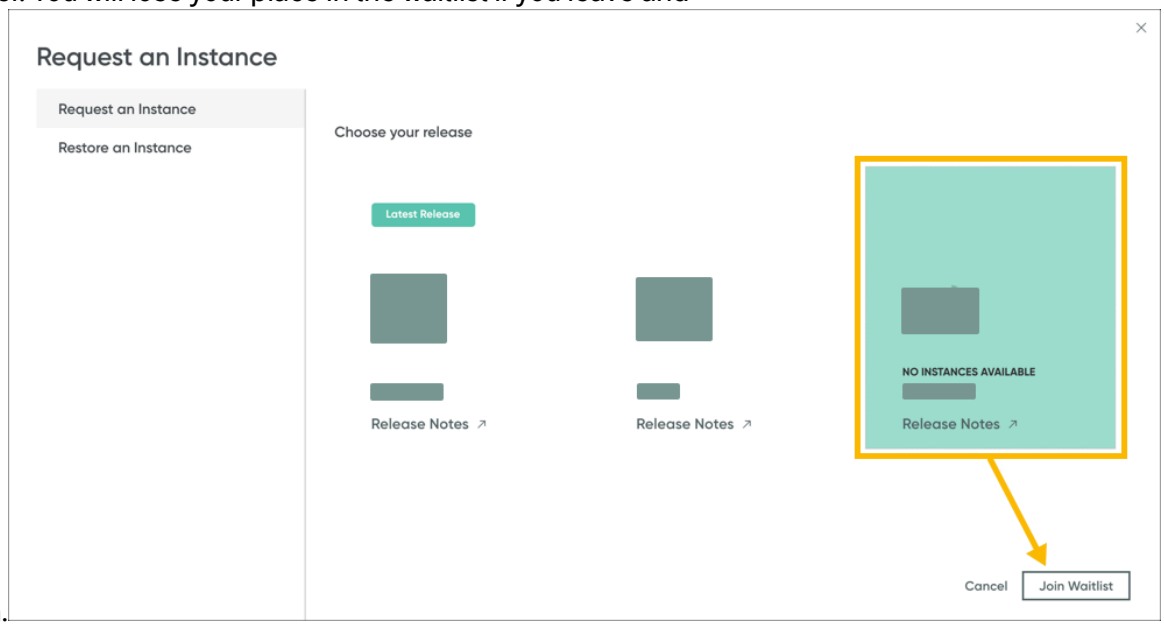
If you do not have a PDI because you released your PDI or went longer than ten days without activity, can request a new instance.

Procedure

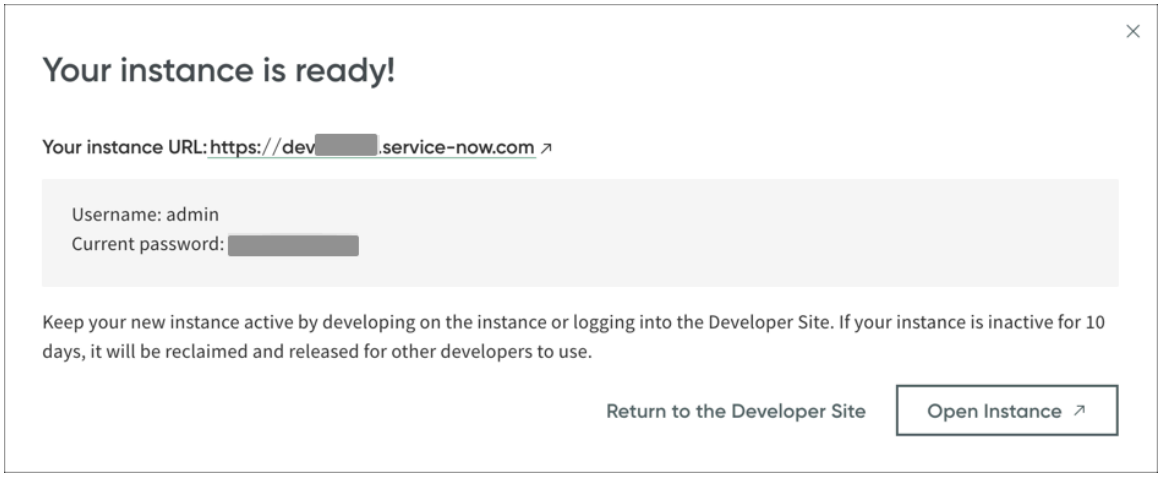
1. Sign in to the Developer Site.
2. Click the **Request Instance** button in the header.
3. In the **Request an Instance** dialog, select a ServiceNow® release for the instance and click the **Request** button.



- PDIs are a limited resource. If no PDIs are available for the desired release, select the release card for the release and click the **Join Waitlist** button. You will be notified when a PDI becomes available.
- To leave the waitlist, click the **Leave Waitlist** link in the header. You will lose your place in the waitlist if you leave and rejoin.



4. When an instance is assigned to you, the **Your instance is ready!** dialog supplies your instance URL and password.



5. Click the **Open Instance** button to open the instance in a new browser tab.

Accessing your PDI

Open your PDI and start building in the instance.

Before you begin

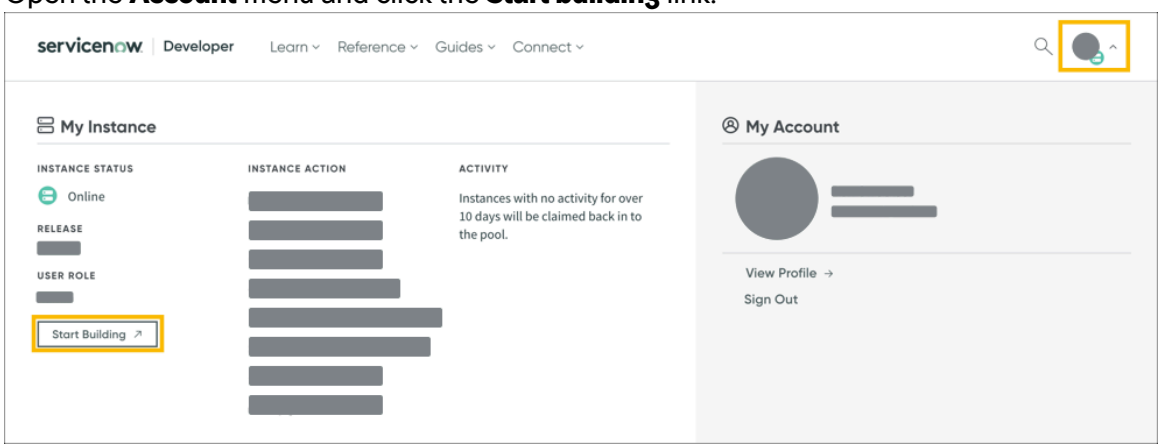
Role required: none

About this task

Once you have obtained a PDI, you can open the instance from **Account** menu.

Procedure

1. Sign in to the Developer Site.
2. Open the **Account** menu and click the **Start building** link.



3. If your PDI is hibernating, wait a couple minutes for your PDI to wake up before you can access it.
   Your PDI wakes from hibernation automatically when you sign in to the Developer site.
4. If your PDI hibernates while you are still signed in to the Developer Site, select the **Refresh Instance** instance action, then click the **Wake Instance** button to wake your PDI from hibernation.
5. If the instance is undergoing maintenance, you will need to wait for maintenance to complete before you can access your PDI.
6. If you have any issues accessing your PDI, review the Getting instance assistance section of this guide for steps you can take.

Activating a plugin from your PDI

One option to get started using an instance is to activate a plugin directly for your PDI.

Before you begin

Role required: none

About this task

You can activate most plugins directly in your PDI. Follow the instructions to Activate a plugin.

Procedure

1. On your PDI, open **All** > **System Definitions** > **Plugins**.
2. In the **Search** field, type the `<name of the plugin to install>`, for example, `app engine studio`.
3. On the plugin's card, click the **Install/Update All** button.
4. *Optional:*In the **Install** dialog, select the **Load demo data** option to install the plugin's sample data.
5. Select the **Install** button.
6. When the installation is complete, click the **Close** button in the **Install** dialog.

Activating a PDI plugin from the developer site

Activate your PDI plugin from the Developer Site to start working on an instance.

Before you begin

Role required: none

About this task

Some plugins require activation by ServiceNow® personnel on company and partner instances. You cannot activate these plugins from the plugins list. You may be able to activate these plugins from the **My Instance** section of the **Account** menu.

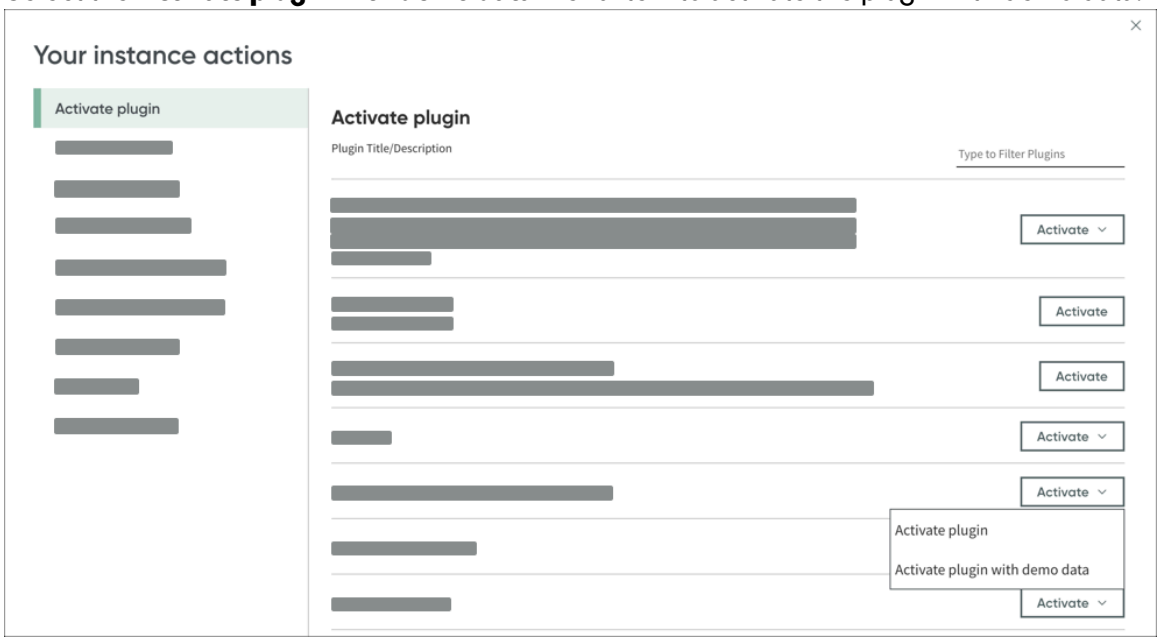
Note:
Many ServiceNow® Store applications cannot be installed to PDIs.

Procedure

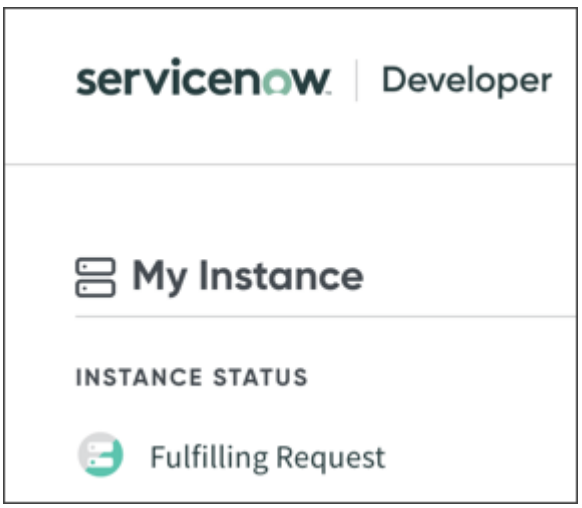
1. Open the **Account** menu to access the **My Instance** section.
2. Click the **Activate plugin** instance action.
3. In the **Your instance actions** dialog, find the plugin and click the **Activate** button.
4. If your plugin has demo data:

a. Select the **Activate plugin** menu item to activate the plugin without demo data.

b. Select the **Activate plugin with demo data** menu item to activate the plugin with demo data.



You cannot perform other instance actions while the plugin is activating. The **Instance Status** is **Fulfilling Request** while the plugin is activated.



Result
You will receive an email from the Developer Site when the plugin activation is complete. Plugins that require activation by ServiceNow® personnel do not appear in the plugins list in your PDI. The **Available Plugins** dialog does not show plugin activation status.

To use the plugin, reload the browser window where you logged in to your PDI.

Managing email properties for your PDI

Configure properties within your PDI to start sending and receiving emails.

Before you begin
Role required: none

About this task

ServiceNow® instances can send and receive email. Configuring email is typically the responsibility of a system administrator, not an application developer. In order to send and receive email with your PDI, email sending and receiving needs to be configured.

Unfortunately, personal developer instances (PDI) have been used both accidentally and maliciously to send email spam. In order to prevent spamming but still allow notifications on PDIs, we have restricted our email servers to sending to a single domain, guerrillamail.com. PDIs can receive email from any domain except guerrillamail.com.

Procedure

1. To enable email sending and receiving from the Developer Site:

   a. Open the **Account** menu to access the **My Instance** section.

   b. Click the **Manage Email Properties** instance action.

   c. In the **Your instance actions** dialog, activate the **Enable email sending and receiving** toggle.

   d. Click the **Save** button.

2. To disable email sending and receiving, deactivate the **Enable email sending and receiving** toggle.

Releasing your PDI

Release your PDI to unassign the instance from you, reset to its original state, and reassign it to another Developer Program member.

Before you begin

Role required: none

About this task

If you no longer need your PDI or you are not going to be able to use it for an extended period of time, save your work and release the instance. When you release your PDI, the instance is unassigned from you, reset to its original state, and reassigned to another Developer Program

member. When you request an instance or restore an instance, you will receive a PDI with a different instance name and URL.

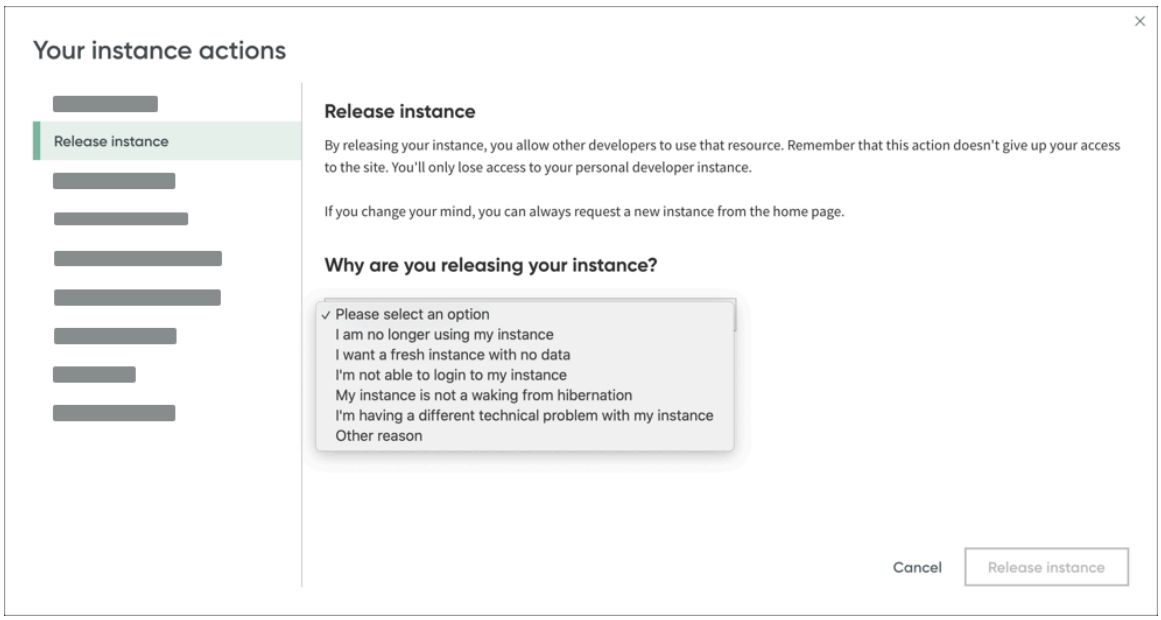
Procedure

To release your PDI:

a. Open the **Account** menu to access the **My Instance** section.

b. Click the **Release instance** action.

c. In the **Your instance actions** dialog, read the details and select a reason for releasing your instance from the choice list.



d. Click the **Release instance** button.

Changing your instance user role

Change your PDI user role to either App Engine Studio Creator or Admin for different views and levels of access.

Before you begin

Role required: none

About this task

Depending on your learning or testing needs, you may need to change the user role for your PDI.

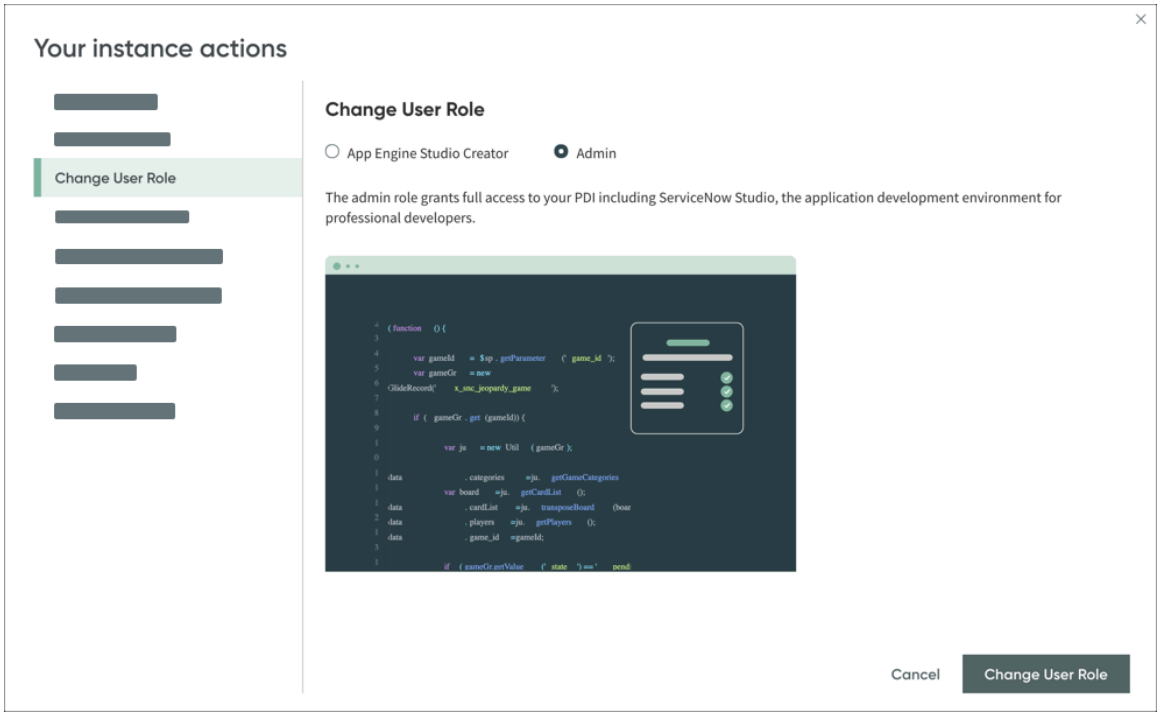
Procedure

1. To change your user role:

a. Open the **Account** menu to access the **My Instance** section.

b. Click the **Change User Role** instance action.

c. In the **Your instance actions** dialog, select **App Engine Studio Creator** or **Admin**.



d. Click the **Change User Role** button.

e. A message indicates when your change user role request is completed successfully.

2. To see the change in your user role:

a. Close any open PDI browser tabs.

b. Relaunch your PDI by clicking the **Start building** button in the **Account** menu.

Removing demo data from your PDI

If you do not need the demo data in your PDI included by default, remove it from your PDI.

Before you begin

Role required: none

About this task

By default, PDIs include demo data. You can remove the demo data from your PDI on the Developer Site.

Procedure

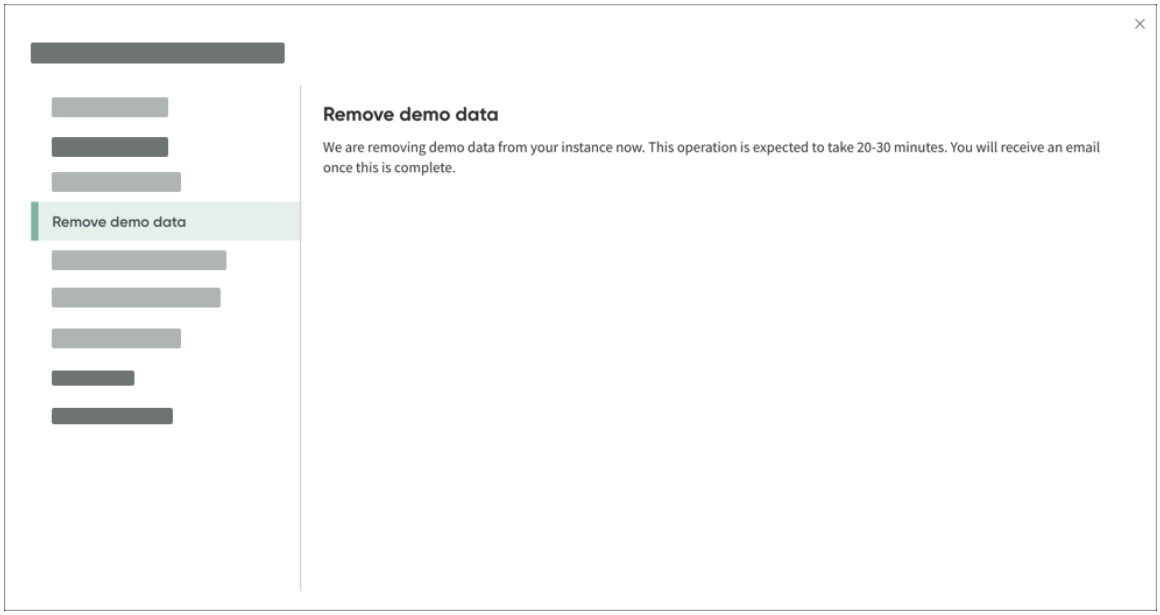
1. Open the **Account** menu to access the **My Instance** section.

2. Click the **Remove demo data** instance action.

3. In the **Your instance actions** dialog, read the description and acknowledge that demo data cannot be restored click the **Remove demo data** button.

Result

Demo data removal takes 20-30 minutes. The Developer Site will send you an email when the process is complete.



Resetting your PDI to its initial state

Reset your PDI to its initial state to start work with a fresh instance.

Before you begin

Role required: none

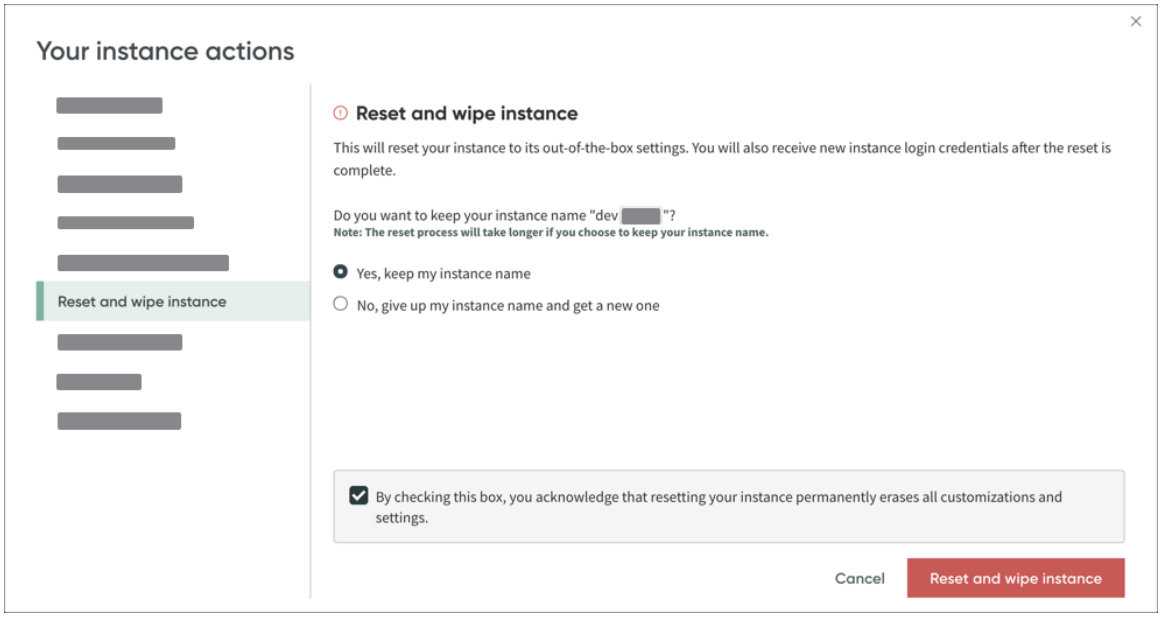
About this task

If you want to start work on a new application or want to work with a fresh instance, you can reset your PDI to its initial state.

> **Note:**
> If you reset and wipe your instance, you will lose your customizations and configurations you made to the PDI. Be sure to back up any work you want to save by committing your work to source control or creating update sets.

Procedure

1. Open the **Account** menu to access the **My Instance** section.
2. Click the **Reset and wipe instance** instance action.
3. In the **Your instance actions** dialog, select how to reset your instance.



- **Yes, keep my instance name**: Reset your instance to its default state. Resetting and wiping your instance may take a couple of hours to complete. You will receive an email when the process is complete.
- **No, give up my instance name and get a new one**: Get a new instance without waiting for the reset process.

4. Select the **By checking this box, you acknowledge that resetting your instance permanently erases all customizations and settings** disclaimer.
5. Click the **Reset and wipe instance** button.

Upgrading your PDI

Apply a patch or new release to your instance to upgrade your PDI.

Before you begin

Role required: none

About this task

When ServiceNow® releases patches and new releases, you can apply the patch or release to your PDI from the Developer Site. You have two options for upgrading a PDI.

Note:
Patches for a release are applied to your PDI automatically up to once a month to maintain compliance with the ServiceNow Patching Program. Sometimes patches may be made available to apply outside the regular patching schedule. Use the **Upgrade instance** option to apply a patch manually.

Procedure

1. Open the **Account** menu to access the **My Instance** section.
2. Click the **Upgrade instance** instance action.
3. In the **Your instance actions** dialog, select the patch or release to apply to your PDI and click the **Upgrade instance** button.

Result
Upgrading your instance may take a couple of hours to complete. Do not run the upgrade until you have time to let the upgrade run.

You will receive an email when the upgrade is complete.

Getting instance assistance

Get assistance for common issues accessing an instance and give feedback.

If you cannot access your PDI or get the **Your instance is currently offline** page, your PDI may be in the process of waking up from hibernation or your PDI just completed patching and needs to restart. Your PDI should be available within five minutes.

If your PDI is not available after five minutes, sign in to the Developer Site, select the arrow next to your avatar, and check the **My Instance** page to see if your PDI is still undergoing maintenance.

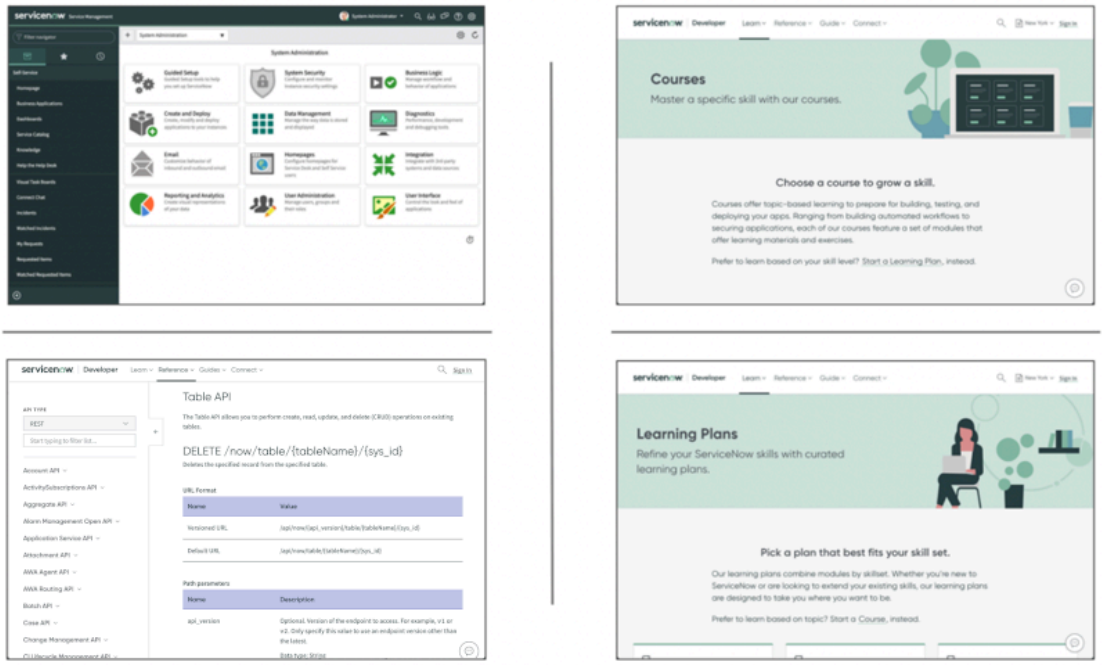
Early Availability guide

Early Availability provides you with exclusive access to the latest release over a month before market launch makes the release available for any customer to use.

The ServiceNow Developer Program provides Early Availability to pre-release versions. You have access to pre-release versions and resources through the ServiceNow Developer Site. As a Developer Program member, Early Availability provides you with exclusive access to the latest ServiceNow release over a month before market launch makes the release available for any customer to use. Early Availability includes:

- Personal developer instances (PDI)
- Learning plans
- Training courses
- APIs
- Documentation

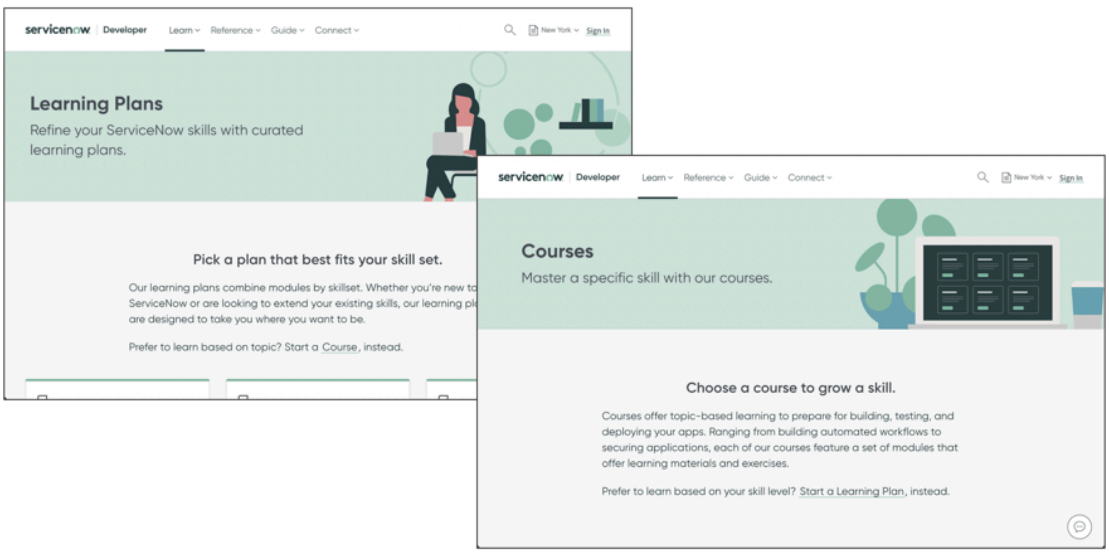
As a Developer Program member, you have the first opportunity to become familiar with the latest ServiceNow release through Early Availability. Early Availability gives you an opportunity to learn skills that will set you apart from other developers in the industry. You can leverage the latest features and upgrades to build new applications.



Early Availability learning plans and training courses

Early Availability gives you access to learning plans and training courses specifically for the latest release.

The Developer Program provides you with the training needed to successfully explore releases at your own pace. Early Availability gives you access to learning plans and training courses specifically for the latest release. Pick from a selection of easy-to-follow training courses or learning plans based on your current knowledge and experience. With either choice, you are guaranteed to build or improve your application development skills on the latest ServiceNow AI



Platform®.

Early availability API documentation

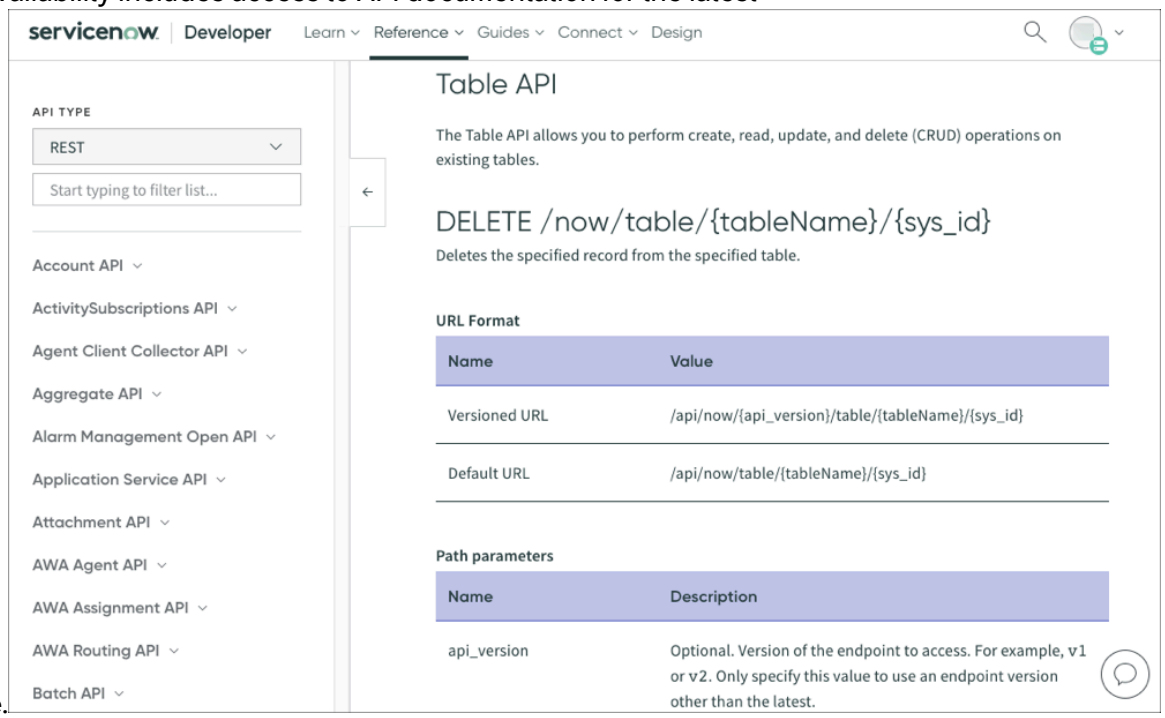
Early Availability includes access to API documentation for the latest release.

The Developer Program also contains API documentation on:

- Server-side APIs (scoped and global)
- Client-side APIs
- REST APIs
- Now Experience UI Framework

Server-side scoped APIs are for use within scoped applications, and may behave differently within the global scope. Server-side legacy APIs are documented for development work in global scope. New applications should be built using scoped APIs.

Early Availability includes access to API documentation for the latest release.



Low-code versus pro-code development

Learn the difference between low-code and pro-code solutions on the ServiceNow AI Platform.

Which builder should I use to create an app?

Types of builders

Want to build an app easily, without code?

Creator Studio specializes in helping you craft request-fulfillment applications without writing code. For example, an application to request office supplies by filling out a form, and someone approves or denies your request. For more information, see Exploring Creator Studio.

Need a more general app but still want low-code options?

App Engine Studio lets you build a broader range of apps than Creator Studio without being a programming pro. For more information, see Exploring App Engine Studio.

Are you a developer who wants more control in a centralized user interface?

Build apps smarter and deliver them faster with the new ServiceNow Studio. ServiceNow Studio empowers platform developers with a modern, unified environment for building on the ServiceNow AI Platform. ServiceNow Studio features streamlined navigation to applications and metadata, integrated low-code tools, efficient tracking and packaging of development work that accelerates development processes and enhances productivity. For more information, see Exploring ServiceNow Studio.

Are you a developer who wants to use industry-standard development tools and processes?

The ServiceNow IDE and ServiceNow SDK support developing applications in source code with ServiceNow Fluent, creating JavaScript modules, and using third-party libraries. ServiceNow Fluent is a domain-specific programming language for creating application metadata in code.

The ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform. The ServiceNow SDK uses Visual Studio Code Desktop locally. For more information, see Building applications in source code.

What is low-code development

Low-code development is a new approach to app creation that allows users with limited coding experience to create powerful apps. Low-code development platforms rely on graphical interfaces and configuration instead of manual coding. These new low-code development platforms enable more people to create and deploy apps quickly and efficiently.

Benefits of low-code development

Low-code app development streamlines the development process to build more apps faster. Low-code solutions require fewer developers, and allow non-developers to build apps. Pre-built templates provide developers a head start building apps. System administrators can manage app development from a single location and collaborate with other developers. Decrease the time that it takes to deploy apps using predefined workflows in the ServiceNow AI Platform.

ServiceNow no-code and low-code development tools

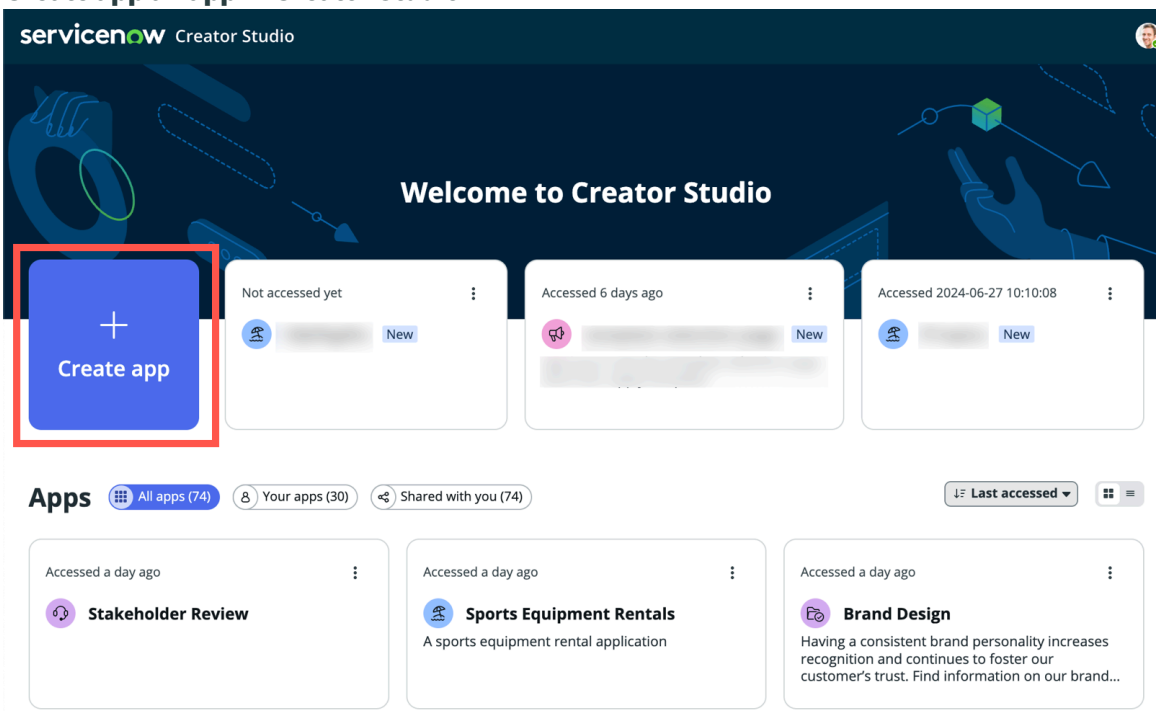
- Creator Studio
- App Engine Studio
- UI Builder
- Guided Application Creator
- Table Builder
- Flows in Workflow Studio
- Workspace Builder
- Exploring decision tables

For more information on low-code development tools, see Building low-code applications.

No-code development tool example

Creator Studio makes creating basic request-fufillment apps easier by dividing their creation into simple steps. You can create forms for users to request catalog items and use form submissions to initiate automated playbooks. Find out more in Creator Studio.

Create app an app in Creator Studio

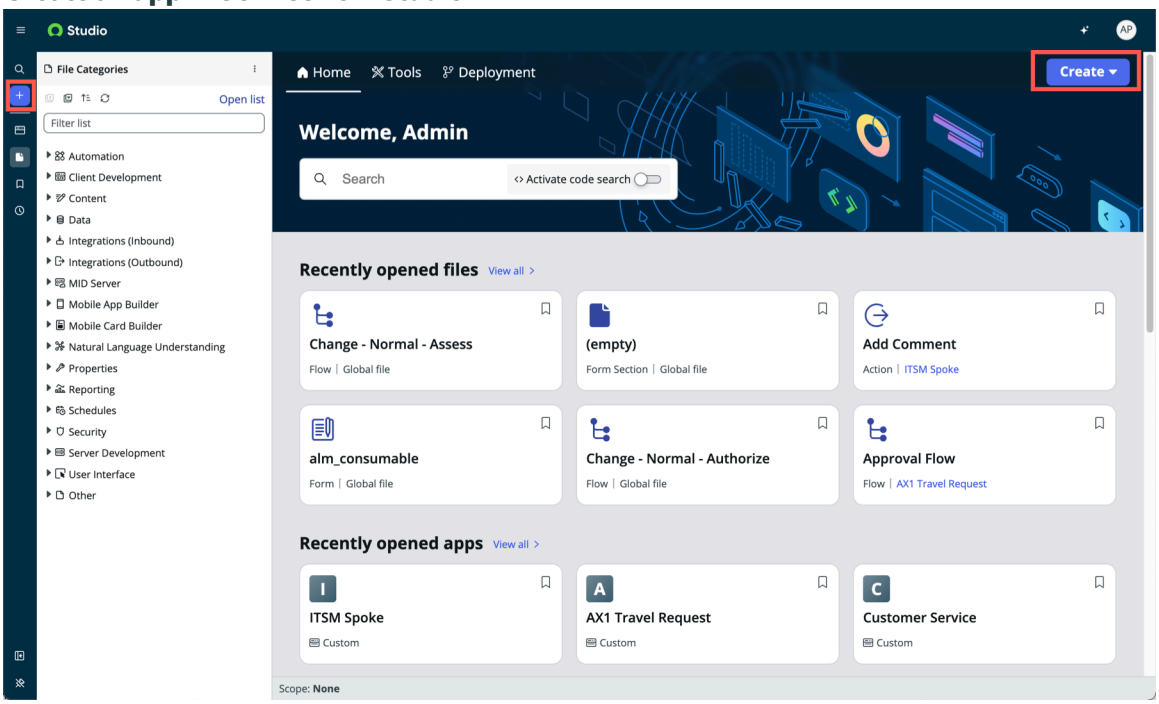


What is platform development

If you're comfortable with the ServiceNow AI Platform and some development tools, use the new ServiceNow Studio to access all of the builders and development tools in one place.

Platform development tool example

Create an app in ServiceNow Studio



What is pro-code development

Pro-code development is used by developers to create complex apps that can't be built with a low-code tool. Traditionally, pro-code development is used to create apps from scratch using custom code to solve a business need. Developers need to have knowledge of coding and how to use programming languages to build apps.

Benefits of pro-code development

The advantage of pro-code development is being able to create custom apps without the limitation of a tool. You can build custom apps unique to your business needs without limits. Developers can create apps with a custom look and feel to match your company's branding.

ServiceNow pro-code development tools

- ServiceNow IDE
- ServiceNow SDK
- Scripting
- REST APIs
- ServiceNow Extensions for Visual Studio Code

For more information on pro-code development tools, see Building pro-code applications.

Low-code versus no-code

The terms low-code and no-code tend to get used interchangeably, but they aren't exactly the same thing. While both low-code and no-code solutions provide tools for simplified app development, the differences are worth considering.

Low-code

Low-code platforms are designed for professional developers and non-technical business users. They require very little training or experience and use visual-based modeling to streamline the development process. They also allow people with coding experience to dive deeper, coding by hand when needed.

No-code

No-code platforms require no development experience, and are designed specifically for citizen developers and business users. No-code solutions open app development up to essentially everyone, but can lead to shadow IT—unsanctioned app development within an organization.

Modifying versus building an application

At a certain point in the lifetime of your applications, it might make sense to create an application to replace the old one. Cost savings, maintenance effort, and features available in new apps can help you determine if it's better to build a new application or modify an existing one.

Consider building a new application for the following reasons:

- The existing application is outdated and doesn't run well on newer hardware.
- Building a new application would produce cost savings over updating and maintaining the existing application.
- The existing application doesn't fundamentally meet your business needs.
- The existing application's features can easily transfer to a new application.
- Updating the existing application would cause significant disruptions to your UI and workflow because the existing application does not support the features you want to add.
- A new application would resonate with more users through an updated UI, more features, and ease of use than the existing application.
- Building a new application would be a quicker and easier process on low-code platforms like App Engine Studio (AES) than maintaining the existing application.

For more information, see the following topics:

- Use App Engine instead of customizations
- Customization vs configuration with ServiceNow Studio

Understand the ServiceNow® UI experiences

You can develop in the following ServiceNow AI Platform user interfaces: the Next Experience UI, the Workspace UI, the Classic Environment, and the Core UI. This topic explains these user interfaces.

Use the information in the following table to select the best UI experience for you and your team.

UI experiences on the ServiceNow AI Platform

UI experience	Benefits
Next Experience UI	**Unified Navigation** • Access app shell items—such as the contextual app pill, menu items, and search—all in one place across the entire

UI experiences on the ServiceNow AI Platform (continued)

UI experience	Benefits
	platform, no matter which application you're using. • Pin and unpin navigation menus to access menu items or free up screen real estate. **Additional menus** • Use the Favorites, History, and Workspaces menu items to navigate to and pin important resources. • Easily switch between Core UI applications and configurable workspaces. • Find your recently viewed items in a single menu. • Create custom menus for your end users. For more information, see Configure custom menus for Unified Navigation.
Configurable Workspace UI	**Improved agent efficiency** Work on multiple issues concurrently in an optimized, intuitive layout. **Speedy resolution** Resolve issues faster with automated suggestions powered by machine learning. **Proactive identification of major incidents** Get notified of potential major incidents based on issue frequency and impact. **Greater visibility for agents** Keep informed of updates and surface important insights with a live activity feed and analytics.
Working in the classic environment	**Work in lists and forms** Work in the classic ServiceNow AI Platform environment, creating lists from records. **Powerful app creation and development**

UI experiences on the ServiceNow AI Platform (continued)

UI experience	Benefits
	Create applications and develop with the full power of the ServiceNow AI Platform.
Working in Core UI	The Core UI interface provides an updated look and usability improvements. Notable features include real-time form updates, user presence, a redesigned application navigator with Favorites and History tabs, and improved activity streams. Core UI is the default user interface for new instances. For upgraded instances, an administrator must activate Core UI.

Support for developers

Here's where ServiceNow developers get support.

Where to find developer support

Resource	Description
ServiceNow Community	• Product hubs - Choose a product area and: ○ Connect to resources and learn about integrations. ○ Get expert and peer advise. ○ Network with peers. • Developer discussions - Connect with developers like you to ask questions, offer solutions, or build together. • Developer blog - See what the developer advocate team has to say.
Developer Site	• Sign up and start building on the ServiceNow AI Platform with a free account. • Join the ServiceNow developer program. • Access learning resources. • Access product and release documentation, APIs, CLI, and Component docs. • Access guides with an overview of the ServiceNow AI Platform, as well as

Where to find developer support (continued)

Resource	Description
	information on how to get started whether you're a new or experienced developer. • Learn ways to connect and collaborate with others working on similar problems.
ServiceNow training	Get started with training and certification.
ServiceNow developer videos	Access the ServiceNow Developer Program YouTube channel.

Application collaboration

People with admin privileges can manage the permissions of developers collaborating on an application.

Collaboration descriptors

You can use the predefined collaboration descriptors that are standard with activation, or create a custom collaboration descriptor. By using a collaboration descriptor, you can assign, manage, and monitor delegated development permissions.

Collaboration descriptors

Descriptors	Description
Owner	Owner of the application that manages other collaborators and can delete the application.
Editor	Standard descriptor to invite collaborators.
Custom	Non-standard (custom) descriptor created by the user.

Development permissions

By setting permissions, you can retain control over the system. You assign permissions to developers (or users who deploy applications) so that they can develop or deploy applications.

Development permissions

Permissions	Description
Application Management	Capabilities to delete the application and version source control access.
File type Access	File types that the user has access to.
Security / Entitlement	Capabilities to manage application security.
Programming Tools	Capabilities for script fields access.
Deployment	Deployment capabilities.

Application collaboration users

You can assign a collaboration descriptor for an individual by creating an app collaboration user. The user can only be assigned one collaboration descriptor for any application.

Application collaboration groups

You can assign a collaboration descriptor for a group of users by creating an app collaboration group. The group can only be assigned one collaboration descriptor for any application.

Install the app collaboration application

Install the app collaboration application so that you can view the collaboration feature in the UI.

Before you begin

Download the app collaboration application so that you can view the collaboration feature.

You must have an App Engine license.

Role required: admin

Procedure

1. Navigate to **System Applications** > **All Available Applications** > **All**.
2. Click the search icon () in the middle of the screen to search for the application collaboration application.
3. Click **Install**.

   Note:
   If app collaboration is already installed, the **Install** button is inactive.

4. Click **Activate**.

Result

The app collaboration feature is active.
After you install and activate the app collaboration plugin, all delegated developers will receive custom collaboration descriptors based on their current permissions and applications. The base system table provides standard Owner and Editor collaboration descriptors which are used in the collaboration feature.

If you install this plugin without App Engine Studio (AES) for an application, you should manage the delegated development permissions with this plugin or use the old Manage Developers screen to manage the permissions. Do not use both the plugin and the Manage Developers screen to manage the delegated development permissions.

To use the old Manage Developers screen, select your application and select Manage Developers in the related links on the form.

Create collaboration descriptors to assign permissions

Create descriptors in the collaboration application so that you can assign permissions to users or groups.

Before you begin

Role required: admin

About this task

Note:
You should create collaboration descriptors in addition to Owner and Editor in the global scope. If you want collaboration descriptors to appear and be used in AES, you should also set them to `standard = TRUE`. AES doesn't support collaboration descriptors that are created in custom scopes, and non-standard collaboration descriptors don't render in AES.

Use the predefined collaboration descriptors that are standard with activation, or create a custom collaboration descriptor. Collaboration descriptors enable you to assign, manage, and monitor delegated development permissions for each application or uniformly across multiple applications. You can assign each collaborator with one collaboration descriptor for an application. However, users can have multiple collaboration descriptors simultaneously if they belong to groups where collaboration descriptors have been assigned.

Procedure

1. Navigate to **All** > **App Engine** > **Collaboration** > **Descriptors**.
2. Click **New**.
3. On the form, fill in the fields.

App Collaboration Descriptor form

Field	Description
Name	Name for the descriptor.
Description	Description of the descriptor that includes permissions capabilities. Examples are as follows: ○ Owner ○ Editor
Application	Scope of the collaboration descriptor. Currently, all collaboration descriptors must be created into the global scope.
Standard	Option for inviting other collaborators with this role.

4. Click **Submit**.

Add permissions to collaboration descriptors

Add permissions to collaboration descriptors to manage your user's capabilities, such as the ability to delete the application or manage collaborators.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **App Engine** > **Collaboration** > **Descriptors**.
2. To modify the permissions, select a collaboration descriptor from the related list.
3. To view the permission's options, click **Edit...** in the related list.
4. To add or remove permissions to the descriptor, click the arrows.

For a list of permissions, see Collaboration permissions.

5. Click **Save** and **Update**.

Assign collaboration descriptors to users

Assign collaboration descriptors to your users for a specific application so that you can define specific permissions for these users.

Before you begin

Role required: admin

Procedure

1. In the related list, click **Application collaboration users**.
2. Click **New**.
3. On the form, fill in the fields.

Collaboration users form

Field	Description
Collaboration Application	Application that the user works on.
Collaboration User	User that works on the application.
Collaboration Descriptor	Descriptor for the user on this application.

4. Click **Submit**.

Assign collaboration descriptors to groups

Assign collaboration descriptors to user groups for a specific application so that you can define specific permissions for these user groups.

Before you begin

Role required: admin

Procedure

1. In the related list, click **Application collaboration groups**.
2. Click **New**.
3. On the form, fill in the fields.

Collaboration groups form

Field	Description
Collaboration Application	Application that the group will work on.
Collaboration Group	Name of the collaboration group.
Collaboration Descriptor	Descriptor for the group on this application.

4. Click **Submit**.

Collaboration permissions

Assign permissions to define what collaborators can do.

Collaboration permissions

Permission	Description
Playbooks	Grants access to work with the Playbooks design environment to create processes. Editing activity subflows or actions requires the **Flow Designer** permission.
All Metadata	Grants access to work with all metadata.
Integrations	Grants access to web service APIs, REST APIs, data sources, and Integration Hub - Import.
UI Builder	Grants access to work with UI Builder to build out more complex interfaces.
Mobile builders	Grants access to build mobile experiences, such as with Mobile App Builder.
Security Management	Grants access to security management files, such as Access Control Lists and roles.
Service Portal	Grants access to work with Service Portal editors and tools.
Notifications	Grants access to create automatic email notifications and work with email templates.
Invite collaborators	Grants access to invite developers to collaborate on an app.
Workflow	Grants access to the Workflow Editor and Activity Creator.
Reporting	Grants access to reports and scheduled reports.
Workflow Studio	Grants access to the Workflow Studio design environment to create flows and actions.
Service Catalog	Grants access to work with catalog-related file types such as catalog items, record producers, and variables to add catalog items to apps.
Tables & forms	Grants access to model and layout-related file types such as table columns, form layout, and list layout.
Decision Tables	Grants access to work with Decision Tables to create decision logic based on multiple if-then rules.

Contextual development environment

The platform is a contextual development environment that displays the currently selected application, identifies the scope of every application artifact, and prevents any changes that violate the access settings for an application.

Application developers can use the contextual development environment to:

- Determine the application context
- View and select applications
- Enforce application version standards
- Enforce application resource throttling
- Enforce script protection policies

Application context

When application developers create new records, the system automatically assigns the records to the currently selected application in the application picker.

When application developers attempt to change existing records, the platform checks whether the currently selected application matches the scope of the application artifact. If they match, the application developer can save changes to the artifact. If they differ, the system makes the following changes to the user interface:

- Makes all the fields on the current record read-only.
- Displays a warning message that the application artifact belongs to another scope.

Application access settings

Application access settings determine whether one application can access resources from another application.

Application access settings are similar to access controls (ACLs) in that they allow you to restrict access to certain resources, but instead of restricting tables and records from users they restrict applications resources from other applications. There are several ways to set cross-scope access.

Setting type	Use	Description	Access setting location
Application design and runtime settings	Your application or application script requires access to a cross-scope resource.	Application designers can configure the following application access settings for the entire application. • Specify whether cross-scope tables can be selected during design-time activities. • Specify when scripts can run on cross-scope resources. • Specify what JavaScript standard the application supports.	Access determined by the cross-scope privilege record owned by the calling application.
Table design and runtime settings	A cross-scope application or web service requires access to perform CRUD operations on a table.	Application developers can also configure application access settings for individual tables.	Access determined by settings on the target table.

Setting type	Use	Description	Access setting location
		• Specify whether the table is available to other application scopes. • Specify what runtime operations from other application scopes the table supports. • Specify whether the table can be selected during design-time activities. • Specify whether the table can be accessed from web services.	
Restricted caller access privilege settings	A cross-scope application or script requires access to your application or application resource.	Admin users can configure the following application access settings for an entire application scope or application resource. • Specify whether a cross-scope script can access your application scope or an application resource. • Track cross-scope requests for access to application resources. • Approve or deny cross-scope requests to access application resources.	Access determined by the restricted caller access record owned by the target application.

Application design and runtime settings

The application design and runtime settings determine whether an application can access cross-scope resources.

Design and Runtime fields

Field	Description
JavaScript Mode	The JavaScript standard that the application supports. Select **ECMAScript 2021 (ES12)** to support features in ECMAScript 12th edition or **ES5 Standards Mode** to support features in ECMAScript 5th edition. Select **Compatibility Mode** to support earlier ECMAScript editions. For more information, see Set the JavaScript mode for an application.
Runtime Access Tracking	The application's handling of script access requests to resources in other applications. Select **None** to authorize all access requests to cross-scope resources without logging them. Select **Tracking** to log and authorize all access requests to cross-scope resources. Select **Enforcing** to log access requests to cross-scope resources but require an administrator to authorize each request.
Restrict Table Choices	The availability of cross-scope tables when designing the application. Clear the option to allow the application to see tables from other application scopes. Select the option to restrict design choices to only tables in the same application.

Runtime access tracking

Runtime access tracking allows administrators to manage script access to application resources by creating a list of script operations and targets that the system authorizes to run.

Runtime access tracking provides the following options:

Runtime access tracking options

Option	Tracking done	Authorization done	Results
None	The system does not track runtime access requests.	The system does not require authorization to run access requests.	Application scripts can access resources from other applications as long as the table-level access settings allow it.
Tracking	During development, the system creates a Cross-Scope Privilege record for each runtime access request. After installation, the system no longer tracks new runtime access requests.	The system sets the status of the Cross-Scope Privilege record to **Allowed**.	The system runs the tracked operation as long as the table-level access settings allow it.
Enforcing	During development, the system creates a Cross-Scope Privilege record for each runtime access request. After installation, the system no longer tracks new runtime access requests.	The system sets the status of the Cross-Scope Privilege record to **Requested**.	The system blocks the tracked operation from running until an Administrator manually changes the status to **Allowed** and the table-level access settings allow it.

During development, application designers must run all of an application's script logic to ensure the system tracks and authorizes the access requests to other applications.

Cross-scope privilege record

Runtime access tracking uses cross-scope privilege records to determine which script operations and targets the system allows to run.

The system creates cross-scope privilege records when:

- Runtime access tracking is set to **Tracking** or **Enforcing**.
- A script attempts to access another application.

Each cross-scope privilege record in the Cross scope privileges [sys_scope_privilege] table contains the following information.

Cross-scope privilege fields

Field	Description
Source Scope	The application requesting runtime access to another application's resources.
Target Scope	The application whose resources are being requested.
Target Name	The name of the table, script include, or script object being requested.
Target Type	The type of request: table, script include, or script object.
Operation	The operation the script performs on the target. The target type determines the available operations. Tables support the read, write, create, and delete operations. Script includes and script objects only support the execute API operation.
Status	The authorization for this record: requested, allowed, or denied

Administrators can manually create cross-scope privilege records for application developers in advance to communicate which cross-scope resources they expect developers to access. For example, administrators could create these cross-scope privilege records to permit application developers access to resources from Incident Management.

Sample cross-scope privilege records

Source Scope	Target Scope	Target Name	Operation	Status
My App	Global	incident	Read	Allowed
My App	Global	incident	Write	Allowed
My App	Global	ScopedGlideRecord	Execute API	Allowed

During testing, application developers should run all of their application scripting logic to ensure the system creates any necessary cross-scope privilege records. After application publication, the system only allows runtime requests to run that have a valid cross-scope privilege record.

Note:
Table privilege granting is limited to, at most, the permissions set on the table object (sys_db_object) record. For example, granting a scope privilege to delete for table incident would not be allowed if the table object for incident did not allow Can delete scopes.

Application design access record

Administrators use application design access records to specify which other applications are available to developers during application creation.

When administrators restrict an application's table choices, they can then create application design access records to grant developers access to the tables of selected applications.

Each application design access record contains the following information.

Application design access fields

Field	Description
Source Scope	The application requesting design access to another application's tables.
Target Package	The application whose tables will be available for design time access.
Application	The application to which this record belongs.

Application design access records allow administrators to have oversight of the resources available to application developers. When creating configuration records, application developers can only select tables from another application if there is an application design access record granting them access to the application. For example, administrators could create the following application design access records to grant developers access to tables from Incident Management and Problem Management.

Sample application design access records

Source Scope	Target Package
My App	Incident
My App	Problem Management

After developers create configuration records to other applications, the system displays these applications as dependencies.

Table design and runtime settings

The Application access fields determine whether a table is accessible to other applications during design-time or run-time operations.

Application access fields

Field	Description
Can read	Select the check box to allow script objects from other application scopes to read records stored in this table. This option offers runtime protection. For example, a script in another application can query data on this table. You must first select read access to grant any other API record operation.
Can write	Select the check box to allow script objects from other application scopes to modify records stored in this table. This option offers runtime protection. For example, a script in another application can modify a field value on this table. This option is available only when the **Can read** check box is selected. Clear the check box to prevent script objects from other application scopes from modifying data stored in this table.
Can create	Select the check box to allow script objects from other application scopes to create records in this table. This option offers runtime protection. For example, a script in another application can insert a new record in this table. This option is available only when the **Can read** check box is selected. Clear the check box to prevent script objects from other application scopes from creating records in this table.

Application access fields (continued)

Field	Description
Can delete	Select the check box to allow script objects from other application scopes to delete records from this table. This option offers runtime protection. For example, a script in another application can remove a record from this table. This option is available only when the **Can read** check box is selected. Clear the check box to prevent script objects from other application scopes from deleting records from this table.
Allow access to this table via web services	Select the check box to allow users to make inbound web service queries to this table. This option offers both design-time and runtime protection. The user performing the query must have the correct permissions to access this table, even when this check box is selected. Clear the check box to prevent users from making web service queries to this table.

Runtime access to applications tables

Runtime access determines if an API or web service call can run against an application table.

Access permissions can be set for the following access points.

Runtime access points

Access points	Description
Script API	Any supported object or method call from the scoped system API such as a GlideRecord call.
Web services	Any supported web service call such as a REST, JSON, or SOAP web service.

The system does not prevent you from creating API or web service calls to the application tables, rather it determines if the API or web service call is allowed to run against the application table. API or web service calls that violate the access permissions for an application table produce an error. For example, making a web service call to a protected application table produces a 403 Forbidden HTTP error.

Default runtime access permissions

The default runtime access permissions apply to new application data tables.

By default, new application tables only allow read access from other application scopes.

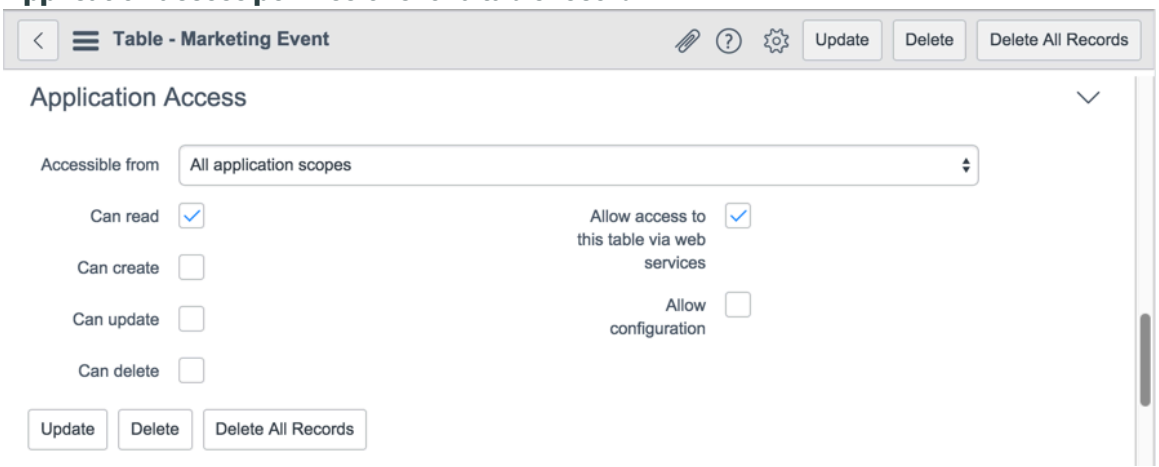
Default runtime access

Field	Value
Accessible from	All application scopes
Can read	Enabled
Can create	Disabled

Default runtime access (continued)

Field	Value
Can update	Disabled
Can delete	Disabled
Allow access to this table via web services	Enabled

Application access permissions for a table record



Set runtime access to application tables

Set these access permissions to protect application tables at runtime.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **Applications**.
2. Click the button for the application type you want to edit.

Option	Description
Developed	displays applications created on this in stance.
Downloaded	displays applications downloaded on this in stance.

3. Click the application name or the **Edit** button for the application you want to work on.
4. From the **Tables** related list, select the table whose access permission you want to set.
5. From the **Application Access** section, set the runtime access permissions.
6. Click **Update**.

Example denying all runtime access to a table

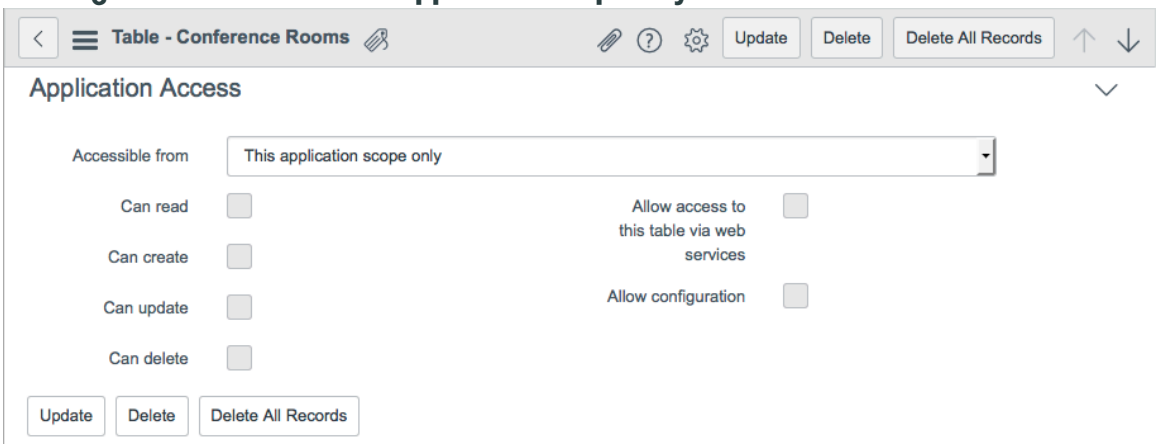
You can prevent script API and web service calls from other application scopes.

Typically, this is to prevent any other application from creating or modifying data in the table. Denying access requires setting the following value in the table record.

Denying all runtime access

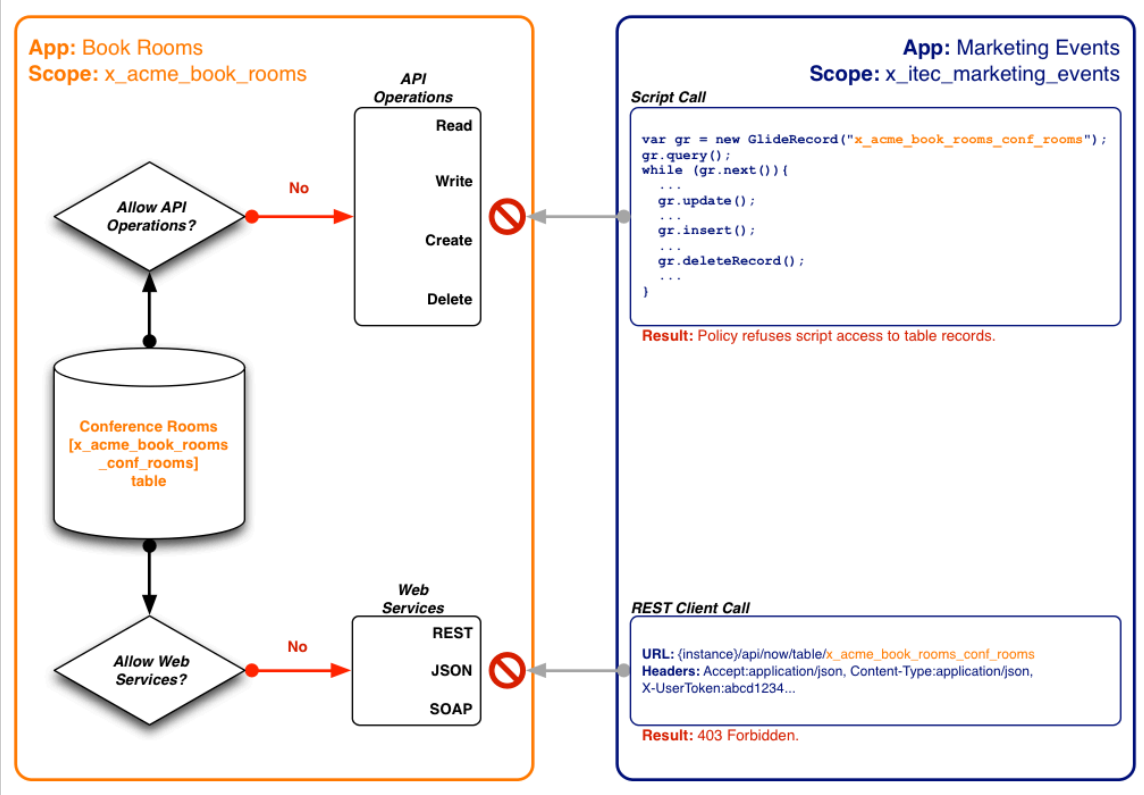
Field	Value
Accessible from	This application scope only
Can read	Disabled
Can create	Disabled
Can update	Disabled
Can delete	Disabled
Allow access to this table via web services	Disabled

Limiting runtime access to this application scope only



The following diagram illustrates the effect of denying other application scopes access to application tables from script API and web service calls.

Deny all runtime access permissions to application tables



Example granting all runtime access to a table

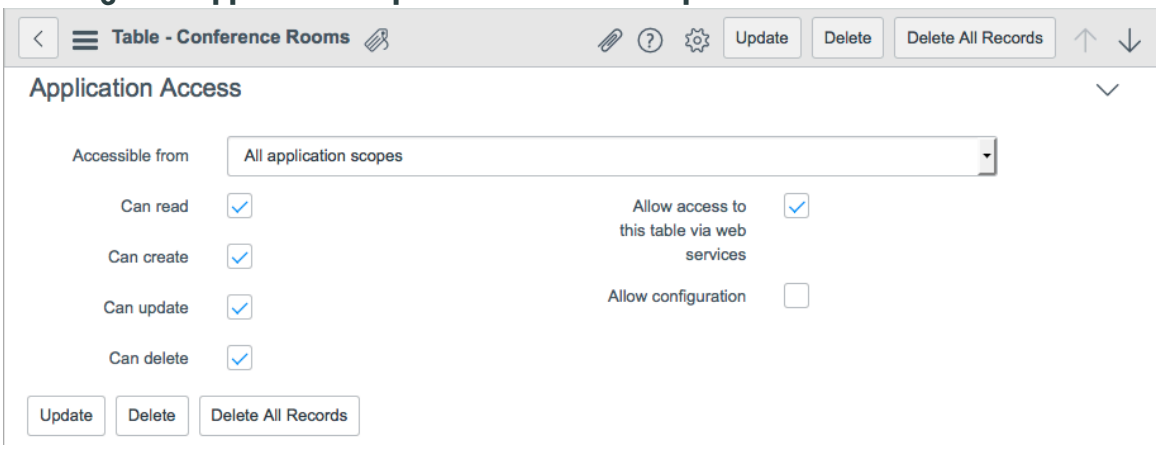
You can permit some or all runtime script API and web service calls from other application scopes.

Granting access requires setting the following values in the table record.

Granting all runtime access

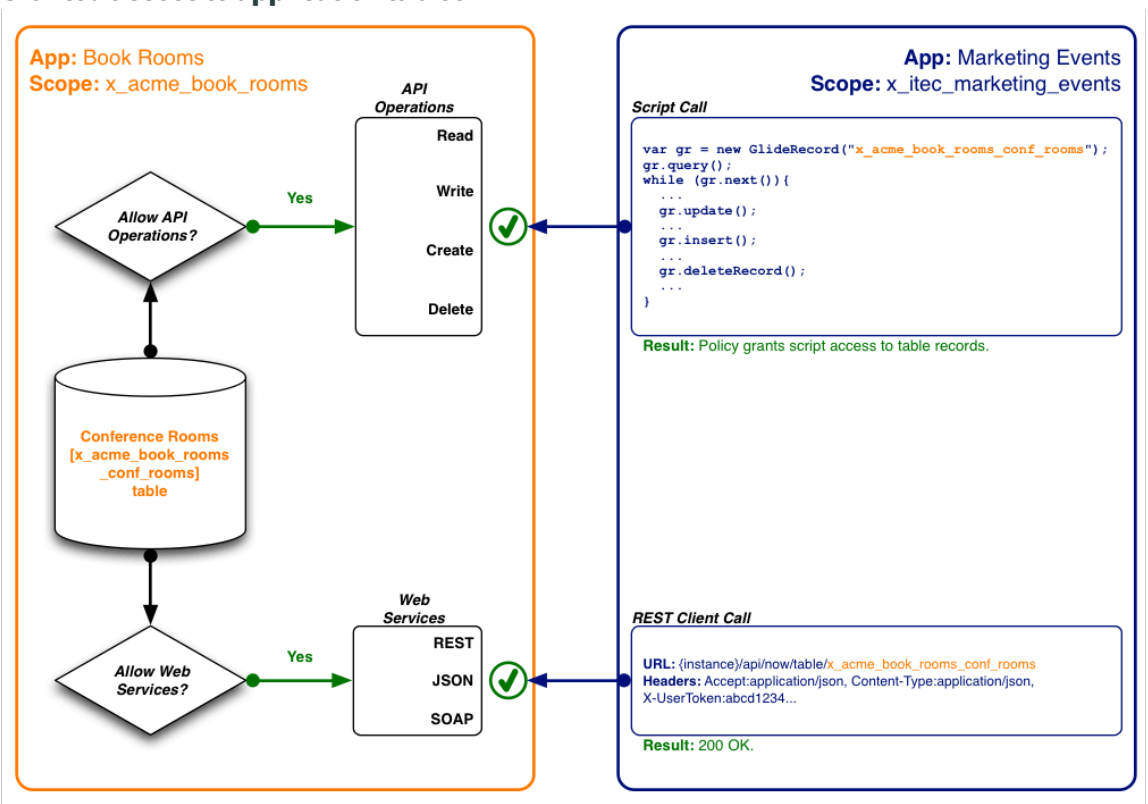
Field	Value
Accessible from	All application scopes
Can read	Enabled
Can create	Enabled
Can update	Enabled
Can delete	Enabled
Allow access to this table via web services	Enabled

Granting other application scopes all runtime access permissions



The following diagram illustrates the effect of granting access to application tables from API calls and web services in other application scopes.

Granted access to application tables



Design-time access to application tables

As the application developer, you can grant or deny other applications the permission to create configuration records, also known as application files, that extend the functionality of an application.

The permission applies to any platform feature that extends the functionality of an application data table such as:

- Business rules
- UI actions
- Client scripts

These access permissions protect the application data table at design-time. The system prevents you from creating configuration records by hiding the application data table as an option in the **Table** field. For example, a protected application table does not appear as an option when you create configuration records such as UI actions and client scripts.

Even when permission is granted to create configuration records, some configuration records have additional restrictions to protect application data from unwanted changes from other application scopes.

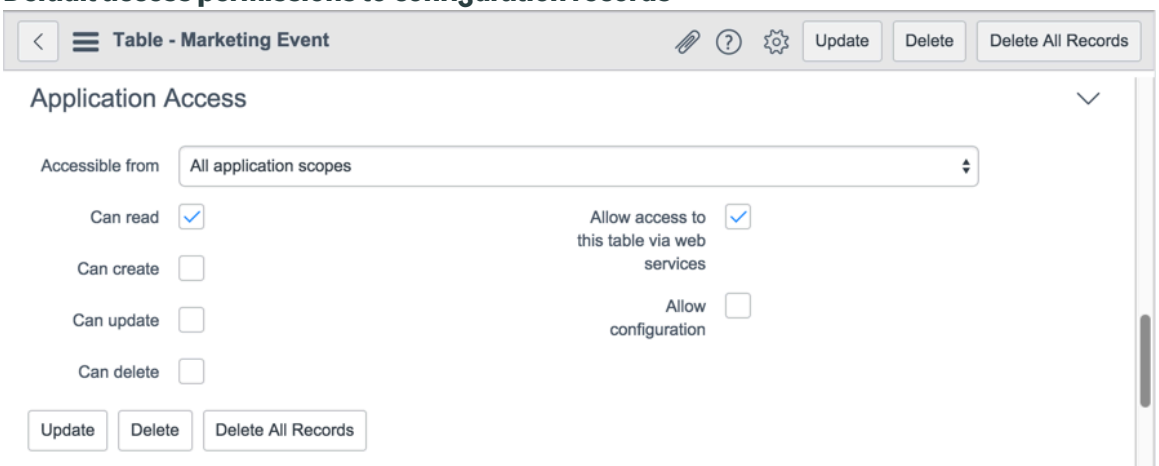
Default design access permissions

By default, new application tables prevent other application scopes from creating configuration records on application data tables. This prevents any other applications from changing the functionality of a table.

Default design-time access

Field	Value
Accessible from	All application scopes
Can read	Enabled
Can create	Disabled
Can update	Disabled
Can delete	Disabled
Allow access to this table via web services	Enabled
Allow configuration	Disabled

Default access permissions to configuration records



Set design-time access to application tables

Set these access permissions to protect application tables at design-time.

Before you begin

Role required: admin

About this task

To set runtime access permissions:

Procedure

1. Navigate to **All** > **System Applications** > **My Company Applications**.
2. Click the button for the application type you want to edit.

Option	Description
Developed	displays applications created on this in stance.
Downloaded	displays applications downloaded on this in stance.

3. Click the application name or the **Edit** button for the application you want to work on.
4. From the Tables related list, select the table whose access permission you want to set.
5. From the Application Access section, set the design-time access permissions.
6. Click **Update**.

Example denying all design access to a table

Example allowing configuration records for a table

Example denying all design access to a table

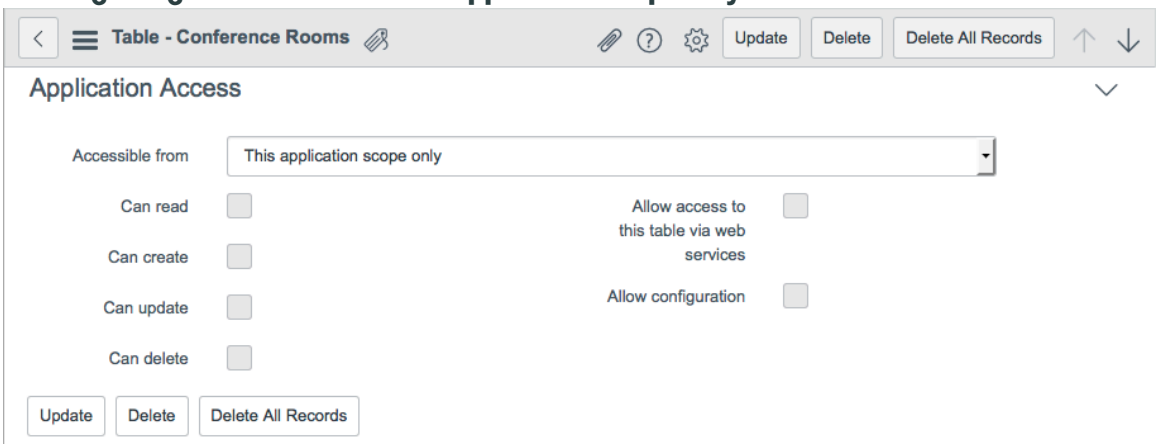
You can prevent other application scopes from creating configuration records on application data tables.

Typically, this is to prevent any other applications from changing the functionality of a table. Denying access requires setting the following value in the table record.

Denying all design-time access

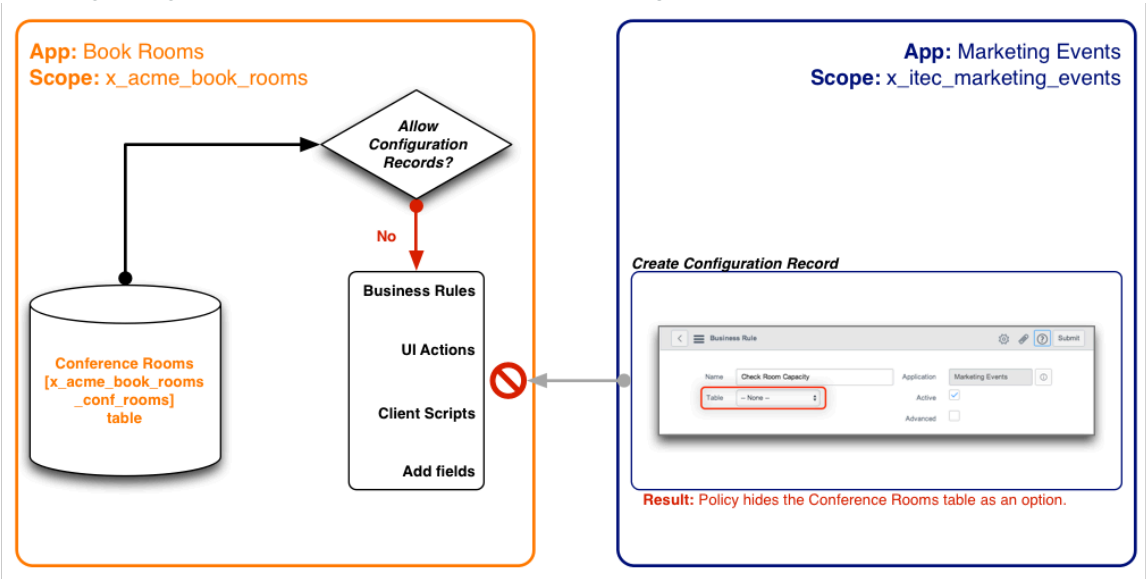
Field	Value
Accessible from	This application scope only
Can read	Disabled
Can create	Disabled
Can update	Disabled
Can delete	Disabled
Allow access to this table via web services	Disabled
Allow configuration	Disabled

Limiting design-time access to this application scope only



The following diagram illustrates the effect of denying other application scopes the ability to create configuration records.

Limiting design access to this application scope only



Example allowing configuration records for a table

You can permit other application scopes to create configuration records on application data tables.

You can grant access to the following configuration records with these settings.

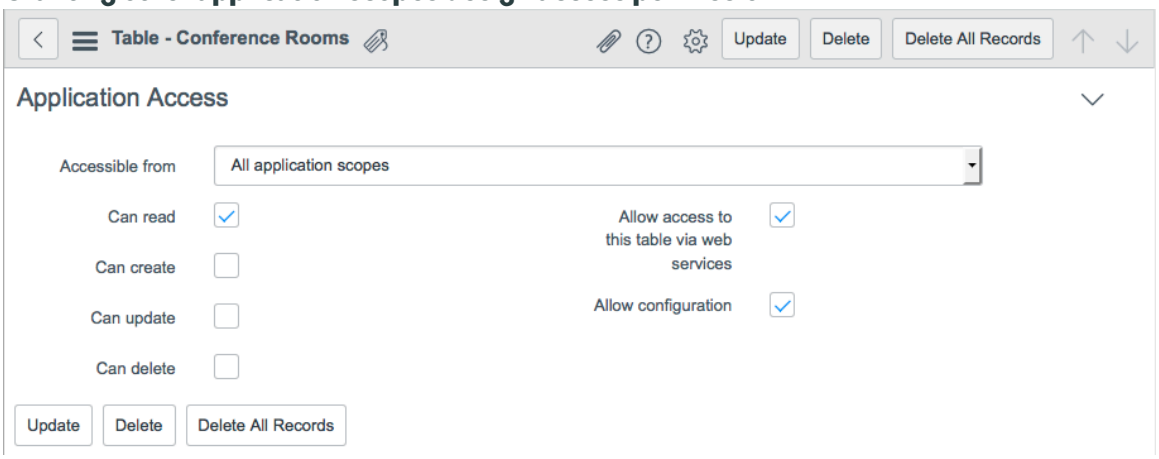
Granting access to configuration records

Configuration record	Setting required to grant access
Access controls	• **Accessible from** set to **All application scopes** • **Can read** is selected
Business rules	

Granting access to configuration records (continued)

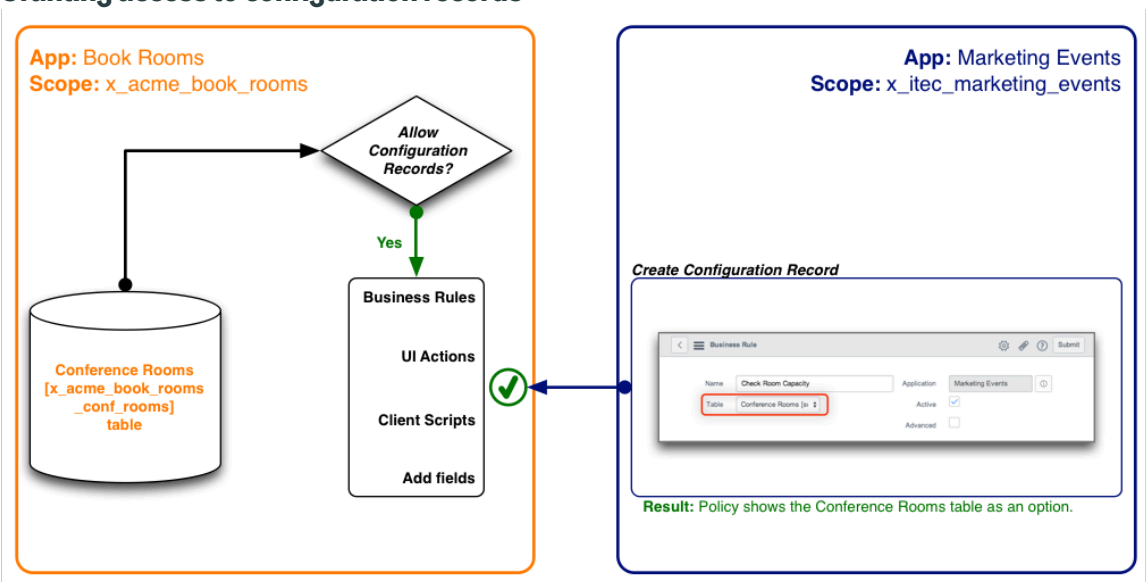
Configuration record	Setting required to grant access
Client scripts	• **Accessible from** set to **All application scopes** • **Can read** is selected • **Allow configuration** is selected
Dictionary entry (new field only)	
UI actions	

Granting other application scopes design access permission



The following diagram illustrates the effect of granting other application scopes the ability to create configuration records.

Granting access to configuration records



Restricted caller access privilege settings

Define cross-scope access to an application, application resource (such as an access control role, a business rule, a UI action, or a script include), or event. You can even use these settings to allow or deny requests for access.

Restricted caller access privilege settings overview

Restricted caller access [sys_restricted_caller_access] records track cross-scope applications or scripts that request access to an application, application resource, or event in the ServiceNow AI Platform. The ServiceNow AI Platform creates sys_restricted_caller_access records when one of these actions occurs:

- Caller access is set to **Caller Restriction** or **Caller Tracking**.
- A cross-scope script attempts to access an application resource or event.

> **Note:**
> A system scope to target scope is an example of a cross-scope.

You can use these records to do these tasks:

- Track cross-scope requests for access to an application resource. You can use access requests to determine which applications need access to resources and data from other application scopes.
- Approve or deny any cross-scope requests for access to application resources or events. For example, you can create a Restricted Caller Access record to allow access for all scope-to-scope requests.

For more information, see Requested restricted caller access (RCA).

Restricted caller access privilege setting combinations

You can define various combinations of privilege settings for restricted caller access and specify whether access is allowed or restricted for each relationship. This process ensures that your application has the privileges to access the correct scope and not one you don't want to access. You can define various combinations of the following settings:

Scope

All application resources in a selected source or target scope. To learn more about application scopes, see Application scope.

Source

A specific application resource in a selected source scope.

Target

A specific application resource in a selected target scope.

These restricted caller access privilege settings combinations include, but are not limited to following combinations:

- Scope-to-scope
- Scope-to-target
- Source-to-scope
- Source-to-target

> **Note:**
> For more information about these access setting combinations and to learn how to create each combination, see Set the application scope, application resource, and event access.

Activating application restricted caller access

You can activate application restricted caller access through one of the following methods:

- Activate the Scoped Application Restricted Caller Access plugin (com.glide.scope.access.restricted_caller).
- Request the HR Service Delivery or Security Incident Response applications. By default, restricted caller access is active in these applications.
- Enable the Restricted Caller Access system property for Workflow Studio.

For more information, see: Activate application restricted caller access.

Activate application restricted caller access

You can activate the Scoped Application Restricted Caller Access plugin (com.glide.scope.access.restricted_caller) if you have the admin role.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Define cross-scope access to an application resource

Track cross-scope requests for access to an application resource and approve or deny requests.

Before you begin

If you enable application administration for the target application, only application administrators of the target application can set access to an application. If application administration is not enabled, an admin user can set access to an application.

Role required: admin or application admin

Note:
To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

Procedure

1. To define access to an application resource, navigate to the application resource record.
   Available application resources include these options.
   - Table
   - Script Include
2. Set the **Accessible from** field to **All application scopes**.
   If set to **This application scope only**, no other application scopes can access the resource.
3. Select the appropriate access level in the **Caller Access** field.

Option	Description
None	Cross-scope calls to the resource are approved or denied based on the value of the **Accessible from** field.
Caller Restriction	Calls to the resource must be manually approved. Access requests are tracked in the Restricted Caller Access table with a status of Re quested.
Caller Tracking	Calls to the resource are automatically approved. Calls are tracked in the Restricted Caller Access table with a status of Allowed.

4. Allow or deny an access request from a calling application.
   When a cross-scope application attempts to access a resource set to Caller Restriction, the system denies access to the resource and creates a record in the Restricted Caller Access table with a status of Requested. An admin user or application administrator must allow or deny the request. When access is allowed, all future access attempts gain access to the restricted resource.

   If a calling resource changes (such as when a business rule's script changes), the restricted caller access record status changes to Invalidated. An admin user or application administrator must update the status to Allowed or Denied.

   a. In the application record, navigate to the **Restricted Caller Access Privileges** tab.

   b. Review records that have a Status of Requested.
      Each Restricted Caller Access Privilege record lists the operation performed, information about the calling source, and information about the target resource requested.

   c. In the **Status** column, set the value from **Requested** to **Allowed** or **Denied**.

   Once a calling source is allowed, all subsequent calls are allowed.

Set the application scope, application resource, and event access

Create a record in the Restricted Caller Access Privileges [sys_restricted_caller_access] table to set cross-scope resource access requests. Approve or deny requests from a source scope or source scope application resources to a target scope or to target scope application resources.

Before you begin

If you enable application administration for the target application, only application administrators of the target application can set access to an application. If application administration is not enabled, an admin user can set access to an application.

Role required: application admin or admin

Note:
To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

About this task

You can set the following restricted caller access privilege settings combinations:

- Scope-to-Scope
- Scope-to-Target
- Source-to-Scope
- Source-to-Target

Note:
In the Rome release, we have enforced that an RCA privilege record must be present in the target application to grant access to a resource. This means that the target scope must match the application scope.

Procedure

1. Navigate to **All** > **System Applications** > **Application Restricted Caller Access**.
2. On the form, fill in the fields.

Restricted Caller Access fields

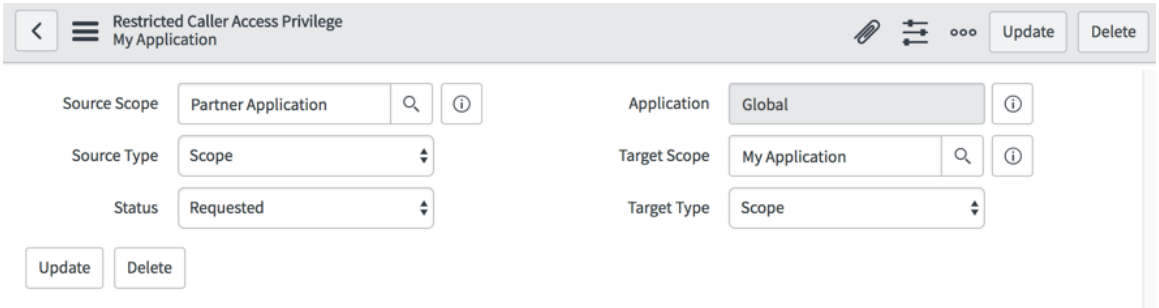
Field	Description
Operation	Operation performed on the target resource. ○ Read ○ Write ○ Create ○ Delete ○ Execute API
Source	Cross-scope record that is accessing a restricted application resource.
Source Scope	Scope of the calling application.
Source Table	Table that contains the Source record.
Source Type	Type of record that is calling the application resource: ○ ACL ○ Business Rule ○ Document Title ○ Flow ○ Flow Action ○ GlideScopedEvaluator ○ Inbound Email Script ○ Orchestration RunScript Activity ○ Record Producer Script

Field	Description
	○ Service Portal Widget ○ Scheduled Script ○ Scope ○ Script Include ○ UI Action ○ UI Macro ○ UI Page ○ Workflow Activity For example, to allow access from an entire application, select **Scope**.
Status	Status of the access request: ○ Requested ○ Denied ○ Allowed ○ Invalidated **Note:** If a calling resource changes, the restricted caller access record status changes to Invalidated. If you enable application administration, only application administrators of the target application can update the status of a request.
Target	Record of the requested resource.
Target Scope	Scope of the requested resource.
Target Table	Table that contains the Target record.
Target Type	Type of requested resource. ○ Event **Note:** An event is a special type of target for restricted caller access. By selecting an event in a target scope, you give a source application permission to queue an event that is registered as part of a target application. However, if you set the caller access on the event registry to None, it prevents cross-scope access calls to an event. This setting combination is a one-to-one relationship. To learn more about events, and their function, see Events. If you set caller access to None on the event registry, the cross-scope access calls to an event are denied. ○ Scope

Field	Description
	○ Table ○ Script Include For example, to allow access to an entire application, select **Scope**.

Scope-to-scope settings

Allow or deny access of all application resources in a source scope to all application resources in a target scope. This setting combination is a many-to-many relationship.



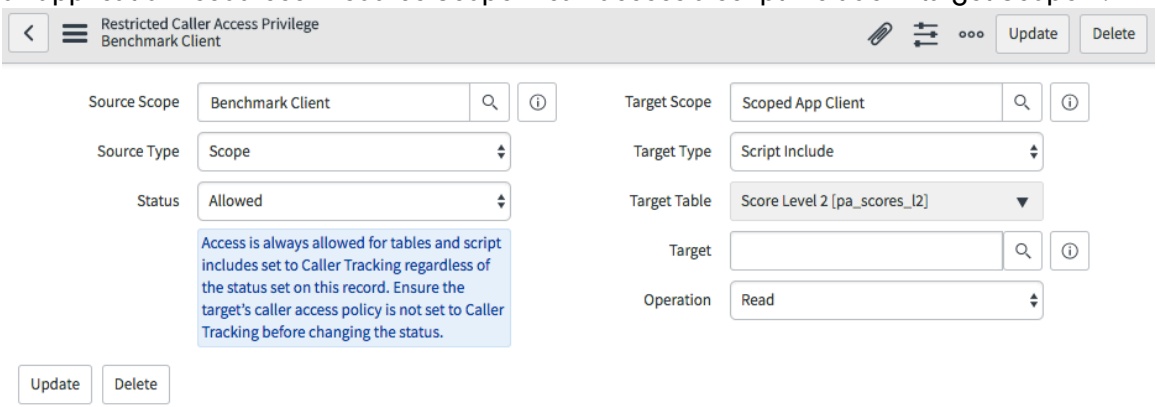
Enter the following field settings for Scope-to-Scope restricted caller access.

Field	Entries
Source Scope	Scope of the calling application that contains the source application resources.
Source Type	Type of record calling the application resource. To allow access from an entire application, select **Scope**.
Status	Status of the access request. Select **Allowed** to allow access, or select **Denied** to restrict access for this source-target resource relationship.
Target Scope	Scope of the requested resource that contains the target application resources that the source application resource requests access to.
Target Type	Type of requested resource. Select **Scope** to include all application resources in the target scope.

Scope-to-target settings

Allow or deny access of all application resources in a source scope to a specific application resource (business rule, table, script include, or event) in a target scope.

This setting combination is a many-to-one relationship. For example, you can specify that all application resources in source Scope A can access a script include in target Scope B.



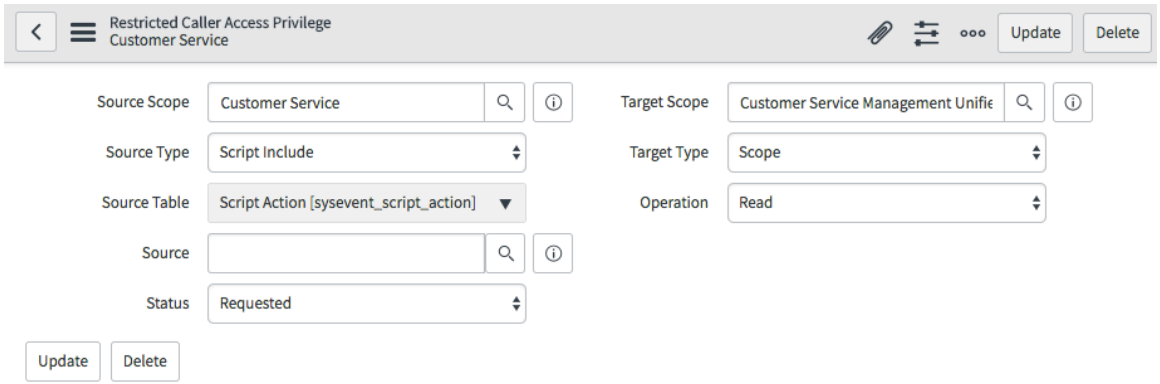
Enter the following field settings for Scope-to-Target restricted caller access.

Field	Entries
Source Scope	Scope of the calling application that contains the source application resources.
Source Type	Type of record calling the application resource. Select **Scope** to include all application resources in the source scope.
Status	Status of the access request. Select **Allowed** to allow access, or select **Denied** to restrict access for this source-target resource relationship.
Target Scope	Scope of the requested resource that contains the target application resources that the source application resource requests access to.
Target Type	Type of requested resource. Select the specific application resource (for example, business rule, script include, UI page, event) the source application resource requests access to.
Operation	Type of operation (for example, Read, Write) in the target application resource the source application resource requests access to.

Source-to-scope settings

Allow or deny access of a specific application resource in a source scope to all application resources in a target scope.

This setting combination is a one-to-many relationship. For example, you can specify that a particular business rule in source Scope A can access all application resources in target Scope B.



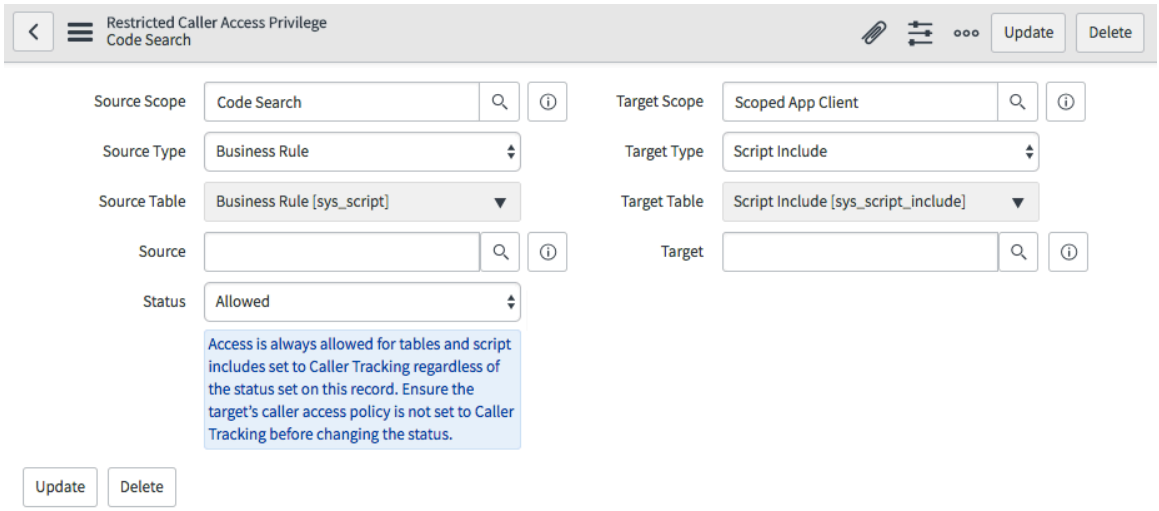
Enter the following field settings for Source-to-Scope restricted caller access.

Field	Entries
Source Scope	Scope of the calling application that contains the source application resource requesting access to the target scope application resource.
Source Type	Type of record calling the application resource. Select the specific application resource (for example, business rule or script include) requesting access to the specified target scope application resource.
Status	Status of the access request. Select **Allowed** to allow access, or select **Denied** to restrict access for this source-target resource relationship.
Target Scope	Scope of the requested resource that contains the target application resources that the source application resource requests access to.
Target Type	Type of requested resource. Select **Target** to include all application resources in the selected target scope.
Operation	Type of operation (for example, Read, Write) in the target application resource the source application resource requests access to.

Source-to-target settings

Allow or deny access of a specific application resource in a source scope to a specific application resource in a target scope.

This setting combination is a one-to-one relationship. For example, you can specify that a specific business rule in source Scope A can access a specific application resource, such as a business rule, table, script include or event, in a target scope.



Enter the following field settings for Source-to-Target restricted caller access.

Field	Entries
Source Scope	Scope of the calling application that contains the source application resources.
Source Type	Type of record calling the application resource. Select the specific application resource (for example, business rule, script include, or UI page) requesting access to the specified target scope application resource.
Status	Status of the access request. Select **Allowed** to allow access, or select **Denied** to restrict access for this source-target resource relationship.
Target Scope	Scope of the requested resource that contains the target application resources that the source application resource requests access to.
Target Type	Type of requested resource. Select the specific application resource (for example, business rule, Script Include, event) the source application resource requests access to.

Requested restricted caller access (RCA)

You can use a requested RCA to grant store apps access to protected resources in the ServiceNow AI Platform without the need to wait for the next family release. If you have the system admin or application admin role, you can review requested RCAs and approve and deny them.

RCAs are classified into two categories:

- Real RCA: sys_scope==target_scope
- Requested RCA: sys_scope!=target_scope

For example: A real RCA record is where the application scope and target scope match. A requested RCA is a record that is still awaiting approval for access to the target scope.

When you install an application, your scheduled jobs generate RCA records with the status of Requested in the target application for each requested RCA record that is packaged in the source application.

Note:
The jobs are generated once Upgrade Summary has run.

Example of how a store app accesses a table

Let's say that a store app called HR Integrations Framework wants to access an HR Core Case table. The table is in the business rule called Find Case in the Integration Service table.

To request access, the HR Integrations Framework app requires that an RCA privilege is packaged in its own scope as follows:

- sys_scope = HR Integrations Framework
- target = HR Core Case
- status = Allowed
- target_scope = Human Resource: Core
- source = Find Case

App development example for developers

When you are developing an application, real RCAs are generated with the status of Requested when the target has a caller restriction. If the target has caller tracking, the status becomes Allowed. The developer can review and finalize all the real RCA records that are required for the application to work. For example, those RCAs with a status of Allowed.

A developer can click the **Generate RCA Privileges in Current App** in the related links to generate requested RCAs that are packaged in the current application. Requested RCAs are synchronized with real RCAs, which means that if a real RCA is updated or deleted, a requested RCA is updated or deleted too.

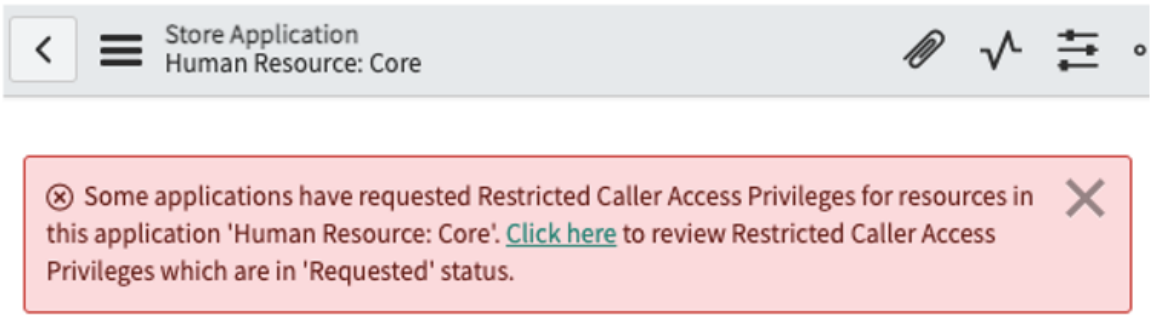
Now, the HR Integration Framework application can be packaged and installed on a customer instance.

App installation example for administrators

When you are installing an app on a customer's instance, real RCAs are generated in the target application. A real RCA would have the Human Resource: Core with a status of Requested. This process is done asynchronously in a scheduled job, where some lag time can occur.

To notify the target app admin about an RCA's pending review, messages have been added to application pages. An example is as follows:

RCA pending review message



Store App backward compatibility

If a store app is compatible and can be installed on an instance that is pre-Rome, then you must package the RCA records in their own scope with the status of Allowed.

Note:
This process ensures that the store app works on all versions.

When upgrading to Rome, you can configure a one-time fix script to move RCAs in the source scope to the target scope. In Rome, if the target app already has the necessary RCA records, no RCA records are generated for the RCAs that are packaged by the source app.

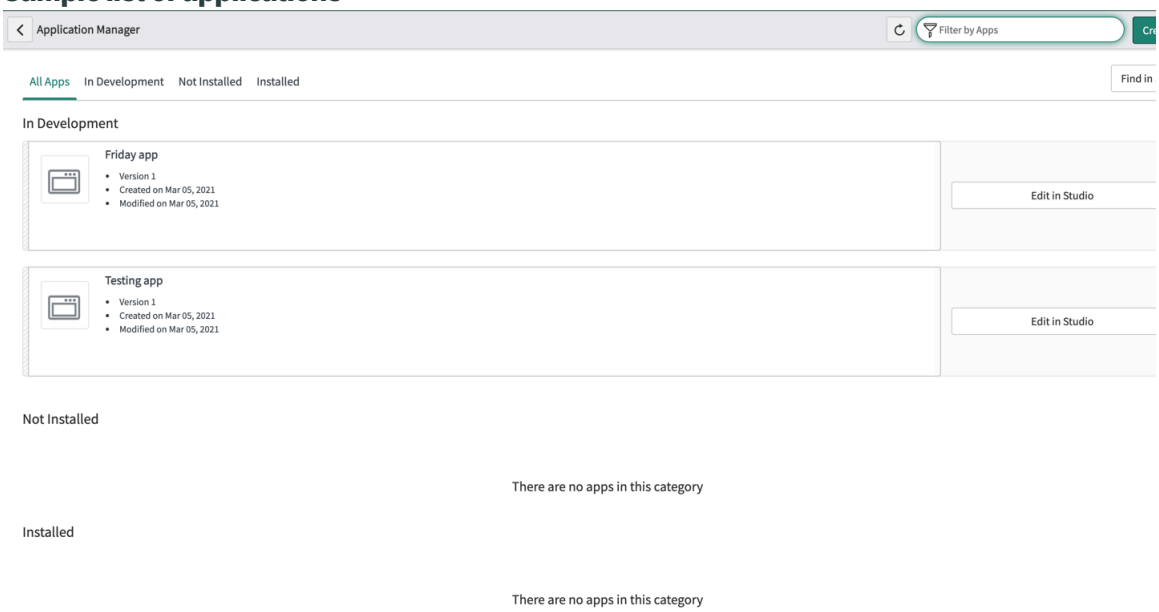
Application list

The applications list allows application developers to view and select applications.

Application developers can use the applications list to open a custom application record. If the contextual development environment detects that you are editing an application artifact in another application scope, it displays a warning message you can use to switch to another application.

Administrators have the following options from the applications list.

Sample list of applications



Application list options

Tab name	Options available	Application source
Develop	• Create new application • Edit existing application • Share application • Delete application	Applications developed on this instance

Application list options (continued)

Tab name	Options available	Application source
Downloads	• Install • View installed files • Edit installed files • Uninstall	• Applications shared on the company application repository • Applications shared on the ServiceNow Store
Updates	• Update • View version information	• Applications shared on the company application repository • Applications shared on the ServiceNow Store

The application list displays the following information.

Applications list

Type	Description
Developed	Display applications created on this instance.
Downloaded	Display applications downloaded on this instance.
Updates	Display available updates for downloaded applications on this instance.

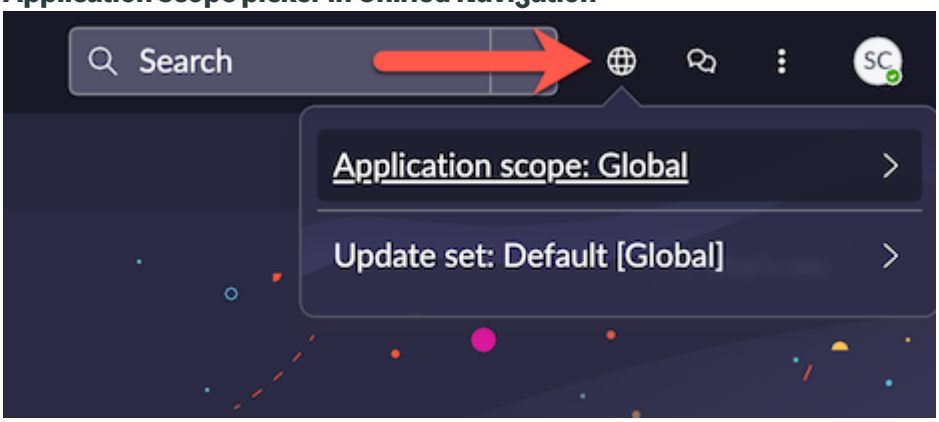
Application picker

The application picker enables application developers to view and select the application scope where their changes apply.

The application picker is available in the Unified Navigation menu. Select the picker icon ( ), then select **Application scope**, to open a list of application scopes that you have access to.

When your application scope is set to a non-Global scope, the picker icon displays with a red ring( ).

Application scope picker in Unified Navigation



Resources

The application picker is part of the Next Experience picker. For more information, see Exploring Next Experience pickers.

For more information about application scoping, see Application scope.

Lists and forms in scoped applications

The current application context determines what customization and form design options are available when working with lists and forms in scoped applications.

The user interface uses visual indicators to identify a list or form in the same or different application scope.

Available layout and design actions

The system allows the following layout and design actions when working on lists or forms in custom applications.

Available layout and design actions

Action	Access granted	Notes
Create a list view	Always allowed	This action is always available to users with access to customization.
Create a form view	Always allowed	This action is always available to users with access to customization.
Create a form section	Always allowed	This action is always available to users with access to customization.
Select fields to display in a view	Only allowed for sections in the view that match the current scope.	This restriction is independent of a user's role. Administrators cannot bypass this restriction.
Change the order of sections in a view	Only allowed for views that match the current scope.	This restriction is independent of a user's role. Administrators cannot bypass this restriction.
Select fields to display in a section	Only allowed for sections that match the current scope.	This restriction is independent of a user's role. Administrators cannot bypass this restriction.
Add or remove section columns	Only allowed for sections that match the current scope.	This restriction is independent of a user's role. Administrators cannot bypass this restriction.
Delete a form section	Only allowed for sections that match the current scope.	This restriction is independent of a user's role. Administrators cannot bypass this restriction.
Create new fields	Only allowed for sections that match the current scope and when the **Allow configuration** option is enabled.	This restriction is independent of a user's role. Administrators cannot bypass this restriction.

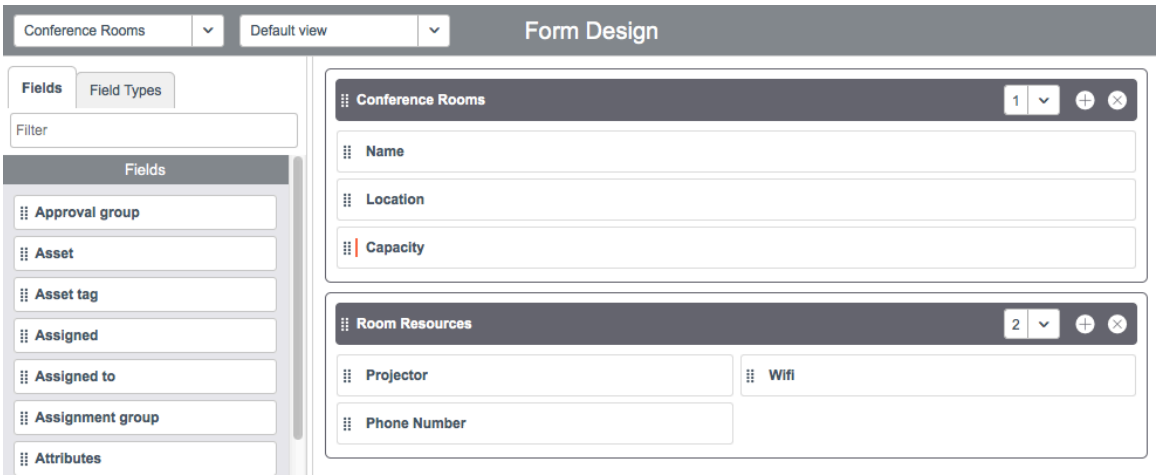
Form design visual indicators

The UI displays the following visual indicators when designing forms in custom applications.

You can only edit views and sections when you are in the same application scope as the form. Editable sections display:

- Section headings with a solid color background.
- A solid line around the section.
- A control to set the number of columns.
- A **Delete this section** button.
- Grip icons beside section headings.
- Grip icons beside fields.

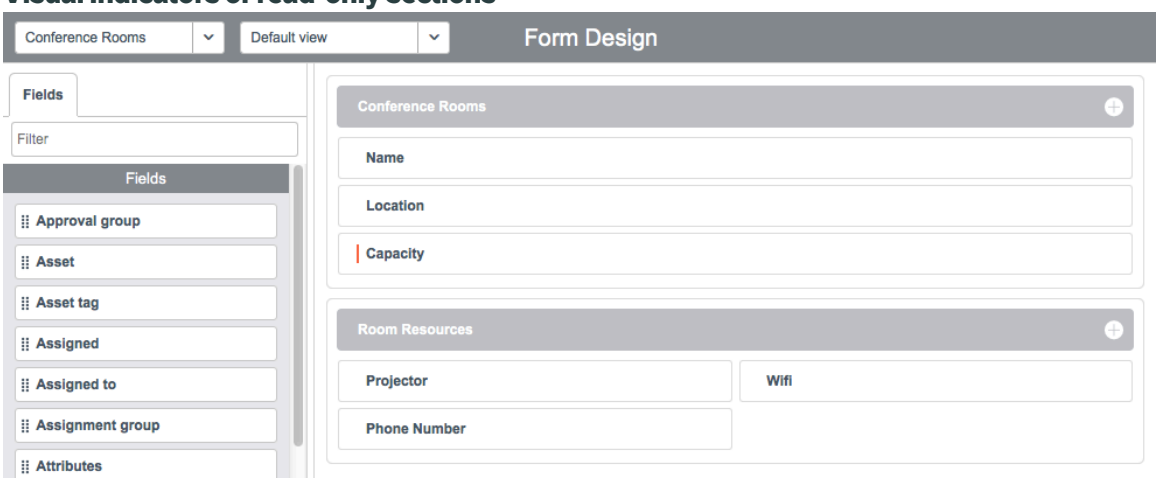
Visual indicators of editable sections



Views and sections in another application scope display as read only. Read-only sections have:

- Section headings with a gray background.
- A gray line around the section.
- No control to set the number of columns.
- No **Delete this section** button.
- No grip icons beside section headings.
- No grip icons beside fields.

Visual indicators of read-only sections



Default form design permissions

By default, new application data tables have the following form design permissions.

Default form design permissions

Form design action	Permission setting
Create new sections in tables belonging to another application scope	Allowed
Create new fields in sections belonging to the same application scope	By default, denied. Requires application designer to set **Allow configuration** for application table.
Add or remove fields from sections belonging to the same application scope	Allowed
Change the order of fields in sections belonging to the same application scope	Allowed
Change the order of sections belonging to the same application scope	Allowed
Add or remove fields from sections belonging to another application scope	Denied
Change the order of fields in sections belonging to another application scope	Denied
Change the order of sections belonging to another application scope	Denied
Create new fields in sections belonging to another application scope	Denied

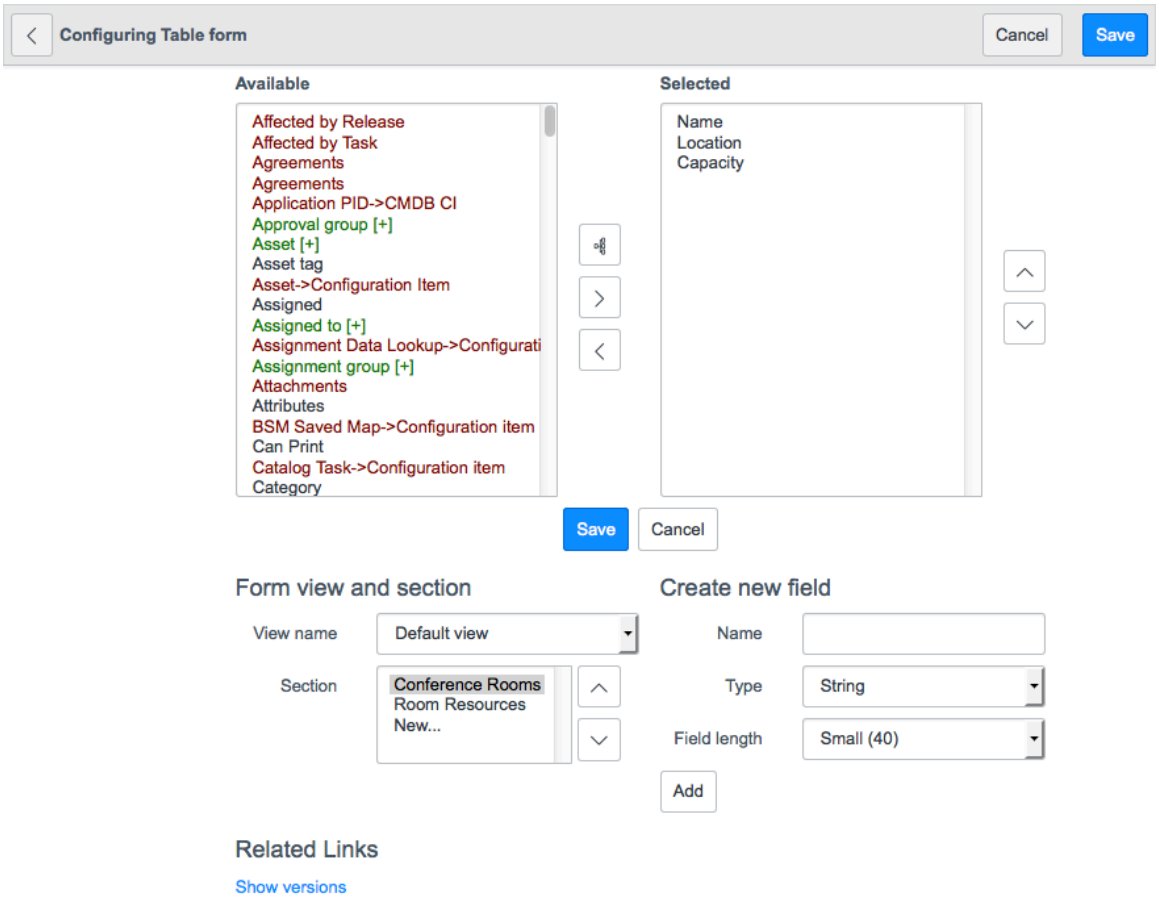
Layout visual indicators

The UI displays the following visual indicators when configuring the layout of a custom application's list or form.

You can only edit fields, views, and sections when you are in the same application scope as the form. Editable sections display:

- Field selections with a white background.
- Buttons to add or remove fields.
- Save button with a blue background.
- Editable fields in the **Create new field** section.

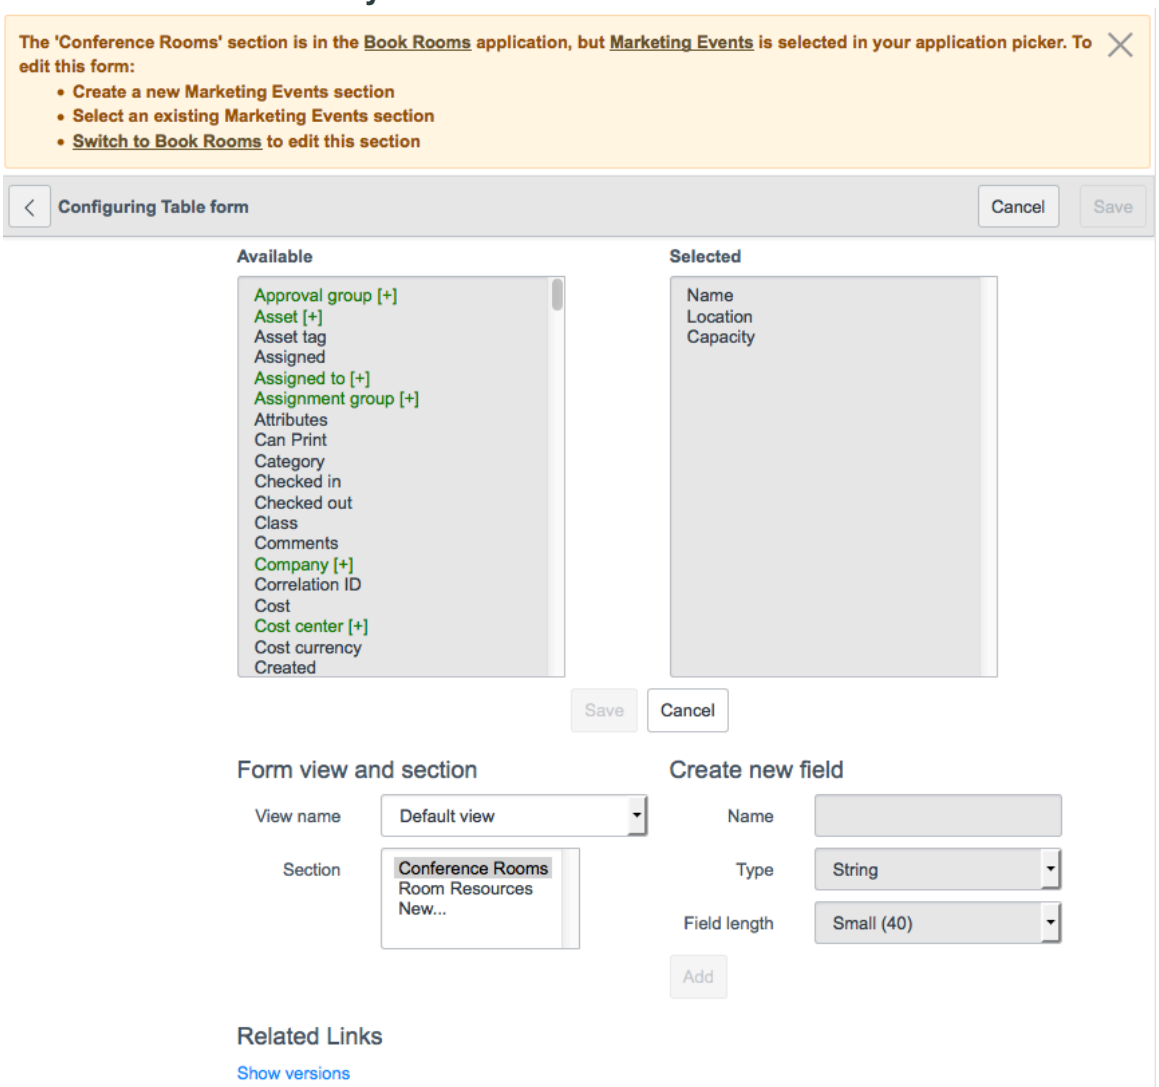
Visual indicators of editable sections



Views and sections in another application scope display as read only. Read-only sections have:

- A warning message about the currently selected application scope and the scope of the form.
- Field selections with a gray background.
- No buttons to add or remove fields.
- Save button with a gray background.
- Read only fields in the **Create new field** section.

Visual indicators of read-only sections



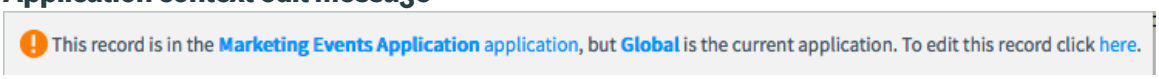
Related topics

- Lists and forms in scoped applications
- Available layout and design actions
- Form design visual indicators

Contextual development edit messages

The platform displays a message if you attempt to edit a Store Application record when you're in a different application scope.

Application context edit message



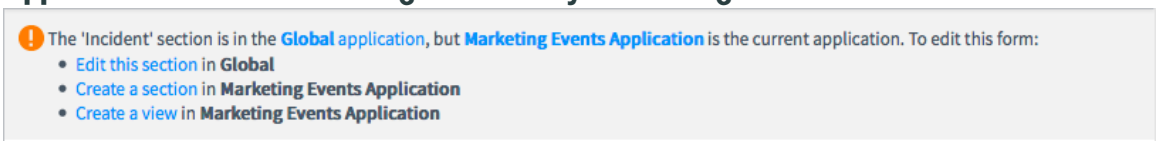
This message can be used to:

- Open the application to which the current configuration record belongs.
- Open the application of the currently selected application in the application picker.
- Temporarily switch to the application to which the current configuration record belongs and edit it.

Note:
The system returns you to the current application context after you save or cancel out of the record.

The system also displays a message when a user attempts to configure a list or form layout while working from another application scope.

Application context edit message for form layout or design



The message provides a list of valid options:

- Edit the current section by temporarily switching to the application that owns it.
- Create a new section in the current application context.
- Create a new view in the current application context.

Note:
The system returns you to the current application context after you save or cancel out of the record.

Script protection policy

Application developers can set a protection policy for script includes published as part of a custom application. The policy determines whether someone can view or edit the script include after the application is installed on their instance.

Application developers have these options to protect their custom application script includes:

Script include protection policy Options

Protection policy	Description
None	Select this option to allow other application developers to customize your script include.
Read-only	Select this option to allow other application developers to see your script logic, but not to change it.
Protected	Select this option to prevent other application developers from changing your intellectual property.

Application administration

Protect sensitive application data by using application administration to restrict how users acquire application-specific roles.

Functions of application administration

Use application administration to:

- Help prevent unauthorized users from accessing sensitive data via forms, lists and UI, such as financial records or personally identifiable information.
- Determine who can assign scope-protected roles such as the administrator and designated developers for the application.
- Help prevent users with the system-level admin role from:
  - Assigning themselves a protected application role.
  - Assigning themselves to a group containing a protected application role.
  - Bypassing existing access controls to a protected application by creating access controls.
  - Impersonating a user who has a protected application administration role, unless the developer or administrator also has that role.
  - Inheriting a protected application role.
  - Overriding existing access controls to a protected application.

Roles in application administration

You can make any role an application-specific administrator by selecting the **Application Administrator** check box in Role Configuration. To learn more, see Restrict access to an application. By convention, create the following roles:

Application administration roles

Role name	Description
Application-specific admin	Users with this role can assign other users to an application-specific role for that application. For example, you can create a role named my_application.admin. It should include the name of the restricted application, with a suffix of "admin" to indicate that it is the admin role for the application.
Application-specific developer	Users with this role can access the restricted application. For example, you can create a role named my_application.developer. It should include the name of the restricted application, with a suffix of "developer" to indicate that it is the developer role for the application. The developer role needs both application administrator and delegated development permissions to modify the application files. To learn more, see Delegated development and deployment and Delegate development and deployment permissions to personnel.

Application-specific admin role

The application-specific admin role enables a user to access a specific application, but does not grant the user any other admin rights. Assign the system-level admin role to a user before that user can do these tasks:

- Configure form and list layouts.
- Change application tables and fields.
- Assign the application-specific admin role to new users.

If you do not want a user with the application-specific admin role to have the system-level admin role:

- Do not assign the system-level admin role to the user. Assign only the application-specific admin role.
- Have the user assign themselves the application-specific developer role.

As an application-specific developer, the user can perform a subset of administrative tasks without having the system-level admin role.

Note:
Assign the application-specific admin role to more than one user. Then if a user with the application-specific admin role leaves the company, you are not prevented from changing the application.

Enabling application administration and assigning application-specific roles

You can enable application administration for an application from the application record and restrict the assignment of application-specific roles from the user role record.

Note:
Enable application administration and assign application-specific roles after completing development of the application, but before adding application records. This practice protects sensitive data in the application records from access by unauthorized users.

The target instance must have at least one authorized user with the application-specific admin role.

- If you enable application administration for an application but do not assign the application-specific roles, no user can access the application.
- If you assign only one application-specific role, you cannot delete that role.

A warning appears if you enable application administration for an application, but no users have the application-specific admin role required to assign roles for the application. The warning reminds you to assign the application-specific roles for administrators and developers of the application.

Set the *[scoped_app_name].min_admin_count property* to require that more than one user must have the application-specific admin role. Assigning the application-specific admin role to multiple users reduces the risk of getting locked out of the scoped application. The *[scoped_app_name].min_admin_count* property has the following limitations:

- If you specify an invalid value for the property, the default requirement for assigning at least one application-specific admin is enforced.
- If you specify a valid value for the property, you can't delete any application-specific admins unless you exceed the specified value. For example, if you specify a value of two and you have three application-specific admins, you can delete only one of those roles.
- You can specify a value higher than the actual number of assigned application-specific admins. However, you can't delete any application-specific admins until you exceed the specified value. For example, if you specify a value of six, but have only three application-specific admins, you can't delete any of those roles.

For procedures, see Restrict access to an application.

Deploying applications with application administration

You must have the system-level admin role in both your developer and production instances to deploy an application protected by application administration. The process is outlined in the following steps.

1. Develop the application on a development instance.
2. Create the application-specific admin role.
3. Grant the application-specific admin role to all system-level admin users.
4. Update the application record to enable application administration and restrict access to the application.
5. Publish the application to the application repository.
6. From a production instance, install the application from the application repository.
7. As a system-level admin on the production instance, grant the application-specific admin role to the appropriate users.
8. Remove the application-specific admin role from all users with the system-level admin role.

For procedures to enable application administration and restrict the assignment of application-specific roles, see Restrict access to an application.

Training

The ServiceNow® Developer Site has training for Securing Applications.

Delegated development and deployment

Restrict access to an application

Restrict management of an application and access to that application to prevent unauthorized users from assigning administrative rights to the application or accessing sensitive information in the application records.

Before you begin

- Records required:
  - Role record to designate a role as the application-specific admin role
  - User record to assign an application-specific admin role to a user
  - Application record to enable application administration for a specific application
- Role required: admin

If an application-specific admin role does not already exist, create it before beginning this procedure. For example, you can create a role named my_application.admin that includes the name of the restricted application with the suffix "admin" to indicate that it is the admin role for the application.

Procedure

1. Navigate to **All** > **System Security** > **Users and Groups** > **Roles** or **User Administration** > **Roles**.
2. Open the role record for the application-specific admin role.
3. Configure the form to add the **Application Administrator** field.

   Note:
   The **Application Administrator** check box replaces the **Assignable by** field. By default, when you upgrade from a Jakarta or earlier release to a Kingston or later release, any role that was in the **Assignable by** field is defined as the application-specific admin role, and the **Application Administrator** check box is selected.

4. In the role record, select the **Application Administrator** check box, and then click **Update**.
5. Navigate to **System Applications** > **My Company Applications**.
6. Open the user record for the admin user.
7. On the Roles tab, add the application-specific role.
   Only users with the application-specific admin role can enable application administration for an application.

   Note:
   Assign the application-specific admin role to more than one user. Then, if a user with the application-specific admin role leaves the company, you are not prevented from performing changes to the application.

8. Click **Update**.
9. Log out and then log in with the application-specific admin role.
10. Navigate to **System Applications** > **Applications**.
11. Select the application for which you want to enable application administration.
12. In the application record, select **Application administration**.
13. Click **Update**.
    The system validates that the following requirements have been met:
    - The application has an application-specific admin role (there is at least one role with **Application Administrator** selected).
    - The current user has the application-specific admin role.

    If the validation passes, the system updates the application record. Otherwise, the system displays this error message and does not update the application record:

    ```
    Application Administration uses the 'Application Administrator'
     role to define what users are application administrators. None
     of the roles defined by this application have 'Application
     Administrator' enabled.
    ```

14. **Optional:** From the Related Links, you can select one of the following options:

Related Link	Description
Manage Developers	Modal that enables the application-specific admin to manage these tasks:

Related Link	Description
	○ Designate developers for the application. ○ Make themselves a delegated developer. After the application-specific admin becomes a delegated developer, the application-specific admin can perform a subset of administration tasks without having the system-level admin role. Learn more: Delegated development and deployment
Grant application administration to all admins	Modal that creates a Contained Role [sys_user_role_contains] record for the system-level admin role. This adds the application-specific admin role as a contained role of the system-level admin role. **Note:** When you publish the application with this record, users with the application-specific admin role can access the application after installing it.

Access control rules in application administration apps

By default, when application administration is enabled for a scoped application, ACL rules for the scoped application are applied. If no ACL rules for the scoped application are found, global ACL rules can apply.

This behavior applies to configuration records created in tables that extend the Application File [sys_metadata] table only. You can also change the default behavior.

When no access control (ACL) rules for an application administration app are defined, global ACL rules can apply to the configuration records of the application administration apps. See Application files for more information.

Note:
Not all applications utilize global ACL rules. If you are unable to perform an action as expected, verify that the application allows global ACL rules. If it does not, you may need to create specific ACL rules for some applications.

To allow a table in an application administration app to inherit global ACL rules, check that the system property is true and follow the instructions detailed in Configure a table in an application administration app to inherit global ACL rules.

- `glide.security.scoped_administration.honor_global_acl` system property: If no scoped ACL rules are defined, application administration apps can inherit global ACL rules. By default, this property is enabled for new and upgraded instances.
- Application Administration ACL Inheritances [sys_scoped_admin_acl_inheritance] table: If no ACL rules for the application administration app are found, tables added to this list inherit global ACL rules. Only the administrator for the application administration app can add, remove, read the records owned by the application administration app in this configuration table.

Configure a table in an application administration app to inherit global ACL rules

To avoid duplicating global access control rules (ACLs) in your applications, you can configure application file tables in application administration apps to inherit global ACLs when no ACL rules for the scoped application are found.

Before you begin
Role required: admin role for the application

Procedure

1. Enter `sys_scoped_admin_acl_inheritance.list` in the navigation filter.
   The Application Administration ACL Inheritance table [sys_scoped_admin_acl_inheritance] opens.
2. Click **New**.
3. In the **Table** field, select an application file table (a table that extends the Application File [sys_metadata] table) from the application administration app.
   Only the administrator for the application administration app can add/remove/read records owned by the application administration app in this configuration table.
4. Click **Submit**.
   If no ACL rules from the application administration app are found, tables added to this list inherit global ACL rules.

Access enforcement for ServiceNow Store apps

All production instances monitor and generate reports on usage patterns for ServiceNow Store apps. When subscription enforcement is enabled, users who are not subscribed to the app are blocked from performing fulfiller actions in the app.

Overview
The following actions are required to enable a production instance to enforce entitled usage of your ServiceNow Store App:

1. The usage admin at your organization uses the Subscription Management application to allocate fulfiller users to the subscription.
2. You decide on the enforcement mode, either:
   - Monitor and report usage with no enforcement (default)
   - In addition to monitoring and reporting usage, enforce that all usage must be by subscribed fulfiller users.
3. To enforce usage only by subscribed users, you configure the tables where only record owners or subscribed fulfiller users can make updates as fulfillment tables.

Licensing

Understand the different types of software licenses and subscriptions available with ServiceNow applications.

Licenses

Note:
Discuss licensing with your ServiceNow account representative for information specific to your contract.

You need a license to get entitlement for an application. If you have entitlement to a particular app, you can activate it on the ServiceNow Store.

All software licenses outline exactly how the software may be used without infringing on copyright law. There are many different subcategories of software licenses. These categories are not necessarily exclusive; different kinds of software will often overlap.

For more information on different types of software licenses, see What is a software license?

Subscriptions

A subscription enables you to upgrade from one family release to the next without dealing with the ServiceNow Store. For example, if you're on Tokyo and have a subscription to an app, you're automatically upgraded to Xanadu as soon as it's in general release.

The type of subscription determines the allocation of users, access to applications, and custom application and table entitlements. For more information on types of subscriptions available for ServiceNow applications, see Types of subscriptions in Subscription Management.

Creation restrictions across application scopes

The system restricts the creation of some configuration records when the current application scope does not match the application scope of the configuration record's target table.

Configuration record creation restrictions prevent one application from making unwanted changes to another application's data tables. These restrictions only apply when you create a configuration record whose target table belongs to another application. Configuration records that belong to the same application scope do not have these restrictions.

The system always enforces the following creation restrictions when a developer adds a configuration record belonging to another application scope.

Configuration record creation restrictions

Configuration record type	Creation restrictions when target table is in another application scope
Access controls	• You can only create field-level access controls with a role-based requirement. • You cannot create table-level access controls for a table in another application scope. • You cannot create field-level access controls that apply to all fields. • You cannot create access controls that use conditions. • You cannot create access controls that use a script-based condition.
Business rules	• You can create a rule where **When** is *async* with any of the following options: ○ *Insert*, *Update*, and *Delete* database operations. You cannot select *Query*. ○ **Set field values** actions and scripts (the **Script** field). • You can create a rule where **When** is *before* with any of the following options: ○ *Insert*, *Update*, and *Delete* database operations. You cannot select *Query*. ○ **Set field values** actions only. You cannot write scripts and you cannot abort the database transaction.
Calculated fields	You cannot create calculated fields for tables in another application scope.

Configuration record creation restrictions (continued)

Configuration record type	Creation restrictions when target table is in another application scope
Data policies	• You cannot create data policy rules for fields in another application scope. • You cannot make a field mandatory.
Field styles	You cannot create field styles for fields in another application scope.
Form sections	• You cannot modify existing form sections created in another application scope. • You can create new form sections.
Record producers	You must have create access to the application table to create records from a record producer.
UI policies	• You cannot create UI policy rules for fields in another application scope. • You cannot make a field mandatory.
UI script	You cannot create a global UI script from a scoped application.
Views	• You can create new views. • You cannot modify existing views created in another application scope.

Planning your application

The application development process starts with planning. Consider how the application will work, who will use it, and how it improves user experience.

Planning on the Next Experience

App intake

With your carefully planned idea in hand, you're ready to submit it through Application Intake for approval and development in App Engine Studio (AES).

Define tables and fields for application records

Applications use tables and records to manage data and processes, such as Incident, Problem, and CMDB.

Security: App Engine Studio roles and permissions

Administrators assign roles to give team members permission to configure or use AES.

Planning on UI16

Delegated development

Delegated development enables designated users without a system admin role to develop or deploy applications on the ServiceNow AI Platform.

Schema map for tables

The schema map displays the details of tables and their relationships in a visual way, enabling administrators to view and easily access different parts of the database schema.

Table Administration

Administrators can use Table Administration to view and modify the database structure.

Team Development

Team Development supports parallel development on multiple, non-production ServiceNow instances.

Related applications and features

Security: Access control

By default, when application administration is enabled for a scoped application, access control (ACL) rules for the scoped application are applied. If no ACL rules for the scoped application are found, global ACL rules can apply.

Security: Edge Encryption

ServiceNow® Edge Encryption encrypts sensitive data on your company premises before sending it over the internet to your ServiceNow instance (encrypted in flight), where it remains encrypted at rest.

Security: Roles

Set up the security and roles for your UI Builder instance. Security and roles in UI Builder are controlled through your application's scope, domain separation, and protection policy settings.

Security: UI policies

Create a UI policy to define custom process flows for tasks.

Security: Users and groups

Create users and groups using the ServiceNow AI Platform user administration feature.

ServiceNow application repository

After you develop and test a custom application, you can make the application available to company instances by publishing it to the ServiceNow application repository.

Source Control integration

Enable application developers to integrate with a Git Source Control repository. Save and manage multiple versions of an application from a non-production instance.

Submit your idea for app development

With your carefully-planned idea in hand, you are ready to submit it through Application Intake for approval and development in App Engine Studio (AES).

Before you begin

If you have not already activated the Apply for Citizen Development standard catalog item, you must do so before you can perform this procedure.

Role required: none

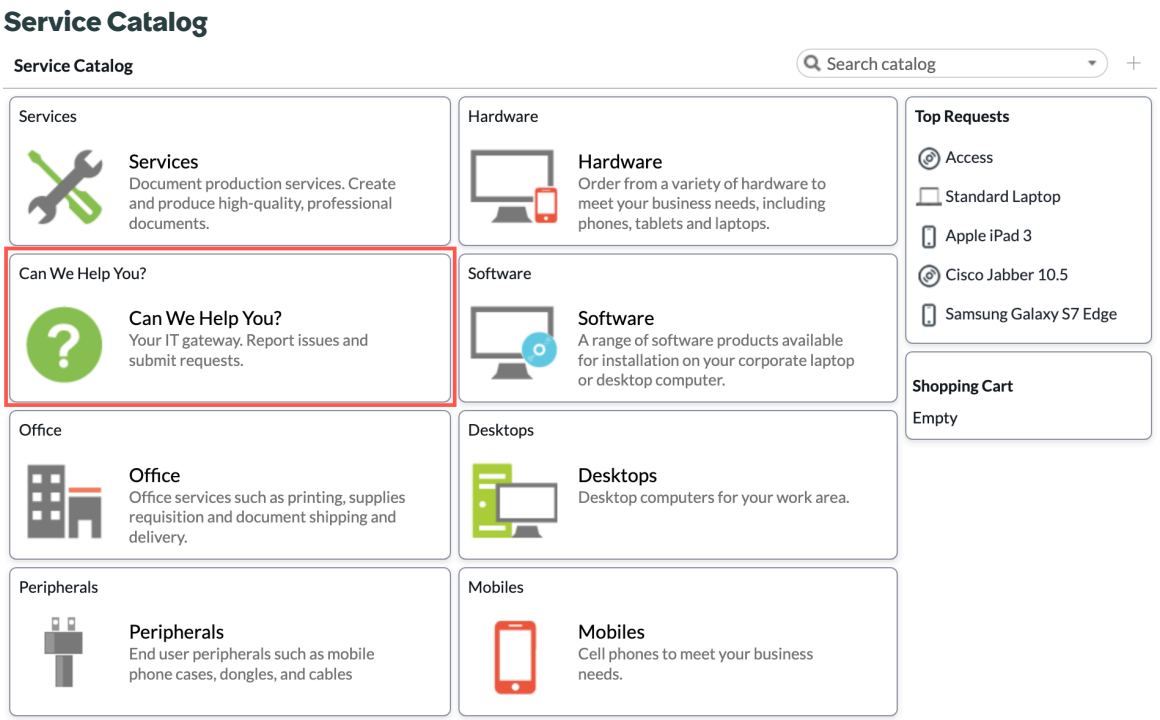
About this task

The intake request process streamlines submitting ideas for app development. Using Application Intake, the idea is shared with your App Engine Studio admin for review. The admin either approves or denies the request based on how well you have sold the business value of the idea.

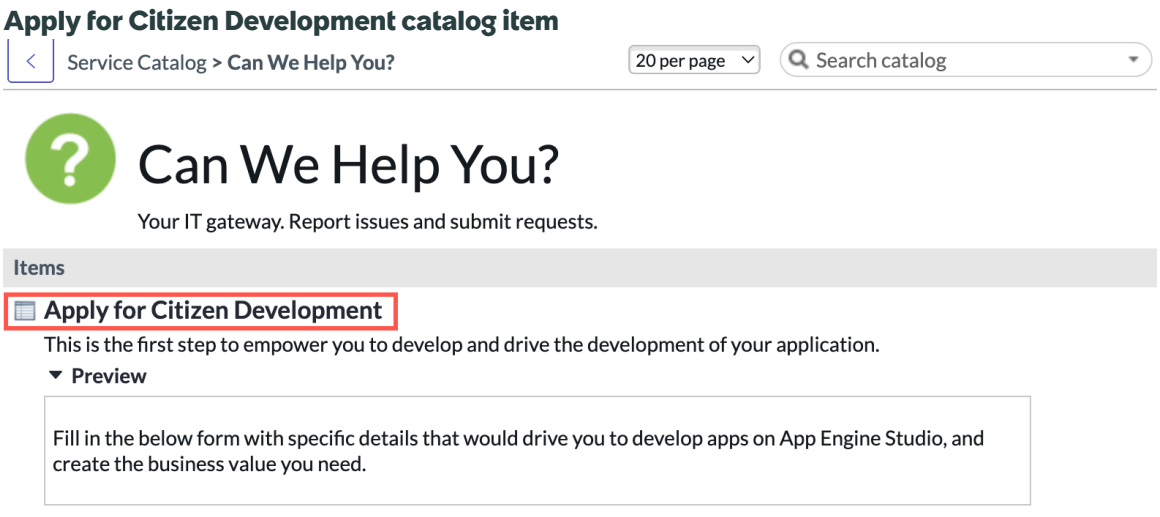
If the idea is approved, developers can build the app with the guided, intuitive app development environment provided in App Engine Studio.

Procedure

1. Navigate to **All** > **Self-Service** > **Service Catalog**.



2. In the Service Catalog, select the **Can We Help You?** category.



3. Select the **Apply for Citizen Development** catalog item to open the Application Intake form.
4. On the form, fill in the fields.

Fields on the Apply for Citizen Development form

Field	Description
Application Name	Unique name for the app.
Describe your idea in a few sentences	Simple description of the application.
Is your process repeatable?	Option to indicate whether the app idea could be used in other areas of the business.
Do you have an email or excel-based process?	Option to indicate whether an existing process is in place that this application would replace.
How many users are involved in this?	Number of users who would use the resulting application.
Does this involve any sensitive/PII data?	Option to indicate if the application would use any of the users' health, financial, or personally identifying information.
Do you need data from other departments?	Option to indicate whether other departments must supply data for the application.
Who are the users that will have access to the data in this application?	Users or groups who need access to the application.

5. Select **Order Now**.

Result

If the admin approves your request, you can start building your app in App Engine Studio. You should receive a confirmation email with access to build the app.

If you are an admin who approves requests, learn more about managing AEMC requests.

Specify data for your application

In its most basic form, building applications on the ServiceNow AI Platform means you're storing and using data in some way. Defining your application's data model is up to you and is based on the type of application you want to build.

You can use any combination of the following three methods to define your application's data model.

- **Reuse existing tables and fields to store record data.** For example, use the existing Task table to work on existing record types such as incidents and problems. Typically, this option is only available for tables in the global scope or tables that make their data available to all application scopes.
- **Extend existing tables to store record data.** For example, extend the Task table to create VIP incidents. The extended table inherits the fields from the parent table, but you can add new fields as needed.
- **Create new tables and fields to store record data.** You can use a variety of available tools to create new tables. If you have access to App Engine Studio, use Table Builder to create new tables and fields as you build applications. Alternatively, you can create tables and fields separately from application development using basic Table administration in the ServiceNow AI Platform.

More resources

These concepts are explained in further detail in the App Engine Studio, Table Builder, and Table administration documentation.

Create a data model for your application

Add data to apps that you build in App Engine Studio.

Table administration

Table administration currently contains more comprehensive functionality and options for managing tables.

Table Builder

Table Builder offers an intuitive way to visually build tables and forms in the ServiceNow AI Platform.

Delegated Development

Delegated development allows designated users without a system admin role to develop or deploy applications on the ServiceNow AI Platform.

Exploring Delegated Development

Delegated development allows designated users without a system admin role to develop or deploy applications on the ServiceNow AI Platform.

Delegated Development overview

If you have the application-specific admin role or the system-level admin role, you can delegate application development to designated developers at the application level.

Delegated Development users

Users

User	Description
Admin	Admin user can delegate developers.
Application Administrator	If Application administration is enabled, only an application administrator of the target application can delegate developers to an application. If application administration is not enabled, an admin user can delegate developers.

What to explore next

To learn more about configuring and using Delegated Development, see:

- Configuring Delegated Development
- Using Delegated Development

Delegated development and deployment

Delegated development allows designated users without a system admin role to develop or deploy applications on the ServiceNow AI Platform.

If you have the application-specific admin role or the system-level admin role, you can delegate application development to designated developers at the application level.

Delegated deployment tasks

You can also delegate deployment tasks (application publishing, first-time installation, or update) to developers or non-admin users, such as Change Management personnel. You delegate deployment tasks to specific users at the application level, or through assignment of specific user roles at the instance level.

Assignment Method	Applies to	Available options
Setting deployment permissions in Manage Developers. See Delegate development and deployment permissions to personnel	Specific applications	Publishing and upgrades of specific applications. Publishing options include the application repository, ServiceNow Store, and update sets.
Assignment of deployment user roles to specific persons. See Instance-specific deployment user roles.	Local non-production instance (for example, Development or QA)	First-time installations and upgrades of all applications that contain the same company as the current instance. For example, applications for ABC Company and XYZ Company display on the Application Client page. A user with this role can only install XYZ Company applications when logged in to a XYZ Company

Assignment Method	Applies to	Available options
		instance. The user cannot install applications for ABC Company.

Application-specific permissions

Developer and deployment permissions are application-specific. For example, a developer who has permission to access all file types for one application does not necessarily have any developer permissions for another application. Administrators must set developer (and optionally deployment) permissions for each application. Administrators must be familiar with application files and the system table structure to set developer permissions. For example, a developer expected to create advanced business rules needs both the **All File Types** and **Allow Scripting** developer permissions.

Important:
If Application administration is enabled, only an application administrator for the target application can delegate developers for an application. Application administrators do not have system admin privileges. To enable a delegated developer to perform the functions granted in the developer permissions, the delegated developer must also be given the application administrator role.

Setting each permission grants one or more system-managed delegated development roles, allowing system admins to retain control over the system. System admins no longer have to elevate developers (or users who deploy applications) to the system admin role to enable them to develop or deploy applications.

Developer and deployment permissions example

As a system administrator, you want to assign Abel Tuter certain developer and deployment permissions for a specific application in your development instance. For more details on developer and deployment permissions, see Delegate development and deployment permissions to personnel.

Domain separation and Delegated Development

Domain separation is unsupported in the Delegated Development feature. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

Related topics

Domain separation for service providers

Configuring Delegated Development

Configure Delegated Development to assign, delete, display or hide permissions.

Configuration overview

- Assign source control permissions

  Ability to assign full access to source control for a particular scope to a delegated developer. The Source Control menu is only visible if you have the correct permissions for the application that you are working in. Before you begin.

- Assign delete permissions

  Assign the ability to delete an application to a delegated developer.

- Display or hide update set deployment permissions

  Display or hide deployment permissions for update sets from the Manage Developers dialog.

- Instance-specific deployment user roles

  Assign roles that enable non-admin users install or upgrade all applications in specific instances. You delegate these tasks by manually assigning specific user roles per instance.

Display or hide update set deployment permissions

Display or hide deployment permissions for update sets from the Manage Developers dialog.

Before you begin
Role required: admin

About this task
System properties control the visibility of the **Publish To Update Set** and **Manage Update Sets** permissions. By default, both deployment permissions for update sets are hidden.

Procedure

1. In the Navigation filter, enter `sys_properties.list`.
   The entire list of properties in the System Properties [sys_properties] table appears.

   Note:
   For details on how to add and enable system properties, see Add a system property.

2. Enable or disable specific deployment permissions by adding or updating the following system properties.

Deployment permissions

System property	Description
com.snc.dd.manage_update_set_enabled	Enables or disables display of the **Manage Update Set** permission. The default value of this system property is **false**. To enable the display of this permission, set this value to **true**.
com.snc.dd.publish_to_app_repo_enabled	Enables or disables display of the **Publish To App Repo** permission. The default value for this system property is **true**. To disable display of this permission, set this value to **false**.
com.snc.dd.publish_to_app_store_enabled	Enables or disables display of the **Publish To App Store** permission. The default value for this system property is **true**. To disable display of this permission, set this value to **false**.
com.snc.dd.publish_to_update_set_enabled	Enables or disables display of the **Publish To Update Set** permission. The default value for this system property is **false** by default, which disables display of this permission. To enable the display of this permission, set this value to **true**.
com.snc.dd.upgrade_app_enabled	Enables or disables display of the **Upgrade App** permission. The default value for this system property is **true**. To disable display of this permission, set this value to **false**.

Instance-specific deployment user roles

Assign roles that enable non-admin users install or upgrade all applications in specific instances. You delegate these tasks by manually assigning specific user roles per instance.

For example, you can assign user roles to Change Management personnel that allow them to perform application installations in non-production (development or QA) instances.

Important:
Give careful thought to whom, and in what instances you assign installation and upgrade user roles. You may only want to assign these roles to non-system administrators in non-production instances (for example, Developer or QA), but decline to do so in production instances. Given the potential impact of installing and upgrading applications, you may want to leave the responsibility for installations and upgrades in production instances to a system administrator.

To learn more about managing per-user subscriptions, see Managing per-user subscriptions in Subscription Management and contact your account representative.

Add deployment user roles

A system administrator can assign user roles to specific personnel that allow them to perform first application installations only, or install and upgrade applications in a local instance.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **User Administration** > **Users** and then open a user record.

   Note:
   For details on how to assign a role to a user, refer to Assign a user role.

2. In the **Roles** related list, select **Edit**.
3. In the **Collection** list, select the desired deployment roles, and then select **Add**.

   Delegated deployment roles

User Role	Description
sn_appclient.app_client_company_installer	Allows a designated person to perform first-time installations of applications displayed on the Application Client page that contain the same company as the current instance. A user with this role cannot install an application for another company. For example, applications for ABC Company and XYZ Company display on the Application Client page. A user with this role can only install XYZ Company applications when logged in to a XYZ Company instance. The user cannot install applications for ABC Company. **Note:** While this role does not grant a user the ability to upgrade applications, the system auto-adds a delegated developer upgrade role after the user does a first-time installation. The user can then perform upgrades for the application in the local instance. For more details, see System-managed developer and deployment roles.
sn_appclient.app_client_user	Allows a designated person to install and upgrade all applications displayed on the Application Client page.

4. Select **Save**.

System-managed developer and deployment roles

Although system admins can still manually assign and remove the user roles, they are encouraged to let the system manage the following delegated developer roles.

To learn more about managing per-user subscriptions, see Managing per-user subscriptions in Subscription Management and contact your account representative.

Role	Description
delegated_developer	User has one or more developer permissions.
Roles that start with an sn_dd prefix (for example, sn_dd_<app_name>_upgrade_app)	User has an application-specific developer permission. The role name indicates the application scope to which i applies. For example, after a user with a sn_appclient.app_client_company_installer role installs a company application, the system automatically grants a sn_dd_<app_name>_upgrade_app delegated deployme role. This role allows the user to upgrade the application when future updates are published to the Application Client page.
glide.security.add_admin_contained_roles_to_system	Default Value: true if the property is true, then all the roles, directly or indirectly contained by the admin role, are added to the system user, including the scoped-admin roles. **Note:** Setting the property to false results in the old behavior, where the system user has the admin role, but not any of the scoped-admin roles contained by the admin role. Example: The admin role contains the *sn_templated_snip.template_snippet_adm* role Old behavior: The system user does not have the *sn_templated_snip.template_snippet_adm* role. New behavior: The system user has the *sn_templated_snip.template_snippet_adm* role and other scoped roles that it contains.

Note:
Users with delegated developer roles cannot add or remove the system admin role.

Assign source control permissions

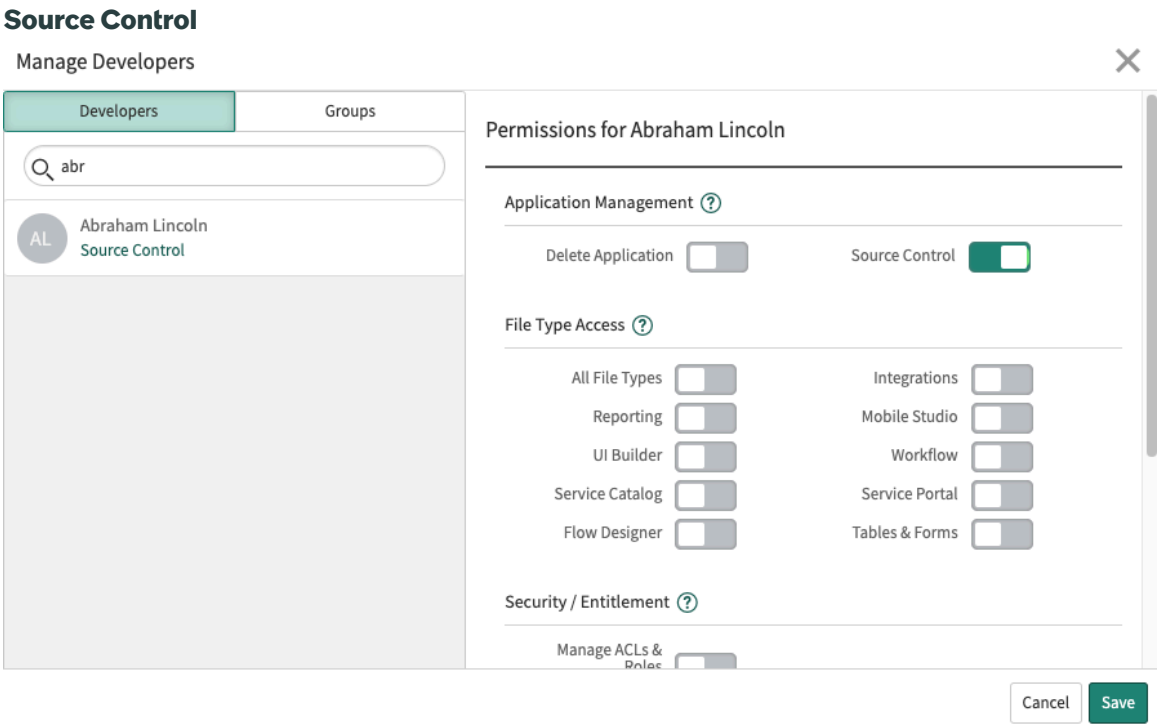
Ability to assign full access to source control for a particular scope to a delegated developer. The Source Control menu is only visible if you have the correct permissions for the application that you are working in.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **My Company Applications**.
2. Open an application for which you want to assign delegated developer permissions.
3. As a System Admin, select **File** > **Manager Developers**.
4. Choose a developer to apply delegated developer permissions.
5. Toggle on **Source Control**, and then select **Save**.



6. The delegated developer can now access the Source Control menu options.
   For more information on source control options, see Legacy - Available source control operations.

Assign delete permissions

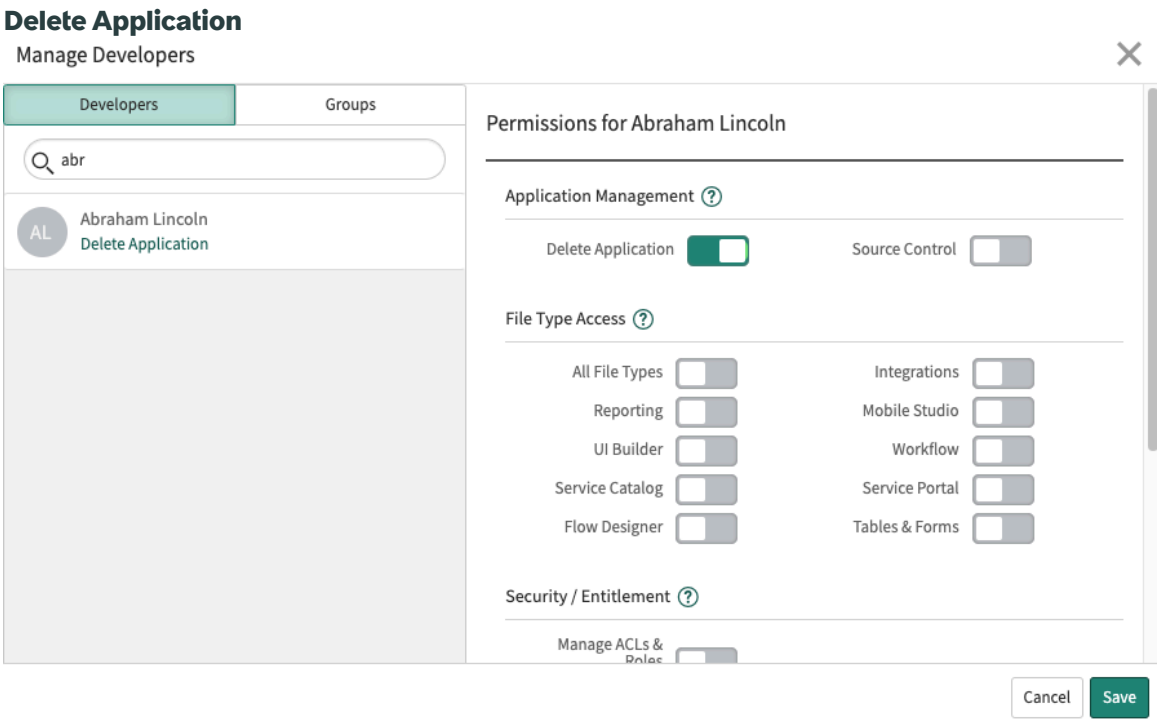
Ability to assign the ability to delete an application to a delegated developer.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **My Company Applications**.
2. Open an application for which you want to assign delegated developer permissions.
3. As a System Admin, select **File** > **Manager Developers**.
4. Choose a developer to apply delegated developer permissions.
5. Toggle on **Delete Application**, and then select **Save**.



6. The delegated developer can now delete the application.

Using Delegated Development

Use Delegated Development to develop or deploy applications on the ServiceNow AI Platform.

Overview of Delegated Development

- Delegate development and deployment permissions to personnel

  A system administrator can assign a non-administrator user or group as a developer or deployment resource for a specific application.

- Developer and deployment permissions

  Using Manage Developers, administrators can assign one or more developer and deployment permissions to a group or user for a specific application.

- Remove a developer

  Removing a user as a developer prevents the user from developing, changing, or deploying the application in the current instance.

Delegate development and deployment permissions to personnel

A system administrator can assign a non-administrator user or group as a developer or deployment resource for a specific application. You can set permissions that designate what specific actions the assigned user can perform in the current instance, or make the user a Delegated Admin to grant access to all permissions at once.

Before you begin

- Role required: admin or application administrator

  If Application administration is enabled, only an application administrator of the target application can delegate developers to an application. If application administration is not enabled, an admin user can delegate developers.

- Records required:
  - Application
  - User
  - Group

Procedure

1. Navigate to **All** > **System Applications** > **My Company Applications**.
2. Select the name of the application to which you want to add developers.
   The system opens the application record.
3. Select **Manage Developers**.

   Note:
   If the App Collaboration Component is installed, the link appears as **Manage Collaborators**.

   The system displays the Developer Permissions window.

   Note:
   Developer permissions are available only for scoped apps, not global apps.

4. Select the type of developer (or user without system admin roles) you want to assign.
5. In **Developer Name** or **Group Name**, enter the name of the user or group you want to grant developer or deployment permissions.
6. Select specific developer and deployment permissions for the application, or select **Delegated Admin** to quickly grant access to all permissions for the application.
   For details, see Developer and deployment permissions.
7. Select **Save**.
   The system assigns the designated developer and deployment permissions for the application.

Developer and deployment permissions

Using Manage Developers, administrators can assign one or more developer and deployment permissions to a group or user for a specific application. These permissions designate the specific actions the assigned user can perform for the application.

For example, you might grant permissions that enable a user to upgrade the application, publish to the application repository and ServiceNow Store, but prevent publishing to an update set.

Developer permissions

Note:
If the App Collaboration Component is installed, the link appears as **Manage Collaborators**.

Permission	Description
Delete Application	Grants the assigned developer within a scoped app rights to delete the application.
Source Control	Grants the assigned developer full access to source control.
All File Types	Grants the assigned developer access to all application file types, including some not granted by the other options. This permission is equivalent to granting the user the admin role but with some limitations. Specifically, it provides access to all file types that are configured in your application per the Manage Developers task in the Application Creator. For an example of such file types, see the permissions example in Delegated development and deployment.
Playbooks	Grants the assigned developer access to the Playbooks design environment to create processes. Editing activity subflows or actions requires the **Flow Designer** permission.
Integrations	Grants the assigned developer access to web service APIs, REST APIs, data sources, and Integration Hub - Import.
Reporting	Grants the assigned developer access to reports and scheduled reports.
Notifications	Grants the assigned developer access to work with automatic email notifications.
Decision Tables	Grants the assigned developer access to Decision Tables to create decision logic based on multiple if-then rules.
Mobile Builders	Grants the assigned developer access to mobile builders, such as Mobile App Builder.
UI Builder	Grants the assigned developer access to UI Builder to create pages for experiences.
Workflow	Grants the assigned developer access to the Workflow Editor and Activity Creator.
Service Catalog	Grants the assigned developer access to catalog-related file types such as catalog items, record producers, and variables.
Service Portal	Grants the assigned developer access to Service Portal editors and tools.
Workflow Studio	Grants the assigned developer access to the Workflow Studio design environment to create flows and actions. Script action steps require the **Allow Scripting** permission.
Tables & Forms	Grants the assigned developer access to model and layout related file types such as table columns, form layout, and list layout.
Manage ACLs & Roles	Grants the assigned developer access to security-related file types such as access controls and user roles.
Allow Scripting	Grants the assigned developer write access to script fields such as those in business rules, client scripts, and Workflow Studio script action steps.
Manage Collaborators	Grants the assigned developer the ability to invite and manage users and groups. This permission allows the delegated developer to further invite and manage other developers to the application.

Permission	Description
Invite Collaborators	Grants the assigned developer the ability to invite users and groups. This permission allows the delegated developer to further invite other developers to the application.
Delegated Admin	Grants access to all Delegated Development permissions so that permissions do not need to be granted individually.

Deployment permissions

The update set deployment permissions are hidden by default and require a system administrator to enable them with system properties. See Display or hide update set deployment permissions for more information.

The Submit for Deployment, Manage Collaborators, and Invite Collaborators delegated development permission sets are only available with the Developer Collaborator feature. They will not be shown in Manage Developers.

Permission	Description
Upgrade App	Grants a user with an assigned delegated developer role permission to upgrade the associated application after it has been installed in the current instance.
Publish To Update Set	Grants a user with an assigned delegated developer role permission to publish the associated application to an update set in the current instance. **Note:** Users with this permission cannot also have the **Manage Update Set** permission.
Publish To App Store	Grants a user with an assigned delegated developer role permission to publish associated application to the ServiceNow Store in the current instance. **Note:** The **Upgrade App**, **Publish To App Repo**, and **Publish To App Store** permissions display by default. The **Publish To Update Set** permission only displays if manually enabled by a system administrator. For more details, see Display or hide update set deployment permissions.
Manage Update Set	Grants a user with an assigned delegated developer role permission to manage local and retrieved update sets. This permission allows users to create, update, and delete local update sets as well as preview, resolve conflicts, and commit retrieved update sets. **Note:** Users with this permission cannot also have the **Publish To Update Set** permission.
Publish To App Repo	Grants a user with an assigned delegated developer role permission to publish the associated application to the application repository in the current instance.
Submit for Deployment	Grants a user with assigned delegated developer role permission to submit the associated application for review and deployment.

Remove a developer

Removing a user as a developer prevents the user from developing, changing, or deploying the application in the current instance.

Before you begin

Role required: admin or application administrator

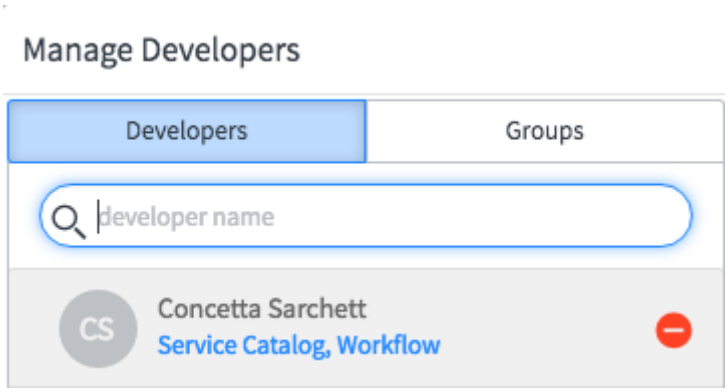
If Application administration is enabled, only an application administrator of the target application can delegate developers to an application. If application administration is not enabled, an admin user can delegate developers.

Procedure

1. Navigate to **All** > **System Applications** > **Applications**.
2. Select the application name of the application from which you are removing developers.
   The system opens the application record.
3. Select **Manage Developers**.

   Note:
   If the App Collaboration Component is installed, the link appears as **Manage Collaborators**.

   The system displays the Developer Permissions window.
4. Point to the developer you want to remove.
   The system displays a minus icon next to the developer name.



5. Select the minus icon next to the developer name.
   The system removes the developer and any associated application roles.

Team Development

Team Development supports parallel development on multiple, non-production ServiceNow instances.

Team Development provides the following features:

- Branching operations, including pushing and pulling record versions between instances.
- The ability to compare a development instance to other development instances.
- A central dashboard for all Team Development activities.

Team Development overview

Team Development allows developers to work on separate development instances while sharing code and resolving collisions throughout the development process.

After setting up the instance hierarchy, you can develop changes on your local development instance. Use the team dashboard to manage Team Development activities, such as:

- Tracking local changes and determining which changes to promote to the parent development instance.
- Pulling changes from the parent instance and resolving any collisions with local changes.
- Comparing your instance with other development instances and resolving any collisions with other development projects.
- Pushing changes when a feature is tested and ready to promote to the parent development instance.

Developers with admin access to their development instance and the parent instance can use team development. For alternative access settings, see Granting access rights to developers.

Related topics

Set up an instance hierarchy

When to use Team Development

Team Development allows multiple developers to work on applications.

Deployment option	Good for	Future considerations
Update Sets	Storing changes to a base system or installed application. Storing and applying a particular version of an application. Producing a file for export.	You can manually create update sets to store a particular application version. Use update sets to deploy patches or changes to installed applications. **Note:** Don't use update sets to install applications. Instead, use the application repository or the ServiceNow Store to install applications.
Application Repository	Installing and updating applications on all company instances. Automatically managing application update sets. Restricting access to applications to the same company. Deploying completed applications to end users.	Consider uploading an application to the ServiceNow Store to share it with other users. Allows installation of and update to the latest application version only. Use update sets to store prior application versions. **Note:** If used with team development, publish applications only from a parent instance.

Local changes

The Local Changes table tracks which customized records have current versions that exist on the development instance but not on the parent instance.

Use local changes to collect changes in preparation for a push.

You queue local changes that are ready to push. Each development instance maintains a single queue, regardless of who develops or queues the changes. You ignore local changes that you do not want to push. For example, you may want to ignore changes to the color scheme that visually distinguish a development instance from the production instance. You can remove a change from the queue or stop ignoring a change.

Changing the parent instance or reconciling recreates the list of local changes that have not been queued or ignored. If you had previously queued or ignored a local change, that designation is maintained.

Local change lists

On the team dashboard, the *Local Changes* list shows the local changes that have not been queued for the next push or ignored for all pushes.

The *Ready to Push* list shows the changes that are queued, and the *Ignored* list shows the changes that are ignored. Use any of these methods to navigate a list of local changes.

local changes list

Action	Option
Click the reference icon beside the row	To open the local change record itself.
Click the link in the first column	To open the customized record.
Right-click the row and select **Show Changes Since Last Pull**. An error message appears if a previous version does not exist (for example, in the case of a newly created record). If a previous version is available, you can revert to that version from the comparison window	To view a comparison between the current local version and the version most recently pulled from or pushed to the parent.
Right-click the row and select **Show Application File**	To open the application file for the customized record.
Right-click the row and select **Show Version**	To open the current version record.

Pull exceptions

Pulling ignores versions when certain conditions occur.

Pull exceptions table

Issue	Description
Matched an exclusion policy	An exclusion policy prevents pulling changes for records matching the policy conditions. The pull identifies the changes but does not include versions for these records.

Pull exceptions table (continued)

Issue	Description
Private properties	A private property is excluded from all Update Sets and pulls.
Collisions	A collision is detected when the pulled version and the current local version both include modifications to the same record. You must resolve all collisions before you can pull.
Previously resolved collisions	When you resolved a collision by accepting either the pulled version or local version of a record, the pull remembers your decision and accepts the version that you indicated as a "previously resolved collision".
Skipped	Pulls skip versions where there is a problem with the version record such as a corrupt or missing version.

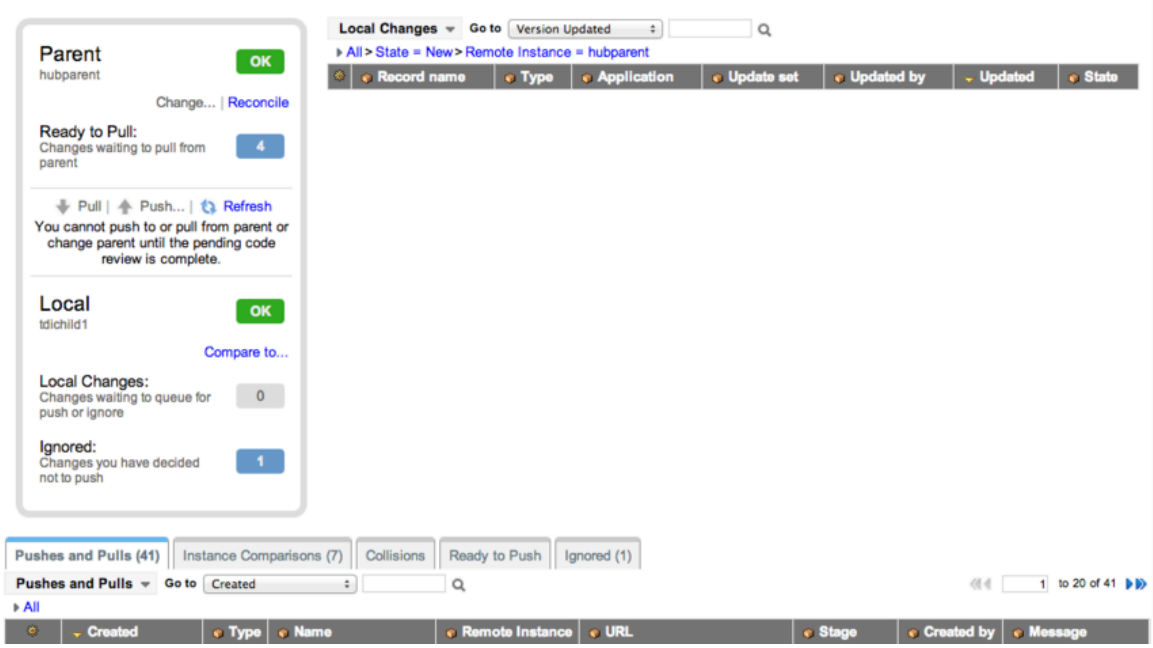
Team dashboard

The team dashboard provides a central place to manage all Team Development activities on your development instance.

You can track local changes, pull and push changes between the local and parent instances, compare the local instance to other development instances, and resolve any collisions. You can also reconcile with the current parent instance or change the parent instance.

To access the dashboard, navigate to **Team Development** > **Team Dashboard**.

Team dashboard



The control panel in the top left provides status indicators and Team Development actions.

- Parent: indicates the status of the connection to the parent instance. If a problem or warning is detected, point to the indicator to view the error messages, or click the indicator to open the remote instance record.
- **Change**: changes the parent instance. See Changing the Parent Instance.
- **Reconcile**: compares the development instance to the parent instance. See Reconciling.

- Ready to Pull: indicates the number of changes on the parent that have not been pulled to the local instance.
- **Pull**: initiates a pull. See Pulling Versions.
- **Push**: opens a page that allows you to review the changes before a push. See Pushing Versions.
- **Refresh**: updates the status indicators on the control panel. The dashboard updates only when you reload or refresh the page.
- Local: indicates the status of the most recent comparison with another instance. If collisions are detected, click the indicator to open the list and resolve the collisions. See Resolve a collision in Team Development.
- Collisions: appears only if any local changes collide with versions pulled from the parent and indicates the number of collisions. Click the indicator to open the list and resolve the collisions. See Resolve a collision in Team Development.
- **Compare to**: allows you to select another development instance to compare with the local instance. See Comparing to Peer Instances.
- Ready to Push: indicates the number of local changes that are queued for the next push. See Queuing and Ignoring Local Changes.
- Local changes: indicates the number of local changes that have not been queued or ignored. Click the indicator to open a list of these changes.
- Ignored: appears only if any local changes are ignored and indicates the number of ignored changes. Click the indicator to open a list of these changes.

The team dashboard includes lists for tracking local changes and viewing the history of Team Development activities.

- Local changes: lists the local changes that have not been queued or ignored.
- Pushes and Pulls: provides a history of pushes and pulls. Expand a row to see the customized records for which versions were transferred as part of the push or pull.
- Instance Comparisons: provides a history of comparisons with other development instances.
- Collisions: lists the collisions that must be resolved before the next pull or push. You can right-click a row and select **Resolve Collision**. See Resolving Collisions.
- Ready to Push: lists the local changes that have been queued for the next push.
- Ignored: lists the local changes that are ignored for all pushes.

Resolve multiple collisions

Local changes

Local change lists

Queue a local change for a push

Ignore a local change

Back out a local change

Approve or reject a push

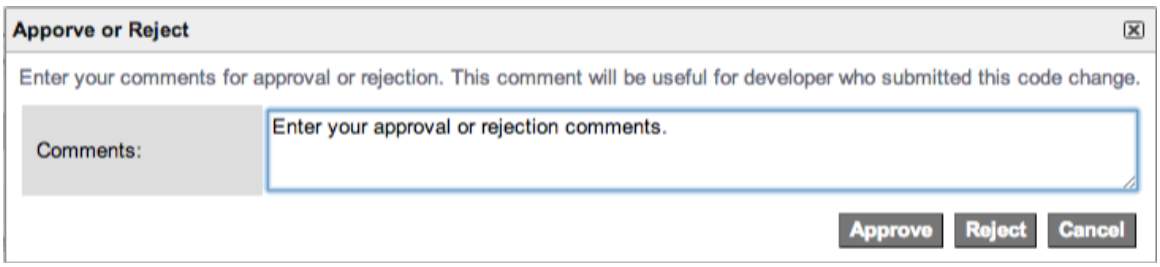
Code reviewers must approve or reject a push from the Team Development application.

About this task

Although reviewers can see the individual versions within a push, they must approve or reject the push as a whole.

Procedure

1. Log in to the parent instance that requires code review.
2. Navigate to **Team Development** > **Code Review Requests**.
3. Select a change in the *Awaiting Code Review* stage.
4. Review the changes in the *Push or Pull Versions* related list.
5. Click **Approve or Reject**.
6. **Optional:** Enter review comments in *Comments*.
   These comments are visible to anyone who can see the Pushes and Pulls history.
7. Click either **Approve** or **Reject**, as appropriate.



Note:
The *URL* and *Remote Instance* fields list the address and name of the instance where the change originated.

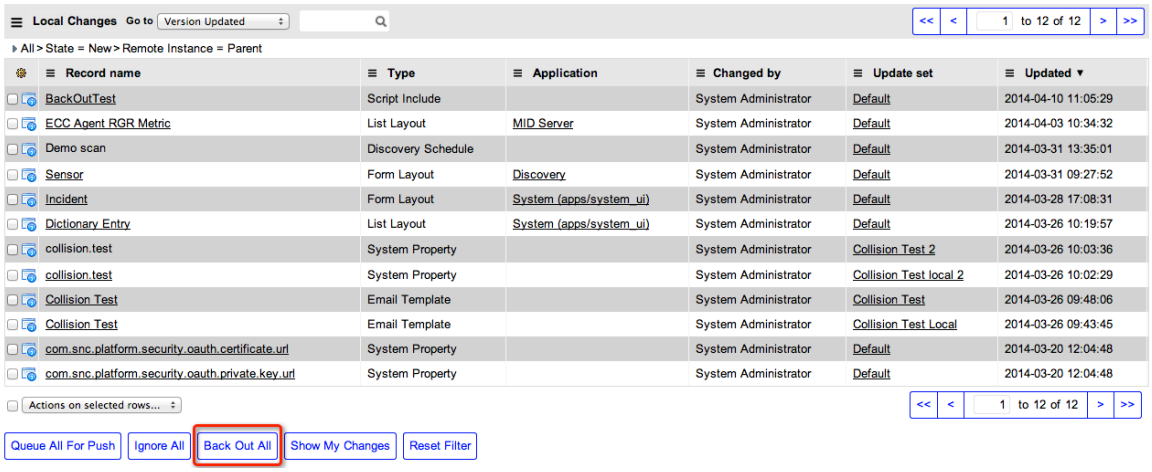
Back out a local change

Back out all local changes and restore the last version reconciled with the parent instance.

Procedure

1. Define a parent instance.
2. Pull changes from the parent instance.
3. Navigate to **Team Development** > **Team Dashboard**.
4. Filter the *Local Changes* list to show only the changes that you want to back out.
5. Do one of the following actions:

- Click **Back Out All**.
- Right-click the local change you want to back out, and then click **Back Out**.



Cancel a code review request

Developers can cancel any push they submitted that is in the *Awaiting Code Review* stage.

About this task

Canceling a request sets the push to the **Code Review Request Cancelled** stage on the submitting instance. The submitting instance retains a version history of the push but the parent instance does not.

Procedure

1. Log in to the instance that pushed the changes.
2. Navigate to **Team Development** > **Pushes and Pulls**.
3. Filter for the push you want to cancel.

> **Note:**
> You cannot cancel a push that has been approved or rejected.

4. Select the Push or Pull record.
5. Click **Cancel Code Review**.

Change the parent instance

If it becomes necessary to modify the instance hierarchy, you can change the parent for a development instance.

About this task

Changing the parent initiates a complete comparison between the development instance and the new parent instance. To optimize comparison speed and reduce the number of collisions and local changes that need review afterwards, ensure that the new parent instance was cloned recently from an appropriate instance (for example, the production instance). Before you change the parent instance, ensure that the change does not conflict with your change management process or other development efforts.

To change the parent for a development instance:

Procedure

1. On the development instance, navigate to **Team Development** > **Team Dashboard**.
2. In the control panel, click **Change**.
3. Select the remote instance you want to use as the parent and click **Select**.

   Alternatively, click the link to define a new remote instance. Then, repeat steps 1–3 and select the remote instance you defined.

   The system initiates a reconcile, which compares the local instance to the parent, and then generates the list of local changes and calculates the number of changes that are ready to pull from the parent.

4. On the completion page, click **Team Dashboard**.
5. Pull versions from the parent instance and resolve any collisions.
6. Review the local changes list and queue or ignore changes, as appropriate.

Check the review status of a pushed change

If the parent instance requires pushed changes to undergo code review, changes are placed in the *Awaiting Code Review* stage.

About this task

If you configure the parent instance to send notifications, it sends the submitting developer a notification when the pushed changes are approved or rejected. Developers can also manually check the status of their pushed changes from the *Pushes and Pulls* module on the submitting instance.

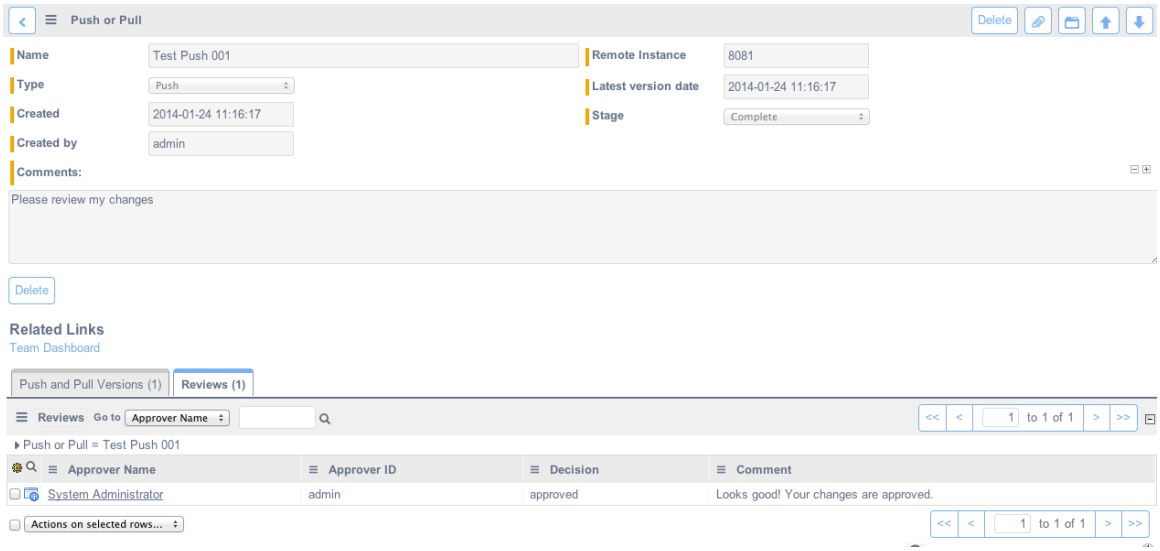
Procedure

1. Log in to the instance that submitted code for review.
2. Navigate to **Team Development** > **Pushes and Pulls**.
3. Filter for the push you want to review.

   - Pushes in the *Complete* stage are approved and applied to the parent instance.
   - Pushes in the *Collided* stage are rejected because of a collision.
   - Pushes in the *Awaiting Code Review* stage are awaiting review.
   - Pushes in the *Code Changes Rejected* stage are rejected by a reviewer.
   - Pushes in the *Code Review Request Canceled* stage are canceled by the submitting developer.

4. Click the **Reviews** related list to see the following information.

- Who submitted a review decision.
- What the decision was: either approved or rejected
- What comments if any the reviewer provided.



Compare a pushed version to a local version

Code reviewers can compare the pushed versions to the local versions to see the potential effect of incoming changes.

Procedure

1. Log in to the instance requiring code review.
2. Navigate to **Team Development** > **Code Review Requests**.
3. Select a change in the *Awaiting Code Review* stage.
4. Review the changes in the *Push or Pull Versions* related list.
5. Right-click a row in the list and click **Compare to Current**.
   A comparison of the differences between the pushed and local versions appears.

Related topics

Revert a change

View customizations and compare with current version

Compare to peer instances

You can compare the local instance to any other remote instance and commit any current versions from the remote instance on your development instance.

About this task

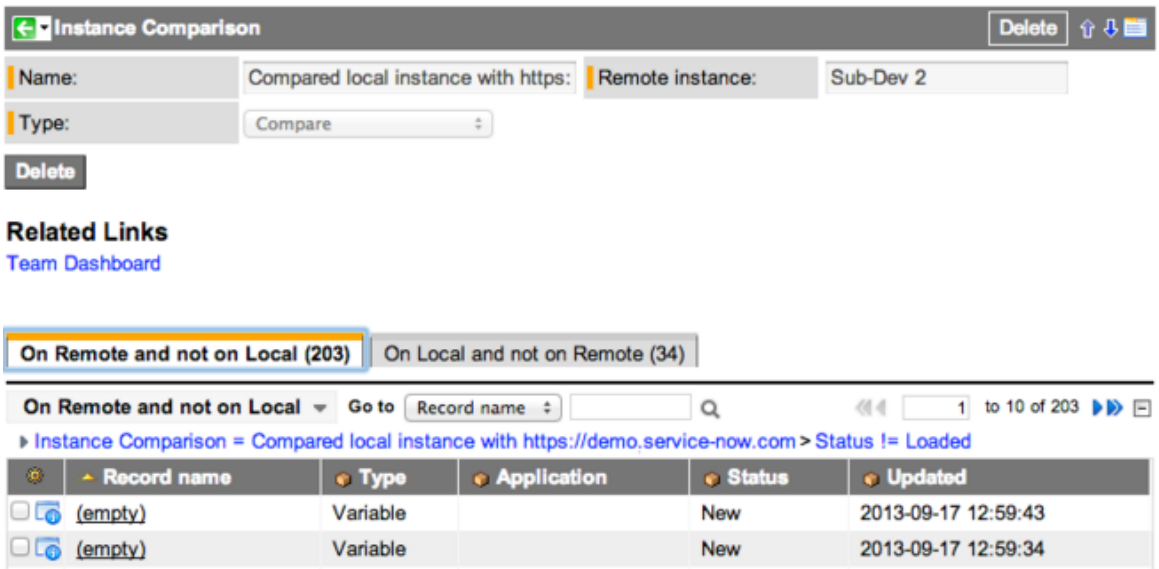
Comparing allows you to share code between instances without pushing to a common parent.

Comparing instances does not automatically commit any versions on the local instance. It initiates a full comparison of all changes on the remote instance and all changes on the local instance, and then reports which customized records have different current versions. You can selectively commit a version from the remote instance or compare it with the version on your local instance. You can delete the instance comparison record when you finish evaluating the differences.

To compare the local instance to a peer instance:

Procedure

1. Ensure that the peer instance is defined as a remote instance.
2. Navigate to **Team Development** > **Team Dashboard**.
3. In the control panel, click **Compare to**.
4. Select the peer instance you want to compare to the local instance and click **Compare**.
5. On the completion page, click **Show Results**.
   The instance comparison record opens.



6. Review the *On Remote and not Local* related list, which shows the customized records where the current version on the peer instance is not on the local instance.

   For each customized record, you can:

   - Compare the current remote version to the current local version by right-clicking a row and selecting **Compare to Current**.
   - Load the current remote version as the current local version by right-clicking a row and selecting **Load This Change**.

Ignore a local change

Ignoring a local change prevents updates to a record from generating new versions in the Local Changes list.

About this task

An ignored local change always points to the current version for the record. You cannot push ignored records to another instance.

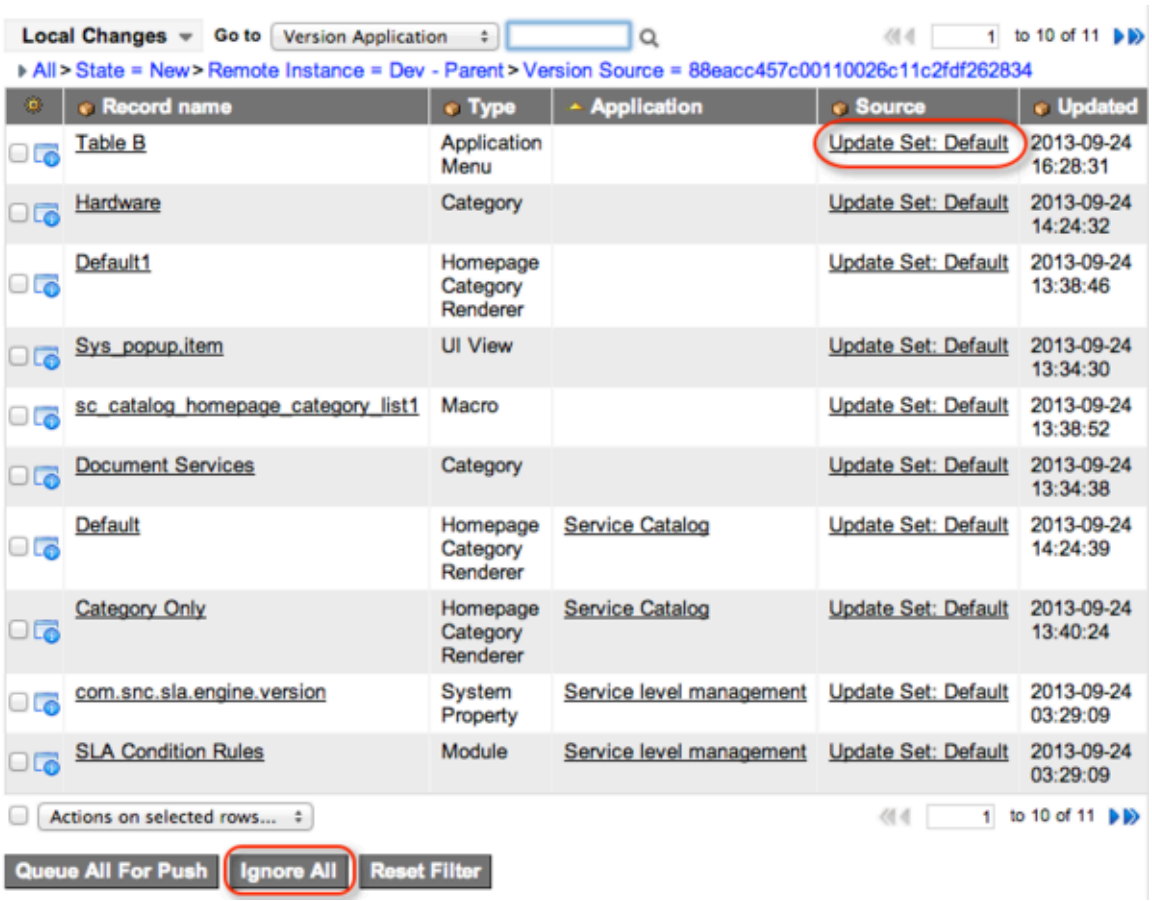
Local change action list

Action	Result
Ignore a record that has a version queued for push	The queued change is deleted
Ignore a record that has a version queued for code review	The queued change is deleted
Pull changes for an ignored record	Collision
Resolve a collision by taking the parent version	There is no longer a local change to ignore
Resolve a collision by keeping the local version	The ignored change remains on the local instance

Procedure

1. Navigate to **All** > **Team Development** > **Team Dashboard**.
2. Filter the *Local Changes* list to show only the changes that you want to ignore.

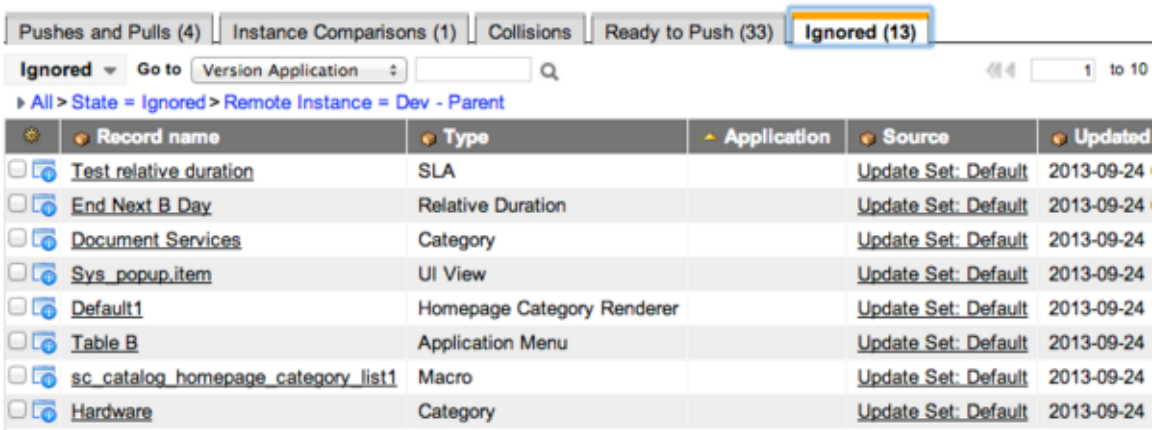
   For example, filter the list to show all changes in the *Default* Update Set.



3. Click **Ignore All**.

4. Review the *Ignored* list to ensure that the correct changes are ignored.
   This step is a recommended best practice.

Option	Description
To stop ignoring changes	Select the check boxes beside the rows and select **Do Not Ignore** from the *Actions* choice list.
To stop ignoring changes and add them to the queue instead	Select the check boxes beside the rows and select **Queue for Push** from the *Actions* choice list.



Pull a version

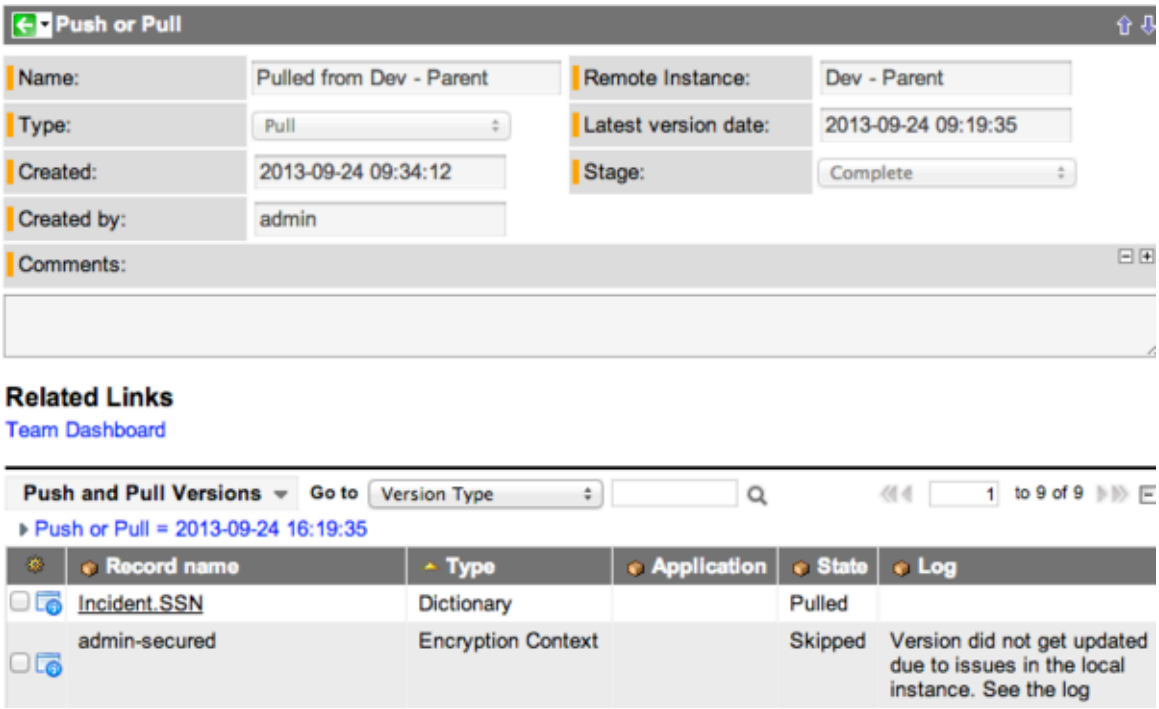
Pulling retrieves versions of customized records from the parent instance and adds them on the development instance. Pulling does not retrieve any versions for changes made by system upgrades, but it retrieves all versions for changes made by users, not just the current version.

About this task

Pulling retrieves all versions for changes made by users that have not already be pulled onto the development instance, and you cannot choose which versions to pull. The first time you pull from a parent instance, the pull retrieves all versions for changes made by users. Subsequent pulls retrieve the new versions since your last pull. Each pull is recorded in the Push or Pull `[sys_sync_history]` table on the development instance. Historical versions are saved with a state of *History*.

Procedure

1. Navigate to **All** > **Team Development** > **Team Dashboard**.
2. In the control panel, click **Pull**.
3. On the completion page, click **Show Results**.
   The *Push and Pull Versions* related list for the Push or Pull form shows the customized records for which versions were retrieved and indicates if any pull exceptions exist.



4. Resolve any collisions.

Push a version

Pushing promotes changes from the development instance to the parent instance and commits the current version of a customized record on the development instance as the current version on the parent instance.

About this task

Pushing adds only the current development version to the parent, not all the development versions.

Note:
Updates to records from different applications cannot be pushed/pulled in the same push/pull. To resolve the error in the case that updates to other applications are mixed in: De-queue the updates to other applications. Push for one application. Re-queue the updates to one application. Push and then repeat as needed.

Pushing creates a local Update Set on the parent that is marked as complete. Pushed changes are also tracked as local changes on the parent. Therefore, you can promote changes through your development and test hierarchy by transferring the Update Set or by pushing the local changes. Each push is recorded in the Push or Pull table on the development instance.

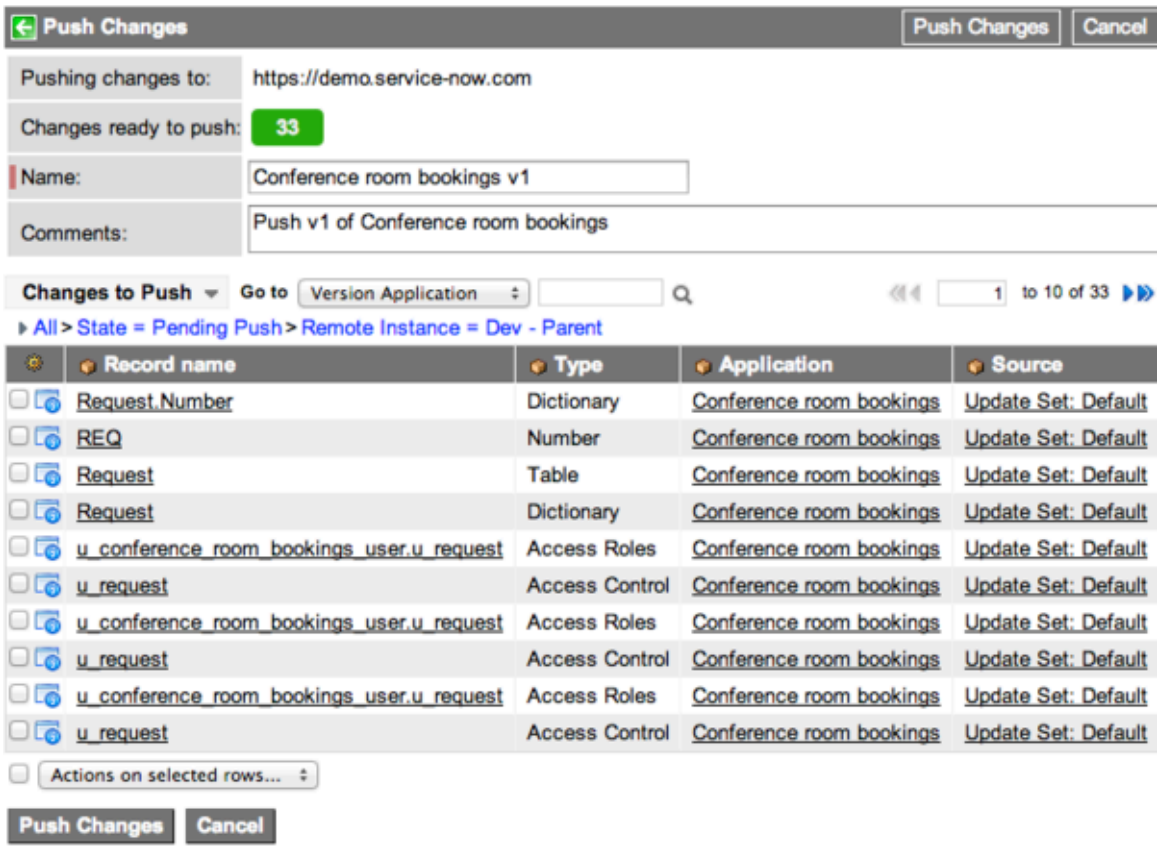
Procedure

1. Navigate to **All** > **Team Development** > **Team Dashboard**.
2. Queue the local changes that are ready to push.
3. Pull versions from the parent instance and resolve any collisions.

   You cannot push changes to the parent instance if collisions are detected.
4. In the control panel, click **Push**.
   The Push Changes page opens.

5. Provide a *Name* for the changes.
6. Review the list of changes to ensure that the correct changes are included.

Option	Description
To remove changes that you do not want to push	Select the check boxes beside the rows and select **Do Not Push** from the *Actions* choice list
To add changes	Click **Cancel** and repeat the procedure from step 2



7. **Optional:** Edit the name.
   The name identifies the push record on the development instance and the local Update Set record on the parent instance.
8. **Optional:** Enter comments.
   The comments are added to the push record on the development instance and the local Update Set record on the parent instance.
9. Click **Push Changes**.

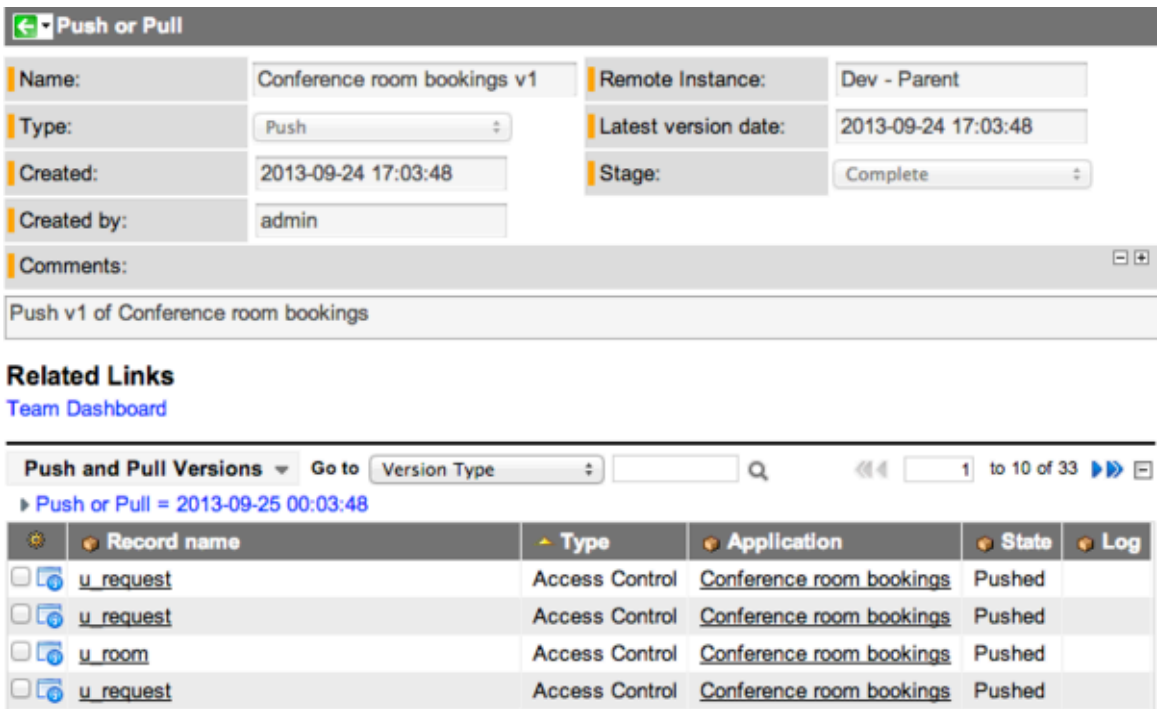
   The system initiates a pull to ensure that there are no collisions before the push proceeds.

   - If collisions are detected, the push is automatically canceled and you must repeat the procedure from step 3.
   - If no collisions are detected, the changes are staged on the parent instance. On the parent, each version is validated and then committed in the correct order to maintain dependencies between records. For example, a new table is committed before a field on that table to ensure the field is properly created.

Note:
You cannot push if there is a version conflict between instances or the pushing instance has changes in the *Awaiting Code Review* stage.

10. On the completion page, click **Show Results**.
11. Review the push record for any errors or skipped changes.
    - Changes with a state of *Pushed* were committed on the parent instance.
    - Changes with a state of *Skipped* were not committed on the parent instance and remain queued as local changes on the development instance.
12. For each skipped change, review the log message to determine why the change was skipped.

    Develop any changes that are necessary to commit the desired version on the parent instance, and then push them. Some examples of why a change may be skipped include:
    - A table does not exist on the parent because it was created when you activated a plugin on the development instance. Ensure the plugin is activated on the parent and push the change again.
    - An error occurred during the push. Try to push again.
    - The current version is invalid. Revert to a previous version and make the change again to ensure the version is valid
    - An error occurred on the parent during the push. The *Log* field on the push record contains the exception message. Review the system logs on the parent instance and troubleshoot any problems with the instance.



Back out a push

Application developers can back out a push to remove unwanted changes.

Procedure

1. Navigate to **Team Development > Pushes and Pulls**.
2. Select the push to back out.
3. Click **Back Out**.
4. Click **OK** when the confirmation message appears.

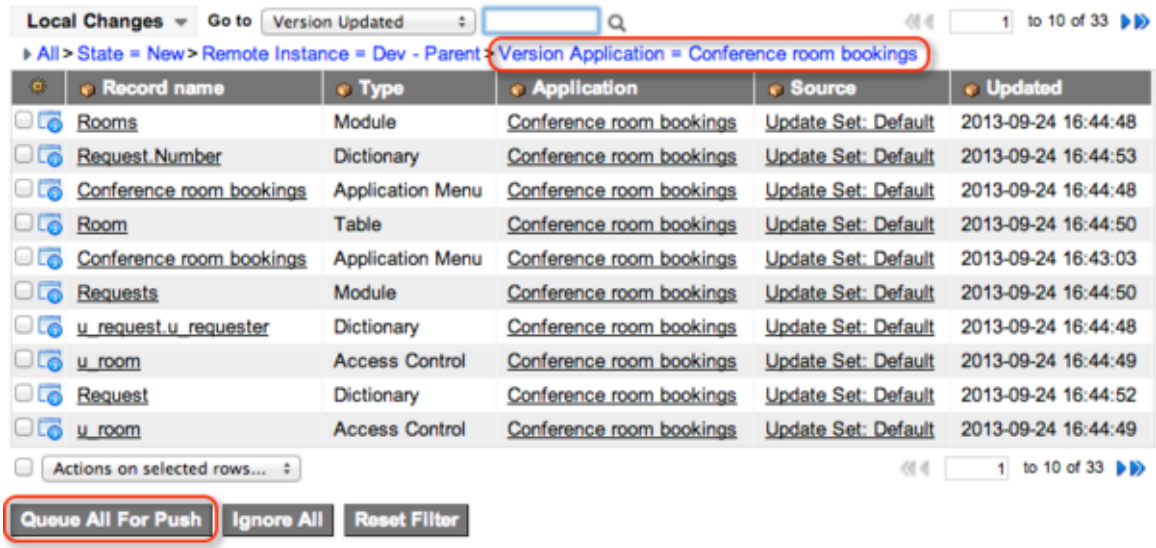
Queue a local change for a push

Application developers can queue a local change for a push to ensure the changes are available to other developers.

Procedure

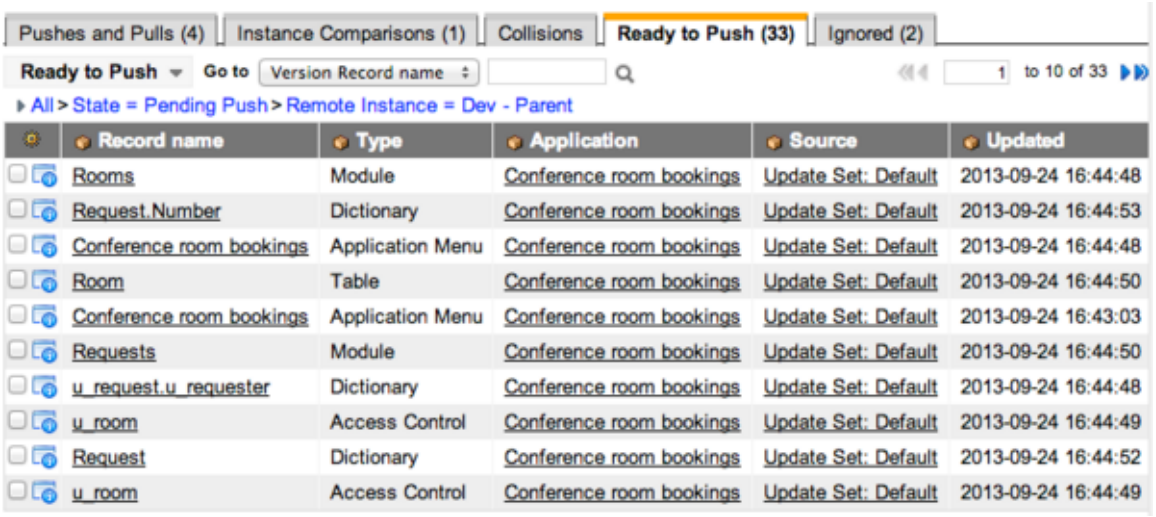
1. Navigate to **All** > **Team Development** > **Team Dashboard**.
2. Filter the *Local Changes* list to show only the changes that are ready to push.

   For example, filter the list to show only the changes associated with a particular application.



3. Click **Queue All For Push**.
4. Review the *Ready to Push* list to ensure that the correct changes are in the queue.
   This step is a recommended best practice.

Option	Description
To remove changes from the queue	Select the check boxes beside the rows and select **Do Not Push** from the *Actions* choice list.
To remove changes from the queue and choose to ignore them instead	Select the check boxes beside the rows and select **Ignore This Change** from the *Actions* choice list.



Record name	Type	Application	Source	Updated
Rooms	Module	Conference room bookings	Update Set: Default	2013-09-24 16:44:48
Request.Number	Dictionary	Conference room bookings	Update Set: Default	2013-09-24 16:44:53
Conference room bookings	Application Menu	Conference room bookings	Update Set: Default	2013-09-24 16:44:48

u_room	Access Control	Conference room bookings	Update Set: Default	2013-09-24 16:44:49

Note:
For the *Local Changes* list, click **Reset Filter** to remove any filter conditions you added and see all the local changes that have not been queued or ignored.

Reconcile changes

Reconciling first compares the local instance to the parent, and then generates the list of local changes and calculates the number of changes that are ready to pull from the parent.

About this task

A reconcile occurs automatically whenever you select a parent instance. You may need to manually reconcile after an external disruptive event on the parent instance, such as a clone or failover.

Note:
This process may take a while to complete depending on the size and age of the instance.

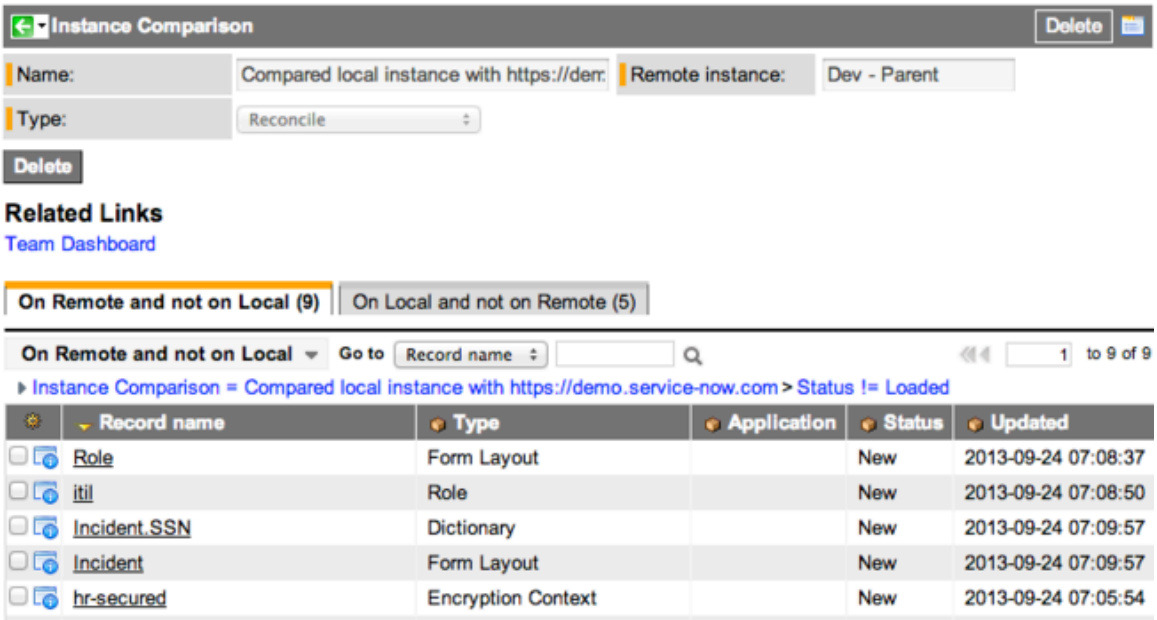
Procedure

1. Navigate to **All** > **Team Development** > **Team Dashboard**.
2. In the control panel, click **Reconcile**.
3. In the confirmation dialog box, click **OK**.

   The list of local changes that have not been queued or ignored is recreated. If you had previously queued or ignored a local change, that designation is maintained.
4. **Optional:** On the completion page, click **Show Results**.

   Review the instance comparison record.

   - The *On Remote and not Local* related list shows the versions that are ready to pull from the parent.
   - The *On Local and not on Remote* related list shows the local versions that are ready to queue or ignore.



5. Click **Team Dashboard**.
6. Pull versions from the parent instance and then resolve any collisions.
7. Review the local changes list and queue or ignore changes, as appropriate.

Resolve a collision in Team Development

A collision is detected when the pulled version and the current local version are modifications of a different version, indicating that someone else has modified the same record that you have modified. The team dashboard displays the number of collisions between the local and the parent instance.

About this task

To ensure that your changes do not conflict with other development efforts, you should resolve collisions as soon as they are identified. You must resolve all collisions before you can pull or push.

Procedure

1. Navigate to **All** > **Team Development** > **Team Dashboard**.
2. In the control panel, click **Collisions** or click the count of collisions.
   A list of collisions opens.
3. Right-click a row and select **Resolve Collision**.
   Alternatively, open the record and click the **Resolve Collision** related link.
   The Resolve Collision page displays a comparison between the version that was pulled from the parent and your local record. The page highlights the differences.
4. Review the differences and perform an action.
   The system performs that action and also clears the collision for future push/pulls.
5. Repeat the process for every remaining collision.

Result

The system saves the merged changes and resolves the collision.

Limitations on updating records

There are some types of records that you cannot merge while resolving differences on the Compare to Current and Resolve Collision pages.

Record types that allow a choice only between reverting or accepting the pulled or current record

The following record types do not allow you to merge individual values. Instead, differences involving the following record types display a read-only comparison and allow a choice between updating and reverting:

- sys_choice [Choice]
- sys_choice_set [Choice Set]
- sys_ui_form [Form]
- sys_ui_list [List]
- sys_ui_related_list [Related List]
- sys_ui_section [Form Section]
- wf_workflow [Workflow]
- wf_workflow_version [Workflow Version]

Team Development, Resolve Collision page: **Use Pulled Version** and **Use Local Version** options.

Upgrade History, Compare to Current page: Comparing non-current update versions to current update version. Allows only **Revert to Base System** option.

Field types that do not support merging

The following field types do not support individual merging between versions or updates:

- auto_increment [Auto Increment]
- auto_number [Auto Number]
- breakdown_element [Breakdown Element]
- catalog_preview [Catalog Preview]
- collection [Collection]
- color_display [Color Display]
- composite_field [Composite Field]
- compressed [Compressed]
- counter [Counter]
- currency [Counter]

- data_array [Data Array]
- data_object [Data Object]
- data_structure [Data Structure]
- date [Other Date]
- datetime [Basic Date/Time]
- days_of_week [Days of Week]
- document_id [Document ID]
- due_date [Due Date]
- Email [Email]
- external_names [External Names]
- field_list [Field List]
- float [Floating Point Number]
- glide_action_list [UI Action List]
- glide_precise_time [Precise Time]
- glide_var [Glide Var]
- image [Basic Image]
- index_name [Index Name]
- int [Integer String]
- integer_time [Integer Time]
- ip_address [IP Address]

Resolve a collision in Team Development

Resolve multiple collisions

You can resolve multiple collisions without reviewing the differences between the local and pulled versions.

Procedure

1. Navigate to **All** > **Team Development** > **Team Dashboard**.
2. In the control panel, click the number of collisions.
   A list of collisions opens.
3. Select the check boxes beside the rows you want to resolve.
4. In the *Actions* choice list, use one of the following methods to resolve the collision.

Option	Description
To load the version pulled from the parent as the current version for all selected collisions	Select **Use Pulled Version**
To maintain the local version (local record) as the current version for all selected collisions. **The pulled versions are added to the version history for the records.**	Select **Use Local Version**

Team Development setup

To enable parallel development on multiple non-production instances, administrators can set up the Team Development instance hierarchy and grant access rights for developers.

Access rights for developers

To use Team Development, application developers must have a set of credentials for each instance in the Team Development hierarchy.

An instance's placement in the team development hierarchy determines the credentials it requires.

Credentials for Team Development access

Desired Access	Credential Requirements
Access to the Team Development application	A user with the admin role on the instance you are accessing
Right to register a remote instance	One of following: • A user with the admin role on the instance you are registering • A user with the teamdev_user role on the instance you are registering
Right to push changes to the parent instance from a development instance	One of following:

Credentials for Team Development access (continued)

Desired Access	Credential Requirements
	• A user with the admin role on the parent instance • A user with the teamdev_user role on the parent instance
Right to compare to a registered remote instance	One of following: • A user with the admin role on the registered development instance • A user with the teamdev_user role on the registered development instance
Access to the Code Review Requests module	One of following: • A user with the admin role on the parent instance • A user with the teamdev_code_reviewer role on the parent instance

Note:
The teamdev_user role does not grant access to the Team Development application and is not intended for developers to work on local development instances. It is intended to grant developers non-admin access to remote instances such as the parent instance or a peer development instance.

Create an exclusion policy

Application developers can create an exclusion policy to prevent pushes or pulls to particular instances in the team development hierarchy.

Procedure

1. Navigate to **All** > **Team Development** > **Exclusion Policy**.
2. Click **New**.
3. Complete the Exclusion Policy form (see table).
4. Click **Submit**.

Exclusion policy form

Field	Description
Name	Enter a unique description of the policy.
Policy	Select when the policy applies. Options include: ○ Push only ○ Push and Pull ○ Pull only

Field	Description
Remote Instance	[Optional] Select a specific remote instance to ignore changes from during pull operations. Leaving this field blank ignores changes from all remote instances.
Table	Select which table to ignore changes for.
Conditions	Select any additional criteria a change must meet to be ignored other than the table name. This field is only visible when the *Policy* is Push only.

Define a remote instance

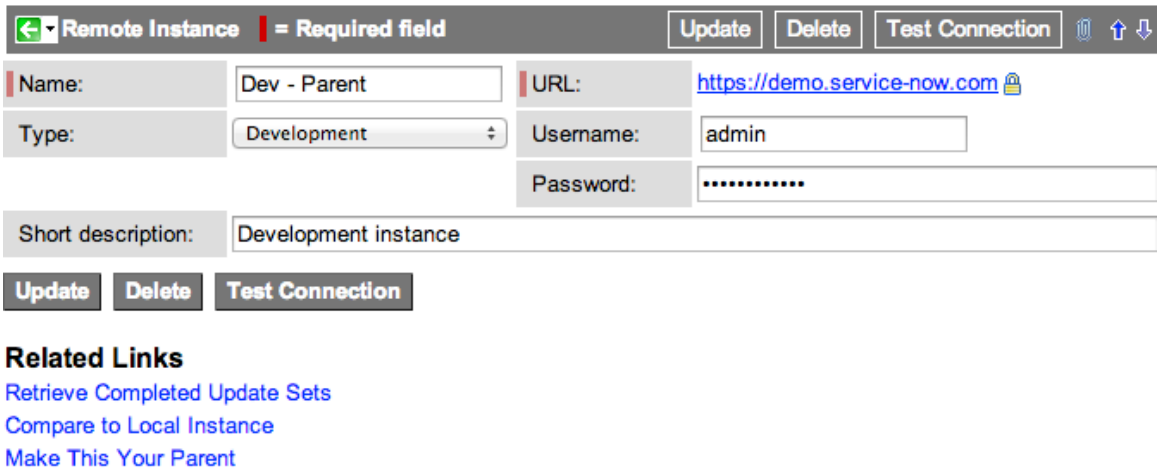
For each instance, define other instances in the hierarchy as remote instances.

About this task

For example, to set up remote instances for Sub-Dev 1:

Procedure

1. If IP address access control is enabled, log in to the remote instance and add Sub-Dev 1 as an exception.
2. On Sub-Dev 1, navigate to **Team Development** > **Remote Instances**.
3. Click **New**.
4. Define the remote instance, such as Dev-Parent, by completing the form (see table).



5. Click **Submit**.
6. Repeat step 1 through step 5 for each instance in the hierarchy that this instance needs to push and pull with (for example, Sub-Dev 2 and Sub-Dev 3).

Remote instance form

Field	Description
Name	Enter a unique name describing the instance.
Type	Specify whether the remote instance is a development, test, or UAT instance.
Active	Specify whether the local instance communicates with the remote instance as a member of Team Development. Team Development operations such as comparing changes between instances or selecting a parent instance are only available for active remote instances.

Field	Description
URL	Specify the URL of the remote instance using the appropriate transfer protocol. Each remote instance record should have a unique URL. Creating duplicate records with the same URL can cause errors.
Username	Enter the user on the remote instance who authorizes Team Development operations on the instance. This user account must have an appropriate role on the remote instance.
Password	Enter the password of the authorizing user.
Short description	[Optional] Enter any other relevant information about the remote instance.

Enable a code review

You can require a code review of all changes pushed to an instance.

Procedure

1. Navigate to **All** > **Team Development** > **Properties**.
2. Select the **Yes** check box for *If this property is set to Yes, code review is required before pushing to this instance* (com.snc.teamdev.requires_codereview).
3. Click **Save**.

   Setting this property adds the Code Review Requests module to the application menu and requires all changes pushed to this instance to remain in the *Awaiting Code Review* stage until someone in the Team Development Code Reviewers group approves them.

Select the parent instance

An instance can have multiple peer instances but only one parent instance.

About this task

The parent instance is the only instance you can pull changes from and push changes to.

The parent instance must be on the same release family as the local instance. For example, a development instance on the Geneva release family must have a parent instance also on the Geneva release family. If you select a parent from a different release family, the Team Development dashboard displays an error message and prevents you from pulling changes and reconciling. If you select a parent from a different patch release, the dashboard displays a warning message but allows you to pull changes and reconcile.

Do not use Team Development with production or test instances.

- Do not use a test or production instance as the parent instance in Team Development.
- Do not make any instance the parent of a production instance.
- Production instances should never have a parent.

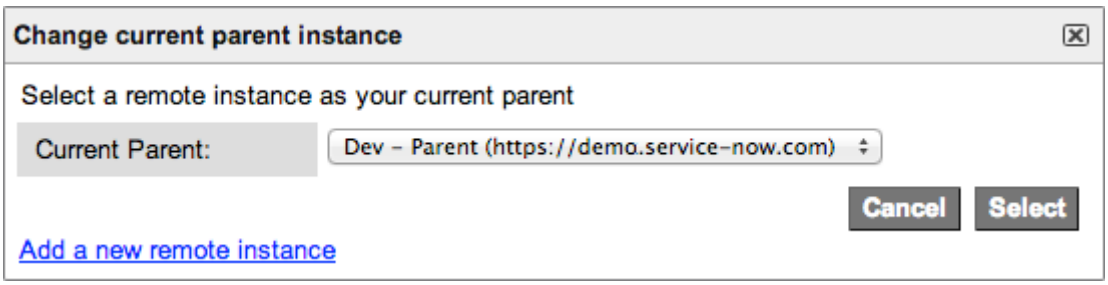
When you back out a change on a Team Development instance, it backs out the change all the way back down the chain, including undoing the work on the source instance. This behavior can cause major problems on test and production instances.

Procedure

1. Navigate to **All** > **Team Development** > **Team Dashboard**.
2. In the control panel, click the appropriate link:

Team dashboard control panel options

Option	Description
Use <instance name and URL>	Selects the most recently defined remote instance as the parent instance.
Select a different instance	Opens a dialog box where you can select another remote instance or define a new remote instance.
Register a new instance or List all remote instances	Opens the remote instance form or list, where you can define a new remote instance. These options are available when no remote instances are defined.



3. If you defined a new remote instance in step 2, repeat step 1 through step 2 and select the remote instance you defined.

   The system initiates a reconcile, which compares the local instance to the parent. It then generates the list of local changes and calculates the number of changes that are ready to pull from the parent. The reconcile also validates the instance versions.

4. Pull all changes from the parent instance if both instances are in the same release family.

Note:
The parent instance is saved in the `glide.apps.hub.current` system property.

Set up an instance hierarchy

Set up an instance hierarchy that best supports your development life cycle.

About this task

This example demonstrates how to set up an instance hierarchy where several peer sub-development instances have the same parent development instance, but a more complex configuration may be required to handle multiple project teams or other customer requirements.

Do not use Team Development with production or test instances.

- Do not use a test or production instance as the parent instance in Team Development.
- Do not make any instance the parent of a production instance.
- Production instances should never have a parent.

When you back out a change on a Team Development instance, it backs out the change all the way back down the chain, including undoing the work on the source instance. This behavior can cause major problems on test and production instances.

Procedure

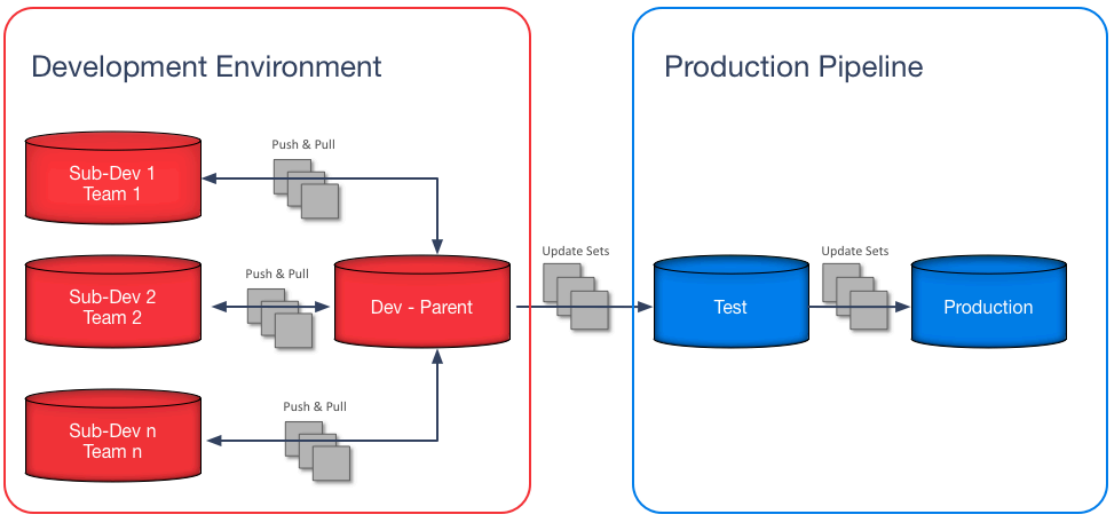
1. Provision a parent development instance on the same software version, such as Dublin, as the target instance, such as production.
2. Clone the production instance to the parent development instance.
   This step is a recommended best practice.
3. Provision sub-development instances on the same software version as the parent development instance.
4. **Optional:** Log in to the parent development instance and clone it to the sub-development instances.
5. On each sub-development instance:

   a. Define remote instance connections to other instances in the hierarchy that this instance needs to push and pull with.

   b. Select the parent instance.

   c. Pull all changes from the parent instance.

   d. Grant access rights to appropriate developers.



Code reviews

Team Development administrators can require that pushes undergo code review before accepting pushes.

When code review is enabled, pushing a change to the parent instance triggers the code review workflow. By default, users with the teamdev_code_reviewer role receive notifications to review changes and can approve or reject changes. The Team Development Code Reviewers has the teamdev_code_reviewer role.

For each change, reviewers can see the following information.

- Which remote instance the pushed change comes from.
- Who pushed the change to the parent.
- What the change is called.

- When the change was created.
- Which versions the change includes.

Reviewers must approve or reject a push from the Team Development application.

While changes are being reviewed on the parent instance, a child instance cannot do the following activities involving the parent instance:

- Push changes to the parent instance.
- Pull changes from the parent instance.
- Reconcile changes with the parent instance.
- Change the parent instance to another instance.
- Delete the remote instance record for the parent instance.

Code review notifications

You must enable email notifications on the instance requiring code review for that instance to send code review notifications.

The Team Development Code Review workflow sends notifications to members of the Team Development Code Reviewers group when:

- A push requires code review.
- A user cancels a push.

If the user who pushed the changes has a user record with an email address on the instance where code review was required, the user receives a notification when the approval stage is set to *Complete* (approved) or *Code Changes Rejected*.

The code review notifications contain the following information:

Code review notification table

Notification name	Table	Contents
Code review update for developer	Push or Pull [sys_sync_history]	• The push name • The approval stage of the push (approved or rejected) • A link to the instance where the code review request was made
Notify code reviewer of canceled review	Push or Pull [sys_sync_history]	• The user who canceled review • The push that was canceled

Code review workflow

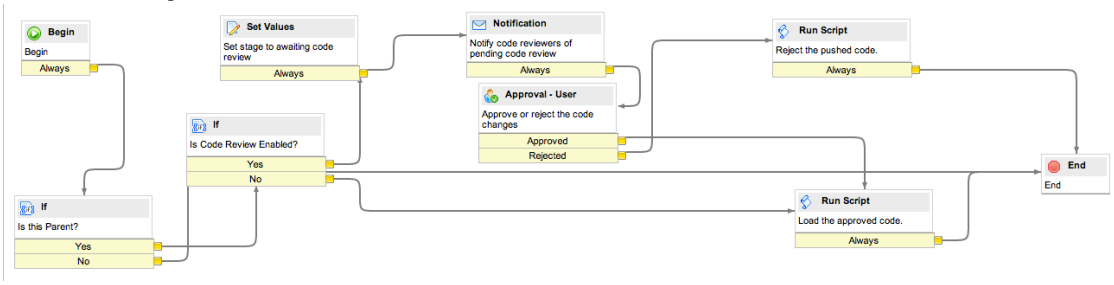
The Team Development Code Review workflow manages how changes are pushed to the parent.

By default this workflow:

- Starts when changes are pushed to the parent instance.
- Verifies that the code review property is active on the parent instance.

- Sets the stage of changes requiring approval to *Awaiting Code Review*.
- Notifies the Team Development Code Reviewers group to review pushed changes, if configured.
- Loads approved changes or sets the stage to *Code Changes Rejected*.

Team Development code review workflow



Warning:
Use caution when modifying this workflow, as the code review feature may not function properly.

Exclusion policies

You can exclude certain files from change tracking by creating an exclusion policy.

When a change matches an exclusion policy, the change does not generate records in the local changes list. The change still generates local version records and Update Set records as normal. See Creating an Exclusion Policy.

Note:
The exclusion policy applies to changes identified during a reconciliation operation. If you create an exclusion policy after a reconciliation, Team Development still tracks the changes until the next reconciliation.

Instance hierarchies

Team Development allows you to set up a distributed version control system between multiple ServiceNow instances where each instance acts as a source repository, or branch.

Developers use separate instances to work on different features, applications, or product releases at the same time. With Team Development, developers can share code between these instances and resolve collisions throughout the development process.

Team Development allows you to establish hierarchical relationships between instances and provides a mechanism for transferring changes between instances that integrates with the Update Set process where necessary. In a Team Development instance hierarchy, each non-production instance has a parent instance. Instances that have the same parent instance are peer instances. The shared parent instance becomes the central hub, or repository, and all peer instances synchronize to it.

Pulls and pushes

Developers synchronize their instances to the parent instance by pulling and pushing versions of customized records and resolving collisions between versions on the parent instance and the development instance.

Developers can compare peer instances to one another and share code or resolve collisions before pushing versions to the parent instance.

Pulling from the parent retrieves versions of records that have customer updates. Pulling retrieves all versions that have not already been pulled onto the development instance, including historical versions, and you cannot choose which versions to pull. You must resolve any collisions before proceeding with further pulls or pushes.

Pushing to the parent adds only the current development version to the parent, not all the development versions. You can choose which changes to push to the parent. Pushing creates a local Update Set on the parent that is marked as complete. Pushed versions are also tracked as local changes on the parent. Therefore, you can promote changes through your development and test hierarchy by transferring the Update Set or by pushing the local changes.

Comparing reports the differences between two peer instances. You can choose which versions to pull from a peer instance.

The *Pushes and Pulls* related list on the team dashboard displays the user who created a change and the remote instance where the change was created.

Team Development process

The basic Team Development process sets up the instance hierarchy, grants developer access rights, manages the movement of development changes from development instances to test instances, and promotes applications to the production instance.

Procedure

1. Set up the development instance hierarchy as described in Set up an instance hierarchy.
   a. Provision development instances on the same software version as the target instance. For example, use the software version that is running on your production instance.
   b. [Recommended] Clone the target to the development instances.
   c. For each instance, define the parent instance.
   d. [Optional] For each instance, define the peer instances.
   e. For each instance, pull all changes from the parent instance.
2. For sub-development instances, grant access rights to appropriate developers.
3. Develop customizations on sub-development instances.

   Use the team dashboard to track development activities.
   - Pull versions from the parent instance, such as versions that were pushed from other sub-development instances. Reconcile any conflicts with the current local version, as necessary.
   - Track local changes. Queue changes that are ready to push to the parent development instance.
   - Compare versions on peer instances. Reconcile any conflicts.
4. When a feature is ready to promote to the parent development instance, push the current version of the customized records.
5. **Optional:** Have code reviewers approve or reject the pushed version.
6. Test and promote the feature into production according to your testing and release management process.

- Push a version

Team Development roles

To use Team Development, developers must have admin access to their development instance.

To allow pushes to the parent instance, a remote instance connection must be defined with a user account that has admin access to the parent instance.

To limit developer access to the parent instance, see Granting Access Rights to Developers.

To use code review features, users must have the teamdev_code_reviewer role. See Code Review.

Versions

Version records track changes to a customized record over time so that administrators can compare or revert to specific versions later.

Administrators can also transfer versions between instances with Update Sets or team development.

Version record navigation

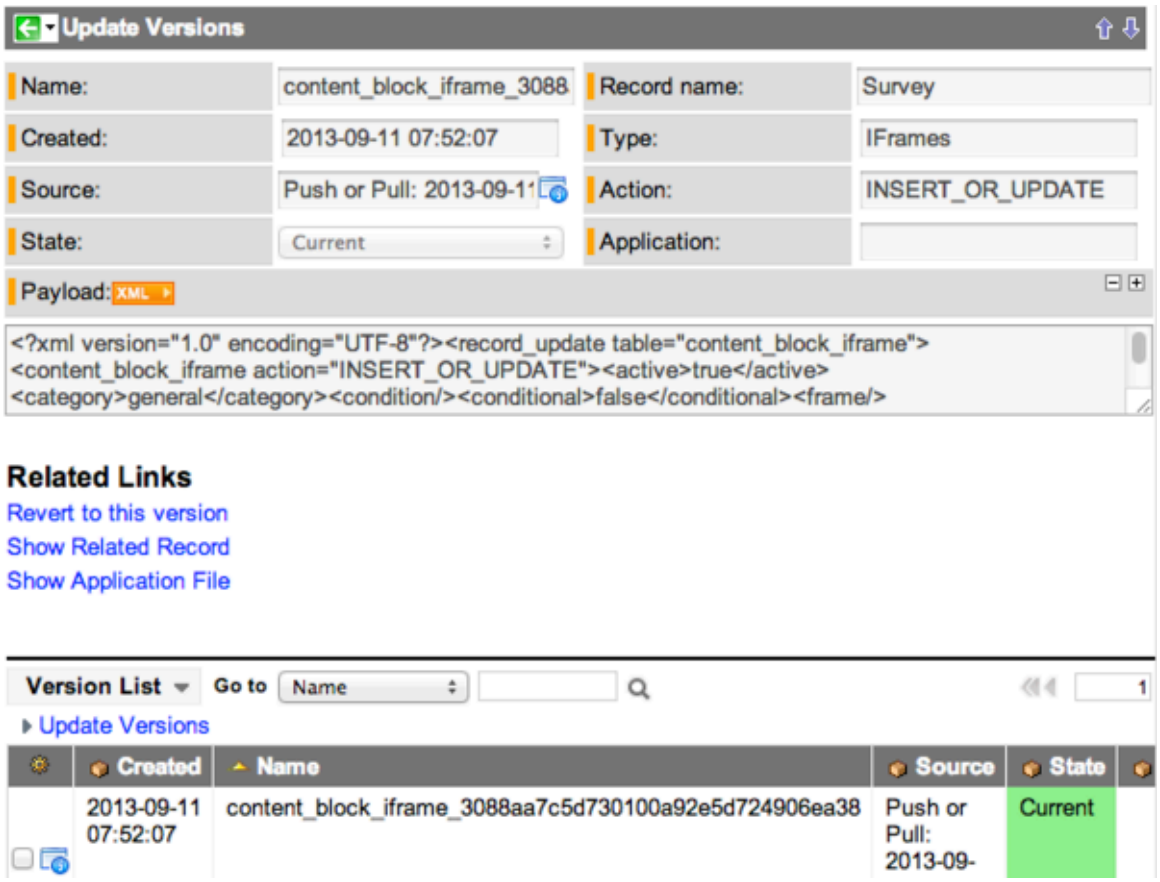
There are a variety of methods for viewing a list of versions for an object.

- For forms, right-click the header and select **Configure** > **Form Layout**.
- For lists, perform the appropriate action for the list version.
  - List v2: Right-click the header and select **Configure** > **List Layout**.
  - List v3: Open the list title menu and select **List Layout**.
- Click the **Show Versions** related link.
- For tables that use the update_synch attribute, add the **Versions** related list to the form. This list is on several forms by default, including, business rules, UI actions, and client scripts.
- For any customizable object, right-click the form header and select **Show Application File**, then scroll down to the *Related Record Versions* related list.

You can navigate from a version record to:

- The customized object: Click the **Show Related Record** related link.
- The application file record for the object: Click the **Show Application File** related link.

Version record



Versions transferring

Administrators transfer version records between instances by moving customizations with Update Sets or the Team Development application.

- Update sets: committing an Update Set adds versions. For each update in the Update Set, the version that corresponds to the update is added on the local instance.
- Team Development:
  - Pulling retrieves from the parent instance all versions of customized records that have not already been pulled and then adds them on the local instance.
  - Pushing adds to the parent instance only the current local version, not all the local versions.
  - Loading changes from peer instances adds selected versions to the local instance.

Version records

The Update Versions `[sys_update_version]` table contains records that represent the state of a customizable object at a particular time.

A customizable record is any object that is tracked by Update Sets, such as business rules or script includes. A new version record is created automatically whenever a user changes a customizable record or changes the application file for the customizable record.

A record represents the version of a base system object as it was delivered in the most recent upgrade. Baseline versions are created only for objects that have been modified by a user, and they are updated each time the system is upgraded.

Update versions table

Field	Description
Name	A unique identifier for coalescing versions of the same customized record.
Record name	Name of the customized record.
Source	Indicator of how the version was added on the instance. • System Upgrade: from a software upgrade (the baseline version). • Update Set: from an update set that was created or committed on the instance. • Pull History: from a pull in Team Development.
State	Indicator of whether the version is or has ever been loaded on the instance. • Current: the version is currently loaded. • Previous: the version has previously been loaded on the instance. When a current version is replaced by a new version, it becomes a previous version. • History: the version was never loaded on the instance and was only inserted for historical purposes, such as when pulling versions from the parent in Team Development.
Application	The application for the customized record, if it is assigned to an application.
Payload	The data for this version of the customized record.
Additional fields on the list view	
Reverted from	A reference to the older version record, if this version was created by reverting to an older version.
Fields that can be added by configuring the form	
Instance Name	The name of the remote instance where the version was originally created.
Instance ID	The URL of the remote instance where the version was originally created.
Related lists on the form view	
Version List	All versions of the customized record that are available on the instance.

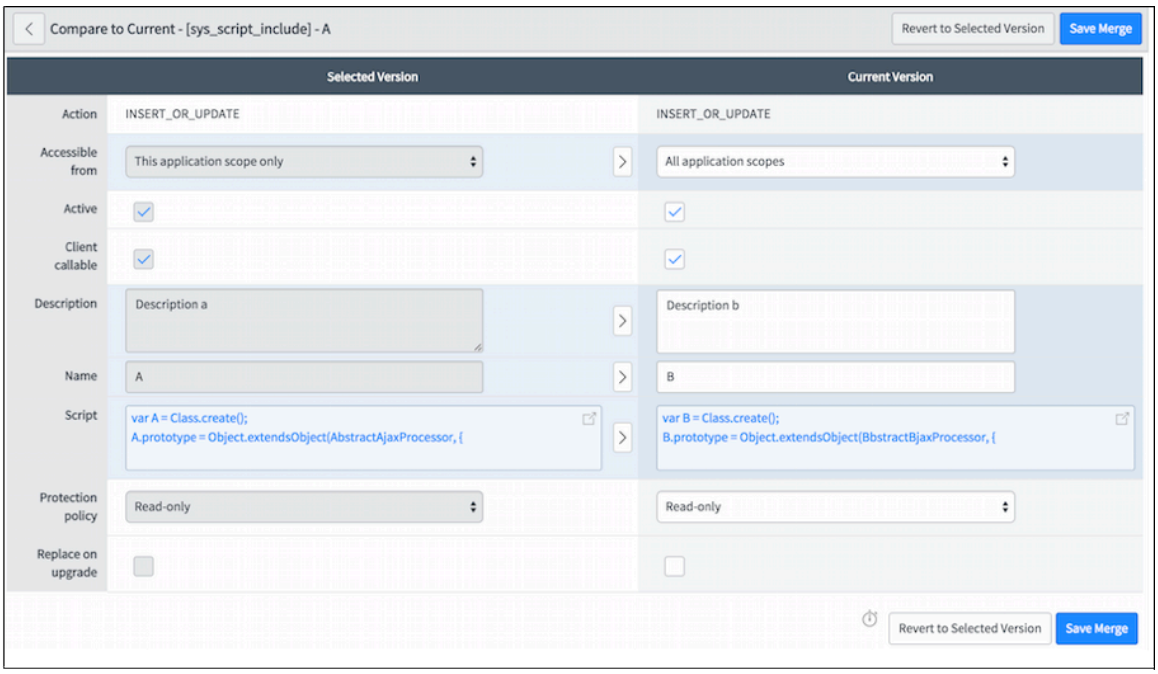
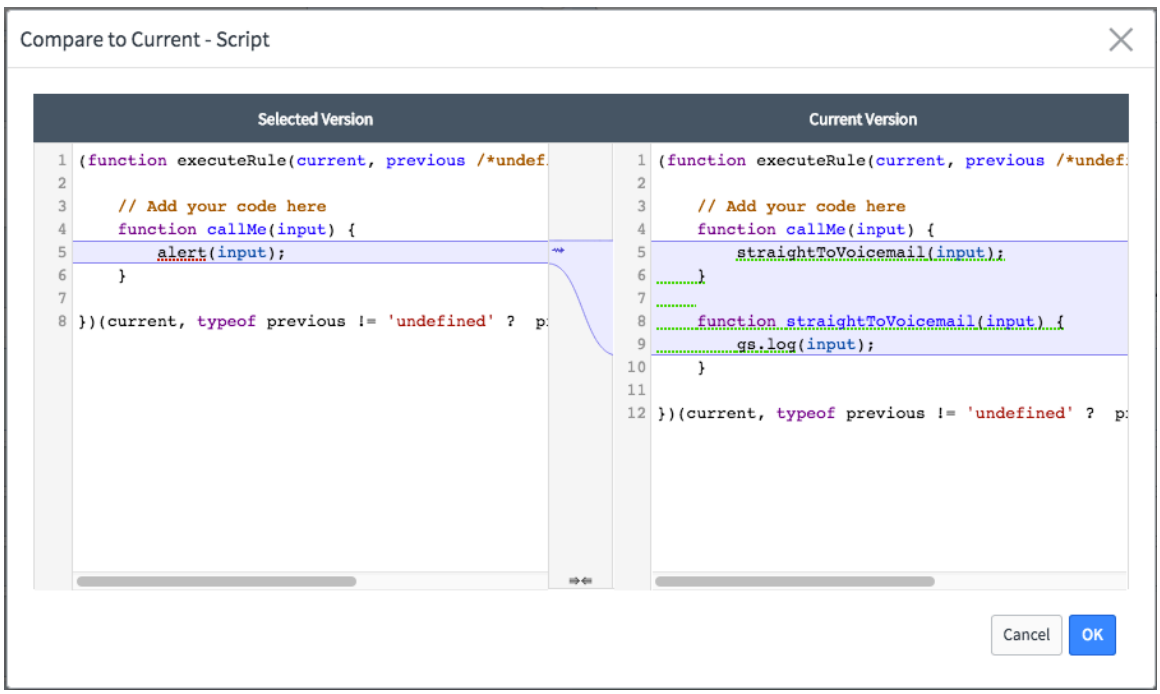
Merge tool

The Diff Merge tool enables administrative users to compare differences between two versions of a record.

Administrators can compare field-level changes between two versions, apply changes using Move Right field-level copy functionality and then merge results, or choose to revert to the non-

current version. You can access the Diff Merge tool by comparing versions, resolving conflicts, or resolving collisions, during development or after upgrades.





Accessibility Functions

The platform includes accessibility features that support Web Content Accessibility Guidelines (WCAG) 2.0 level A and make the interface accessible to users with disabilities. These features

improve the user experience when accessing platform functions with Using accessibility features.

In general, you can use the following set of standard keyboard navigation functions:

- Press **Tab** to navigate major groupings in a pre-defined sequence, including moving between standard interface controls (fields and lists) in a module, or between records within a tab.
- Press **Shift Tab** to move backwards in a pre-defined sequence.

Visually impaired users can navigate the Diff Merge tool. Screen readers can read all critical page content. All links and buttons can be reached when a section that is critical must be read. VoiceOver audible cues describe the content of the section that is necessary to read.

To enable accessibility functions, administrators should set these sys_properties:

1. Setting **glide.ui.javascript_editor** to false makes the following functions accessible:
   - Script fields (such as Script Include).
   - Side-by-side script comparison.
2. Setting sys_properties color settings enables high contrast visibility, which makes the left and right columns more accessible and easier to read by visually impaired users.
   - **mergetool.bg.left.highlight** - Left column cell color when values differ between versions.
   - **mergetool.bg.right.highlight** - Right column cell color when values differ between versions.
   - **mergetool.bg.left** - Left column cell color when version values are the same.
   - **mergetool.bg.right** - Right column cell color when version values are the same.

Compare to the current version

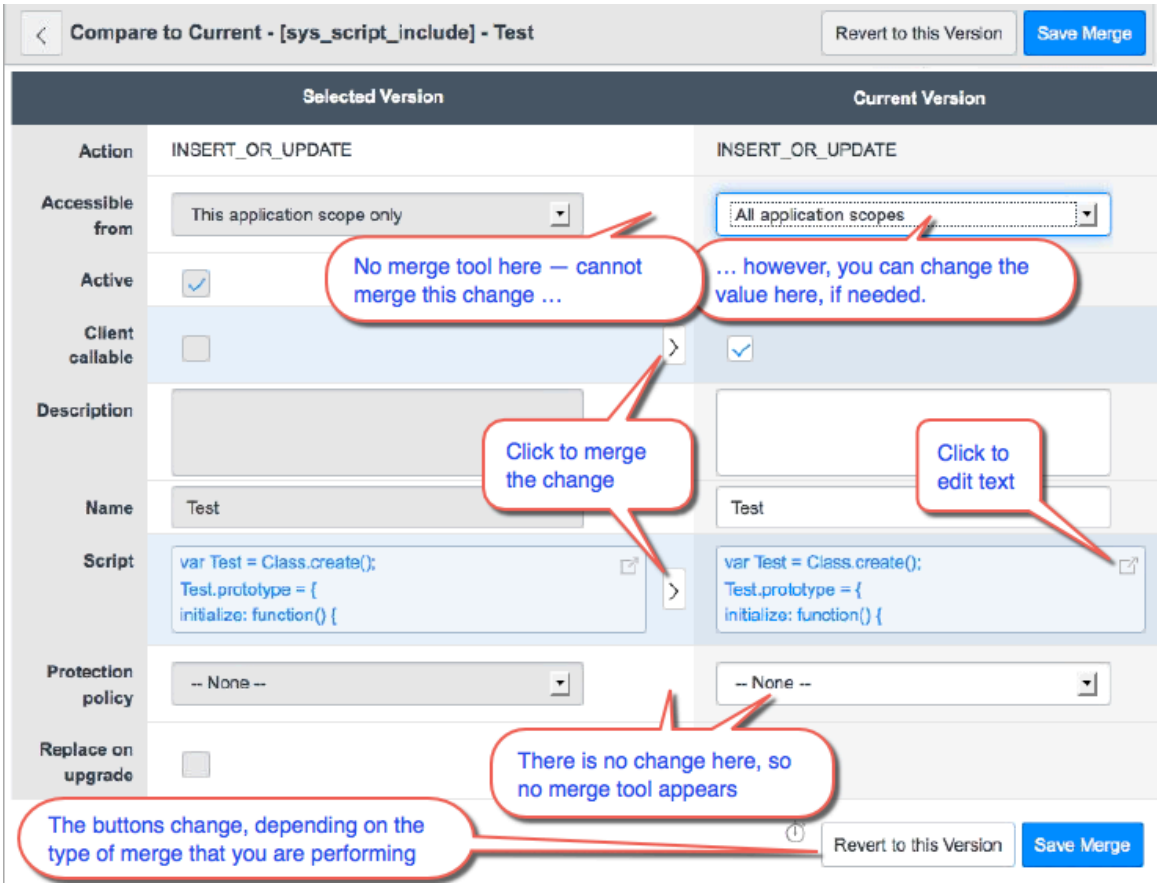
You can compare a version to the current version for any customizable object that a user has modified, such as a form layout or business rule. You can also compare the local and current pulled version of an object in Team Development. Administrators can suppress versions for specific tables.

About this task

To compare a version to the current version of an object:

Procedure

1. Open the Compare to Current page using one of the methods given in the below table.



2. On the Compare to Current page, review the fields that differ.

Related topics

- Merge tool
- Compare to the current version
- Compare a pushed version to a local version
- Compare two versions of an article
- Resolve conflicts for an individual record
- Resolve a collision in Team Development
- Revert a change
- View customizations and compare with current version

Revert a change

You can undo changes to a customized record by reverting to an older version.

Procedure

1. View a list of version records for an object.
2. **Optional:** Compare the current version to the older version to ensure that you are reverting the desired changes.
3. Right-click the older version and select **Revert to this version**.
   A confirmation dialog box appears.

If reverting to this version results in data loss due to a database schema change, a warning message appears in the dialog box.

4. Click **OK** to confirm the action.
   - The current version is marked as a previous version.
   - A new version record is added that duplicates the version that you selected in the preceding step. This new version is marked as the current version.

Note:
You can revert to the most recent baseline version. You cannot revert to an older baseline version.

Suppress versions

Administrators can configure a table so that it does not track customizations in the Versions `[sys_update_version]` table.

About this task

Warning:
If you suppress versions for tables, Team Development may work incorrectly, and you may be unable to compare and revert versions of records on the tables.

Procedure

1. Navigate to **sys_properties.list**.
2. Create a new property:
   - Name: glide.update.suppress_update_version
   - Type: string
   - Value: a comma-separated list of tables. The default value is sys_user,sys_import_set_row.

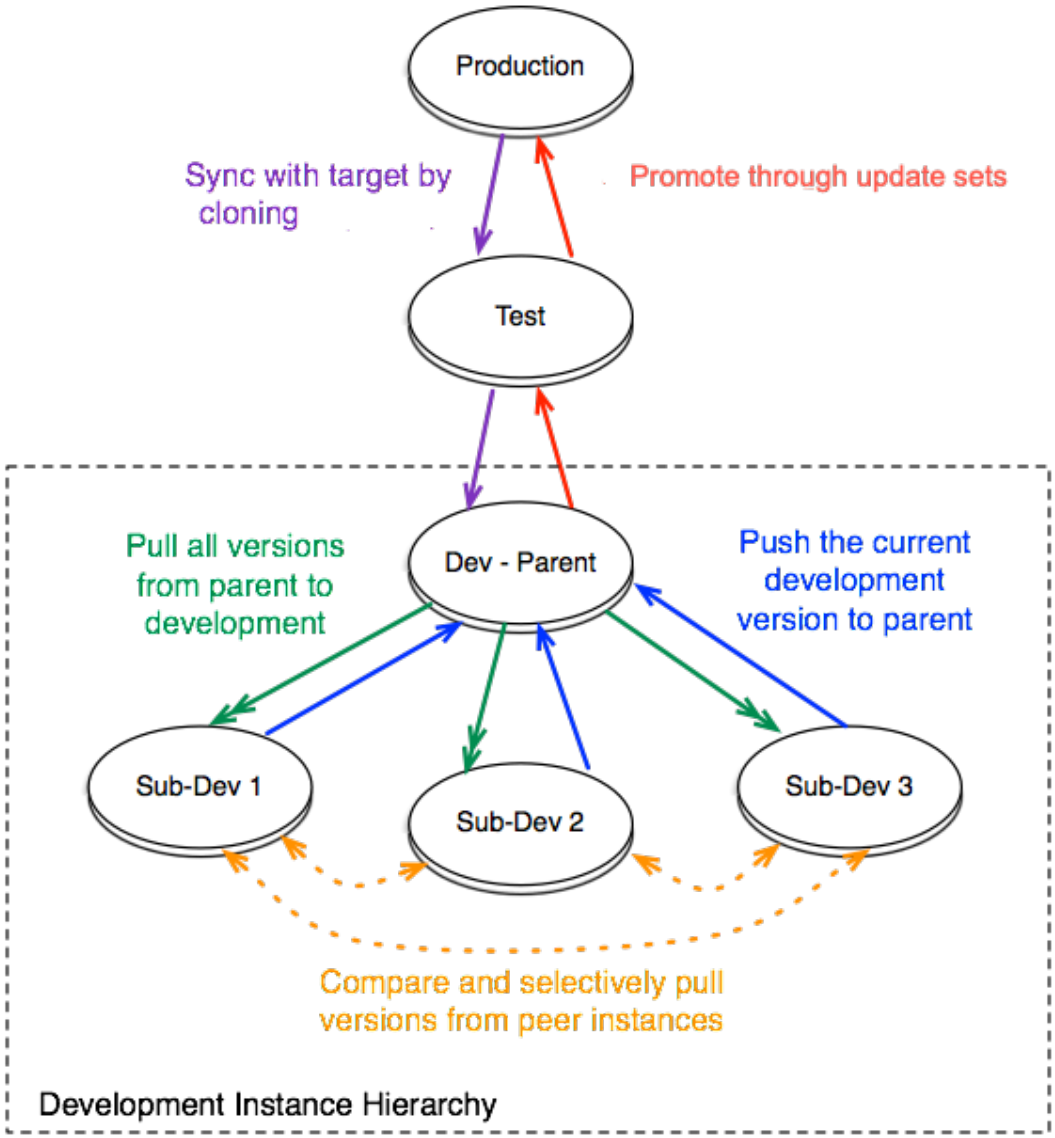
Versions and local changes

Version records track changes to a customizable record over time so that you can compare or revert to a specific version later.

A version record is created every time a developer changes a customizable record, so a single record can have multiple version records associated with it. A local change record is created or updated to reference the current version every time a developer modifies a customizable record, so a single record can have only one local change record associated with it.

Local change records track which customized records have changes on the development instance that are not on the parent instance so that you can collect changes in preparation for a push.

Team Development concepts



Developers can back out a local change to restore a previous version of a customizable record. The back out action sets the local customizable record to the last revision identified by a reconciliation action.

Developing your application

Build a custom application to meet the business needs of your organization. Choose a builder for the type of user experience or workflow that you want to create.

Build no-code applications with Creator Studio  Create and manage custom applications in a simple, no-code environment.	**Build low-code applications with App Engine**  Accelerate innovation with more creators and less complexity. Empower developers of all skill levels to build applications at scale.	**Build applications with ServiceNow Studio**  Empower developers with a modern, unified environment for building on the ServiceNow AI Platform using integrated builders and tools.
Build pro-code applications  Extend or maintain existing applications and user experiences. Connect applications and data across the enterprise.	**Builder library**  Choose a builder tool to quickly develop an application.	

Which builder should I use to create an app?

Types of builders

Want to build an app easily, without code?

Creator Studio specializes in helping you craft request-fulfillment applications without writing code. For example, an application to request office supplies by filling out a form, and someone approves or denies your request. For more information, see Exploring Creator Studio.

Need a more general app but still want low-code options?

App Engine Studio lets you build a broader range of apps than Creator Studio without being a programming pro. For more information, see Exploring App Engine Studio.

Are you a developer who wants more control in a centralized user interface?

Build apps smarter and deliver them faster with the new ServiceNow Studio. ServiceNow Studio empowers platform developers with a modern, unified environment for building on the ServiceNow AI Platform. ServiceNow Studio features streamlined navigation to applications and metadata, integrated low-code tools, efficient tracking and packaging of development work that accelerates development processes and enhances productivity. For more information, see Exploring ServiceNow Studio.

Are you a developer who wants to use industry-standard development tools and processes?

The ServiceNow IDE and ServiceNow SDK support developing applications in source code with ServiceNow Fluent, creating JavaScript modules, and using third-party libraries. ServiceNow Fluent is a domain-specific programming language for creating application metadata in code.

The ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform. The ServiceNow SDK uses Visual Studio Code Desktop locally. For more information, see Building applications in source code.

Build no-code applications with Creator Studio

Create applications without coding

Build request-fulfill applications in a simple environment, without using code, in Creator Studio.

Build low-code applications with App Engine

Build low-code apps quickly, with more creators and less complexity. Safely scale cross-enterprise experiences that users want.

Empower creators

Bring creator workflow apps to production quickly for mission-critical tasks. Design with guidance and templates that are all within a holistic low-code dev experience.

Scale low-code development

Empower business and IT to collaborate, manage, and govern low-code app development.#Set development guardrails, apply standards, and check for compliance, all in one place.

Accelerate process automation

Automate processes fast and show value quickly with native integration and low code. Scale your workflows from simple to complex, with consistency across the enterprise.

Engage your users

Captivate users with a modern unified experience that's easy to understand. Build mobile-first experiences using an intuitive, low-code designer.

Build applications with the new ServiceNow Studio

Build apps smarter and deliver them faster with the new ServiceNow Studio. ServiceNow Studio empowers platform developers with a modern, unified environment for building on the ServiceNow AI Platform. ServiceNow Studio features streamlined navigation to applications and metadata, integrated low-code tools, efficient tracking and packaging of development work that accelerates development processes and enhances productivity.

Build pro-code applications

Build and deploy apps with fine-grained control. Debug code, manage source control, and publish your apps from a central hub.

Build your apps faster

Get all your work done in one place, accelerating the process from coding to deployment.

Develop applications in source code

Write code that defines application metadata in an integrated development environment.

Manage your source

Commit, branch, and merge to your Git repository with integrated source control.

Work as a team

Provide individual developer access to specific application resources for better collaboration.

Builder library

Each builder fulfills a specific need or produces a specific type of data, such as Decision Builder, UI Builder, and Workspace Builder. For a complete list of builders, see Builder Library.

Building no-code applications

Create and manage custom applications in a simple, no-code environment.

Creator Studio

Have you ever wanted to create an application, but you don't know how to code? Then Creator Studio was designed for you!

Related applications and features

App Engine Management Center

Track and manage your Creator Studio requests, deployments, applications, and collaborative developers using App Engine Management Center (AEMC).

App Engine Studio

Open Creator Studio apps in AES to build more custom experiences, such as email notifications and additional security.

Catalog Builder

Create or edit a catalog item using a visual and guided experience.

Form Builder

Visually create, configure, and customize the different form views for your users using the form editor in Form Builder.

Workflow Studio

Integrate workflow authoring, configuring, and monitoring into a single-page experience.

Workspace

Address customer requests and issues in a workspace, which provides a suite of tools where agents, case managers, help desk professionals, and managers work with tools to resolve customer needs.

Creator Studio

If you've ever wanted to create an application but you don't know how to code, then Creator Studio was designed for you!

https://player.vimeo.com/video/1024834247?badge=0&autopause=0&player_id=0&app_id=58479

Creator Studio specializes in helping you craft request-fulfillment applications. In these types of apps, one person makes a request, such as for a new keyboard, and another person fulfills the request by providing them with one.

Keyboards, auto parts, recognition gift cards — imagine all the items employees use and ask for at your company. Your app could handle requests to approve travel, receive new equipment, make purchases, or get permission to take vacations. Your app would also enable someone to review, approve, and reject the requests.

Okay, so Creator Studio won't let you write an application for the next lunar landing module, but for what it's designed to do, it can do a lot!

Don't worry if you're new to creating applications. We're here to guide you every step of the way. Are you ready to dive in and start creating?

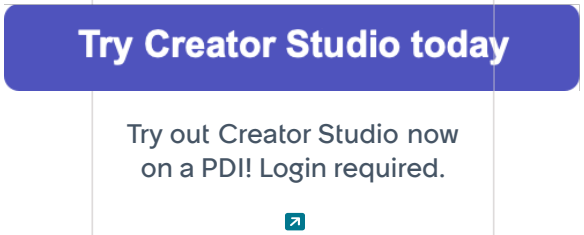
What you can do after you build an app in Creator Studio

If you build a simple app in Creator Studio and later decide that you want to make it more complex, you can open the app in any of the other ServiceNow builders. For example, you can add more complex automations in Workflow Studio or different interfaces in App Engine Studio.

Give Creator Studio a try

Ready to give Creator Studio a try? You can test it out using your own Personal Development Instance (PDI), which requires you signing in to the Developer Site. Find out more on PDIs in the Personal developer instance guide.



Exploring Creator Studio

Creator Studio makes creating apps easier by dividing their creation into simple steps. In this section, we'll explain each one.

All the steps involve requests. So, we'll start by explaining how Creator Studio stores requests.

Summary:
After reading this section, you'll understand:

- How requests are stored
- How people enter requests
- How your app automatically does things

Let's talk about storing requests

When people make a request, we have to store it somewhere so someone can review it later.

Tables hold requests

Creator Studio stores requests in a table. Each row in that table is a request. Here's a simplified version of a table with three requests.

Use cases:

- My monitor stopped working. I need a new one.
- I'm requesting a new mouse so I can have one at home and in the office.
- My laptop is over four years old. I want to request a replacement.

People enter requests using forms

How do people enter requests that eventually get stored in the app's table? They use your app to fill out a form. The questions on the form contain the information your fulfiller needs.

In our app's table, questions are stored as part of the record, which is composed of all the information on the form.

Request	Name	Email	Request date
I need a new monitor.	Sushma Singh	SushmaSingh@example.com	04-05-2024
I need a new laptop.	Peter Smith	PeterSmith@example.com	05-01-2024

In this example, the form has four fields:

- Request
- Requester's name
- Requester's email address
- Request date

These fields contain all the info the reviewer needs to accept or reject the request. You'll have to figure out all the information your reviewer needs to make a decision. Later, we'll show you how to create a form in the section Working with forms in Creator Studio.

Key terms:

Requester

Someone requesting something, like a piece of equipment or permission to do something.

Fulfiller

Someone who works on requests. Fulfillers may also approve or deny requests, depending on any approval automation for the app.

Okay, now you understand that requesters fill out forms to create requests and Creator Studio stores those requests in the app's table.

Try Creator Studio on a PDI

Want to play with Creator Studio on your Personal Development Instance (PDI)? It comes automatically installed from the Application Manager on your PDI. For more information, see Personal developer instance guide.

Example apps you can build in Creator Studio

Creator Studio enables you to build apps where people can make requests.

List of example apps

The following are some ideas of apps you can build in Creator Studio. These examples support ad-hoc requests that fall outside the scope of standard ServiceNow offerings, filling in gaps in non-routine business processes:

- Requesting marketing collateral
- Travel approval and booking apps
- Asset borrowing and returns, for example borrowing company art for an office
- New hire gift box
- Employee recognition awards and approval
- Help with using a product
- Request a head shot
- Backup coverage app where people can volunteer to cover for people on leave
- One-time funding requests, such as a retirement party
- Birthday party planning
- Internal skill sharing, where a department creates an app of skills they need for a project where people can sign up

Use App Engine instead of customization

App Engine development tools, such as Creator Studio, offer an excellent alternative to customizing existing applications on the ServiceNow AI Platform.

When your company needs to add new functionality to the ServiceNow AI Platform, you can customize existing applications, such as IT Service Management (ITSM), or create a new application using App Engine developer products, such as App Engine Studio, Creator Studio, or ServiceNow Studio. A simple guideline for which path to choose is:

- If the customization extends the intended purpose of the application, it works better to customize. For example, you can add IT functionality to ITSM.
- If the customization doesn't extend the intended purpose of the application, it works better to create a new application using App Engine developer products. For example, do not repurpose the ITSM workflow to add a travel request workflow.

Examples of when to use App Engine

ServiceNow products work best when they're used as they were intended. If you find yourself heavily customizing an application to repurpose it, a better plan is to create a new application using App Engine developer products.

The following scenarios demonstrate where creating a new application works better than heavily customizing an existing ServiceNow application:

- Your company has a business process that augments existing product functionality but doesn't follow the same workflow exactly.
- You have a novel use case for an app that doesn't align with any product workflow.
- You have a use case that could be built by heavily customizing an out-of-the-box application, but it doesn't align with what the existing application was intended to do.

Let's dive deeper into the last use case.

Issues with repurposing existing products

ServiceNow applications come with roles, processes, and flows that are specially tailored to their use case. For example, ITSM apps help with IT users, IT issues, IT reports, and IT cases.

You might have an idea for an app that's similar to but doesn't exactly align with ITSM. Because ITSM gives you a starting point, you might be tempted to customize ITSM to add the new functionality. For example, ITSM tracks IT issues, and a travel app you want to create might track travel requests. While the workflows sound similar, in fact, they use very different data, different user interfaces, and the details of each workflow vary greatly. Rather than heavily customize ITSM to repurpose it, a better plan is to use App Engine developer products for the following reasons:

- Combining two workflows creates conflicts.
- Customizing applications has implications.

Combining two workflows creates conflicts

In the ITSM example, the repurposing of ITSM to include a travel workflow uses different data, different tables, different roles, and different workflows than ITSM. As ITSM, ITSM customizations, and the travel workflow grow over time:

- Their features will continue to diverge.
- Adding new functionality or fixing problems in one workflow might adversely impact the other.

- The performance of ITSM may suffer.
- The code base will grow and the two purposes of ITSM will make troubleshooting more difficult.
- Quality engineers will require two different testing frameworks.

All these issues may cause unnecessary complications, poorer performance, upgrade delays, and software problems.

Customizing applications has implications

The ServiceNow AI Platform is built to embrace customization and configuration. The ServiceNow AI Platform is flexible enough to fit your company's business needs. How you customize ServiceNow applications, however, can have significant impacts on ServiceNow support, upgrading to future ServiceNow AI Platform versions, and the functionality of the platform.

Let's start by differentiating customization and configuration:

- Customization is any change made to the code that is part of the baseline installation of a ServiceNow instance. You use code to customize applications.
- Configuration is any change you make to the behavior of a product that does not touch the code in the baseline installation of a ServiceNow instance. You can use system properties, ServiceNow products, or code to configure an application.

The following are some of the implications that result from customizing applications:

- If you add code to an application, you own it whether or not it modifies the code in the baseline installation on a ServiceNow instance.
- The platform marks all customizations and skips them when you update to a new version of the platform. That means you are responsible for manually updating the customizations. This can have a significant impact on the time and resources required to update to new platform versions.
- The ServiceNow AI Platform uses a framework that supports applications in how they process tasks, how forms are rendered in multiple browsers, and the overall user experience. Introducing customizations can have unintended consequences on this framework.
- You own the burden of testing custom code and determining if it impacts platform functionality.
- ServiceNow Customer Support cannot troubleshoot custom code or issues caused by custom code.

Customization is one of the key features of the ServiceNow AI Platform. However, over-customizing an application to repurpose it is likely to generate technical debt, lengthen your upgrade cycle, and complicate future platform upgrades because the custom code may not easily migrate to new platform versions.

Conclusion

Customization and configuration are hallmarks of the ServiceNow AI Platform that enable your company to customize workflows to fit its specific needs. Proceed with these tasks in the following order:

1. Configure ServiceNow applications as much as you can before customizing them.
2. Customize an application only when it extends the intent of the application.
3. Use App Engine developer products, such as App Engine Studio, Creator Studio, and ServiceNow Studio, to create new applications rather than customizing an application to create functionality that doesn't align with its original purpose.

Customization vs. configuration with Creator Studio

There are important differences between customizing and configuring ServiceNow applications. The ServiceNow platform is built to embrace customization and configuration but how you do so can have significant impacts on ServiceNow support, upgrading to future ServiceNow platform versions, and the functionality of the ServiceNow platform.

The general rules around customization are:

- Customize an application only if it extends the original intent of the application. For example, add IT functionality to ITSM but don't add a travel workflow. Instead of over-customizing an application, create a new application using App Engine products, such as Creator Studio or ServiceNow Studio.
- Configure as much as you can before customizing an application.
- If you add code or make other modifications to out-of-the-box functionality, you own them.

What is configuration

Configuration is the process of using ServiceNow built-in tools and features to modify an application's behavior without making changes to flows or the code that is part of the baseline installation on a ServiceNow instance.

Configuration can take the form of using ServiceNow built-in tools to add tables and more, setting instance-wide parameters, as well as using code to extend an application's functionality to meet business needs as long as the code does not modify the baseline code installation. The entire platform is designed for you to add configuration code.

If you add code, such as workflow scripts, you own it, even if it doesn't alter the baseline code installation. That includes owning the impact it has on the entire ServiceNow platform. Issues that arise from added code are beyond the scope of ServiceNow support to debug.

Reverting a configuration should not require any change to the baseline code.

Configuration examples include:

- Forms: Configure tables, fields, data types, default values, and field dependencies to configure the data you capture and display.
- UI elements: Modify layouts, add related lists, add buttons, and change field names.
- Service Catalog: Configure portals where your customers can request catalog items such as service and product offerings.
- ACLs: Restrict unauthorized users from accessing forms and data.
- System property values: Modify the application's experience for all users.

What is customization

Customization is any change made to the flows or the code that is part of the baseline installation on a ServiceNow instance. You use ServiceNow products or code to customize applications.

If you add code, you own it, even if it doesn't alter the baseline installation. That includes owning the impact it has on the entire ServiceNow platform.

Customization examples include:

- Scripting: Customize ServiceNow through scripting using JavaScript. This includes creating client scripts, server-side scripts, and business rules with intricate logic that modify the baseline code.
- Custom tables: Develop custom tables to accommodate specialized data that doesn't fit within standard tables.
- Integration: Customize integration with external systems, such as APIs and web services, for seamless data exchange.
- Widgets and portals: Create custom widgets and portals to provide unique features and user experiences.
- Workflows: Create and modify workflows using Workflow Studio. Create and manage playbooks, flows, actions, decision tables, and integrations from one design environment to automate tasks. Upgrading to a new version of a flow requires reapplying your customizations.

Tools for customization and configuration

ServiceNow offers many tools and features, such as business rules, to modify the out-of-the-box behavior of ServiceNow applications. Whether they customize or configure an application depends on how they're used. Using these tools to modify the installed code base constitutes customization. Using these tools to add code that does not modify the flows, or the installed code base constitutes configuration. In both cases, you own the code you add as well as the impact it has on the ServiceNow platform.

ServiceNow tools include:

- UI Policies: Dynamically modify the visibility of fields and attributes on a form according to user inputs.
- Business rules: Automatically trigger actions based on specified conditions.
- UI Actions: Extend and customize forms and lists by adding buttons, context menu items, or other UI elements that perform specific actions when clicked.
- Client-side scripts: Scripts that execute within the user's browser when certain actions occur on a form or a UI page.
- Server-side scripts: Scripts that execute on the ServiceNow server or database, for example, to update record fields when a database query runs.

What is personalization

Personalization is when users use out-of-the-box application tools to modify an application's look and feel only for themselves. Admins can change the look and feel for all users and that is considered configuration. Personalization examples include a user choosing to use dark mode or choosing which table columns to display.

Personalization does not change the baseline code installation on a ServiceNow instance. So, personalization does not impact customer support or interfere with upgrades to new ServiceNow versions.

Ramifications of customizing ServiceNow products

The ServiceNow platform is extremely flexible and built to embrace customization and configuration to fulfill a wide range of business requirements. How you customize ServiceNow applications, however, can have significant impacts on ServiceNow support, upgrading to future ServiceNow platform versions, and the functionality of the platform. Instead of customizing ServiceNow applications, consider using App Engine development products, such as Creator Studio and ServiceNow Studio to create new applications.

The ServiceNow platform uses a framework that supports applications in how they process tasks, how forms are rendered in multiple browsers, and the overall user experience. ServiceNow relies on the framework's integrity to develop and provide support in a consistent manner. Customizations can impair this framework, change platform functionality, and impair workflows and upgradeability.

Customizations trigger the platform to create sys_update_xml records, which are stored in the Customer Update table. The platform marks all customizations and skips the customized records when you update to a new version of the ServiceNow platform. That means you are responsible for manually updating the customizations. This can have a significant impact on the time and resources required to update to new platform versions.

Note:
The Customer Update table also contains modifications or additions to configuration metadata, for example, creating a new catalog item or a new workflow.

For more information, see the Customer Updates table. Note that the complexity of maintaining customizations dramatically increases as the number of customizations increases.

Customizing the installed code base can be costly, generate technical debt, lengthen your upgrade cycle, and complicate future platform upgrades because the custom code may not easily migrate to new platform versions. Custom code can change the standard functionality of the ServiceNow platform in unintended ways. Evaluate demands for customization carefully and only resort to customization where there is clear business value and no alternative. Wherever possible, avoid customization by using configuration instead.

If you customize a product:

- You are responsible for maintaining the customization going forward.
- Customer Service and Support will not support problems caused by custom code. If it is the cause of the problems, the support team will likely advise you to revert to the out-of-the-box code.

What is the Customer Service and Support stance on supporting customization

The ServiceNow Customer Service and Support stance on customization is if you add code, you own it and its consequences. Why? Customer Support is not privy to your custom business logic, doesn't know what the expected behavior should be, is unable to reproduce the issue on an out-of-the-box instance, and customer support engineers are not certified implementation specialists, so they are not certified to review customized code logic.

Alternatives to customization

If you have requirements and ideas for enhancements, instead of customizing the installed code base, you can:

- Use configuration instead of customization.
- Submit an Enhancement Request to the ServiceNow development team. Each request is evaluated and, if approved, will be incorporated into a future release.
- Create an app using App Engine developer products to handle desired functionality.

When to use App Engine developer products instead of customizing

When your company needs to add new functionality to the ServiceNow platform, you can customize existing applications, such as ITSM, or create a new application using App Engine developer products, such as Creator Studio or ServiceNow Studio. A simple guideline for which path to choose is:

- If the customization extends the intended purpose of the application, it works better to customize. For example, you can add IT functionality to ITSM.
- If the customization doesn't extend the intended purpose of the application, it works better to create a new application using App Engine developer products. For example, do not repurpose the ITSM workflow to create a travel request workflow.

For example, ITSM is designed to handle IT issues. To customize it to handle travel requests goes beyond the original intention of ITSM. Because IT and travel requests have different workflows, it's better to create a travel request app using App Engine developer tools, such as Creator Studio and ServiceNow Studio, instead of customizing ITSM.

For more information, see Creator Studio.

Examples of when to use App Engine developer products

ServiceNow products work best when they're used as they were intended. If you find yourself heavily customizing an application to repurpose it, a better plan is to create a new application using App Engine developer products.

The following scenarios demonstrate where creating a new application works better than heavily customizing an existing ServiceNow application:

- You have a novel use case for an app that doesn't align with any product workflow.
- You have a use case that could be built by heavily customizing an out-of-the-box application, but it doesn't align with what the existing application was intended to do.
- Your company has a user group or business process that should be separate from the OOTB product workflow.

Guidelines for customizing ServiceNow products

If you must make a customization, consider the following suggestions:

- Maximize configuration options first.
- Avoid copying objects. Instead, update objects in place wherever possible, except for Service Portal widgets and other items designated to be reused.
- Default to "add before edit." This means that you should, for example, add fields to forms rather than change the type of an existing field. Avoid using the same names as out-of-the-box objects, methods, or classes when adding them.
- Minimize the number of fields you add to a form. The more fields you have on a form, the longer it may take to load.
- Export original records as backups before customizing them. Keep track of their out-of-the-box sys_id's in case you must restore them in the future.
- Use scoped applications as your default for any new custom development.
- Document all customizations. Add comments explaining why you customized (including business justification). Review all comments before upgrading to determine if you can revert to out-of-the-box code.
- Create tests for all customizations. Write Automated Test Framework (ATF) tests for all customizations where possible.
- Use HealthScan regularly to identify unnecessary customizations.
- Customizations should be made to baseline objects where necessary so that conflict resolution and decision-making can be appropriately recorded in the updates. Hidden

customizations may cause administrators to overlook updates in future assessments in case reverts or merges are necessary.

- Test your customization for all use cases. Include performance testing and the introduction of unintended consequences.
- Administrators are responsible for verifying that their customizations work after a ServiceNow platform upgrade, and for keeping track of what customizations are made.

Handling customizations when you upgrade

Customizations trigger the platform to create sys_update_xml records, which are stored in the Customer Updates table. These records are not updated during platform version upgrades. ServiceNow marks them as skipped records in the ServiceNow Upgrade Monitor. To make sure they're successfully ported to the upgraded instance, you must manually process the skipped changes. For more information, see the Customer Updates table.

Assuming you've documented all your customizations—including the business justification—take your documented inventory and compare it with the skipped records identified in the Upgrade Monitor. After filtering out low-risk changes that have resulted in skipped records (for example, field labels or form layouts), you'll need to decide whether to:

- Retain each customization
- Revert to out-of-the-box
- Merge your customization with the base system to resolve conflicts

Creator Studio quick start

This quick start guides you through the process of building your first app in Creator Studio and requesting its deployment.

At a minimum, you need to create the foundation of an app and customize its form, which is where users submit their fulfillment requests.

Building your first app is a good way to understand how Creator Studio enables easy app creation.

Your system administrator must add you to the Creator Studio Users group.

Quick start: Build the foundation of an app

Create your app's foundation before building it out.

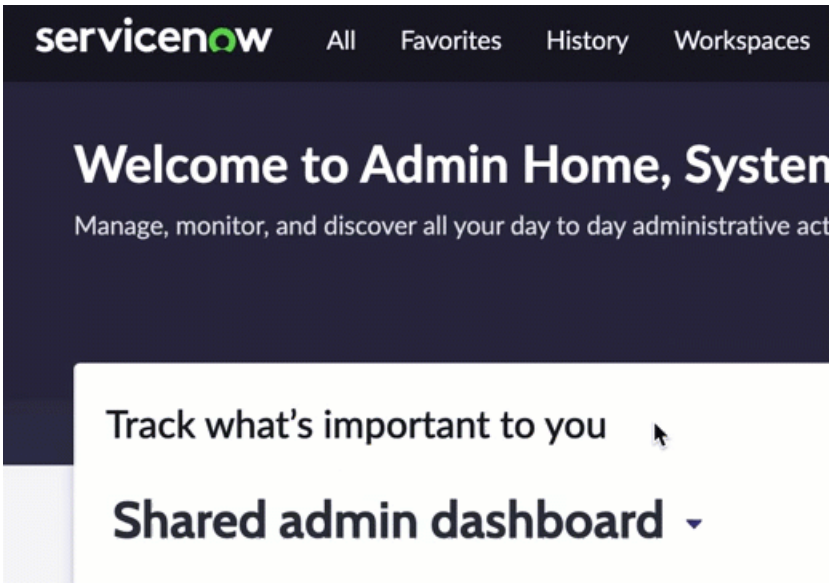
Before you begin

Your system administrator must add you to the Creator Studio Users group.

Procedure

1. Head over to the Creator Studio home page by going to **All** > **App Engine** > **Creator Studio**.

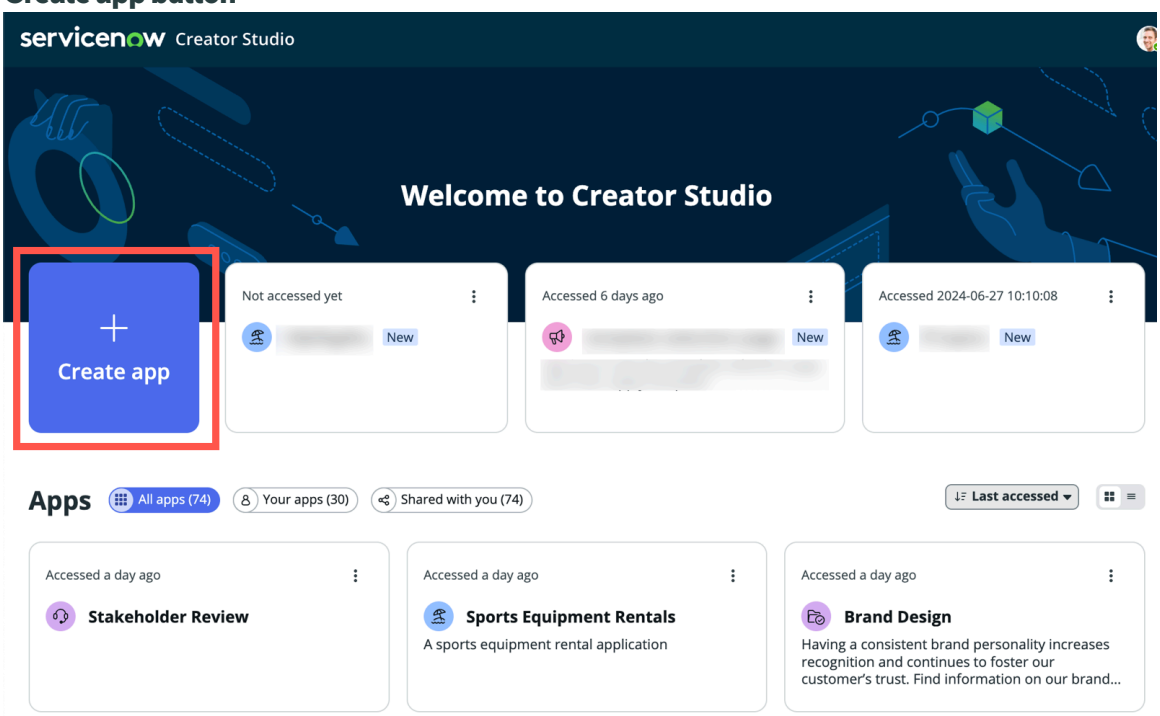
Start Creator Studio



The Creator Studio home page appears. To learn more about working in the home page, check out Find existing apps in Creator Studio.

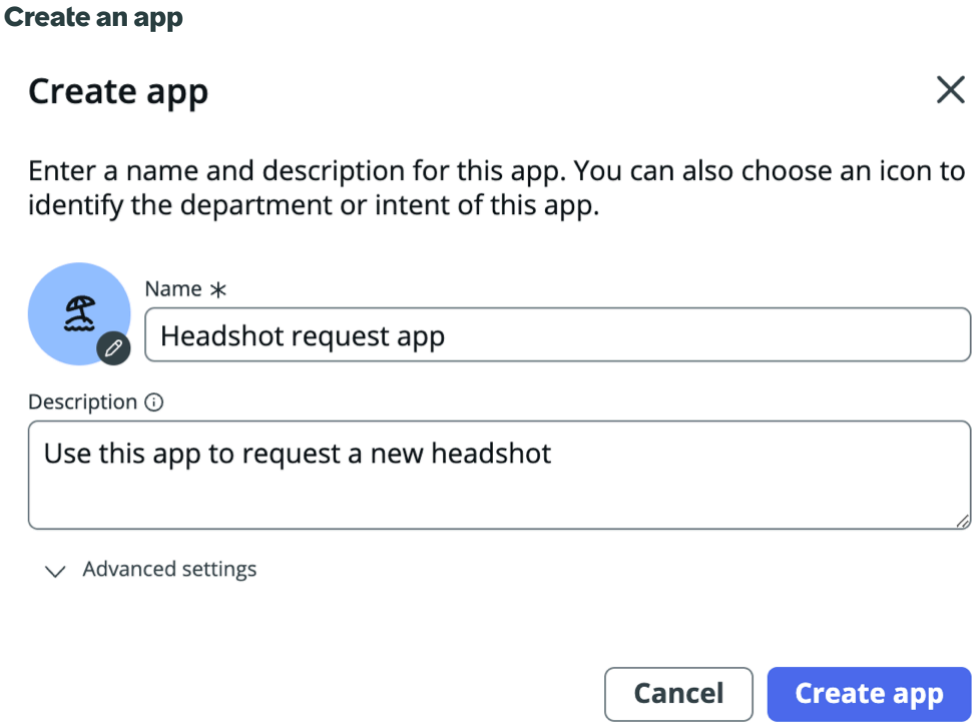
2. Select the **Create app** button to start the process of creating an app.

Create app button



- If you're a system administrator, you can read more about this topic in Application collaboration.
- If you want to know how to request an admin to create the app for you, check out Ask an admin to create an app for you in Creator Studio.

3. On the modal that pops up, enter a **Name** and brief **Description** of the app's purpose.



4. Select **Create app** to finish building the foundation of the app.

Result

Okay, you've created the beginning of your very own application! You've named and described it. A list of catalog templates appears.

Quick start: Choose catalogs and topics

Associate your app with catalogs and topics to determine and categorize their content.

Before you begin

Your system administrator must add you to the Creator Studio Users group.

Procedure

1. Select a catalog template from the list, which your admin can customize, and then select **Apply this template**.

   You may not see a catalog template that is exactly what you want. So, choose one that's the closest. If none look close, select the **Creator Studio Default Template** option, if your admin hasn't removed it. It's your best bet.

   Tip:
   Feel free to click through the list of catalog templates. Previews will help you pick the one you want.

   Don't worry if you don't see other catalog templates to choose from! Your admins may not have created any custom catalog templates for you yet.

2. Add a form to a catalog to specify its business area.

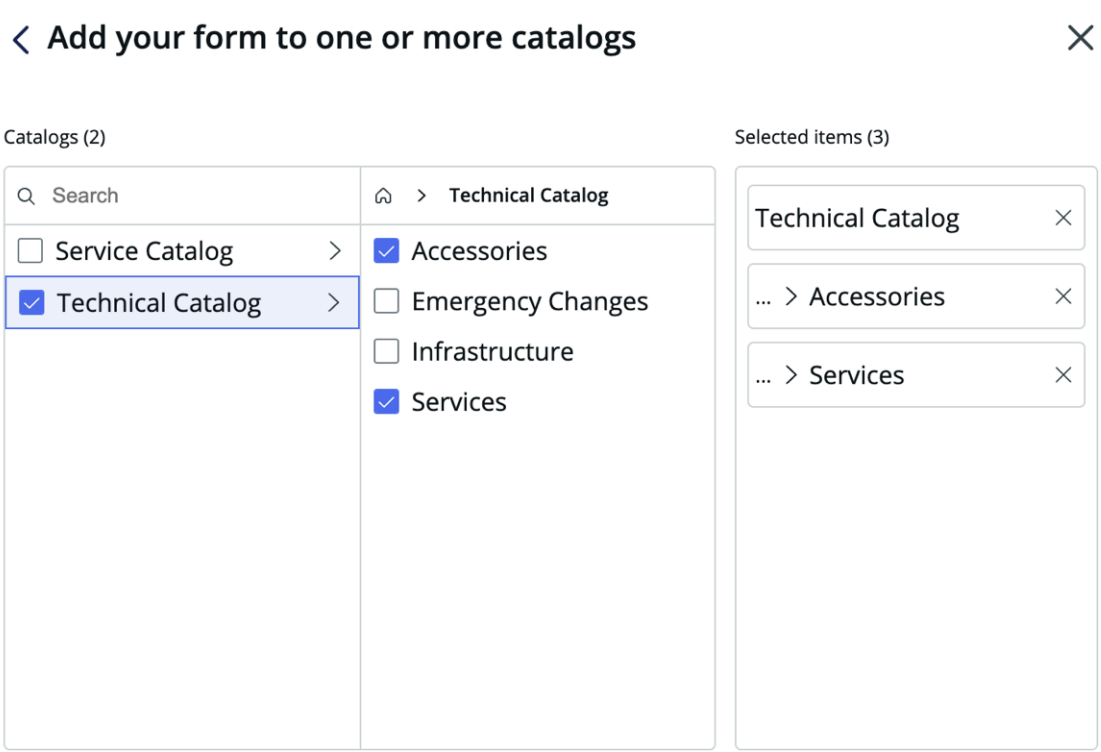
Note:
You can skip this step for now and revisit it later when you have a better idea of where it fits.

The available catalogs are configured by your admin, contact them if you don't see the one you want.

a. Select the **Edit button** (Edit) for the Catalogs and categories card.

b. Select the catalog that represents the business area the app will use.
For example, choose a service catalog that contains software and laptop cables. Expand the carat for each catalog to see its sub-catalogs.

Select the catalog



c. Select as many items in the catalogs as you need.

d. Select **Apply**.

You can edit any of the app's basic settings any time after you finish creating the app. For more information, see Creator Studio form settings.

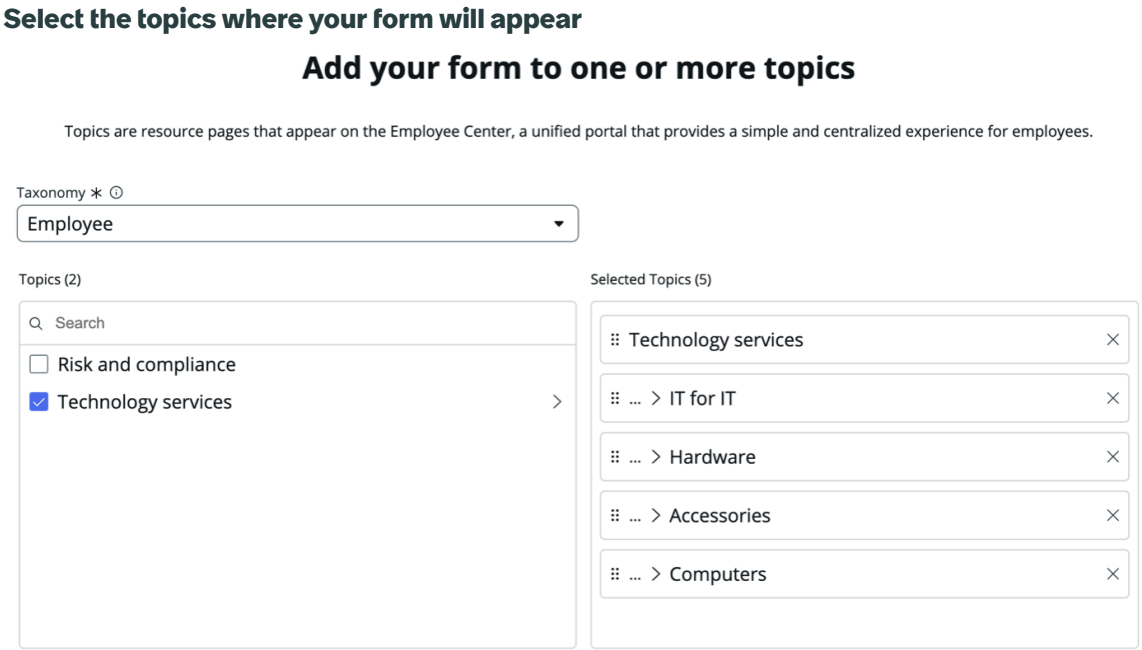
3. Next, choose one or more topics to specify where the form will appear.
Find out more about topics in Associate a catalog item with a taxonomy topic in Employee Center, and more about taxonomy, which is a categorization method, in Unified Taxonomy for Employee Center.

Note:
You can skip this step for now and revisit it later when you have a better idea of where it fits.

a. Select the **Edit button** (Edit) for the Topics card.

b. Choose the **Taxonomy** page where you want the form to appear, such as **Employee**.
Taxonomy is a method of categorization that Employee Center uses.

c. Select the topic(s) that represent the Employee Center areas where you want the form to appear.
For example, choose a topic that contains technology services, and expand its carat to see each of its sub-topics.



d. Select the topics where you want the form to appear, as many as you need.

e. Select the **Apply** button to save your changes.

4. Select **Save and continue**.

Result

Great, you've defined where the app will appear! Next, we'll customize how it looks.

Quick start: Customize your app's look and feel

Check out how your app will appear and then make adjustments to how it looks.

Before you begin

Your system administrator must add you to the Creator Studio Users group.

Procedure

1. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

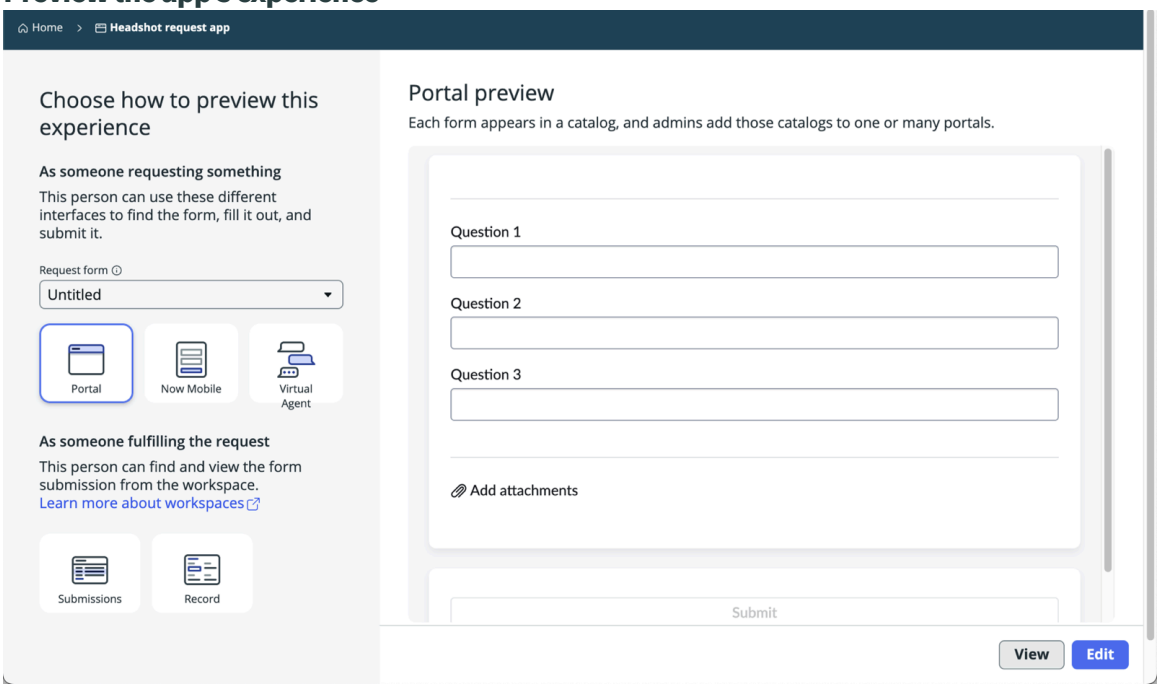
   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

- **Portal** (see a preview of how it'll appear on a desktop website)
- **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
- **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

> **Note:**
> Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

Preview the app's experience



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

2. **Optional:** Next, you can customize the form's look and feel on the **Request forms** tab by completing one of the following steps.

   a. Add or modify the image that appears on your form by selecting the add image icon ( ) and then selecting an image.

   b. Change the form's title, short description, and other text by selecting those parts of the form and typing in your changes.
   You can enhance how the longer **Description** appears using rich text, such as font changes and sizing.

Result

Get more details on customizing your form in Customize your form for an app in Creator Studio.

Next, we'll build and publish a form.

Quick start: Add questions to and publish a form

Add questions to the form to gather the information that your fulfiller needs to evaluate the request, and then publish it to make its catalog items available.

Before you begin

Your system administrator must add you to the Creator Studio Users group.

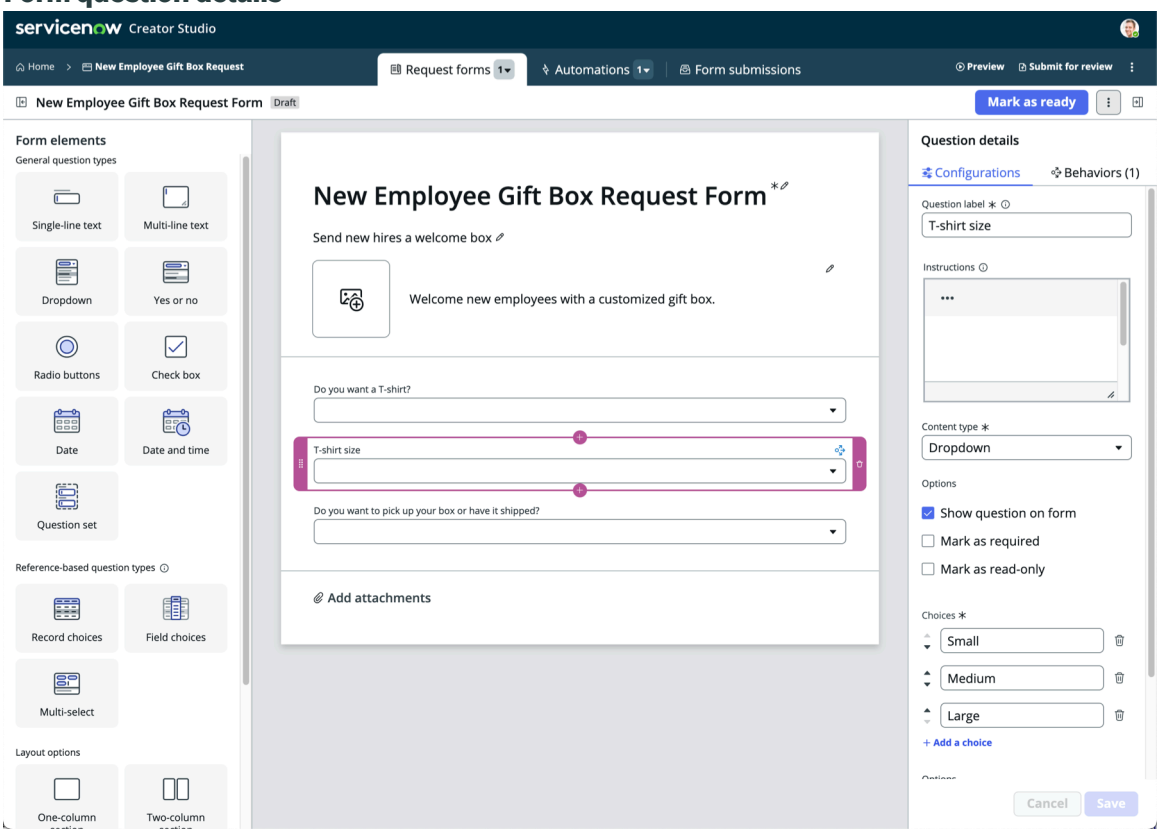
Procedure

1. In the Form elements panel, drag the type of question you want onto the form and drop it on the canvas where you'd like it. You can also add questions by selecting the add icon (+) that appears when you click on an existing question on the form.
   If you're adding a pre-configured **Question set**, you must select the question set from the modal that appears when you drag it onto the form.

   For a description of question types and how they're used, see Available question types in Creator Studio.

2. Select the question.
   When you select a question, it's highlighted on the form so you know what you're working on.
3. In the **Configurations** tab of the Question details panel, specify information about the question you added, such as whether a question must be answered for the requester to submit the form.
   The details vary by question type. For example, if you add a **Dropdown** question, you must supply the options to choose from.

Form question details



4. **Optional:** Make the form's appearance change based on how users answer questions by adding dynamic behavior to it on the **Behaviors** tab.

For example, if a user says they want a T-shirt for an event they're attending, you can make a **T-shirt size** field required. Get the details on adding dynamic in Make a form change based on responses in Creator Studio.

5. Select **Save and close** when you finish modifying the question.
6. Revise or add more questions to the form using this procedure. To change a question type, select the question and then select the new question type in the **Content type** field of the Question details panel. Selecting a new type may introduce new values you must supply. Keep these specifications in mind as you create your questions:
   - You can't change an existing question into a question set. To include a question set on a form, you must newly add it to the form.
   - If you put two checkbox questions side-by-side on a form, they make a section. You can't add other types of questions to that section.
7. Now, let's arrange the questions and images that you've added to the form.

   a. From the Form elements panel, drag the layout option you like onto the form and drop it where you want it to appear, for example, a **Divider line**.
   Don't worry if you don't like the layout, just try another one by dragging it onto the form's canvas.

   b. Revise the form layout you chose using the Section details or Question details panel (depending on the layout you're working on). You can do things like make text bold, add links, and so forth.

   Note:
   To edit or delete a section, you must hover over the section name and then select **Section** to see the section details in the properties panel, as well as the delete icon.

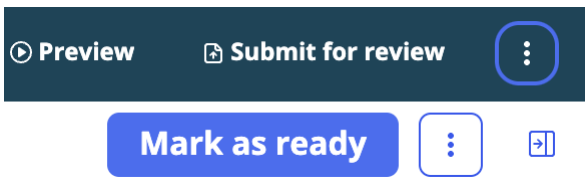
   Selecting a section

   For more information, see Layout options for forms in Creator Studio.

   c. Select **Save** in the Section details/Question details panel when you're done revising the form's layout.

8. Finally, publish the form when it's ready by selecting the **Mark as ready** button.
   Publishing forms makes them available as catalog items in the production instance for published apps.



Result

Now that the form is available as a catalog item, we can use it to create an automated playbook.

Quick start: Add a playbook

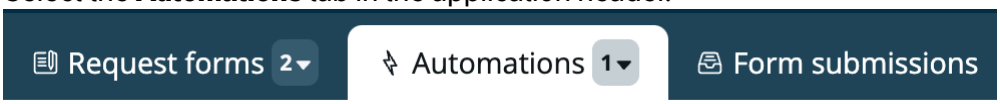
Add a playbook to create automation for your app, for example, to automatically assign a record to a manager for approval.

Before you begin

Your system administrator must add you to the Creator Studio Users group.

Procedure

1. Select the **Automations** tab in the application header.

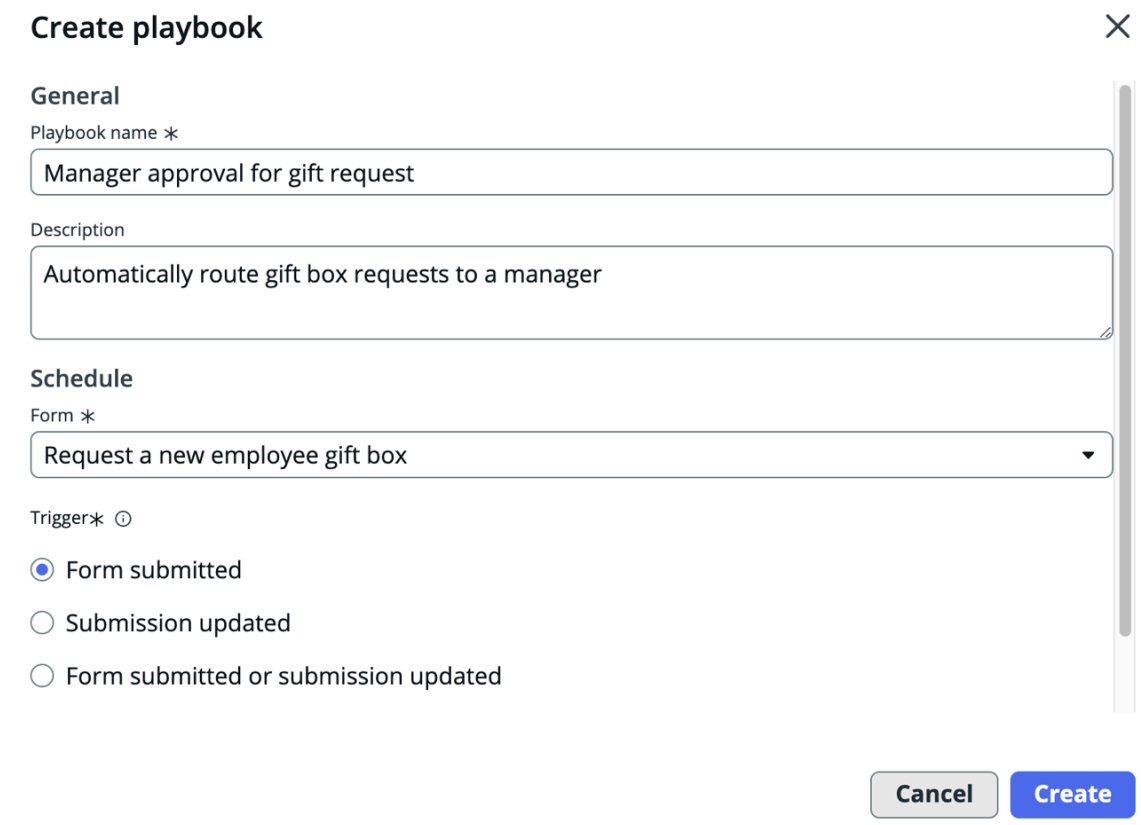


2. Select the **Create a playbook** button.
3. Specify the playbook's General attributes in the Create playbook modal.

General playbook definition fields

Field	Description
Playbook name	Descriptive name for the playbook you're creating.
Description	Brief explanation of what the playbook does, for example, the end goal for the record type.

Create a playbook



4. Specify the Schedule for the playbook.

   a. Select the **Form** whose catalog item generates the record type that you want the playbook to run on.
   The table for the form you choose is always the app's task table, which is specified when the app is created.

   b. Select the type of **Trigger** that initiates the playbook.

   Playbook trigger options

Trigger	Description
Form submitted	Start running the playbook when a user submits the form you chose.
Form updated	Start running the playbook when a user updates the form you chose.
Form submitted or updated	Start running the playbook when a user submits or updates the form you chose.

   Note:
   You can't change an playbook's trigger type after you finish creating the playbook. Instead, create a new playbook with a different trigger.

   However, you can edit the trigger condition, such as making the playbook run conditionally based on a specific answer to a question. For more information, see Edit the trigger for a playbook in Creator Studio.

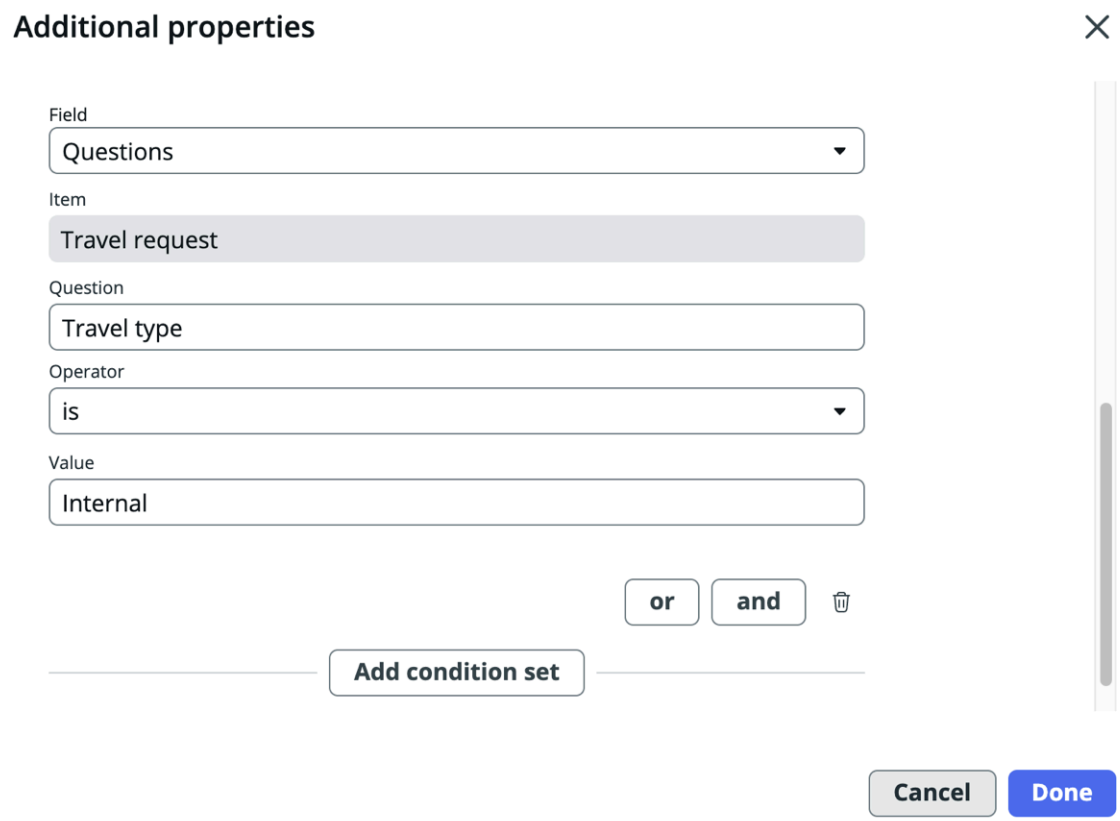
   c. If you chose a trigger that includes a form being updated, specify how often that app should **Run your playbook**.
   The options are:

   - **Once**
   - **For each unique change**
   - **Only if not currently running**
   - **For every update**

   d. Specify the conditions that must be met for the playbook to begin running by selecting **Add condition set**.

- If you want to trigger the playbook based on the value of a column in a table, select the **Field** that you want to be the trigger, as well as its condition **Operator** and the specific trigger **Value**. For example, when a **Start date** is **after** the **Date** needed.
- If you want to trigger the playbook based on the response from a form, select **Questions** as the trigger **Field**. Then select the question you want in the **Question** field, the condition **Operator** and the answer's **Value**.

Question answer as trigger for an automation



Add as many conditions as you need. For more information, see Create a condition statement using the condition builder.

5. Select **Save** before moving on to add an activity.

Result

Next, we'll add an activity to the playbook to define what the automation does.

Quick start: Add an activity and activate a playbook

Add an activity to your playbook to define what the automation does.

Before you begin

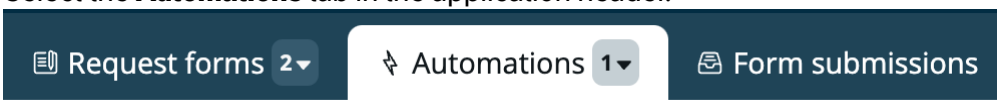
Your system administrator must add you to the Creator Studio Users group.

About this task

If you want to include an if/then statement to define circumstances for the activity, add a decision. See Add a decision to an app's playbook in Creator Studio for details.

Procedure

1. Select the **Automations** tab in the application header.



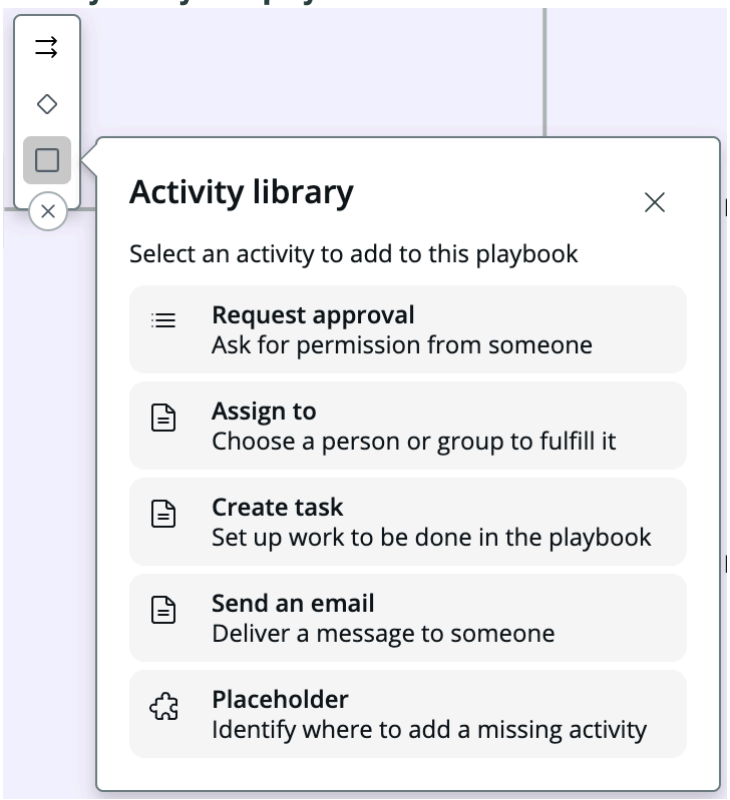
2. Select the add icon on the connector where you want to add an activity and choose the square **Add an activity** icon ( ) in the menu that pops up.
3. Choose the type of activity that you want from the Activity library pop-up.

Note:
In addition to the following standard activities, you may see some custom activities that your admin created.

Types of activities

Activity type	Description
Request approval	Ask someone for permission to accomplish a task.
Assign to	Choose a person who should fulfill the task.
Create task	Specify a process that must be done as part of the playbook.
Send an email	Send an email to one or more people. You can specify images and enrich text for the email that gets sent automatically.
Placeholder	Set an undefined activity to be specified later, or a more advanced activity such as an email notification, when an activity is completed. Placeholder activities don't have any logic assigned to them yet, and must be edited in Workflow Studio. Or, you can swap them out later for another type of activity in Creator Studio.

Activity library for a playbook

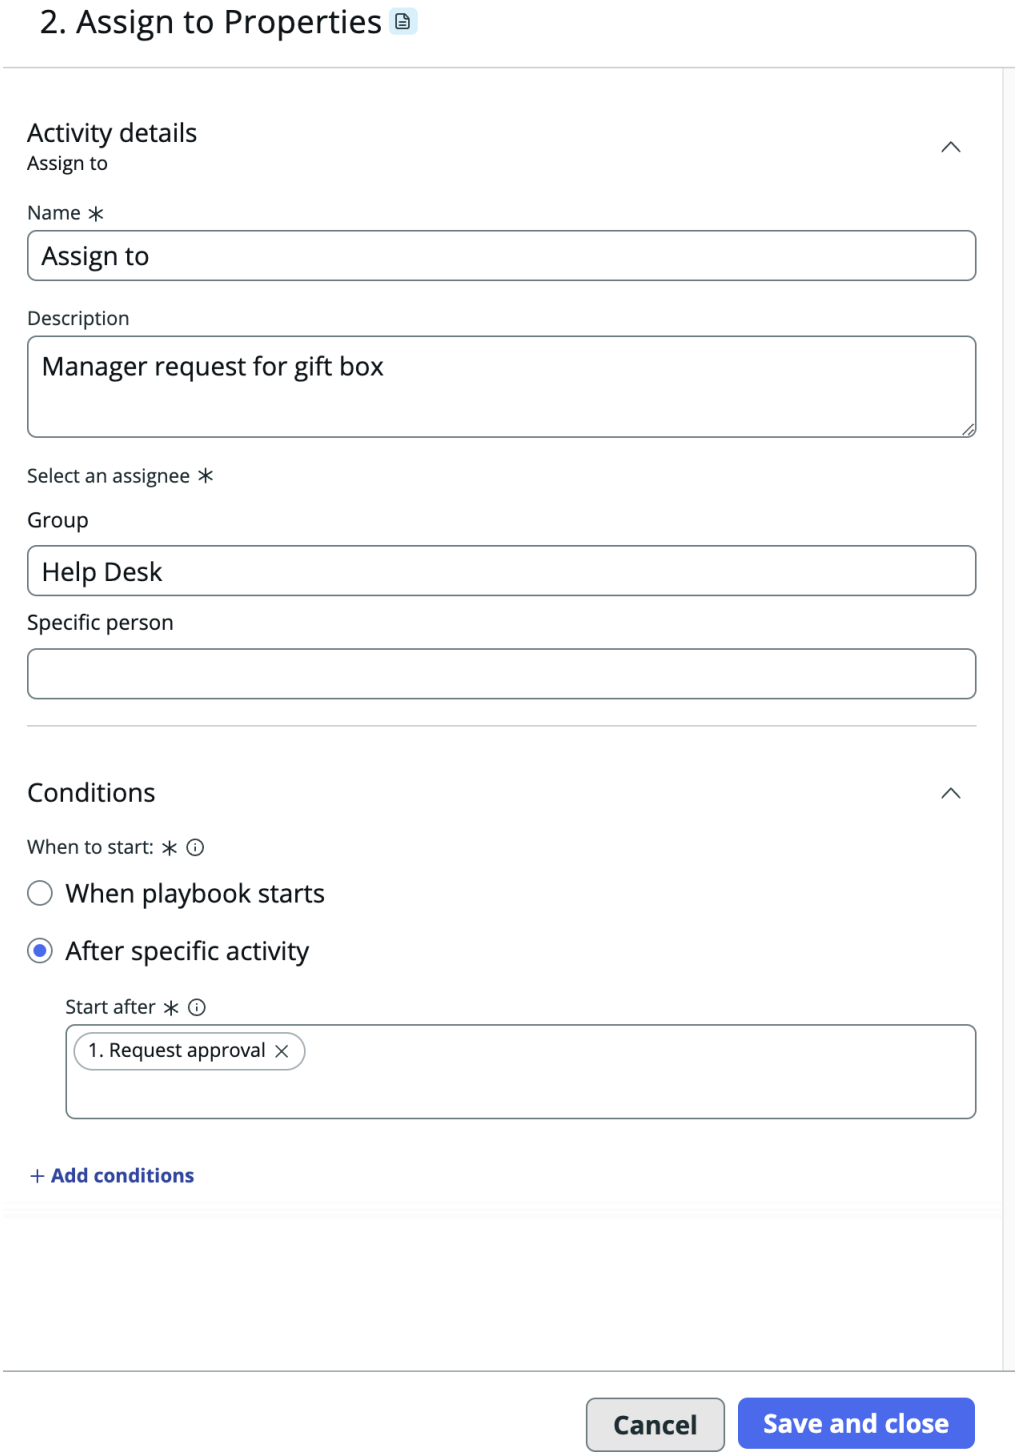


4. Enter the basic details for the activity.

General activity details

Field	Description
Name	Unique, user-facing name for your activity, which appears to agents and fulfillers while the playbook is running.
Description	Optional details about what the activity accomplishes.

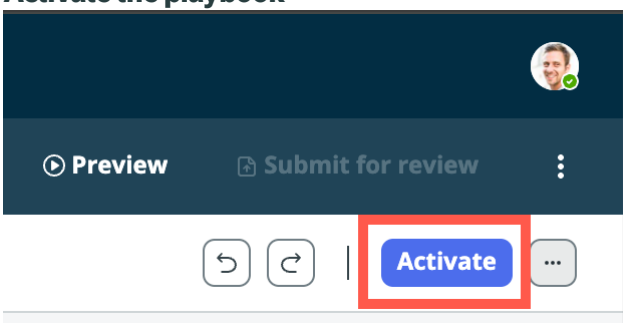
Activity details panel



5. Complete the details for the activity, using Add activities to an app's playbook in Creator Studio for information on how to finish creating the activity.
6. Select the **Save and close** button to finish setting up your activity.
7. Once the automation is done, activate it by selecting the **Activate** button.

Activating a playbook makes it available to run when its related form is created or updated on your non-production, development instance.

Activate the playbook



Result

The app is now ready to be deployed to production! Let's request deployment in the final step of this quick start guide.

Quick Start: Submit your app for deployment

Now that you've made an app, it's time to submit it for review so admins can approve and deploy it.

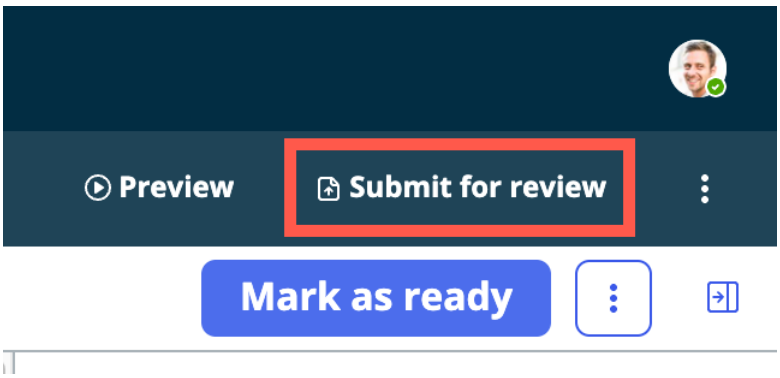
Before you begin

Your system administrator must add you to the Creator Studio Users group.

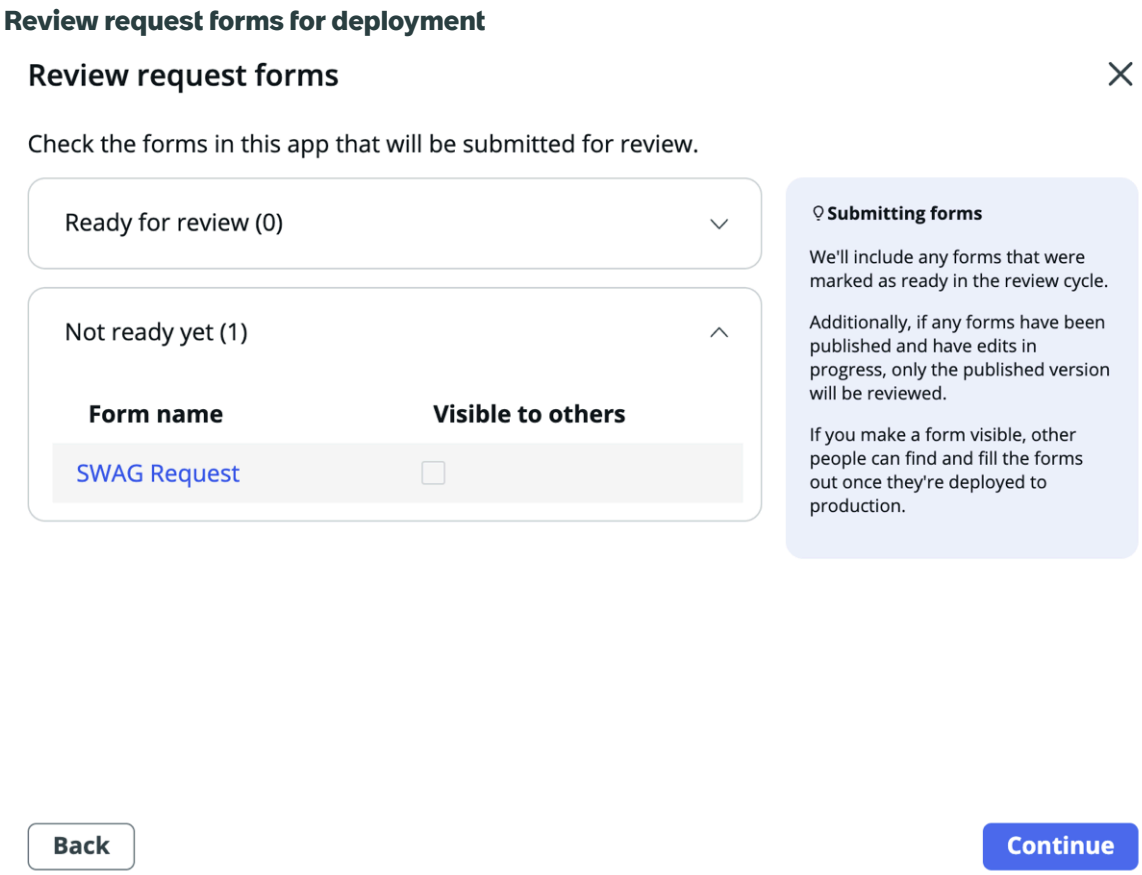
Procedure

1. In the application header, select **Submit for review**.

Submit for review



2. Select **Continue** on the Submit app for review modal.
3. Now you need to choose which published forms are visible to users in the catalog. In the Ready for review section of the Review request forms modal, select which of the app's published forms that you want to be available after the app is deployed selecting the **Visible to others** option.



4. Select **Continue** when you're happy with the forms being deployed to production.
5. Next, you must decide which of the app's activated playbooks will run on production after the app is deployed. In the Review playbooks modal, select the **Run on production** option for each playbook that you want to run on records that the app generates.

   Note:
   If you can't select a playbook, you need to go back to the **Automations** tab of Creator Studio and activate it. If you need a refresher on that, check out Activate a playbook in Creator Studio.

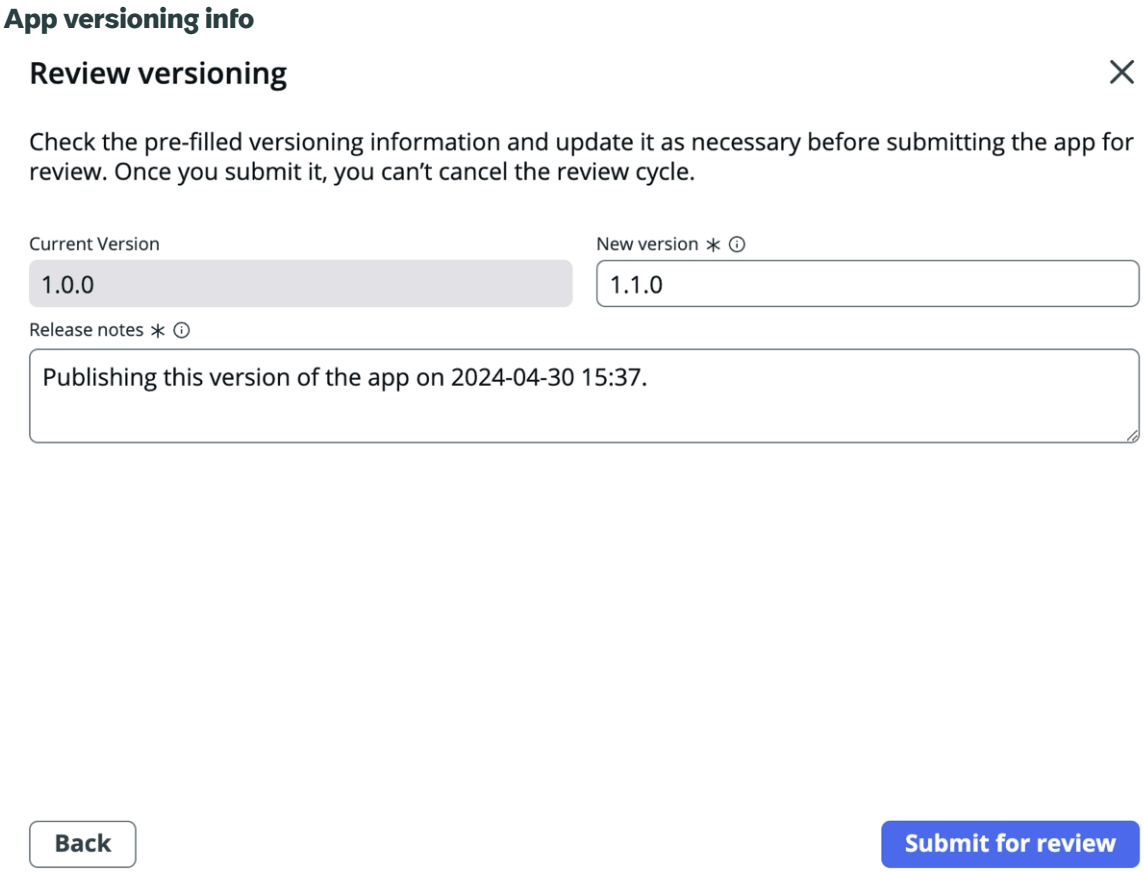
6. Select **Continue** when you're happy with the playbooks being deployed to run on production.
7. Finally, make sure that all the release details for the published app are correct.

Versioning options for deployment

Field	Description
New version	Version number of the app you're requesting for deployment. Creator Studio automatically generates an updated version number, but you can change it. Follow your organization's versioning guidelines, or use the x.y.z format, where x = major update, y = minor update, and z = patch.

Field	Description
Release notes	Details on what's changed in this new version of the app, or a general description of what the app does if this is its first version.

Read more about this step of requesting deployment in App versioning and release notes for Creator Studio apps.



8. Select **Submit for review** when everything is correct and ready for your admin to review and deploy.

Result

Congrats:
Hooray! You've created your app, customized the form, added automation, and submitted it for review. After your admin reviews and deploys it, people will use your brand-new app to make requests.

Get help with Creator Studio

If you need help with Creator Studio, you can watch a short video on how to contact your admin and check out some helpful resources.

Get help now from your Now Support administrator

Watch the following video to find out how to get help quickly.

FAQs

Creator Studio FAQs

Support

Migrating to Creator Studio from Service Creator

Creator Studio is intended to replace the legacy Service Creator offering, which will be retired in the Australia release.

Note:
You can find content for old versions of Service Creator in previous release documentation.

Why you should use Creator Studio instead of Service Creator

Creator Studio has a more modern interface than Service Creator. Creator Studio uses Record Producers directly, implements workflows with Playbooks, and allows fulfillment via Workspaces. It also integrates with deployment pipelines to promote applications created with Creator Studio to production environments.

Process for trying out Creator Studio

If you're a Service Creator user ready to check out Creator Studio, you must do the following:

- Confirm that your instance is on a minimum version of Xanadu patch 3.
- Purchase an App Engine Enterprise license.
- Download Creator Studio from the ServiceNow Store. For more information, see Installing Creator Studio from the ServiceNow Store.
- Activate Creator Studio.

Playbooks vs. workflows

Unlike the workflows that Service Creator used, Creator Studio uses playbooks to automate processes in the apps you build.

Playbooks are a set of activities that occur in order based on a trigger. Each activity is more like a step in a chain of steps. You can add multiple playbooks to an app if you need to.

Playbook activities in Creator Studio replace the process of defining service configurations in Service Creator.

In Service Creator, you had to first create a category for services, and then create the service and its table. Creator Studio automatically creates the table for you when you create an app, and streamlines the category selection process.

For more information, see Working with automation in Creator Studio.

Creating your first app with Creator Studio

Creator Studio helps you create your app by dividing it into smaller parts. Each does something special, and you work on them sequentially.

Summary:
After reading this section, you'll understand:

- The general workflow for building an app
- What goes into the idea for an app
- Who to ask for help

Let's give you a very high-level overview of what you will do in each part.

1. **Let us help you get started.** Start by selecting a catalog template that closely matches the app you want to create. For instance, if you're creating an app for IT issues, there could be a catalog template with pre-designed fields for specifying IT-related problems. While the template might not cover everything you need, it gives you a solid starting point. Check out how you select a catalog template to create your app's first form in Create the foundation of an app in Creator Studio.
2. **Or ask to work on someone else's app!** If you see an app that you want to work on but don't have access to, you can request to get access to it. Find out how in Ask to work on an app in Creator Studio.
3. **Ask for the info you need.** Customize the default catalog template to ask for the specific information your fulfiller needs. How do you know what customizations to make? Ask yourself what info the fulfiller needs to fulfill a request. We'll show you how to add, subtract, and modify the form fields in Customize your form for an app in Creator Studio.
4. **Make your forms available.** Once your form is ready, publish it to make it accessible to requesters. The process is straightforward, and we'll walk you through it in Publish a form for your app in Creator Studio.
5. **Specify the automatic actions that your forms trigger.** You'll want your app to take some action when a requester submits or revises a form. For instance, a new request might trigger approval from a manager. Another action could be emailing the requester to confirm their request submission and provide them with a tracking number. Discover more automation possibilities in Working with automation in Creator Studio.
6. **Customize the workspace fulfillers use.** Creator Studio automatically creates a form submission workspace category where fulfillers work on requests that are ready to use, out of the box. However, you can tweak it to suit your needs, find out how in Working with form submission workspaces in Creator Studio.
7. **Get your app deployed to production.** Once your app is spiffed up, tested, and ready to go, ask an admin to move it to a production environment for you so real users can begin using it to make requests. Find out how in Request deployment for your app from Creator Studio to production.

Use case:
Sam's job at the Example Company is to answer employee requests for office equipment. They've done this for years by receiving emails and keeping spreadsheets of requests, requesters, equipment, prices, dates, and fulfillments. Their company is growing, and the number of requests is now overwhelming. "I'm spending all my time reviewing requests instead of doing all the other parts of my job." They'd like to create an app that enables people to request office equipment, automatically sends an email confirmation of the request, stores the request, and enables them to fulfill or reject the request with the click of a button. They've never written a line of code in their life, but with Creator Studio, they can create the exact application they want.

App compatibility with Creator Studio

You can open apps built in Creator Studio in other ServiceNow products, but only apps built in Creator Studio can be opened in Creator Studio.

Opening Creator Studio apps in other products

After you build an app in Creator Studio, you can open it in several other products. For example, you could build an app in Creator Studio and then open it in ServiceNow Studio to add more complex flows in the automation.

If you add complex functionality to an app in another builder and then re-open the app in Creator Studio, you'll be warned in the appropriate context. For example, if you add complexity to a playbook that's not supported in Creator Studio, then Creator Studio will display a minimal version of the playbook or activity and instruct you to open it in Workflow Studio.

For more information, see the following products:

- ServiceNow Studio
- App Engine Studio
- Catalog Builder

Opening apps built in other products in Creator Studio

You can't open apps created outside of Creator Studio in Creator Studio. For example, you can't open apps built in ServiceNow Studio in Creator Studio.

However, if you create an app in Creator Studio and then add a form to it from outside of Creator Studio (for example, from Service Catalog), then Creator Studio tries to show the outside form.

Creator Studio apps and tables

Creator Studio uses catalog templates to streamline the app creation process. Apps use the Task table, generating a new row for each submitted request.

Summary:
After reading this section, you'll understand:

- The parts that go into building an app
- Where requests from the apps go
- How tables are used to store requests

Parts of building an app

Apps contain one or all of the following parts.

Parts of an app

Functionality	Description
Form	When filled out, forms create a record with an associated task or workflow on the ServiceNow AI Platform.
Automation	Automation contains playbooks, or automated processes with limited actions that enable users to update records and complete tasks across multiple activities.

Parts of an app (continued)

Functionality	Description
Form submissions	Workspace configuration that shows requests for the app built in Creator Studio, with standard and customizable filtered lists. Selecting a record in the **Form submissions** tab displays the record, which you can interact with in Creator Studio, enabling you to see how it will look.

Your admin can create catalog templates to guide the process of building forms. For more information, see Working with forms in Creator Studio.

Where requests from the apps go

Every app in Creator Studio automatically creates a task table where all opened records go when people use the app. The tables that Creator Studio apps generate extend the Request Task table that comes with Creator Studio, which extends the Task table.

Extending a table means the new table inherits the parent (extended) table's columns, as well as its business logic. For more information on Task tables, see Working with the Task table.

For sys admin eyes only: Every app built in Creator Studio adds a record in the Request App Config table. The name of the table follows the format of scope_request, for example, x_snc_02_03_request.

Key term:

Record

A record is what the ServiceNow AI Platform generates for each request submitted through your app. Each record corresponds to a row in the app's Request Task table.

Publishing, activation, and deployment workflow for forms, automation, and apps

When you build an app in Creator Studio, you must create forms and automation. You can also customize the form submission workspace before everything is deployed to production.

As you develop apps in Creator Studio, you should move sequentially through the following sections. For example, you should mark all of an app's forms as ready in the **Forms** section of Creator Studio before you begin to work on the app's **Automations** section.

1. When you're done building forms, publish them by marking them as ready.

   Published forms are then available in the catalog on the non-production instance that you're using for development.

2. When automated playbooks (which are based on the forms you already created) are ready, activate them.

   Published playbooks can be triggered when a form is created or updated on the non-production instance you're using for development.

3. The app's form submission workspace is already available on the non-production instance that you're using for development for you to test and customize. Additionally, you can interact with

test records by selecting the record in the **Form submissions** tab, which opens the test record in a new tab within Creator Studio.

4. When everything looks good and you're ready to deploy the app to production, you submit it for review.
5. After your admin deploys the app to production, the app is available to users whose role gives them access to it. On the production instance:
   - The app is available to users
   - The catalog contains all published forms
   - Activated playbooks are triggered on applicable records
   - Unactivated playbooks are deployed but must be activated by an admin before they can run
   - Users can access the workspace to review the app's form submissions
6. To update a published app, make the changes on your non-production instance and then request that your admin redeploys the updated app to production.

Configuring Creator Studio

Admins need to install Creator Studio before it can be configured for users to start building apps.

Configuration overview

The following is a general overview of installing and configuring Creator Studio.

1. Decide on an instance strategy, for example, what are your development (non-production) and production instances. For more information, see Creator Studio development instance strategy.
2. Download Creator Studio from the ServiceNow Store and install it. For more information, see Installing Creator Studio from the ServiceNow Store.
3. Run Guided Setup to configure administration and collaboration. For more information, see Configure Creator Studio using Guided Setup.
4. Ensure all users who need access have the correct role. For more information, see Creator Studio roles and personas.

Using Guided Setup to implement Creator Studio

Guided Setup provides a sequence of tasks that help you configure Creator Studio on your ServiceNow instance. Currently, the Guided Setup helps you to set up the following:

- The admin group to define who can administer Creator Studio
- Collaboration descriptors to manage what app owners and editors can do
- Who has full and restricted access to creating apps in Creator Studio

To open Guided Setup for Creator Studio, navigate to **All** > **App Engine** > **Guided Setup – Shared**.

For more information, see Guided setup.

Catalog configuration requirement for Creator Studio

To ensure that forms appear correctly for users, the non-production and production instances must have the same Service Catalog and all of its categories.

Configuring Virtual Agent chatbot previews

If you want forms to appear in the Virtual Agent chatbot, you must install the necessary plugins. For more information, see Activate Virtual Agent.

Installing Creator Studio from the ServiceNow Store

Installing Creator Studio from the ServiceNow Store makes it available for people to build apps on your instance.

Your company must have an App Engine Enterprise license to install and configure Creator Studio.

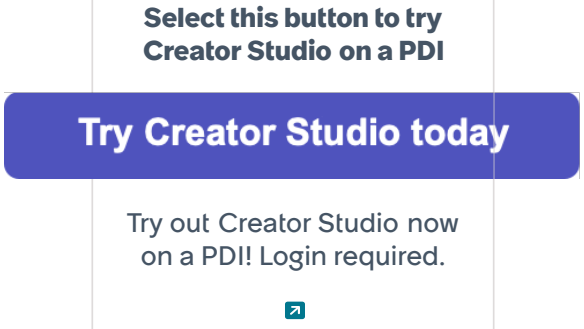
For instructions on installing Creator Studio and other products from the ServiceNow Store, see Install a ServiceNow Store application.

Note:
If you want forms to appear in the Virtual Agent chatbot, you must install the necessary plugins. For more information, see Activate Virtual Agent.

After Creator Studio is installed on an instance, admins have to configure it. The easiest way to do that is using Guided Setup, find out how in Configure Creator Studio using Guided Setup.

Give Creator Studio a try

Ready to give Creator Studio a try? You can test it out using your own Personal Development Instance (PDI), which requires you signing in to the Developer Site. Find out more on PDIs in the Personal developer instance guide.



Creator Studio development instance strategy

Make sure to install Creator Studio on all ServiceNow instances where users will be building applications, including the production instance.

Deciding on your instance strategy

You need to decide how you want to manage access to Creator Studio within your company. Consider the following options:

- **Open Access:** Allow everyone in your company to use Creator Studio to create apps.
- **Restricted Access:** Limit access to a specific group of users.
- **Request-Based Access:** Set up a form where users can apply for access. Admins will review these requests and decide whether to grant access.

Development and deploying to production instances

A non-production instance that is similarly configured to your production instance may be the best candidate for your test environment. You can then more accurately find issues that may arise if the application is deployed to production.

You should ensure that developers build apps in Creator Studio on a non-production instance, and then deploy apps that are ready and approved to production.

When you deploy an app, the records are referenced in the Store Apps [sys_store_app] table on the production instance. But when you're developing an app, the records are referenced in the System Applications [sys_app] table. So if you develop in production, you're developing using the [sys_app] table instead of [sys_store_app].

After you establish your instance strategy, you must also establish and automate your approval or review process. Creator Studio runs on your non-production environment, and admins then deploy apps to the production environment. For more information on the deployment process, see Deploying your Creator Studio app.

If your organization has multiple non-production environments, you must decide which non-production environment Creator Studio will run on. You must also determine which pipeline to use for promoting apps from a particular non-production instance to your test instance, and then finally to production where the app will be running live. For more information, see Pipelines and Deployments.

Catalog configuration requirement for Creator Studio

To ensure that forms appear correctly for users, the non-production and production instances must have the same Service Catalog and all of its categories.

Developer roles and testing apps on instances

If you have a Creator Studio role of sn_creatorstudio.user or sn_creatorstudio.restricted_user, you won't be able to test the apps you build on the non-production instance's Request App Workspace. You should be able to test the app on the non-production instance using Creator Studio's app previews. You will be able to test the apps as a fulfiller in the workspace on the app that's been deployed to production.

Use case:

Let's say that a user is in the Creator Studio Users group, so when that user builds an app, that user gets delegated development permissions for that app. That user can then publish a request form, and if there are no roles required for the form, that user can submit requests with the form.

However, that user won't be able to fulfill requests or access the Request App Workspace because that user won't have the x_acme_user_app.agent role, and that user can't give that role to themself. Administrators must assign additional roles as necessary.

Components installed with Creator Studio

When you activate the Creator Studio plugin, various components like tables and user roles are automatically installed.

Note:

The Application Files table lists the components that are installed with this application. For instructions on how to access this table, see Find components installed with an application.

What plugins are required to activate Creator Studio?

You must install the following plugins for Creator Studio:

- Creator Studio [sn_creatorstudio]
- Creator Studio - Global [com.glide.creator_studio.global]

Properties installed with Creator Studio

sn_creatorstudio.history_record_limit

Limits the last accessed history, for example in recent apps and sorting on the Creator Studio home page.

- Type: integer
- Default value: 1000
- Set this value to -1 to disable the limit
- Reduce this value from the default if the home page isn't loading fast enough

Roles installed with Creator Studio

The following table lists all roles installed with Creator Studio. For details on how the roles work with Creator Studio, see Creator Studio roles and personas.

Roles installed with Creator Studio

Role	Description	Contains role
sn_creatorstudio.user	• Provides access to Creator Studio • Users can create new apps	• catalog_builder_editor • sn_collab_request.basic_write • sn_udc.basic_read • sn_creatorstudio.basic_read • sn_collab_request.basic_read • app_template_runner • sn_g_app_creator.app_creator
sn_creatorstudio.restricted_user	• Provides access to Creator Studio • Users can't create new apps	• catalog_builder_editor • sn_creatorstudio.app_requestor • sn_collab_request.basic_write • sn_udc.basic_read • sn_creatorstudio.basic_read • sn_collab_request.basic_read • app_template_runner
sn_creatorstudio.basic_read	Primitive read access to Creator Studio resources	
sn_creatorstudio.basic_write	Primitive write access to Creator Studio resources	

Roles installed with Creator Studio (continued)

Role	Description	Contains role
sn_creatorstudio.admin_write	Admin write access to Creator Studio	• sn_creatorstudio.basic_read • sn_creatorstudio.basic_write
sn_creatorstudio.app_requestor	Primitive app requester access to Creator Studio resources	
sn_creatorstudio.basic_fulfiller	Gives some fulfillers the following: • Access to the Request App Workspace • Ability to edit some fields in the sn_creatorstudio_task table	canvas_user

Tables installed with Creator Studio

Tables installed

Table	Description
Request Subtask [sn_creatorstudio_child_task]	Extends the Task table.
New Application Admin Task [sn_creatorstudio_new_application_admin_task]	Extends the Task table.
New Application Task [sn_creatorstudio_new_application_task]	Extends the Task table.
Request App Config [sn_creatorstudio_request_app_config]	Extends the Application File table.
Request Task [sn_creatorstudio_task]	Table where all requests from apps made in Creator Studio are stored. **Note:** You must have the Request Task table installed on the production instance as well as the non-production instance.
Creator Studio Activities [sn_creatorstudio_activity]	Table where all standard and custom activities for Creator Studio automations are stored. **Note:** This table is readable by Creator Studio users and delegated developers.

Configure Creator Studio using Guided Setup

So you've installed Creator Studio on an instance. Now what? You must configure it before users can start building apps.

Before you begin

Creator Studio must be installed on the instance before you can configure it. Find out more about that in Installing Creator Studio from the ServiceNow Store.

To ensure that forms appear correctly for users, the non-production and production instances must have the same Service Catalog and all of its categories.

Role required: admin

About this task

Guided Setup streamlines configuring Creator Studio, and keeps track of what you have completed, so you can stop and start again where you left off.

In this Guided Setup, you'll configure user access and collaboration settings to control who can do what in Creator Studio.

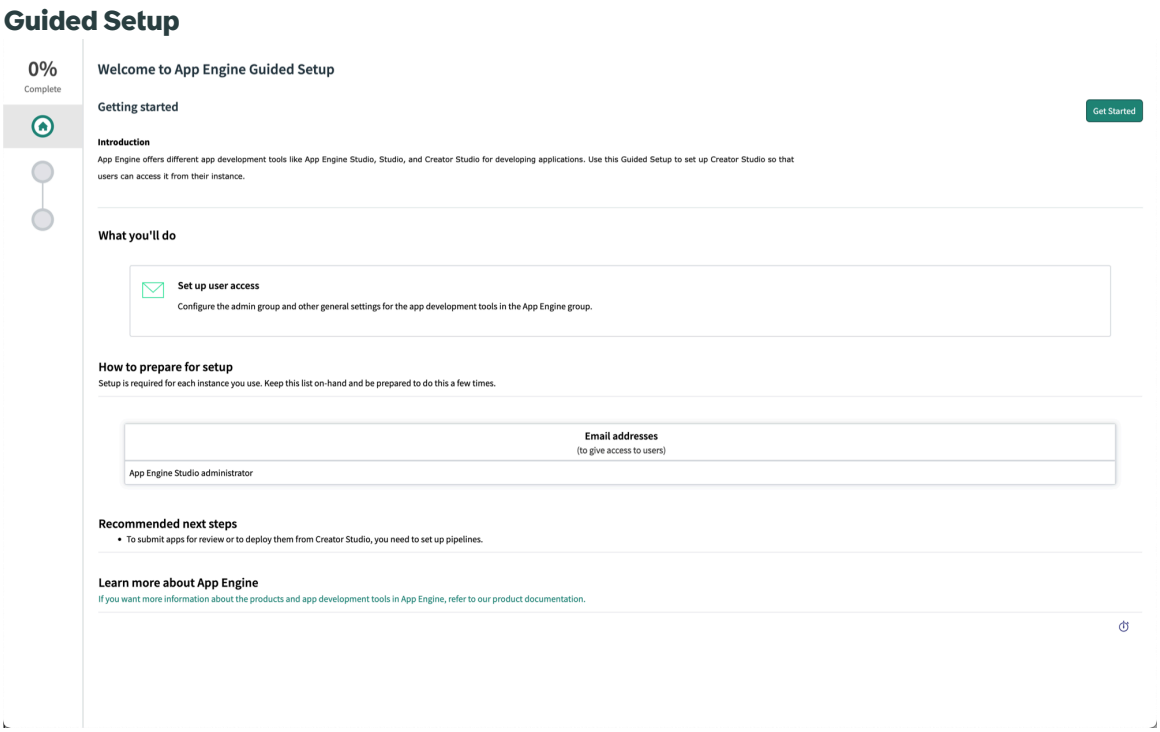
Procedure

1. Let's open Guided Setup. On your instance, select the **All** tab.

   All tab

   
   This tab lets you see all the apps installed on your instance.

2. In the white text field, enter `App Engine`.
   The list of apps displayed underneath the text box now pertains only to App Engine.
3. In the list, select **Guided Setup – Shared**, which starts the configuration process.
   The Guided Setup app opens, where you make some basic configurations.



4. Start the setup process by selecting the **Get Started** button.
5. Configure user access by selecting the **Get Started** button in the Set up user access section.
6. Set up the admin group to enable ServiceNow administrators access to work on and configure Creator Studio.

   a. Select the **Configure** button for the Set up the admin group section.

   b. Make any changes to the App Engine Admins group.
   App Engine Admins approve tasks for app development, such as when restricted users need an app created for them.

   c. Update the record to save your changes.

   d. Select the **Mark as complete** button on the Guided Setup page to indicate that you're done with this step.

7. Set up collaboration descriptors to manage what app Owner and Editor collaboration types can do.
   By default, owners can do anything on an app, while editors are more restricted in what they can do. For more information, see Collaboration in Creator Studio.

   a. Select the **Configure** button for the Set up collaboration descriptors to manage your user's capabilities section.

   b. Customize the collaboration roles or add new ones.
   For more information, see Application collaboration.

c. Update the record to save your changes.

d. Select the **Mark as complete** button on the Guided Setup page to indicate that you're done with this step.

8. Select the **Welcome to App Engine Guided Setup** breadcrumb link to return to the main Guided Setup page.
9. Set up who has full access to Creator Studio by selecting the **Get Started** button in the Set up access to Creator Studio section.
   In this section, you decide which users get full access to work on app in Creator Studio, and who has more limited capabilities. For example, restricted users must request that an admin create a new app for them. For more information, see Creator Studio roles and personas.
10. Set up full access for users by selecting the **Configure** button for the Grant full Creator Studio access to users section.

    a. Add users to the Creator Studio Users Group.
    People in the Creator Studio Users Group have full access to working with apps, and can create apps without needing help from an admin.

    b. Update the record to save your changes.

    c. Select the **Mark as complete** button on the Guided Setup page to indicate that you're done with this step.

11. Set up limited access for users by selecting the **Configure** button for the Grant Creator Studio Restricted Access section.

    a. Add users to the Creator Studio Restricted Users Group.
    People in the Creator Studio Restricted Users Group have limited access to working with apps, and must request that admins create apps for them.

    b. Update the record to save your changes.

    c. Select the **Mark as complete** button on the Guided Setup page to indicate that you're done with this step.

What to do next

After you finish configuring Creator Studio, you can configure Pipelines and Deployments to enable apps built in Creator Studio to be deployed to production. For information on how, see Configure Pipelines and Deployments.

Configuring Pipelines and Deployments to deploy apps built in Creator Studio

You can install Pipelines and Deployments and configure a controller instance to deploy apps built in Creator Studio to production instances.

For details on how to set up Pipelines and Deployments, see Configure Pipelines and Deployments.

Creator Studio roles and personas

Roles control what everyone you work with can do in Creator Studio. Administrators assign roles to give team members permission to configure or use Creator Studio.

The two roles for Creator Studio are used to restrict access from creating new apps, which helps make sure your instance isn't overfilled with redundant, unplanned, or unused apps.

Personas that use Creator Studio

Personas aren't explicitly part of Creator Studio, but administrators assign roles to give team members permission to configure or use Creator Studio.

Low-code/citizen developer

Low-code/citizen developers are tech savvy and interested in creating apps. Though they might not have formal coding or app development training, citizen developers can submit ideas for new apps and, if approved, build them using Creator Studio.

Low-code/citizen developers have either the sn_creatorstudio.user or sn_creatorstudio.restricted_user role.

App Engine admin

App Engine admins manage all processes related to app development in Creator Studio. They review new app ideas, handle app deployment, and manage collaborators, usually in the App Engine Management Center.

App Engine admins have the app_engine_admin role and must be in the app_engine_admin group.

Security admin

The security admin creates and modifies roles and access control lists for apps. This role is set on the platform level, and it is required for making updates to roles in Creator Studio.

System administrator

The system administrator has access to all system features, functions, and data, regardless of security constraints. Grant this privilege carefully. If you have sensitive information, such as HR records, that you must protect, create a custom admin role for that area and train a person who is authorized to see those records to act as the administrator.

Roles and what they can do in Creator Studio

In addition to the roles in the following table, users with the admin and delegated_developer roles can also access Creator Studio.

For complete details on which roles each role contains, see Components installed with Creator Studio.

Creator Studio roles

Role	Name	Description
Creator Studio User	sn_creatorstudio.user	• Users can create apps in Creator Studio. • The user is automatically delegated as the app owner. For more information, see

Creator Studio roles (continued)

Role	Name	Description
		Delegated development and deployment. • Contains sn_g_app_creator.app_creator. **Note:** This role gets assigned the delegated_developer role when they create or get access to an app.
Creator Studio Restricted User	sn_creatorstudio.restricted_user	• Users can't create apps in Creator Studio. • Users can request apps to be created for them, and to work on an app. • Users can work on apps that they've been designated as developers for. • When assigned to work on an app, this user gets the delegated_developer role for that app.
App Engine Admin	app_engine_admin	• Approve requests from restricted users to create an app. • Approve collaboration requests. • Contains sn_creator_studio.admin_write and sn_creator_studio.basic_write to enable admins to see the apps they need to approve.

Note:

To ensure that users can use the Collaboration Approval Workflow regardless of instance versions, admins must assign the catalog _builder_editor role to Creator Studio user groups.

User groups and what they can do in Creator Studio

Groups are a standard functionality that help you quickly control people's access to Creator Studio by adding them to a group.

Creator studio user groups

Group	Description
Creator Studio Users	• Users are automatically approved to create apps in Creator Studio. • Contains sn_creatorstudio.user.
Creator Studio Restricted Users	• Users in this group need to request applications be created in Creator Studio on their behalf. • Contains sn_creatorstudio.restricted_user.

Developer roles and testing apps on instances

If you have a Creator Studio role of sn_creatorstudio.user or sn_creatorstudio.restricted_user, you won't be able to test the apps you build on the non-production instance's Request App Workspace. You should be able to test the app on the non-production instance using Creator Studio's app previews. You will be able to test the apps as a fulfiller in the workspace on the app that's been deployed to production.

Use case:

Let's say that a user is in the Creator Studio Users group, so when that user builds an app, that user gets delegated development permissions for that app. That user can then publish a request form, and if there are no roles required for the form, that user can submit requests with the form.

However, that user won't be able to fulfill requests or access the Request App Workspace because that user won't have the x_acme_user_app.agent role, and that user can't give that role to themself. Administrators must assign additional roles as necessary.

Collaboration roles and instances on different versions

As admins implement Creator Studio, they may have it installed on a non-production instance while their production instance is on a previous version of the ServiceNow AI Platform that doesn't have Creator Studio. This mis-match of instance versions affects the Collaboration Approval Workflow, which specifies the non-production instance as the source and the production instance as the controller. If the controller doesn't have the version of the collaboration plugin that supports Creator Studio, collaboration is unsupported.

To ensure that users can use the Collaboration Approval Workflow regardless of instance versions, admins must assign the catalog _builder_editor role to Creator Studio user groups.

Roles and app development collaboration

Roles define user access to Creator Studio. Permission to work on individual apps is controlled on an app-by-app basis. That is, you must manage the collaborators for each app by inviting other citizen developers to work on the app with you, or request to join someone else's app. For more information, see Collaboration in Creator Studio.

Creator Studio and domain separation

Domain separation is not supported in Creator Studio. This means that you can't separate data, processes, and administrative tasks into distinct groups, called domains, within the ServiceNow AI Platform.

No support for domain separation

Though there may be a domain specified on data tables that Creator Studio uses, Creator Studio doesn't provide any special handling of data based on domains.

For more information on support levels, see Application support for domain separation.

Related topics

Domain separation for service providers

Administering Creator Studio

Admins have special privileges to approve and update tasks in Creator Studio that regular users can't. Admins can create apps for restricted users, manage collaboration requests, configure custom activities for playbooks, and deploy apps to production.

Approve Creator Studio requests to create an app

Respond to app creation requests made by users who can't create apps themselves, ensuring that your organization doesn't have too many or redundant apps.

Before you begin
Role required: app_engine_admin

About this task
People with the Creator Studio Restricted User role aren't allowed to create apps themselves, but they can work on them after you approve their creation in the Application Tasks table of Request App Administration.

If your organization has App Engine Management Center, you can approve requests there, too. For more information, see Manage app requests from Creator Studio.

Procedure

1. Navigate to **All** > **App Engine** > **Request App Administration** > **Application Tasks**.
   You can also select the link in any emails you receive notifying you of app creation requests.
2. Find the request you want to approve or decline.
   Filter on columns or use the search bar if you need help finding requests.
3. Select the **Number** of the request to review.
4. Select the **Approve** or **Reject** button to approve or decline the app creation request.

Result
The user who made the request receives an email notification with the approval result. If you approved, they can start building out their app in Creator Studio!

Administering collaboration in Creator Studio

In Creator Studio, as an administrator or App Engine admin, you have the power to manage how people work together on projects.

You can approve collaboration requests, enabling delegated developers to work together on an app.

Collaboration descriptors are like permission levels that determine what someone can do in an app. Admins can assign and customize collaboration descriptors.

The following collaboration descriptors are available for Creator Studio:

Collaboration descriptions

Permission	Description	What they can do in the app
Manage collaborators	You can control who has access to the app and what they can do.	• Change permissions for users and groups. • Remove people from working on the app.
Invite collaborators	You can bring in new people to work on the app.	• Invite users and groups to join the app. • Invited people become editors of the app, meaning they can make changes.

Approve a collaboration request

Admins and App Engine admin can review and approve (or reject) people's requests to join an app's development in Creator Studio.

Before you begin

If you have a controller instance configured, you must approve collaboration requests on your controller instance, not the non-production instance with Creator Studio. The controller instance is typically the production instance, but it can vary depending on how your Pipelines and Deployments application is configured. For more information, see Configure your controller instance.

Role required: app_engine_admin

About this task

Note:
Users with a delegated developer role are automatically approved for collaboration.

Procedure

1. Navigate to **All** > *App Engine* > **Collaboration** > **Collaboration Tasks**.
2. Select the collaboration request in the **Number** column of the collaboration table.
   You can search or filter on the **App name** or **Invitee name** columns to find the request faster.
3. Update the approval status in the **State** field.
   - **Closed – Approved**
   - **Closed – Rejected**
   - **Canceled**
   - **Closed – Failed**
4. Update the record to save your changes.

Manage Creator Studio collaboration permissions on the ServiceNow AI Platform

In Creator Studio, you can control how people work together on apps by setting up permissions called collaboration descriptors. These descriptors define what users can and cannot do.

Before you begin

Role required: app_engine_admin, and permission to Manage collaborators

About this task

Users with the Manage collaborators permission can adjust who can collaborate on the apps they own. For more information, check Manage collaborators for an app in Creator Studio.

Note:
The way that collaboration permissions appear may vary depending on whether your instance has App Engine Studio installed.

Procedure

1. Navigate to **All** > *App Engine* > **Collaboration** > **Descriptors**.
2. Edit the permissions for a collaboration descriptor, such as owner or editor.
   a. Find and select the **Name** of the descriptor you want to modify.
   b. Choose a **Development permission set**, such as **Service Catalog**, to update its permissions. For a list of permissions, see Collaboration permissions.
   c. Select **Save** and **Update**.
3. Assign the updated descriptor to users or groups.
   a. Select the descriptor **Name**, such as **Owner** or **Editor**.
   b. Select the applicable tab to assign either users or groups:
      - **App Collaboration Users** tab: For individual users
      - **App Collaboration Groups** tab: For groups of users
   c. Select the **New** button.
   d. On the form, fill in the fields.
      For more information, see the following topics:
      - Assign collaboration descriptors to users
      - Assign collaboration descriptors to groups
   e. Select **Save**.
4. **Optional:** If you need a new collaboration descriptor, create a custom one.
   a. Select the **New** button.
   b. On the form, fill in the fields.

App Collaboration Descriptor form

Field	Description
Name	Name for the descriptor.
Description	Description of what the descriptor can do. Examples are as follows: ▪ Owner ▪ Editor
Application	Scope of the collaboration descriptor. Currently, all collaboration descriptors must be created in the global scope.
Standard	Option for inviting other collaborators with this role.

c. Select **Submit**.

Result

You've now set up collaboration descriptors, defined permissions, and assigned roles to users and groups for specific apps. For complete details on using the Collaboration app, see Application collaboration.

Customized app collaboration permissions in Creator Studio

When you customize collaboration permissions, you can choose more granular actions and parts of the app that users can work with in Creator Studio.

Use these permissions when managing collaboration, either as an admin or app owner. For more information, see the following topics:

- Manage Creator Studio collaboration permissions on the ServiceNow AI Platform
- Manage collaborators for an app in Creator Studio

File types custom collaboration permissions

File type collaboration permissions

Permission	Description	Owner default setting	Editor default setting
All File Types	Grants access to work with all types of files, including additional file types not granted by the other options.	Yes	Yes
Integrations	Grants access to web service APIs, REST APIs, data sources, and Integration Hub - Import.	Yes	Yes
Reporting	Grants access to reports and scheduled reports.	Yes	Yes

File type collaboration permissions (continued)

Permission	Description	Owner default setting	Editor default setting
Mobile builders	Grants access to build mobile experiences, such as with Mobile App Builder.	Yes	Yes
UI Builder	Grants access to work with UI Builder to build out more complex interfaces.	Yes	Yes
Workflow	Grants access to Workflow Editor and Activity Creator.	Yes	Yes
Service Portal	Grants access to work with Service Portal editors and tools.	Yes	Yes
Workflow Studio	Grants access to the Workflow Studio design environment to create flows and actions.	Yes	Yes
Service Catalog	Grants access to work with catalog-related file types such as catalog items, record producers, and variables to add catalog items to apps.	Yes	Yes
Tables & forms	Grants access to model and layout-related file types such as table columns, form layout, and list layout.	Yes	Yes
Decision Tables	Grants access to work with decision tables to create decision logic based on multiple if-else rules.	Yes	Yes
Playbooks	Grants access to work with the Playbooks design environment to create processes. Editing activity subflows or actions requires the **Flow Designer** permission.	Yes	Yes
Notifications	Grants access to create automatic email notifications	Yes	Yes

File type collaboration permissions (continued)

Permission	Description	Owner default setting	Editor default setting
	and work with email templates.		

Security/Entitlement custom collaboration permissions

Manage access control grants access to security management files, such as Access Control Lists and roles.

The default setting for both owners and editors is selected.

Programming tools custom collaboration permissions

Allow scripting grants access to script fields, such as those in Business Rule, UI Action, and Client Script.

The default setting for both owners and editors is de-selected.

Application management custom collaboration permissions

Application management collaboration permissions

Permission	Description	Owner default setting	Editor default setting
Delete application	Grants access to delete the app.	Yes	No
Manage collaborators	Grants access to change the developers and their permissions to collaborate on an app.	Yes	No
Source control	Grants access to work with source control tool integrations.	No	No
Invite collaborators	Grants access to invite developers to collaborate on an app.	Yes	Yes

Deployment custom collaboration permissions

Deployment collaboration permissions

Permission	Description	Owner default setting	Editor default setting
Upgrade app	Grants access to upgrade applications.	No	No
Submit for deployment	Grants access to request deployment for an app.	Yes	No

Deployment collaboration permissions (continued)

Permission	Description	Owner default setting	Editor default setting
Publish app to repo	Grants access to publish the app to your repo.	No	No
Publish to app store	Grants access to publish the app to your app store.	No	No

Administering templates and forms for Creator Studio

As an admin, you can create custom templates and pre-configured questions to help streamline and guide users when they build apps in Creator Studio.

Check out an article on Creating catalog templates for Creator Studio.

Creating catalog templates for use in Creator Studio apps

As a ServiceNow admin, you can create customized catalog templates in Service Catalog to guide users through adding forms in Creator Studio.

For example, if your users will be building several apps for IT fulfilment, you may want to create a catalog template that contains only IT service requests.

When you add a catalog template to help users create forms in Creator Studio, you must use the following configurations:

- Create a record producer template.
- Leave the **Destination table** (which is called the **Record submission table in Creator Studio**) as undefined.
- Ensure that the Creator Studio Users group can access the template. The template can also be available to all users.

Additionally, you may want to use the catalog template to restrict the catalogs that users can choose when creating an app.

For more details on how to add catalog templates, see Creating or editing catalog item template.

Check out an article on Creating catalog templates for Creator Studio.

Creating question sets for use in Creator Studio forms

Admins can create pre-configured question sets that can be reused across multiple forms without being changed in Creator Studio.

Question sets enable admins to create curated, uneditable questions that users can include on forms without worrying about tweaking their content.

Additionally, you can create question sets with multiple questions if you want several reusable questions to always be grouped together.

See Create a variable set and add it to an item to find out how to create a question set in Service Catalog.

Administering activities in Creator Studio

As an admin, you can define custom activities, make them available in Creator Studio, and hide existing activities to help guide users when they add automation to apps.

You may want to create custom activities for complex or company-specific workflows. For example:

- The standard Request approval activity has a **Requester's manager** option, but you may need a **Department manager** instead.
- You may need an approval or flow with more complex decision logic than is easily built in the Creator Studio automation. You could use Workflow Studio to build that flow, and then create a custom action that calls it.
- You may want more notification types than the standard Email notification activity. You could create a flow that sends a notification to a MS Teams integration, and create an activity that calls that flow.

Steps to create a custom activity in Creator Studio

There are multiple steps to add custom activities for use in Creator Studio automations.

Adding a completely new activity

The steps to create a custom activity for a playbook are as follows:

1. **Create the flow, subflow, or action**: An admin or someone with the correct role must first create the flow, subflow, or action in Workflow Studio. For more information, see General guidelines for Workflow Studio flows, subflows, and actions.
2. **Define the activity**: An admin then defines the activity by adding it to the Activity Definition table and assigning the flow/subflow/action to a playbook activity. This step is also when the admin specifies which inputs can be made available as fields in the activity settings in Creator Studio playbooks. For more information, see Activity definitions and Create an activity definition.

   Note:
   If an activity definition already exists for the activity you want, you can skip this step.

3. **Make the activity available in Creator Studio**: An App Engine admin adds the activity to the Creator Studio Activities table. For more information, see Make a custom activity available for playbooks in Creator Studio.

Making existing activities and playbooks available in Creator Studio

Admins can make existing flows, subflows, and actions available in Creator Studio by defining the activity and then adding it to the Creator Studio Activities table (the preceding steps 2 and 3).

Admins can also make existing playbook activities available in Creator Studio by adding them to the Creator Studio Activities table (the preceding step 3).

Note:
Creator Studio admins can see the Activity Definitions [sn_pd_activity_definition] table by default, which also enables them to administer processes in Workflow Studio.

Make a custom activity available for playbooks in Creator Studio

You must add custom activities to the Creator Studio Activities table [sn_creatorstudio_activity] before users can add them to playbooks when building apps.

About this task

You may want to create custom activities for complex or company-specific workflows. For example:

- The standard Request approval activity has a **Requester's manager** option, but you may need a **Department manager** instead.
- You may need an approval or flow with more complex decision logic than is easily built in the Creator Studio automation. You could use Workflow Studio to build that flow, and then create a custom action that calls it.
- You may want more notification types than the standard Email notification activity. You could create a flow that sends a notification to a MS Teams integration, and create an activity that calls that flow.

Before you begin

The following steps must be completed before you can make a custom activity available in Creator Studio:

1. **Create the flow, subflow, or action**: An admin or someone with the correct role must first create the flow, subflow, or action in Workflow Studio. For more information, see General guidelines for Workflow Studio flows, subflows, and actions.
2. **Define the activity**: An admin then defines the activity by adding it to the Activity Definition table and assigning the flow/subflow/action to a playbook activity. This step is also when the admin specifies which inputs can be made available as fields in the activity settings in Creator Studio playbooks. For more information, see Activity definitions and Create an activity definition.

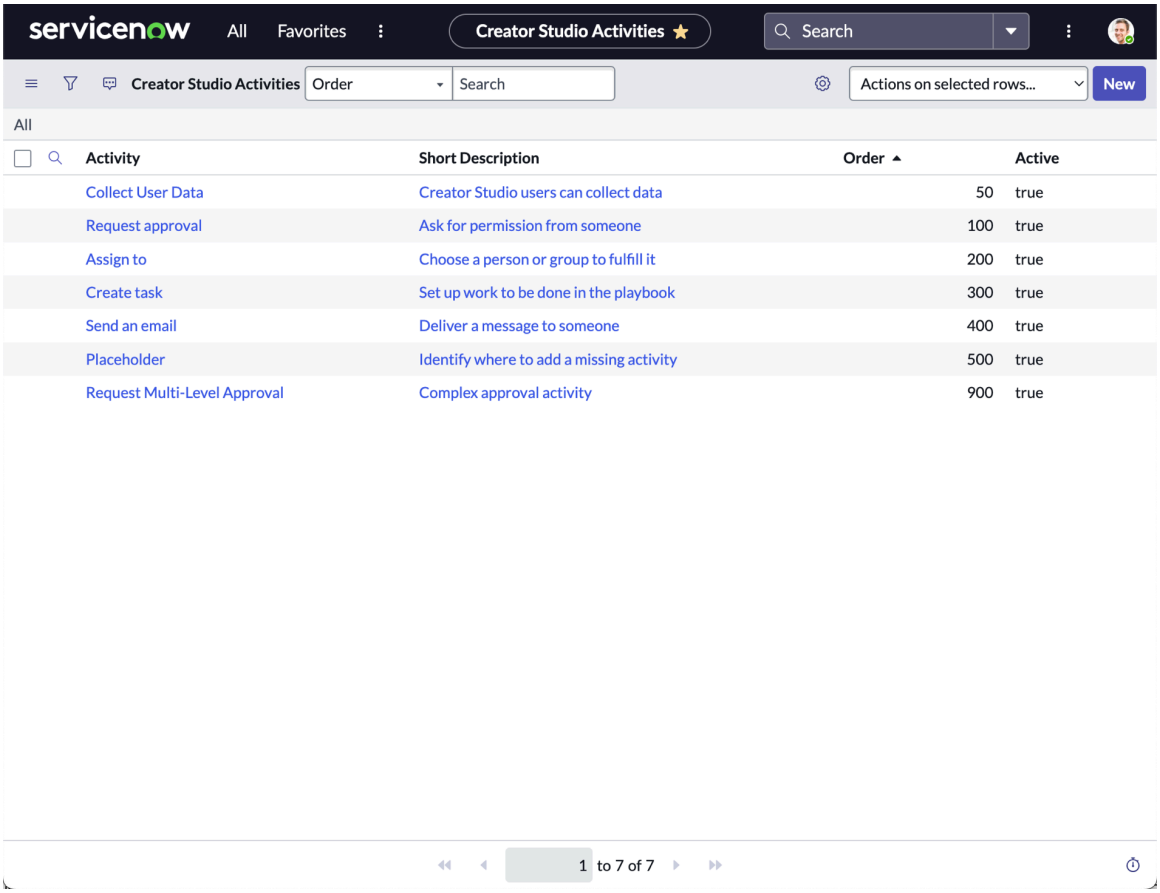
   Note:
   If an activity definition already exists for the activity you want, you can skip this step.

Role required: admin or app_engine_admin

Procedure

1. Navigate to **All** > *App Engine* > **Request App Administration** > *Creator Studio* **Activities**.
   All of the standard Creator Studio activities appear in the list, not just custom activities.
   The Creator Studio Activities table appears.

Creator Studio Activities table



2. Create the foundation of the new activity.

a. Select the **New** button.

b. On the record, fill in the fields.

Field	Description
Activity	Search for and select the type of activity that will be the foundation of your custom activity. For example, create a complex approval activity by selecting **Request Multi-Level Approval**. **Note:** Once you choose an activity, you can select the information icon ( ) to preview its Activity Definition record.
Order	Order that the activity appears in the Creator Studio activity picker list.

Field	Description
	For example, an activity with order number 400 appears before an activity with order number 500.
Short description	Brief description of the custom activity, which appears in the activity picker.

To see a list of all the available activities you can add:

- See Workflow Studio actions for all standard actions.
- See Workflow Studio flow logic for a list of all flows.
- See your list of all available subflows in Workflow Studio.

c. Confirm that the **Active** option is selected to make the activity appear in Creator Studio.

d. Select **Submit**.

3. Specify which fields appear in the playbook activity's properties panel.

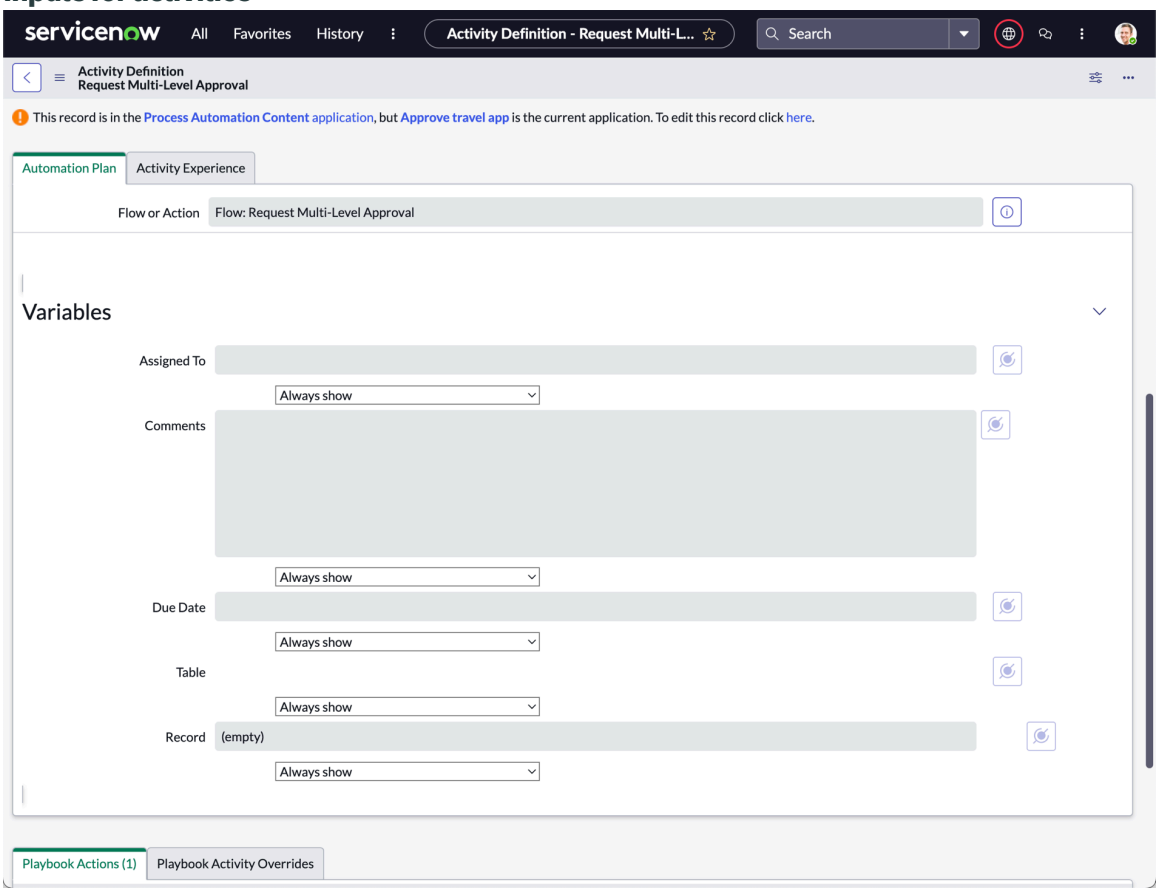
Note:
The fields that appear may have already been configured in the process of defining the activity. If so, follow these steps to verify that the available fields are correct.

a. Open the definition for the newly created activity by selecting it from the **Activity** column of the Creator Studio Activities table.

b. Confirm that the **Automation Plan** tab is selected.

c. Make the field appear for the activity's properties in a Creator Studio by selecting **Always Show**.
For example, set the **Assigned To** field to **Always Show** to users building a playbook in Creator Studio.

Inputs for activities



For more information, see Add dynamic inputs to an activity.

d. **Optional:** Hide a field from the properties panel by setting it to **Show as additional property for admins only.**

e. Repeat these steps for every field that should be visible on the properties panel.

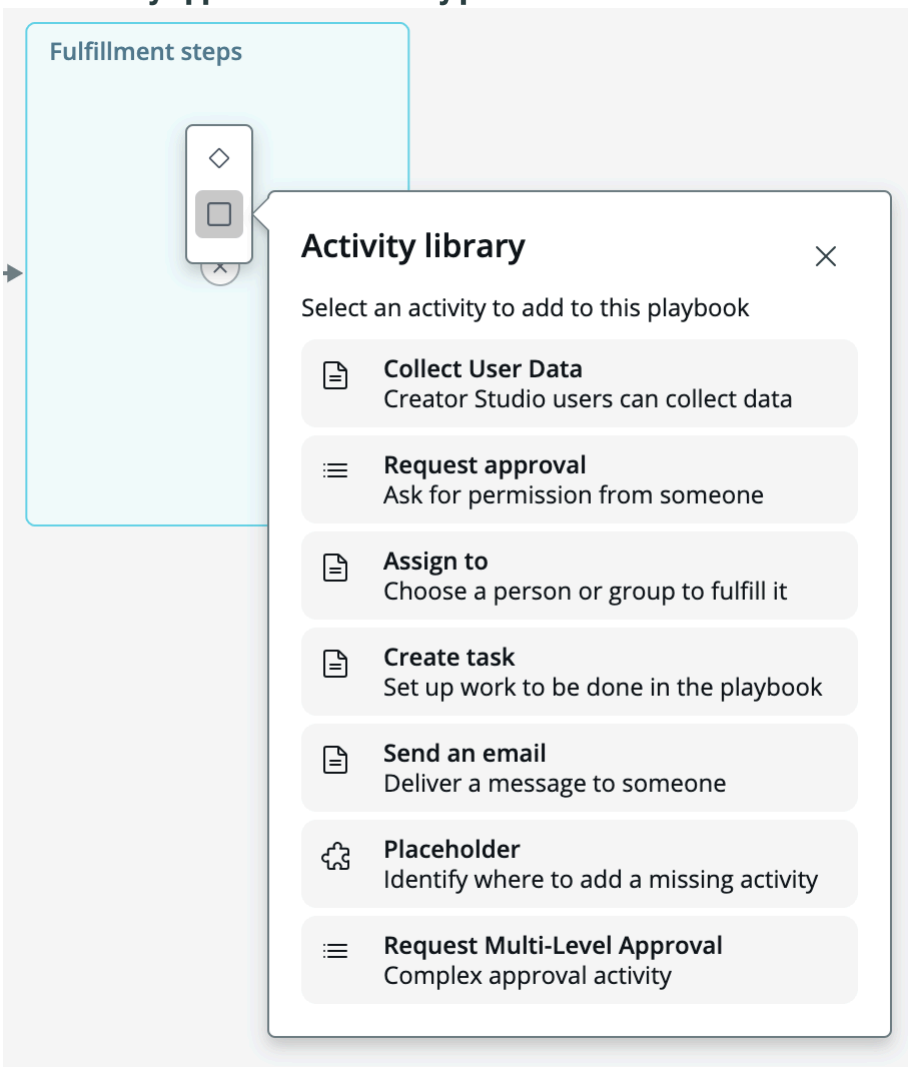
f. Save the record.

4. Return to the Creator Studio Activities table.
5. Review the Creator Studio Activity record by selecting is **Short Description** field.
6. Confirm that the **Active** option is selected, and that everything else is correct.
7. **Optional:** Save the record if you made any additional changes by selecting the **Update** button.

Result

The new activity appears in the activity picker in Creator Studio.

New activity appears in the activity picker



Reorder how activities appear in a playbook's activity picker

Change the order that activities appear in the activity picker in Creator Studio to present them in the order you want.

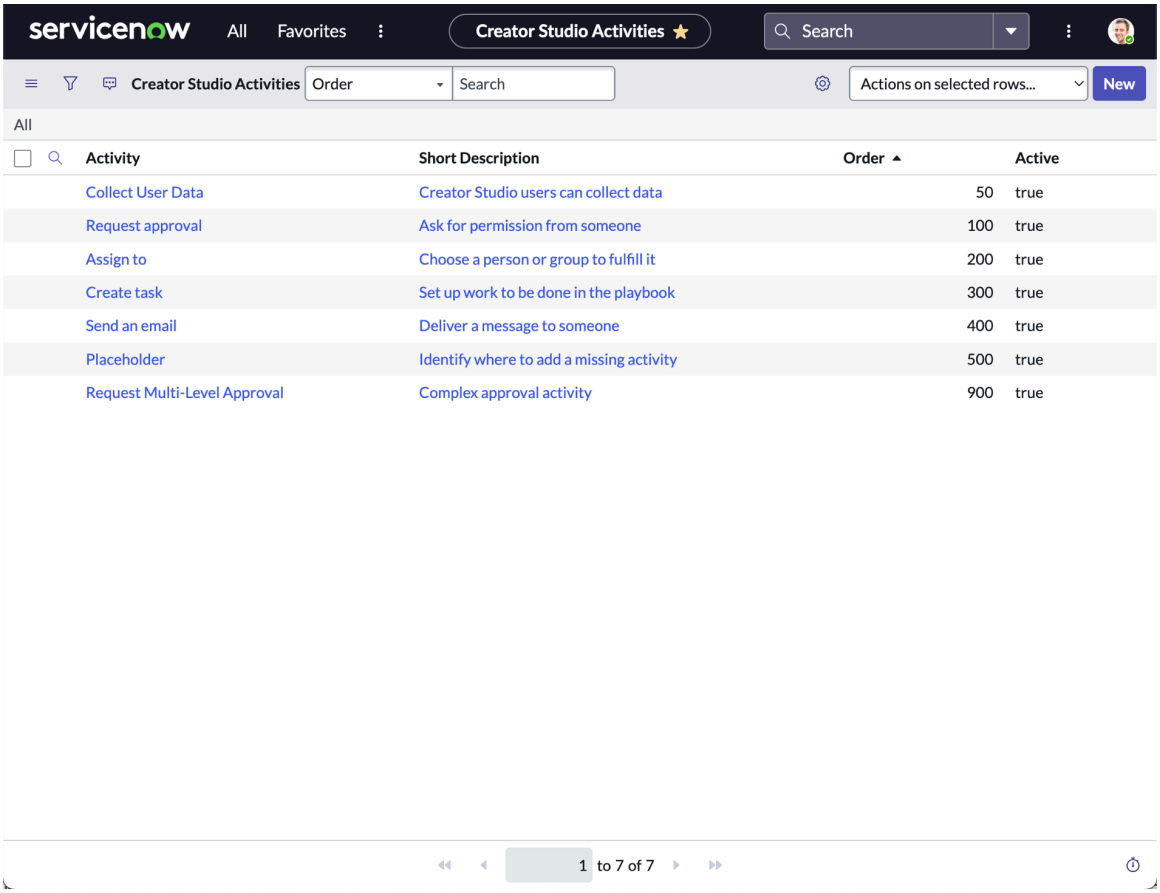
Before you begin

Role required: admin or app_engine_admin

Procedure

1. Navigate to **All** > *App Engine* > **Request App Administration** > *Creator Studio* **Activities**.
   All of the standard Creator Studio activities appear in the list, not just custom activities.
   The Creator Studio Activities table appears.

Creator Studio Activities table



2. Select into the **Order** column for the activity that you want to change the order of.
3. Enter a number to represent where in the activity picker list the activity should appear.

   For example, an activity with order number 400 appears before an activity with order number 500.

4. Select the save icon ( ) to complete the update.
5. Change the **Order** for every activity that you want.

What to do next

Alternatively, you can open each Creator Studio Activity record and update the **Order** one record at a time.

Make an activity unavailable in playbooks

Deactivate an activity to stop users from adding it to playbooks in Creator Studio.

Before you begin

For example, you could hide an base system activity, like sending an email, if it's not relevant to your workflow.

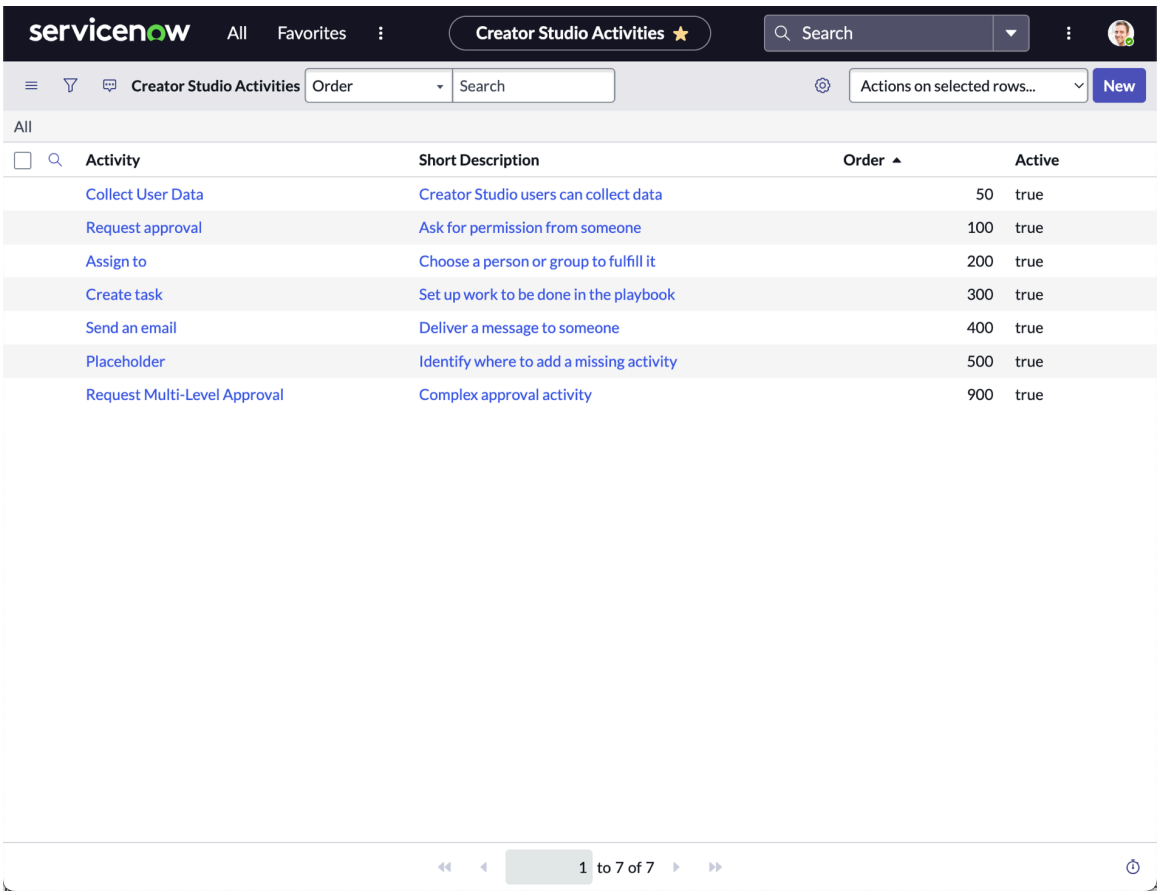
Note:
Hiding an activity doesn't change anything about the processes using that activity. Hiding an activity only makes it unavailable in Creator Studio.

Role required: admin or app_engine_admin

Procedure

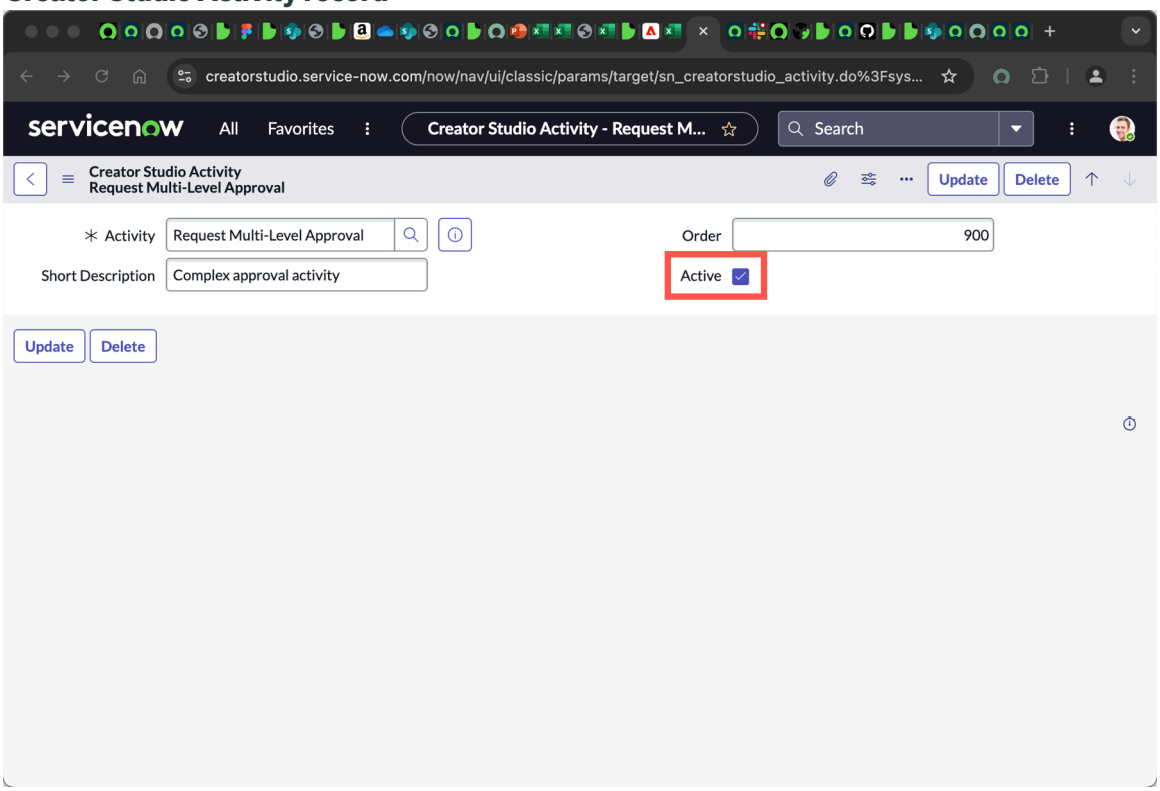
1. Navigate to **All** > *App Engine* > **Request App Administration** > *Creator Studio* **Activities**.
   All of the standard Creator Studio activities appear in the list, not just custom activities.
   The Creator Studio Activities table appears.

Creator Studio Activities table



2. Open the Creator Studio Activity record for the activity that you want to hide by selecting is **Short Description** field.
3. Hide the activity by clearing the **Active** check box.

Creator Studio Activity record



4. Select **Update** to save the record.

Managing Creator Studio deployments and monitoring app usage

After users create apps, they submit them for you, the admin, to review and deploy. How you deploy them depends on whether you have App Engine Management Center (AEMC) installed on the instance.

Managing app deployment with AEMC

Apps aren't deployed directly from Creator Studio. Instead, use App Engine Management Center (AEMC).

Find details on deploying apps in Managing deployments using pipelines in AEMC.

Managing app deployment without AEMC

If you don't have AEMC installed, you can use Pipelines and Deployments and the Deployment Tasks table to publish to the Application Repository. For more information, see Pipelines and Deployments workflow version 24.1.2.

You can view and edit details of the deployment on the **Scheduled Deployments** tab of Pipelines and Deployments For more information, see Managing app deployments using Pipelines and Deployments.

Monitoring deployed app usage

After you deploy an app to production, you can monitor its usage, adoption, and response rate, for each request form in the same way that you do for catalog items/record producers or scoped apps.

For example, you can use AEMC to monitor apps. For more information, see Managing custom apps using AEMC.

Artifacts that Creator Studio generates when users create an app

When a user creates an app in Creator Studio, the ServiceNow AI Platform creates several metadata artifacts, such as tables.

For each app users add in Creator Studio, the following artifacts are added to the ServiceNow AI Platform.

Installed with each created app

Artifact	Details
New table that extends from the base Request Task table	• Name: [scope]_request (for example, x_snc_marketing_request) • Label: [App name] + Requests (for example, Marketing Request) **Note:** All of the form questions are stored as catalog variables in the app's Request Task table.
Fulfiller role	• Name: [scope].agent • Provides access to the table created by the app
Access Control Lists (ACLs)	Provides CRUD access to the new table for the fulfiller and requester roles.
Category for the new app's workspace	Name: [App Name] + Requests
Default lists for the new workspace category	• Open (active=true) • Open – Unassigned (active=true^assigned_toISEMPTY) • Closed (active=false) • All (no conditions)
Dashboard in the new workspace category	Dashboard name: [App Name] + Requests Contents: • A row of single scores: ○ Open requests (active=true) ○ Unassigned requests (active=true and assigned to is empty) ○ Closed last 30 days (closed >= 30 days ago) • A simple list showing all open requests

Administering user access for deployed Creator Studio apps

After users build apps in Creator Studio and you deploy them to production, as an admin, you are responsible for granting access to those apps to users.

Assign user access in production

Applications must be deployed to the production instance, which is where you assign user access.

Users with the agent role are fulfillers, and should automatically get access to apps built in Creator Studio.

Assign users the agent role for the app's scope, for example, `x_snc_jd_it_fulf_0.agent` for an app with the scope `x_snc_jd_it_fulf_0`. For details on assigning roles to users, see Managing roles.

Restricting user access to forms

By default, all users on the production instance get access to forms built in Creator Studio, but Creator Studio developers can choose from existing access criteria if they want to restrict access. The **Available For** and **Not Available For** form settings are lists of User Criteria Records. For more information, see Set security for items and categories.

Developers can work with admins to define new access criteria for their app's forms to define the proper access from within Creator Studio. For more information, see Edit the settings for a form in Creator Studio.

Personas for apps built in Creator Studio

Requester

Someone requesting something, like a piece of equipment or permission to do something.

Fulfiller

Someone who works on requests. Fulfillers may also approve or deny requests, depending on any approval automation for the app.

Building apps with Creator Studio

By now, your admin has set up Creator Studio, given you permission to build an app, and you've got a great idea for a request-fulfillment app! How should you think about using Creator Studio to create your app?

Create forms to gather request information

When finished, your app will look like a catalog of items that people can request. To create your app, you'll:

1. Select one of the available catalog templates.
2. Customize a form to be included in the catalog using a WYSIWYG editor.

   A form describes one item in the catalog and provides space for questions that a requester will answer to specify details about what they want, such as the model number of a laptop. If your catalog needs multiple items, you can create multiple forms.

Automate workflows and simplify tasks with playbooks

Streamlining your request-fulfillment process goes beyond just collecting information. Creator Studio empowers you to automate tasks with powerful playbooks. Think of them as pre-programmed workflows that kick in after a form is submitted.

Here are some things that playbooks can do:

- **Effortless approval routing:** Automatically route requests to the right person for approval, eliminating manual steps and bottlenecks. Imagine a laptop request automatically going to the IT manager for a thumbs-up.
- **Intuitive playbook builder:** No coding required! Create custom playbooks using an easy-to-use editor.

The playbooks you create use the information that people supply when they fill out your forms. So, the more details you ask for, the smoother the process runs.

Workspaces give fulfillers a place to address requests

Once deployed, your app will sit in its own workspace category, which makes it easy for fulfillers to answer requests. You can customize the workspace or use it as-is.

For sys admin eyes only: Every app built in Creator Studio adds a record in the Request App Config table. The name of the table follows the format of scope_request, for example, x_snc_02_03_request.

Find existing apps in Creator Studio

Perhaps you've been given permission to work on an app someone else created, or you want to add new items to the catalog in your app. The Creator Studio home page acts as your central hub, listing all the apps people in your company have built using Creator Studio.

Before you begin

Summary:
In this topic, you'll learn how to:

- Find an app in Creator Studio.
- Open an existing app.
- Perform actions on an app without opening it.

Get permission

To work on an app, your system administrator has to assign you the role of sn_creatorstudio.user or sn_creatorstudio.restricted_user.

About this task

Techy detail:
All the apps listed on the Creator Studio home page have an entry in the Request App Config table (sn_creatorstudio_request_app_config).

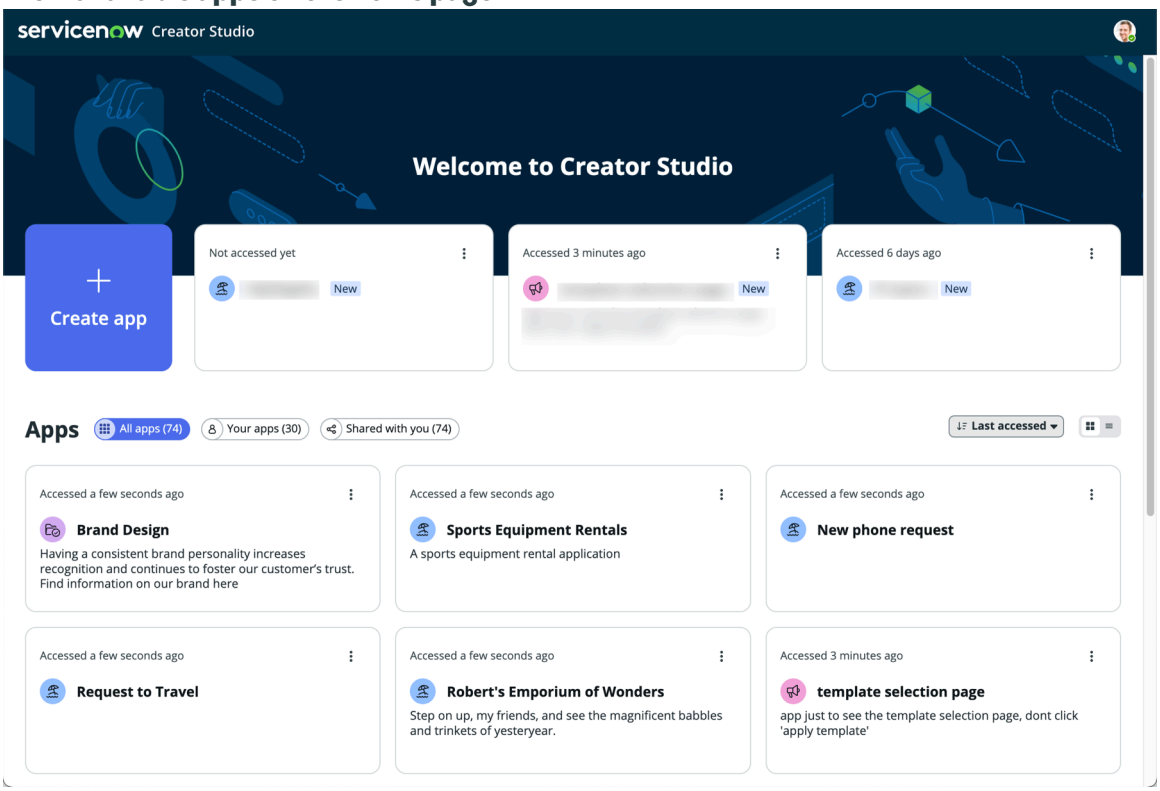
Find the app you want to work on

There could be a lot of apps listed on the Creator Studio home page. Here's how to find the one you want to work on.

Procedure

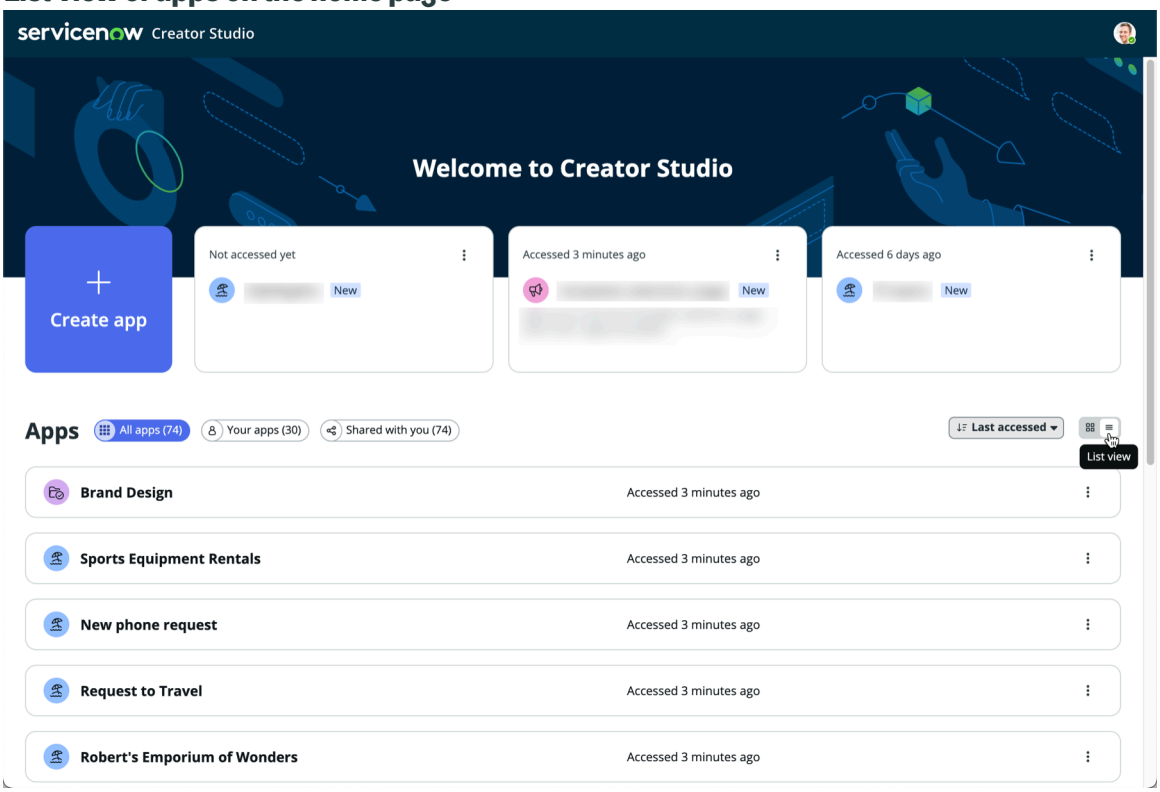
1. Go to **All** > **App Engine** > **Creator Studio**.
   The Creator Studio home page appears, which displays the apps most recently created by everyone in your company using Creator Studio.

View available apps on the home page



2. **Optional:** Would you prefer to see the apps in a list instead of displayed as cards? Select the view icon ( ) and switch to **List View**.

List view of apps on the home page



3. **Optional:** Narrow down the list of apps displayed by selecting one of the following:
   - **All apps**: Displays all the apps everyone in your company created using Creator Studio.
   - **Your apps**: Displays only the apps that you created. (You own the apps that you create.)
   - **Shared with you**: Displays only the apps you didn't create, but the owner said you could work on.

     For more information about working collaboratively on an app, see Delegated development and deployment.

4. **Optional:** Sort the list of displayed apps by selecting the drop-down sorting menu and then selecting one of the following options:
   - **Last accessed**: Lists the displayed apps based on the last time you worked on them; the most recently accessed app appears first in the list.
   - **Newest**: Lists the apps in the order of their creation date, newest to oldest.
   - **Oldest**: Lists the apps in the order of their creation date, oldest to newest.
   - **A-Z** or **Z-A**: Lists the displayed apps alphabetically in the order you choose.

5. **Optional:** 5. Select an app to open it in Creator Studio or select the more actions icon (…) and select one of the following:
   - **Open in new tab**: Open the app in a different browser tab.
   - **Manage collaborators**: If you're the app owner, you can invite others to work on the app with you. For more information, see Manage collaborators for an app in Creator Studio.
   - **Copy link**: Send collaborators a link to the app so they can find it.
   - **Settings**: Update the app's image and other settings. For more information, see Edit an app's settings in Creator Studio.

6. **Optional:** Select **Request access** to open an app that you don’t have permission to work on. To open an app, you must own it, or the owner must give you permission. For more information about requesting access, see Ask to work on an app in Creator Studio.

Result

Congrats:
Congratulations! You’ve found and opened an app or performed an action on it. Next, we’ll see how to work on it.

App creation in Creator Studio

Have you ever dreamed of creating your own app? With Creator Studio, you might be closer than you think! The following links will send you to the sections in this guide that will walk you through the steps.

Do you have permission to create an app?

If you don't have permission to build apps yourself, just ask an admin. They can give you permission, or you can give them an app name and a short description, and they can start the app for you. Then, you can jump in later and edit it.

Don't build your app from scratch!

Creating an application from scratch takes a lot of work. That's why Creator Studio does all the basic work for you. Just pick a form template (think starter kit) and provide some basic info (like a name). Later, we'll show you how to customize your app.

Edit your app's look and feel

Want your app to stand out? By editing the settings, you can give it a unique name, a head-turning image, and other great features.

Create the foundation of an app in Creator Studio

Before you can build out an app for people to use, you must create its foundation. Eventually, you'll have to customize the default values, but in the following procedure you'll select a catalog template for your first form and specify basic info for the app you're building in Creator Studio.

Before you begin

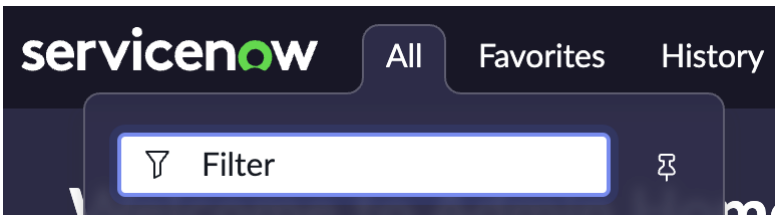
If you don't have permission to create an app, you can request that a teammate create one for you. For more information, see Ask an admin to create an app for you in Creator Studio.

Your administrator must add you to the Creator Studio Users group.

Procedure

1. Let's open Creator Studio. On your instance, select the **All** tab.

All tab



This tab lets you see all the apps installed on your instance.

2. In the white text field, enter `App Engine`.
   The list of apps displayed underneath the text box now pertains only to App Engine.
3. In the list, select **Creator Studio**.
   That's how you open Creator Studio! You've landed on its home page. Under **Apps**, you see all the apps that people already created.
4. Select **Create app** to begin your journey.
   - If you're a system administrator, you can read more about this topic in Application collaboration.
   - If you want to know how to request an admin to create the app for you, check out Ask an admin to create an app for you in Creator Studio.
5. Fill in the fields on the modal that pops up.

   a. Give your app a **Name**, which should be descriptive and intuitive.

   b. Describe what your app does in the **Description**.

      For example, `This app enables a person to request office equipment.`

   c. **Optional:** Select **Advanced settings** and confirm that your app's name and tables are unique by specifying the **Scope**.
      For more advanced information about scopes, see Application scope.

   d. Select **Create app**.

   Okay, you've created the beginning of your very own application! You've named and described it. A list of catalog templates appears.
6. Select a catalog template from the list, which your admin can customize.

You may not see a catalog template that is exactly what you want. So, choose one that's the closest. If none look close, select the **Creator Studio Default Template** option, if your admin hasn't removed it. It's your best bet.

Tip:
Feel free to click through the list of catalog templates. Previews will help you pick the one you want.

Don't worry if you don't see other catalog templates to choose from! Your admins may not have created any custom catalog templates for you yet.

7. Select **Apply this template**.
8. Add a form to a catalog to specify its business area.

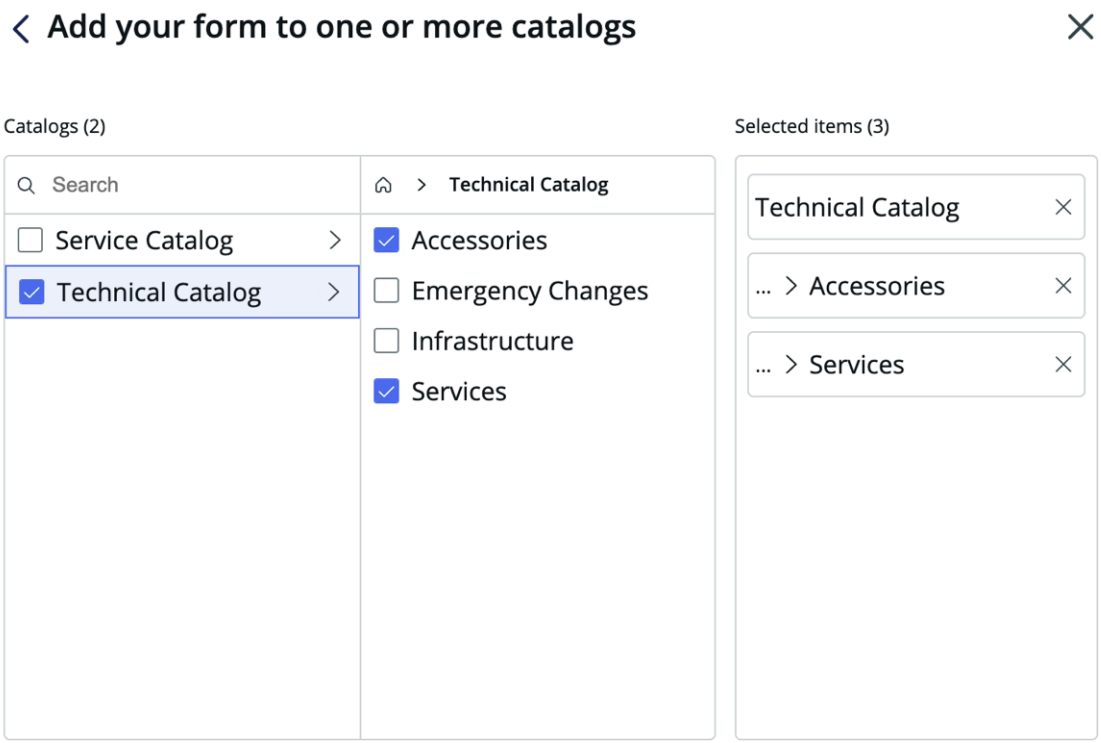
Note:
You can skip this step for now and revisit it later when you have a better idea of where it fits.

The available catalogs are configured by your admin, contact them if you don't see the one you want.

a. Select the **Edit button** (Edit) for the Catalogs and categories card.

b. Select the catalog that represents the business area the app will use.
For example, choose a service catalog that contains software and laptop cables. Expand the carat for each catalog to see its sub-catalogs.

Select the catalog



c. Select as many items in the catalogs as you need.

d. Select **Apply**.

You can edit any of the app's basic settings any time after you finish creating the app. For more information, see Creator Studio form settings.

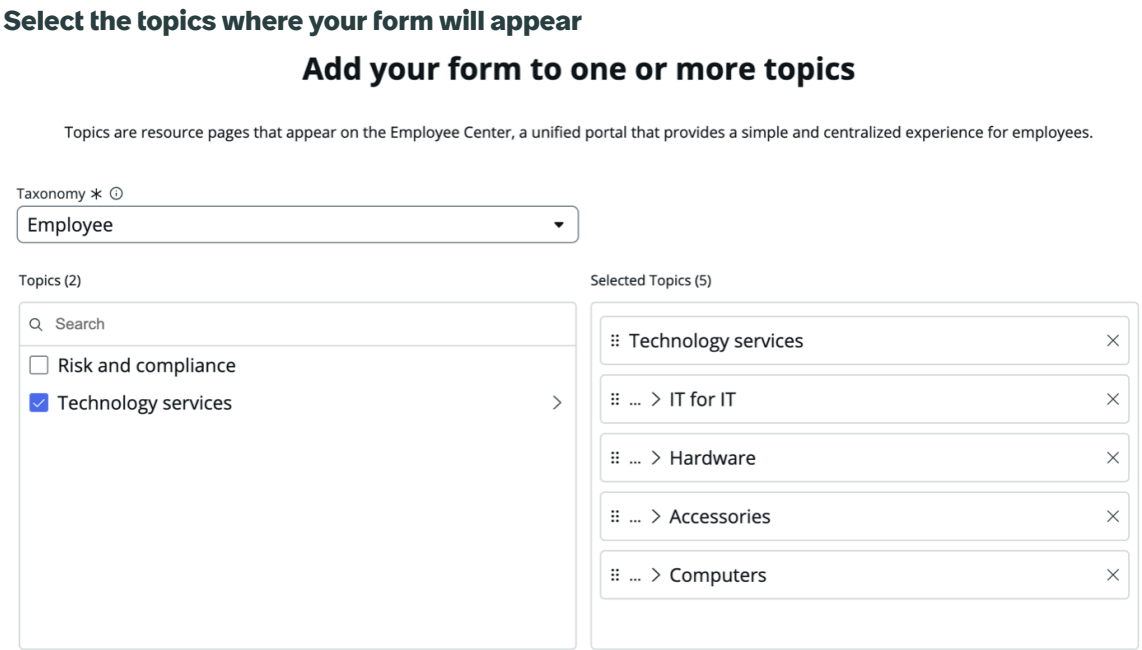
9. Next, choose one or more topics to specify where the form will appear.
Find out more about topics in Associate a catalog item with a taxonomy topic in Employee Center, and more about taxonomy, which is a categorization method, in Unified Taxonomy for Employee Center.

> **Note:**
> You can skip this step for now and revisit it later when you have a better idea of where it fits.

a. Select the **Edit button** (Edit) for the Topics card.

b. Choose the **Taxonomy** page where you want the form to appear, such as **Employee**.
Taxonomy is a method of categorization that Employee Center uses.

c. Select the topic(s) that represent the Employee Center areas where you want the form to appear.
For example, choose a topic that contains technology services, and expand its carat to see each of its sub-topics.



d. Select the topics where you want the form to appear, as many as you need.

e. Select the **Apply** button to save your changes.

10. Select **Save and continue**.

11. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

    Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

    - **Portal** (see a preview of how it'll appear on a desktop website)
    - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
    - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

    Note:
    Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

    The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

    Preview the app's experience

    
    You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

Result

Congrats:
Hooray! You've named your app and selected a catalog template that provides the basics for how your app's first form will look and work. Next, we will customize the forms people will use to fill out requests in your app in the section Working with forms in Creator Studio.

To learn all the things you can do as the app owner when building the app, see Application collaboration.

For sys admin eyes only: Every app built in Creator Studio adds a record in the Request App Config table. The name of the table follows the format of scope_request, for example, x_snc_02_03_request.

Ask an admin to create an app for you in Creator Studio

Don't have permission to build an app? Ask your admin to get you started by creating a basic app for you. Just give them a name and tell them what you want the app to do. Once they start it, you'll take over and modify it.

Before you begin

To request an app to be created for you, the admin needs to assign you the role of sn_creatorstudio.restricted_user.

About this task

When you ask an admin to create an app for you, you automatically become the owner of it. For more information, see Collaboration in Creator Studio.

Here's how to ask an admin to create an app for you.

Procedure

1. Let's open Creator Studio. On your instance, select the **All** tab.

   This tab lets you see all the apps installed on your instance.

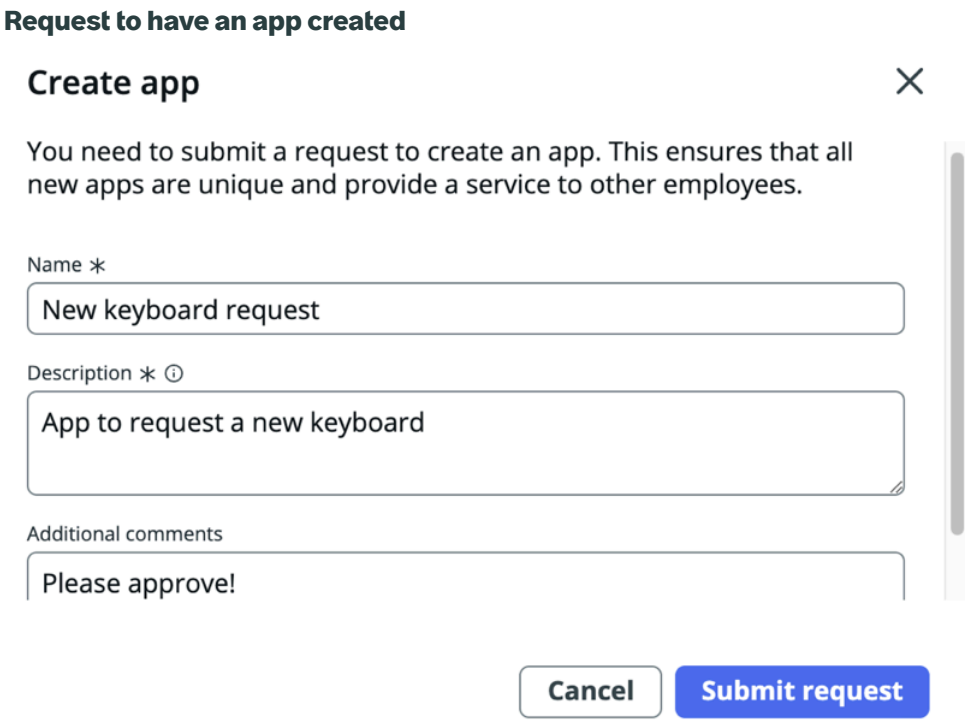
2. In the white text field, enter `App Engine`.
   The list of apps displayed underneath the text box now pertains only to App Engine.
3. In the list, select **Creator Studio**.
   That's how you open Creator Studio! You've landed on its home page. Under **Apps**, you see all the apps that people already created.
4. Select **Create app** to get started with your request.
5. Fill in the fields on the modal that pops up.

   a. Give your app a **Name**, which should be descriptive and intuitive.

   b. Describe what your app will do in the **Description**.

      For example, `This app enables a person to request office equipment.`

   c. Enter any additional comments that you want the admin to know when approving your request.



6. Select the **Submit request** button.

Result

After you ask your admin to create the app, they'll review and approve the request. They might need more details about the app from you. You'll get an email notification once they approve and create it. At that point, you're the owner of the app. You can find your app in Creator Studio and start building out the app's forms, automation, and workspace category.

To learn all the things you can do as the app owner when building the app, see Application collaboration.

For admins:

- Every app built in Creator Studio adds a record in the Request App Config table. The table's name follows the format of scope_request, for example, x_snc_02_03_request.
- You'll review and approve app requests in the Application Tasks table of the Request App Administration app.

Edit an app's settings in Creator Studio

Maybe you want to jazz up your app a bit, for example by giving it a new name, tweaking the description, or swapping in a new image. All it takes is just a few clicks in the settings! Let's dive into how you can do it, even if you're not a tech whiz.

Before you begin

To edit an app's settings, you must be given permission to work on the app.

About this task

There are some things you can't change after you've created the app, like its table or scope. If you want to change things up big time, you'll need to start from scratch with a new app.

Procedure

1. Head over to the Creator Studio home page by going to **All** > **App Engine** > **Creator Studio**. You'll see a list of all your apps right there on the home page.
2. Select the app you want to work on.
   It'll open up so you can start making changes.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

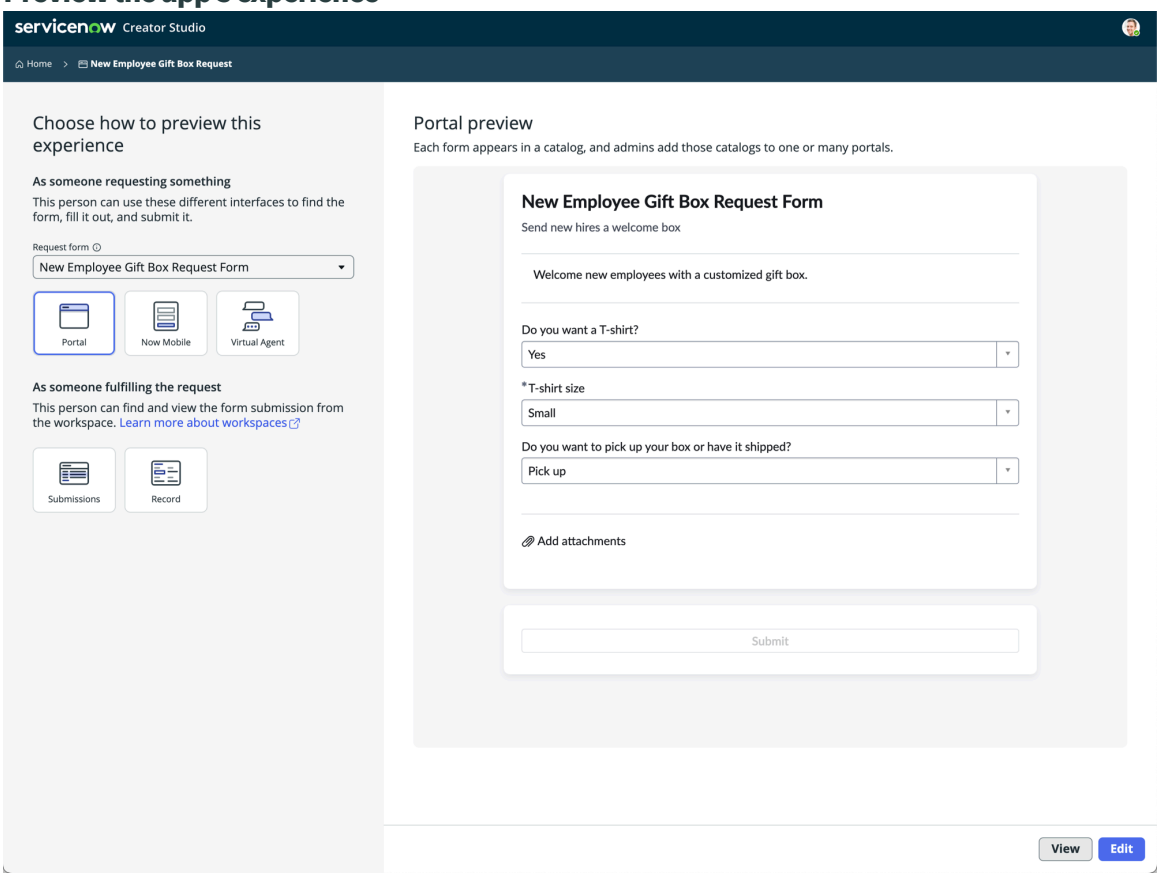
   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

   Note:
   Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

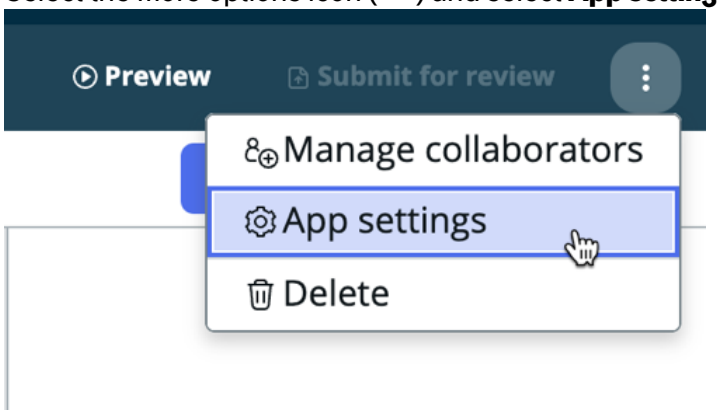
   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

Preview the app's experience



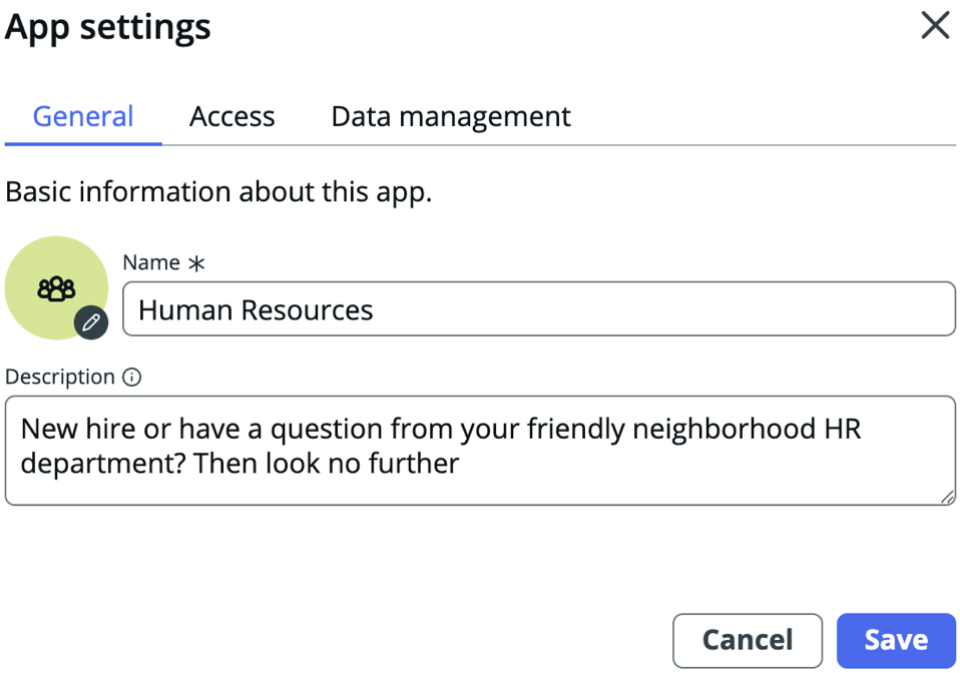
You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the more options icon ( ) and select **App settings** from the menu that pops up.



5. Now it's time to make those changes on the **General** tab, including updating the app's image. You can't make changes to security settings on the **Access** tab after the app has been created.

App settings



6. Once you're happy with everything, select the **Save** button.

Result

And there you have it: With just a few simple steps, you gave your app a whole new vibe. So go ahead, get creative, and make it yours!

Collaboration in Creator Studio

Sometimes you need help building out your app, and that’s ok! And sometimes other people need your help building their apps, which is great! This is where collaboration comes into play.

You can collaborate on apps you don't own by requesting permission to edit them, and invite other people you work with to collaborate on your apps with you.

Collaboration, also referred to as delegated development, builds on the existing delegated development feature set in the ServiceNow AI Platform. It enables developers to invite other developers into apps so they can co-create and develop the app together. Depending on your permissions, you can invite others to collaborate on an app with you, or request to join someone else's app.

Note:
You must have an App Engine Enterprise license to take full advantage of collaboration.

The ServiceNow AI Platform Collaboration app is automatically installed with Creator Studio. For more information about the Collaboration app, see Application collaboration.

Collaboration descriptors: Owners and Editors

So, you realize you either need help with your app, or you want to help someone else building their app. What's next? You need the right collaboration role.

There are two standard types of collaborators when you co-develop an app with other people: Owners and Editors. These two roles are called collaboration descriptors. The collaboration descriptor that someone is assigned determines if they can assign, manage, and monitor delegated development permissions. For example, people who are Owners can do more than people with the Editor collaboration type.

If needed, your admin can define custom collaboration descriptors to select when managing collaborators, either in the Creator Studio Guided Setup or in the Collaboration app. For more information on custom descriptors, see Configure Creator Studio using Guided Setup and Create collaboration descriptors to assign permissions.

Default collaboration descriptors

Descriptor	Description
Owner	Owner of the application. • If you created the app, you're automatically the owner. • Owners can manage other collaborators for the app. • Owners have the delete app permission, which enables them to edit app settings, such as name, description, and icon. • Owners automatically get the delegated_developer role for the app.
Editor	• Editors can invite collaborators. • Editors have limited ability to edit the app.

Collaboration development permissions

You've designated Owners and Editors in your app, now what? You need to invite other collaborators to work in your app.

Collaboration permissions enable you to control who's building apps in Creator Studio. You assign permissions to developers (or users who deploy applications) so that they can develop and deploy applications.

If you invite someone to collaborate on an app and they don't have the Delegated developer (delegated_developer) role, an App Engine admin must approve the collaboration request. For more information, see Delegated development and deployment.

When you add a user or group, a collaboration task is generated behind the scenes, and an approval flow kicks off. If you have App Engine Management Center (AEMC) installed, your admin can review and approve/deny these collaboration request tasks there. If you don't have AEMC installed, admins can navigate to **All** > *App Engine* > **Collaboration** > **Collaboration Tasks**.

The collaboration task that goes to your admin provides information on which application a developer is being added to, and what permissions are granted. Approvers sometimes need to review these task records before they add developers to the application.

What can owners and editors do?

If you're in the Creator Studio users group, you can see all users and groups collaborating on an app, as well as their collaboration descriptors.

If you can't see the users and groups, you may have a different permission with more restrictions. But fear not! You can always contact your admin if you have any questions about who's working on an app.

The following table provides a list of general defaults for what owners and editors can do in Creator Studio.

Note:
For the full list of default Owner and Editor collaborator collaboration type permissions, see Customized app collaboration permissions in Creator Studio.

Collaboration on Creator Studio features

Creator Studio feature	Owner	Editor
Invite collaborators	Yes	Yes
Manage collaborators	Yes	No
Edit app settings, such as name, description, and icon	Yes	No
Create, edit, and delete forms	Yes	Yes
Create, edit, and delete automation	Yes	Yes
Manage the workspace for form submissions	Yes	Yes
Submit app for deployment	Yes	No
Delete app	Yes	No

Collaboration roles and instances on different versions

As admins implement Creator Studio, they may have it installed on a non-production instance while their production instance is on a previous version of the ServiceNow AI Platform that doesn't have Creator Studio. This mis-match of instance versions affects the Collaboration Approval Workflow, which specifies the non-production instance as the source and the production instance as the controller. If the controller doesn't have the version of the collaboration plugin that supports Creator Studio, collaboration is unsupported.

To ensure that users can use the Collaboration Approval Workflow regardless of instance versions, admins must assign the catalog _builder_editor role to Creator Studio user groups.

Ask to work on an app in Creator Studio

Want to work on an app but don't have access to it? No problem. We'll show you how to ask for access.

Before you begin

First things first, you need the right access to get involved. Your system administrator must give you the role of sn_creatorstudio.user or sn_creatorstudio.restricted_user.

About this task

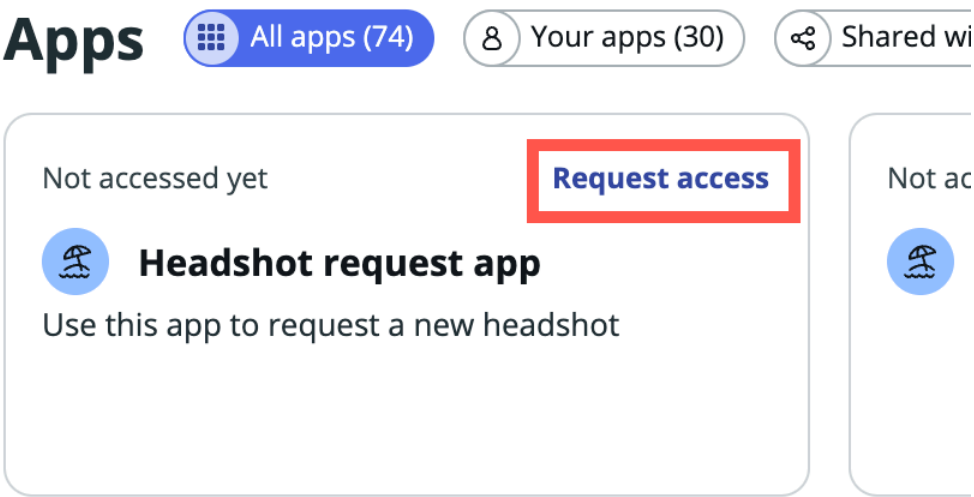
Getting permission to work on an app delegates you to its development, which means you can start pitching in and making things happen. For more information, see Delegated development and deployment.

Note:
Admins don't see the **Request access** option because their permissions enable them to access all apps.

Procedure

1. Head over to Creator Studio by going to **All** > **App Engine** > **Creator Studio**.
   You'll see a list of all the apps built in Creator Studio right there on the home page.
2. Look for the app you want to help with and select its **Request access** link.

Request access



3. **Optional:** Use the **Enter an optional message** field if you want to leave a little note explaining why you're interested in joining the app. Maybe you've got some great ideas, or just want to learn the process.
4. Once you're ready, select the **Request access** button.

Result
With any luck, the App Engine admin will approve your request, and you'll be in! Then, it's time to roll up your sleeves and start working on the app.

Note:
Users with a delegated developer role are automatically approved for collaboration.

What to do next

Important:
After your request to join an app gets approved, you must sign out of the ServiceNow AI Platform and then sign back in to access the app.

If your organization uses App Engine Management Center (AEMC), App Engine admins approve collaboration requests there.

If your organization doesn't have AEMC, admins approve requests to join apps in the Collaboration Tasks table. For more information, see Approve a collaboration request.

Manage collaborators for an app in Creator Studio

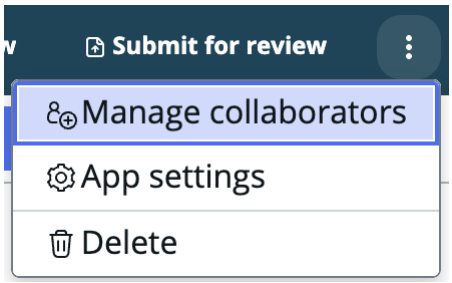
Add or remove people who can work on an app, or change their permissions for the app using the **Manage collaborators** option.

Before you begin
Your system administrator needs to assign you the Manage collaborators permission. Admins can also manage collaborators.

About this task
You can invite collaborators or manage collaborators depending on your permissions for each app. For example, if you have the Invite collaborators permission, you can't change the collaborator type of existing collaborators, such as Editor or Owner.

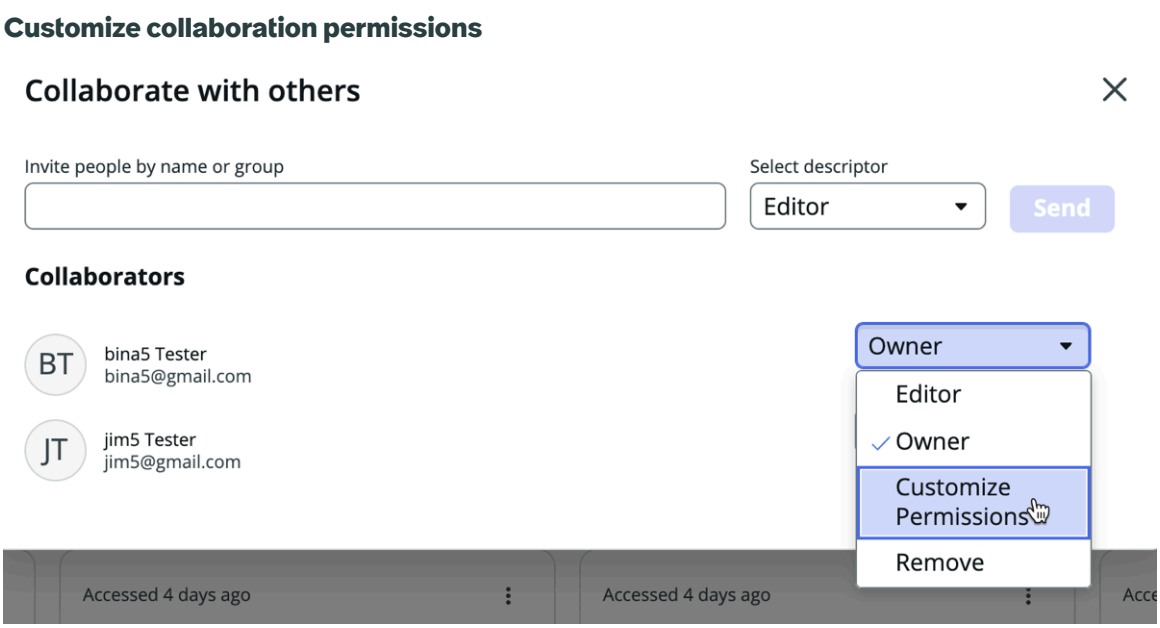
Procedure
1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Find the app you want to manage collaborators for.
3. Access the Collaborators with others modal in one of two ways:

- From the Creator Studio home page, select the app's more actions icon ( ) and select **Manage collaborators** from the menu that appears.
- Open the app, select **Edit**, select the more actions icon in the application header, and select **Manage collaborators** from the menu that appears.

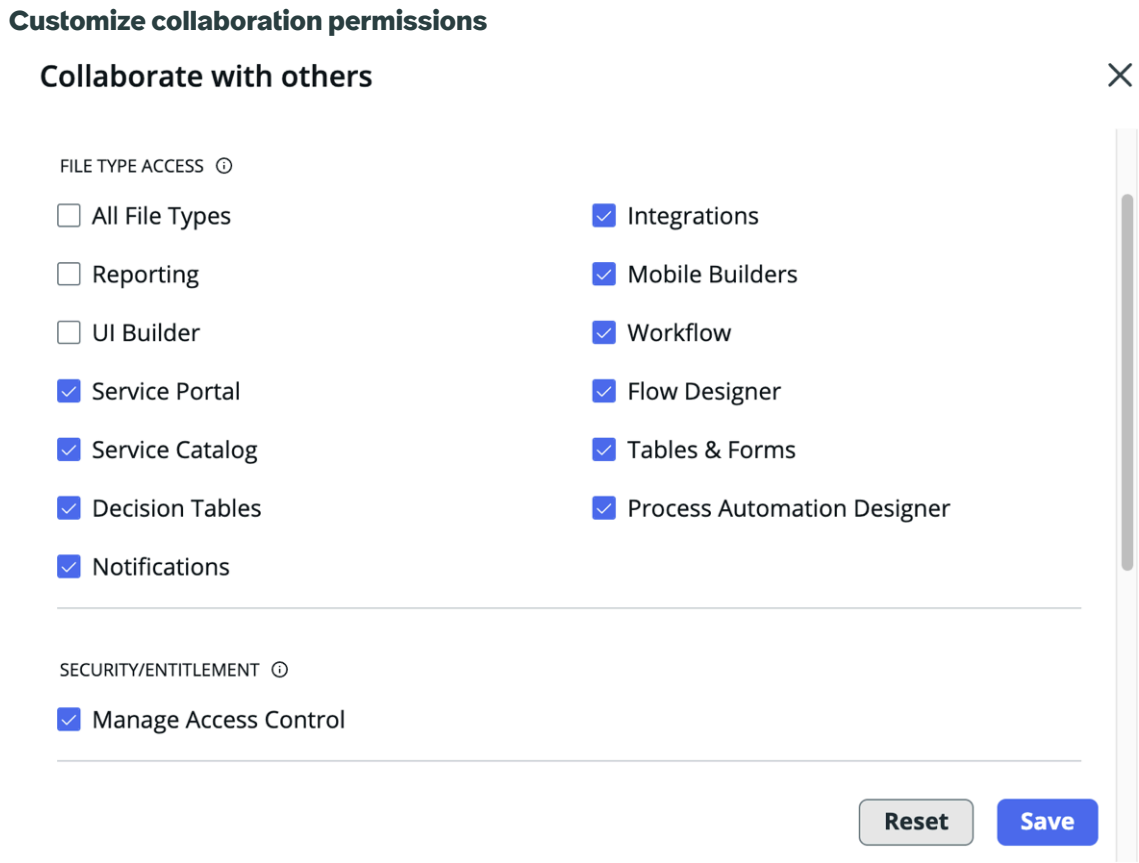


4. Change the permission of existing collaborators in the Collaborator section using the **Select descriptor** field.
   - **Owner** changes the user or group to be an owner for the app.
   - **Editor** changes the user or group to be an editor for the app.
   - **Customize permissions** enables you to select specific things that users can do with the app. For more information, see Customized app collaboration permissions in Creator Studio.
   - **Remove** revokes the user or group's access to work on the app.

   Note:
   The collaboration descriptor must be in the global scope for it to be used by others.



5. Customize collaboration permissions by selecting **Customize permissions** and selecting the permissions the user should have.



6. **Optional:** Add any additional collaborators.
   a. Start typing the people or groups you want to invite in the **Invite people by name or group** field.
   b. Specify the collaboration level in the **Select descriptor** field.
   c. Select the **Send** button to start the approval process.
   You can specify as many users and groups as needed.

Result

Unless you customized permissions, which requires the **Save** button, your changes are automatically saved when you close the Collaborate with others modal.

What to do next

Your App Engine admin must then approve the changes to collaborators.

Working with forms in Creator Studio

To add items or services to your catalog, you must create a different form for each thing being requested.

Summary:

After reading this topic, you'll understand:

- How form templates get you started creating your own forms.
- How to customize the layout and questions on your forms.
- How to make a form (AKA catalog item) appear in your app.
- How to make a form stop appearing in your app!

What is a form?

A form is a list of questions that people answer to make a request. They might ask for a keyboard, a laptop, or permission to take a vacation. The answers to those questions provide the fulfiller with all the information that they need to fulfill the request. For example, if someone asks for a laptop, the fulfiller might need to know the size, the model number, the operating system, and so forth.

In addition to questions, forms can contain images, headings, and text descriptions to explain the questions.

You'll need a different form for every type of item or request that a requester can ask for. Why? Because the questions you must ask for a keyboard differ from the questions that you must ask to give a requester permission to take a vacation. So, there's one form for each type of request that people can make. You can think of a form as representing a catalog item.

Your app will likely have multiple forms, meaning multiple things the requester can ask for. We call a collection of forms a catalog of items.

Key terms:

Item

Something a requester can ask for. Each item requires its own form.

Catalog

A collection of items that represent all the items a requester can ask for.

Some examples of catalogs and items

The following table shows three catalogs. The final column shows the names of the items in each catalog. If you have three items, you'll need three forms.

Example catalogs and their items

Service catalog	Example app	Sample catalog items
HR self-service	Human Resources global people portal app	• Benefits coverage question • Time off request • Change of address needed
Branding resources	Marketing and branding app	• PowerPoint templates • Approved Zoom backgrounds • Logo files
IT fulfillment	Hardware request app	• Mouse device • Headset • Replacement charging cable

Let Creator Studio give you a head start

When you choose a form template to start creating your app, Creator Studio builds a form with questions you might like to use. The questions and their layout make up the form.

Key term:

Form template

A set of questions arranged on a form provided by Creator Studio.

The form template that Creator Studio provides is called the Creator Studio Default Template. It contains three questions to get you started. You can customize, add, and subtract questions on your form.

Your administrator can delete the default template, create additional form templates, and restrict who can fill out the forms. If you're an administrator, you can read more about this topic in Creating catalog templates for use in Creator Studio apps.

To store the forms that requesters fill out, Creator Studio creates a table by default. One row represents one filled-out form.

Your application can contain as many forms as you need. When you create a form, Creator Studio uses the app's request table to hold the submitted answers for each form. All requests from all of an app's forms are stored in the same table.

Types of questions you can ask

You get to pick the questions to ask requesters. Creator Studio provides two types of questions you can ask:

- **General questions** are where you give requesters an empty box to write a short answer (think name or email) or a list of choices to pick from (like a dropdown menu or those little circles you fill in).
- **Reference-based questions** are where you provide a list of choices that you define in a table.

You can add questions to forms that have been preconfigured by your admin, and can't be edited. Adding a **Question set** element to a form enables you to select from the curated options.

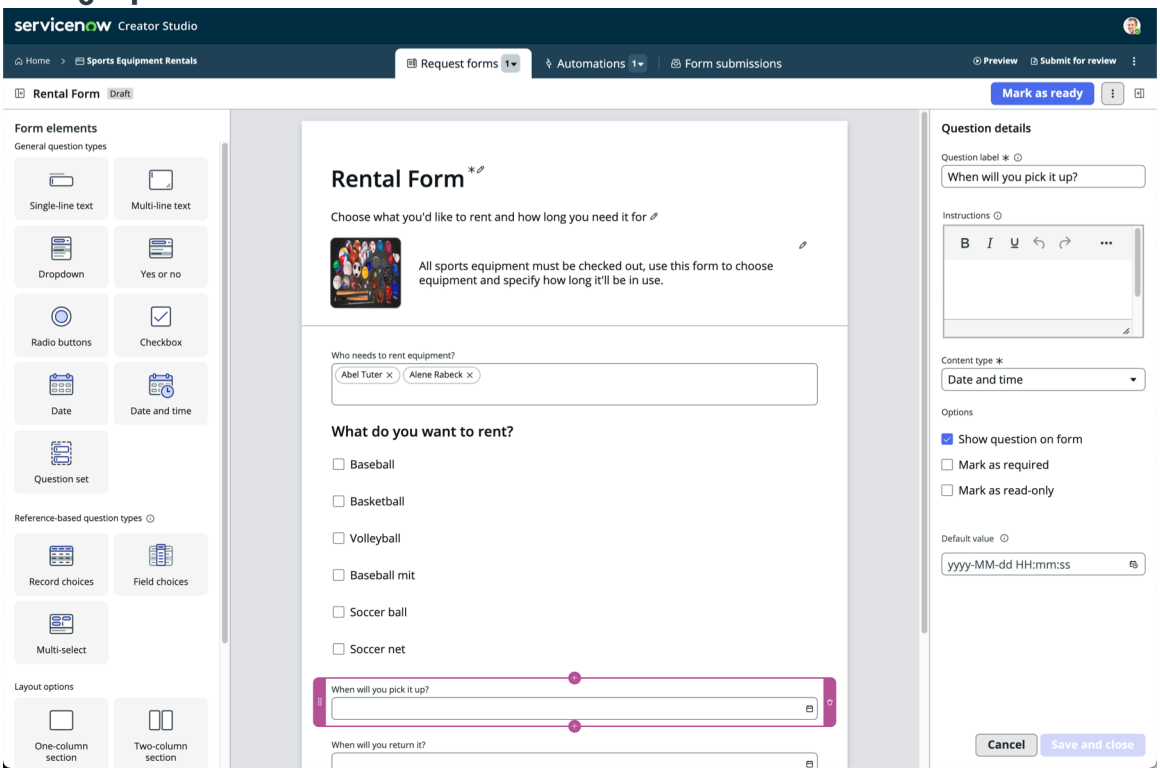
Forms can automatically update how questions appear (or are hidden) based on how users answer a them. We call this dynamic behavior. For example, if a user says they want a T-shirt for an event they're attending, you can make a **T-shirt size** field required.

Laying out the questions

Creator Studio provides an initial layout for its default form. You can use columns, images, divider lines, and more to customize the layout of the questions on the forms. There are two procedures that you can use to customize a form:

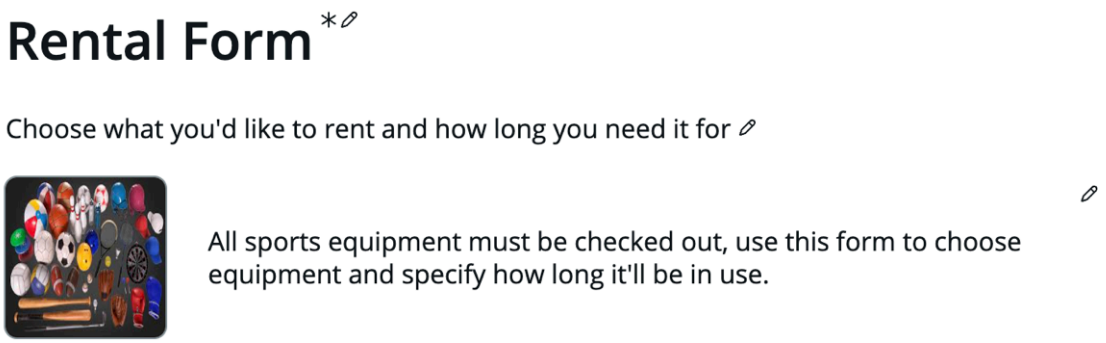
- Changing the questions – Change the number of questions, what they're asking, and adjust where questions appear on a form. Find information on changing questions in Customize your form for an app in Creator Studio.

Editing a question on a form



- Changing the look and feel of the form – Add pictures, write some text to explain the questions, and even move them around to make them flow smoothly. You can read about that in Change the layout of an app's record in Creator Studio.

Edit the look and feel of the app's tile



Where can I see forms?

After deployment, your app lives as forms in the Service Catalog and categories you specified when creating the forms.

Users can access those forms directly in Service Catalog, as well as Service Portal and Employee Center.

If you associate the app's form with one or more topics, the form will appear in the relevant, dynamically created topic pages in Employee Center. Find out more about topics in Associate a

catalog item with a taxonomy topic in Employee Center, and more about taxonomy, which is a categorization method, in Unified Taxonomy for Employee Center.

Making forms available for an app

Forms have two states:

- Draft
- Published

Keeping forms in a Draft state lets you work on them until you're finished. When you're pleased with the form, publish it by selecting the **Mark as ready** button. Only then will it appear in your application (assuming your app has been deployed).

A published form appears as an item in your catalog of offerings. For example, your site might enable requesters to ask for computers, mice, monitors, keyboards, technical support, and so forth. Each item requires a different form, and appears as a different catalog item in your app.

Key terms:
Don't confuse deploying your app with publishing a form.

- Publishing a form means that the form will appear as a catalog item only after your app is deployed. That's why the button label is **Mark as ready**.
- Deploying an app is what system admins do to make your app available for people to use.

Changing published forms

It's inevitable. You deploy your app and find that you need to revise the questions on your form. No problem! Just edit the form as you did when you created it.

Editing a form creates a new Draft version of the form that you can update and then **Mark as ready** when you're finished. Any changes you save to the Draft version won't affect the catalog item in your deployed app. To update the forms in the deployed app, you must redeploy the app.

Undoing form changes

You can select the **Undo all changes** option, available in the form header's more options icon (), to reset a form to the most recently published version.

Deleting published forms

You can't delete a form, whether it's in a Draft or Published state.

- If it's in the Draft state, just don't **Mark it ready**.
- If the form is in a Published state, you can hide it so it no longer appears in the catalog. See Hide a form from use in the ServiceNow AI Platform in Creator Studio for more information on hiding forms.

Customize your form for an app in Creator Studio

Forms help people ask for things they need, such as a new keyboard or permission to take time off. The default form that's added when you create an app in Creator Studio needs some changes to fit your needs. For example, you must add question labels to gather information about the request.

Before you begin
To customize a form, you must be given permission to work on the app.

About this task

You can add additional forms to your application if you need them. Additional forms are stored in the app's same table. No need to worry about those tables right now, but if you want to know how to add more forms besides the form that was generated when the app was created, check out Add more forms to an app in Creator Studio.

Summary:

After finishing the following steps, you'll know how to:

- Open the form that was automatically generated when the app was created.
- Add questions and images to the form.
- Arrange the questions and images that you added.

Let's open a form and customize it.

Note:

For example, you can create a form that people use to register for a company event, with questions like dietary preference and accessibility needs.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio**.
   All the apps built in Creator Studio appear on the home page.
2. Open the application that contains the form you want to customize.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

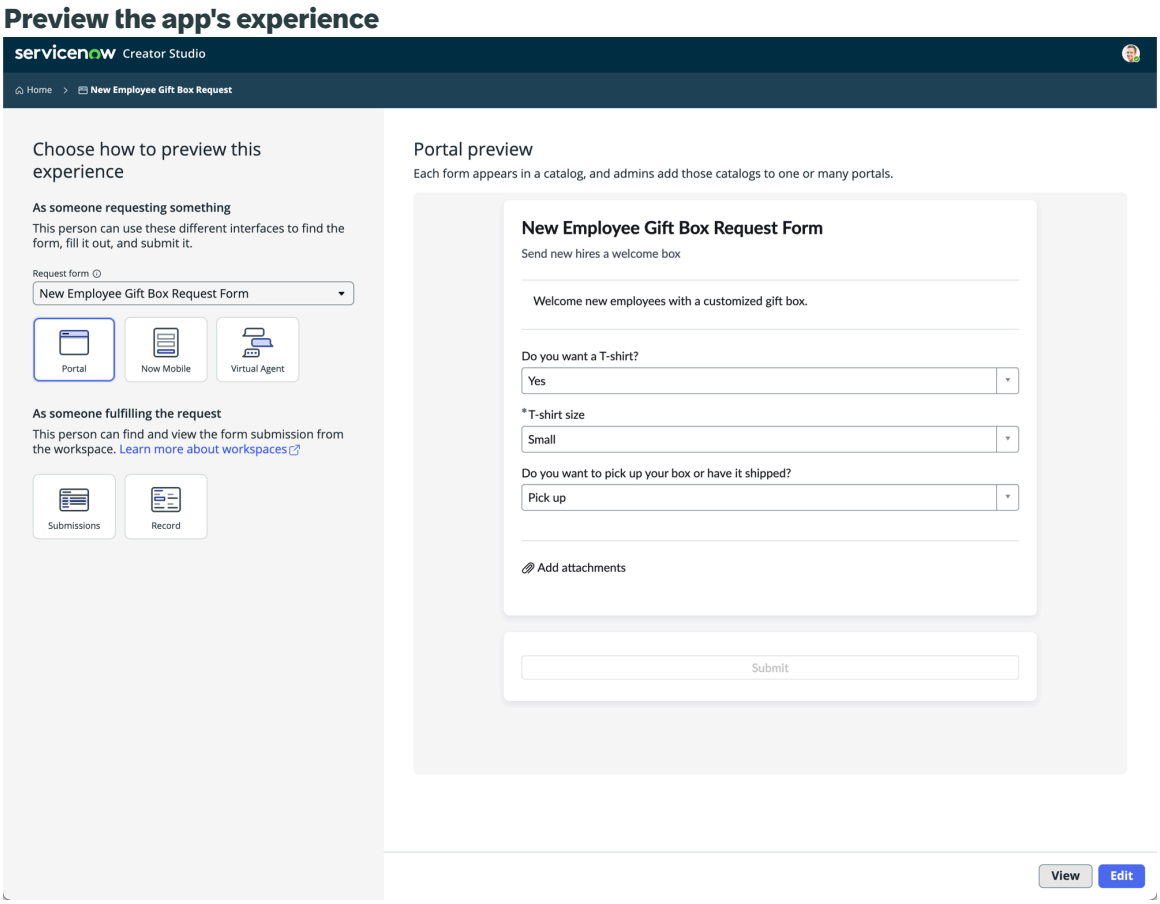
   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

     Note:

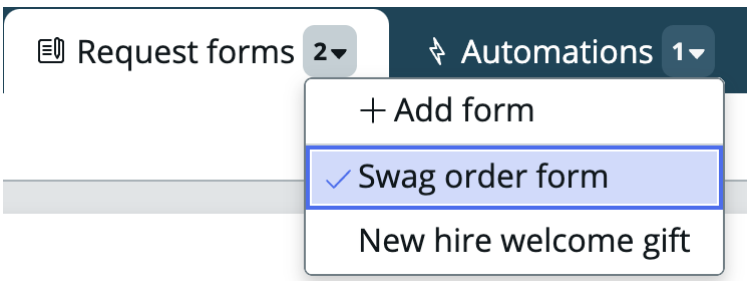
     Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the **Request forms** tab to make sure you're editing the correct form in your app.
   If you're not, select the form you want to edit.



5. Let's customize the form by doing one or more of the following optional steps.

   a. Add or modify the image that appears on your form by selecting the add image icon ( ) and then selecting an image.

   b. Change the form's title, short description, and other text by selecting those parts of the form and typing in your changes.
   You can enhance how the longer **Description** appears using rich text, such as font changes and sizing.

6. Next, add questions to the form your fulfiller needs to evaluate the request. To add and customize a question, complete the following steps.

   a. In the Form elements panel, drag the type of question you want onto the form and drop it on the canvas where you'd like it. You can also add questions by selecting the add icon (+) that appears when you click on an existing question on the form.
   If you're adding a pre-configured **Question set**, you must select the question set from the modal that appears when you drag it onto the form.

   For a description of question types and how they're used, see Available question types in Creator Studio.

   b. Select the question.
   When you select a question, it's highlighted on the form so you know what you're working on.

   c. In the **Configurations** tab of the Question details panel, specify information about the question you added, such as whether a question must be answered for the requester to submit the form.
   The details vary by question type. For example, if you add a **Dropdown** question, you must supply the options to choose from.

Form question details

   d. **Optional:** Make the form's appearance change based on how users answer questions by adding dynamic behavior to it on the **Behaviors** tab.
   For example, if a user says they want a T-shirt for an event they're attending, you can make a **T-shirt size** field required. Get the details on adding dynamic in Make a form change based on responses in Creator Studio.

   e. Select **Save and close** when you finish modifying the question.

f. Revise or add more questions to the form using this procedure. To change a question type, select the question and then select the new question type in the **Content type** field of the Question details panel. Selecting a new type may introduce new values you must supply. Keep these specifications in mind as you create your questions:

- You can't change an existing question into a question set. To include a question set on a form, you must newly add it to the form.
- If you put two checkbox questions side-by-side on a form, they make a section. You can't add other types of questions to that section.

7. Now, let's arrange the questions and images that you've added to the form.

a. From the Form elements panel, drag the layout option you like onto the form and drop it where you want it to appear, for example, a **Divider line**.
Don't worry if you don't like the layout, just try another one by dragging it onto the form's canvas.

b. Revise the form layout you chose using the Section details or Question details panel (depending on the layout you're working on). You can do things like make text bold, add links, and so forth.

> **Note:**
> To edit or delete a section, you must hover over the section name and then select **Section** to see the section details in the properties panel, as well as the delete icon.

Selecting a section

For more information, see Layout options for forms in Creator Studio.

c. Select **Save** in the Section details/Question details panel when you're done revising the form's layout.

Result

> **Congrats:**
> Congratulations! You've customized the default form that came with your app.

What to do next

You must then mark the form as ready to publish it, which makes it available for the app to use. Find out how to publish a form in Publish a form for your app in Creator Studio.

You can select the **Undo all changes** option, available in the form header's more options icon (···), to reset a form to the most recently published version.

Make a form change based on responses in Creator Studio

Make a form update based on how users answer a question using dynamic behavior. For example, if a user says they want a T-shirt for an event they're attending, you can make a **T-shirt size** field required.

Before you begin

You must name the form before you can add dynamic behavior to it.

To add dynamic behavior to a form, you must be given permission to work on the app.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the application that contains the form you want to add dynamic behavior to.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

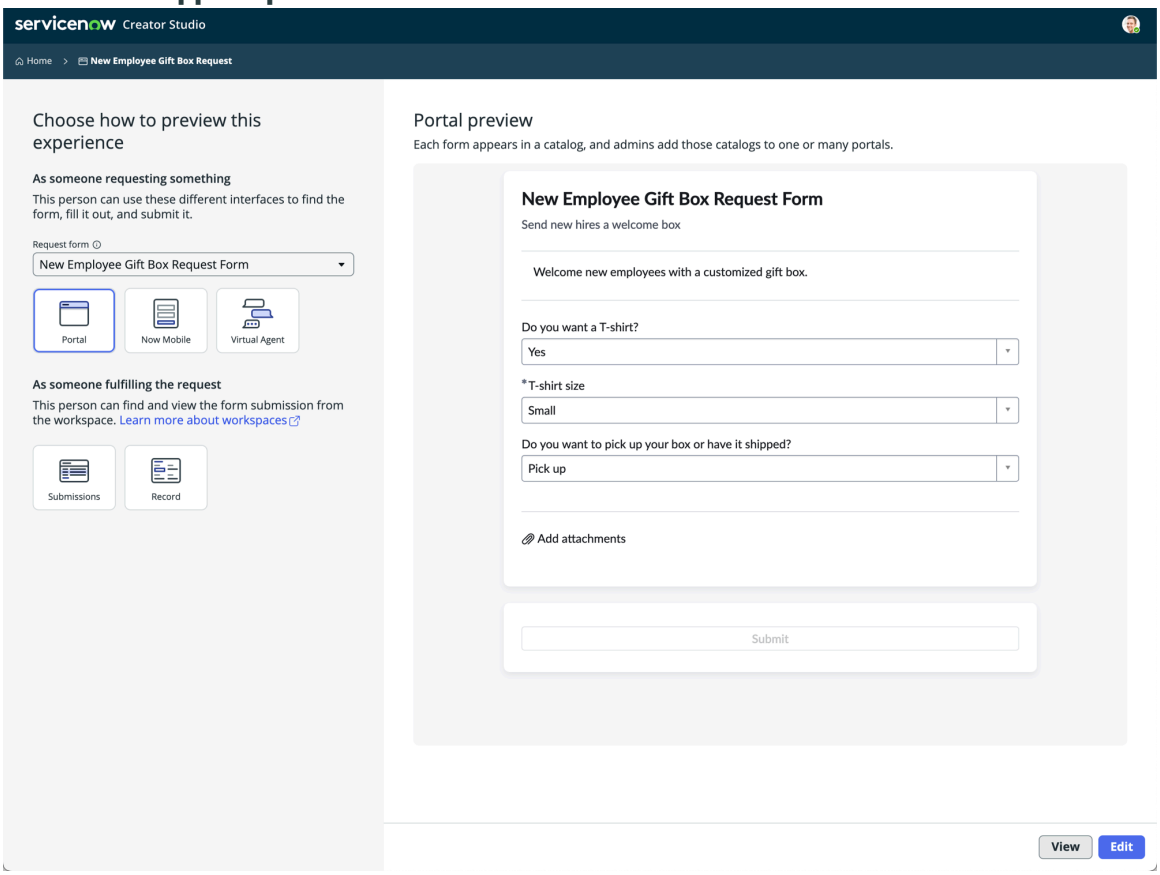
   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

   > **Note:**
   > Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

Preview the app's experience

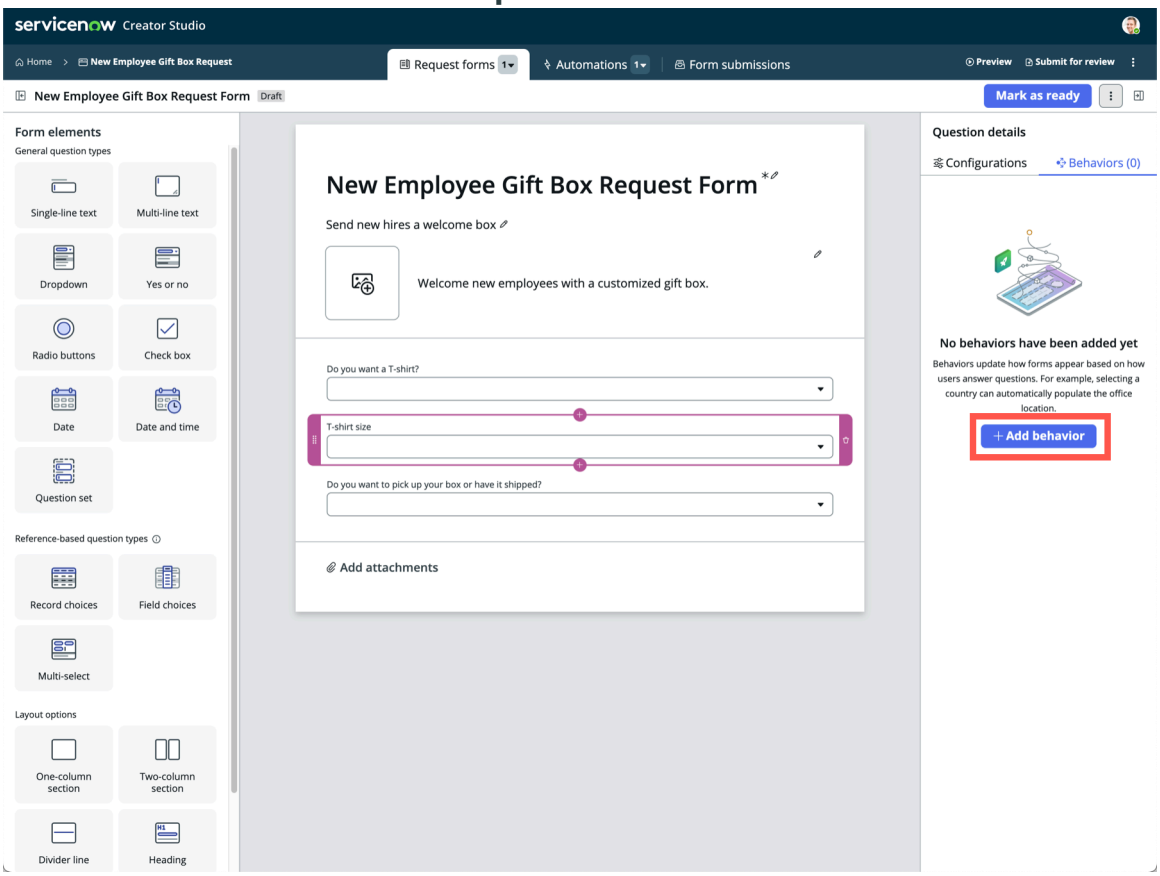


You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Check that you're editing the correct form in your app by selecting it from the **Request forms** tab.

5. Select the question that should be affected by how users answer one or more previous questions.
   For example, select the **T-shirt size** field to make it required if a user answers `Yes` to the **Do you want a T-shirt?** question.
6. Select the **Behaviors** tab of the settings panel.

Add behavior button on the Behaviors panel



7. Define the conditions that will make the form change in the Conditions section.

   a. Select **Questions** in the **Field** field to specify that you're choosing questions from the form. The name of the form automatically appears in the **Item** field.

   b. Choose the question whose answer triggers the dynamic behavior in the **Question** field. For example, select the **Do you want a T-shirt?** question.

   c. Select the condition **Operator** to determine the status of the selected field that will trigger the dynamic behavior.
   For example, you could select **Is** as the operator for the **Do you want a T-shirt?** field.

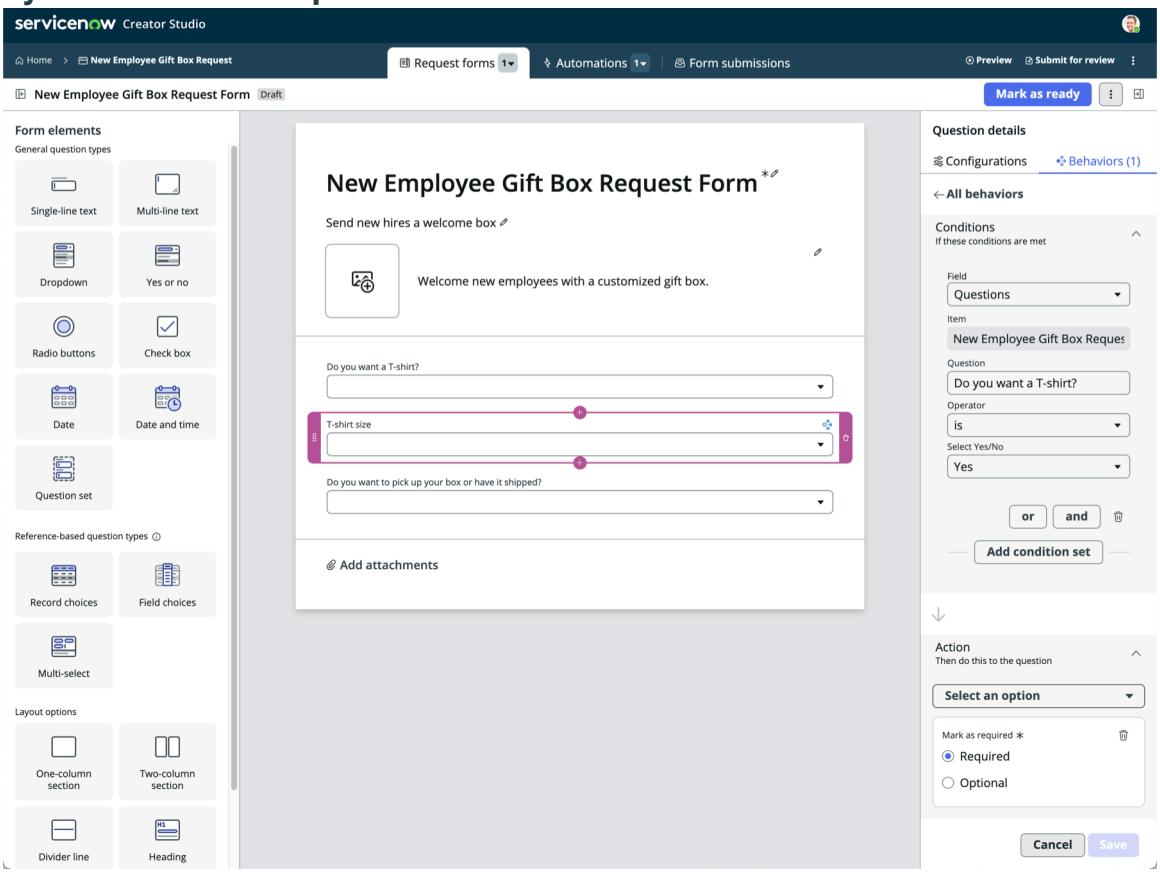
   For more information, see Condition builder.

   d. Enter or select the value for the user's response to the trigger question.
   For example, the value could be **Yes** if they want a T-shirt.

   e. **Optional:** Specify another field and value to create a more complex set of triggering conditions by selecting the **or** button or the **and** button.

   f. **Optional:** Build another set of conditions by selecting the **Add condition set** button and repeating steps a-e.

Dynamic behavior example



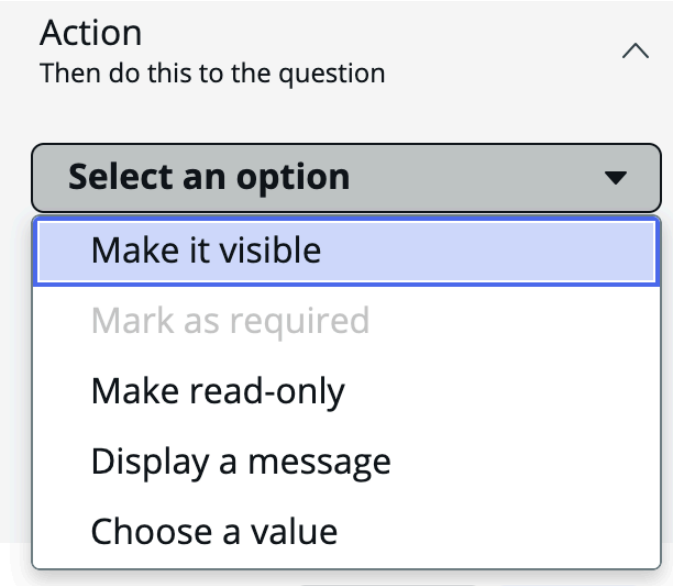
8. Define how the form changes in response to the conditions that you defined in the Action section of the **Behaviors** panel.

   a. Choose what the form does when the triggering conditions are met in the **Select an option** field.
   Depending on the conditions you created, the following actions may be available:

   - **Make it visible**
   - **Mark as required**
   - **Make read-only**
   - **Display a message**
   - **Choose a value**

   You can add multiple actions, but you can add only one of each type of action for each set of dynamic behavior.

Dynamic behavior actions



b. Choose what happens for each action that you select.
For example, if you chose to **Display a message**, you can make it an **Info**, **Warning**, or **Error** message, and then you must enter the message that appears.

9. Select **Save**.

Result

The question appears with a dynamic icon ( ) to indicate that it has dynamic behavior.

The dynamic behavior appears in a card on the **Behavior** tab of the settings panel. You can select the card at any time to view or edit its details, or select the **Add behavior** button to add another dynamic behavior.

Development states of a form in Creator Studio

Think of your app as an online store that contains a catalog of items. To request something, a person needs to fill out a form. It's your job to create and customize forms for every item in your catalog using Creator Studio.

Summary:
Forms have two states:

Draft

The state of a form when you're editing it. It can be a new form or a copy of a published form. Forms in this state do not appear in your catalog.

Published

The state of a fully-designed form that appears in your catalog.

You want to publish forms only when they're ready—not some half-baked version you're working on. That's why forms have states.

Draft state for forms

Forms in the Draft state don't appear in your catalog of items. That means you can work on them without affecting your online catalog.

The forms you edit can be new, or copies of forms that have already been published. You can revise forms as much as you like in this state, but the revisions are kept behind the scenes until you publish the form. So, no worries about leaving a form unfinished when it's in Draft state!

Published state for forms

When you finish editing a form, you mark it as ready, which puts it in the Published state. This version of the form then appears in its specified catalog of items.

> **Note:**
> The published form appears only on the non-production instance where you're developing your app. You must request that your admin deploy the app to production for the form to appear in the catalog on the production instance.

If you edit a form that's been published, Creator Studio creates a copy of the form, and puts the copy in the Draft state so you can work on it. The published version of the form remains available in your online catalog until you submit the revised copy of the form, which will replace the published form.

Add more forms to an app in Creator Studio

Add as many forms as you need to create catalog items for your app. For example, you could have an office booking app with three different forms: one for requesting parking spaces, one for requesting a desk, and one for reserving conference rooms.

Before you begin

To add forms to an app, you must be given permission to work on the app.

About this task

> **Note:**
> An IT fulfillment app could already have one form for requesting hardware accessories (such as a mouse or headphones), and you can add a second form for requesting software applications.

Procedure

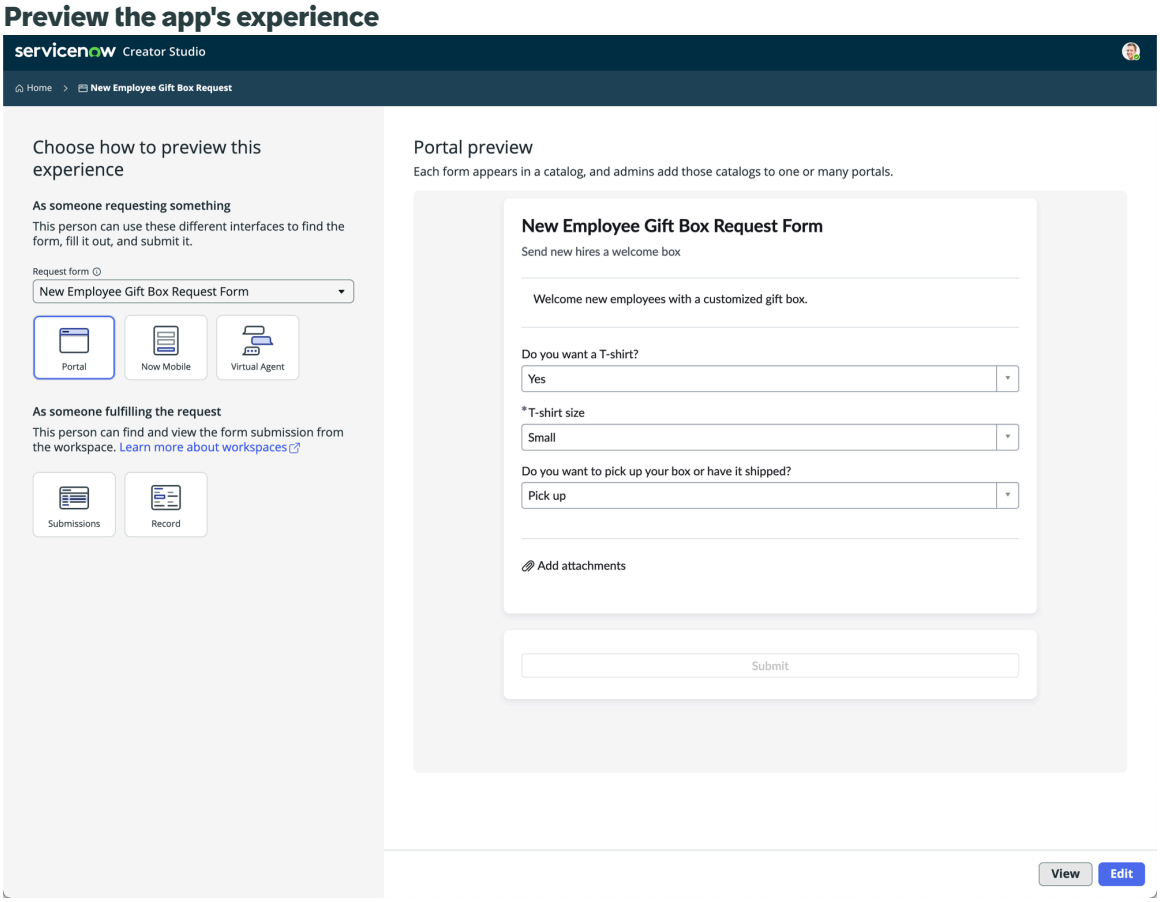
1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that you want to add more forms to.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

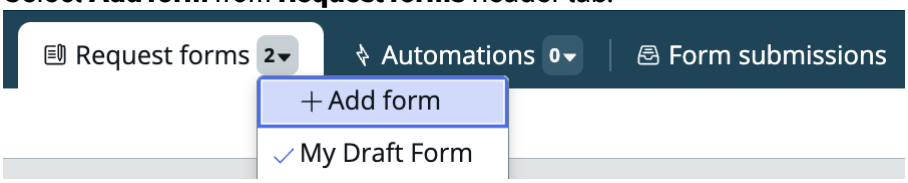
     > **Note:**
     > Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select **Add form** from **Request forms** header tab.



5. Select the catalog template that you want to use to build the form from the list.
6. Select the **Apply this template** button.
   You can select the **Preview** button to see a quick mockup of what the form will look like without any modifications.
7. Add a form to a catalog to specify its business area.

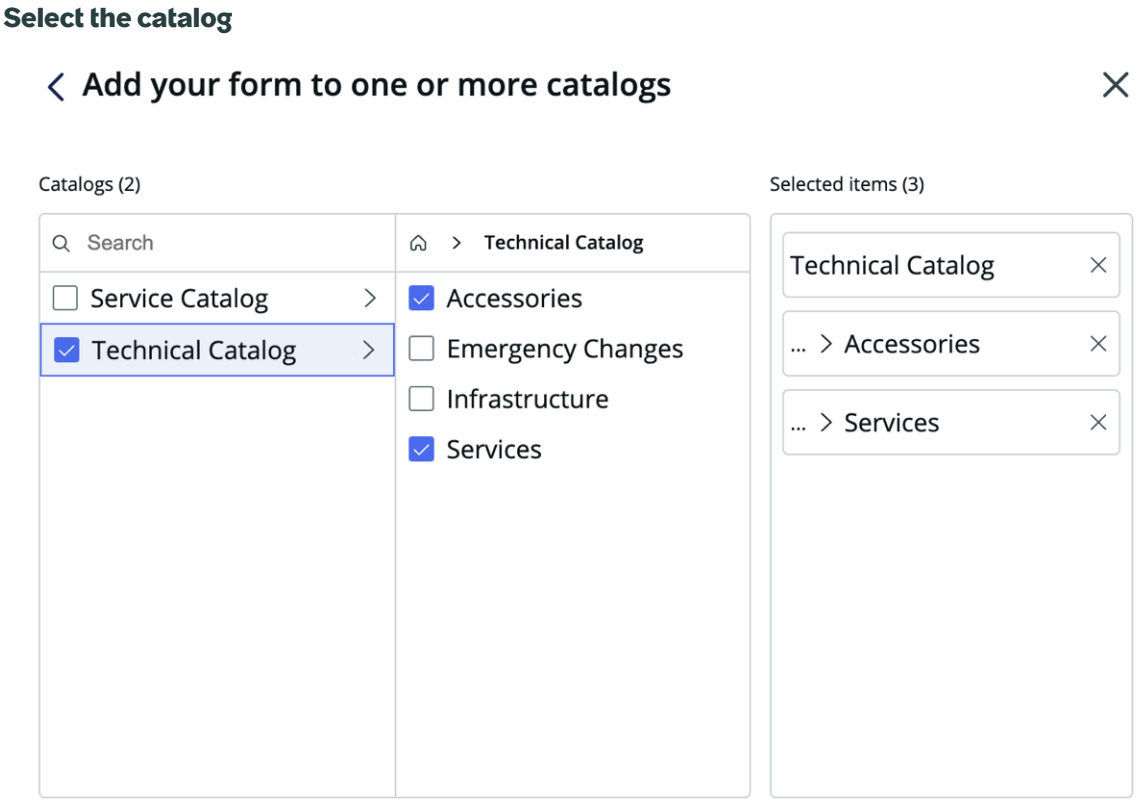
> **Note:**
> You can skip this step for now and revisit it later when you have a better idea of where it fits.

The available catalogs are configured by your admin, contact them if you don't see the one you want.

a. Select the **Edit button** (Edit) for the Catalogs and categories card.

b. Select the catalog that represents the business area the app will use.

For example, choose a service catalog that contains software and laptop cables. Expand the carat for each catalog to see its sub-catalogs.



c. Select as many items in the catalogs as you need.

d. Select **Apply**.

You can edit any of the app's basic settings any time after you finish creating the app. For more information, see Creator Studio form settings.

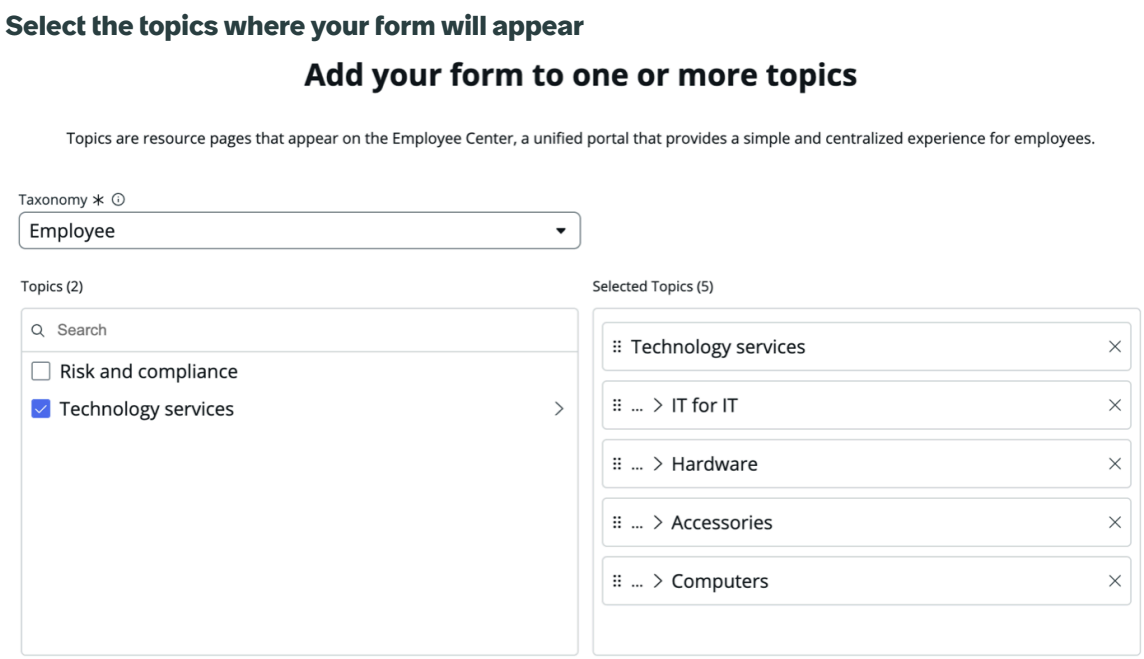
8. Next, choose one or more topics to specify where the form will appear.
Find out more about topics in Associate a catalog item with a taxonomy topic in Employee Center, and more about taxonomy, which is a categorization method, in Unified Taxonomy for Employee Center.

> **Note:**
> You can skip this step for now and revisit it later when you have a better idea of where it fits.

a. Select the **Edit button** (Edit) for the Topics card.

b. Choose the **Taxonomy** page where you want the form to appear, such as **Employee**.
Taxonomy is a method of categorization that Employee Center uses.

c. Select the topic(s) that represent the Employee Center areas where you want the form to appear.
For example, choose a topic that contains technology services, and expand its carat to see each of its sub-topics.



d. Select the topics where you want the form to appear, as many as you need.

e. Select the **Apply** button to save your changes.

9. Select the **Save and continue** button.

Result

Congrats:
Hooray! You've added another form to the app.

What to do next

Next, you can edit the form to populate its questions and customize its layout. For more information, see Customize your form for an app in Creator Studio.

Edit the settings for a form in Creator Studio

Edit form settings if you need to change its basic attributes, such as its associated image or attachments are allowed.

Before you begin

To edit the settings for a form, you must be given permission to work on the app.

About this task

Note:
After you create the app, its **Template** can't be edited. If you want to change it, create a new form using a different catalog template. The **Record submission table** is automatically generated, and can't be changed.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.

2. Open the application that contains the form you want to edit.

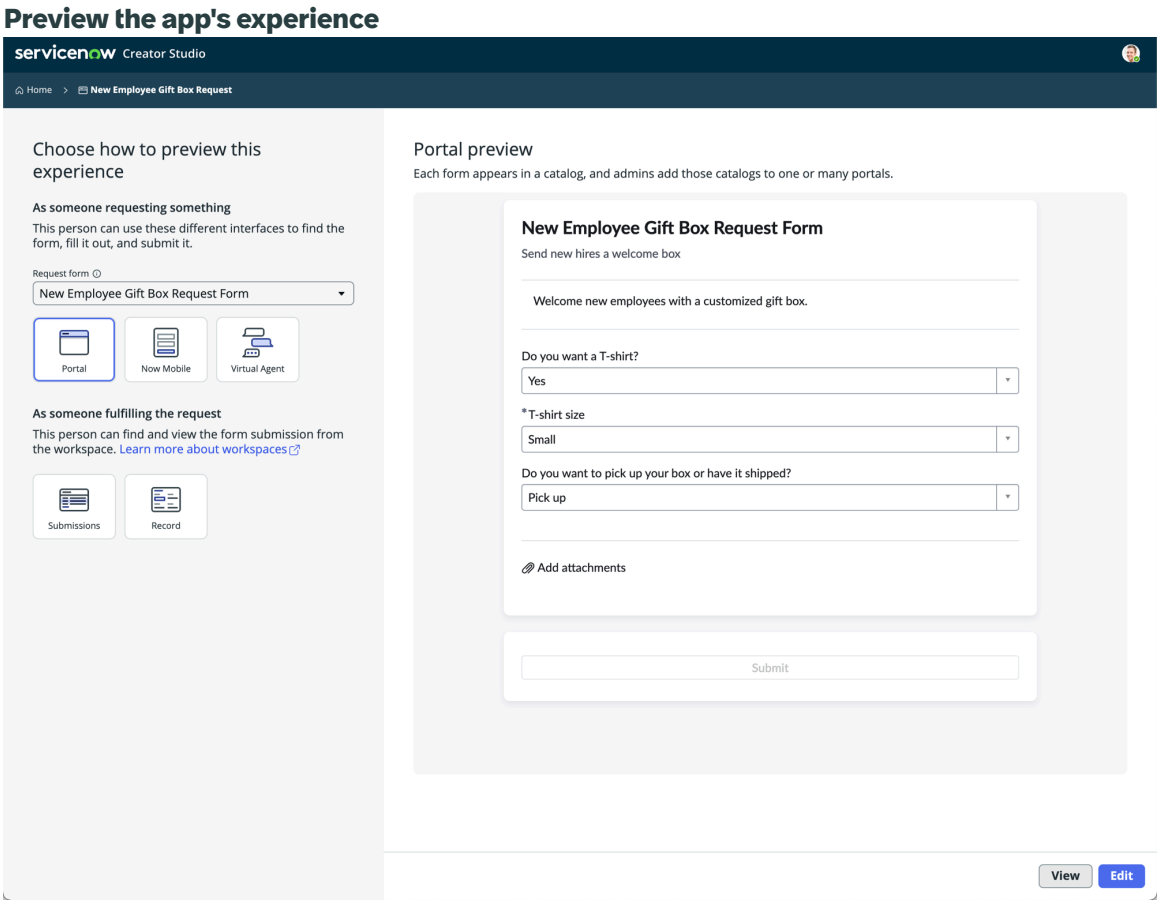
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

- **Portal** (see a preview of how it'll appear on a desktop website)
- **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
- **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

> **Note:**
> Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.



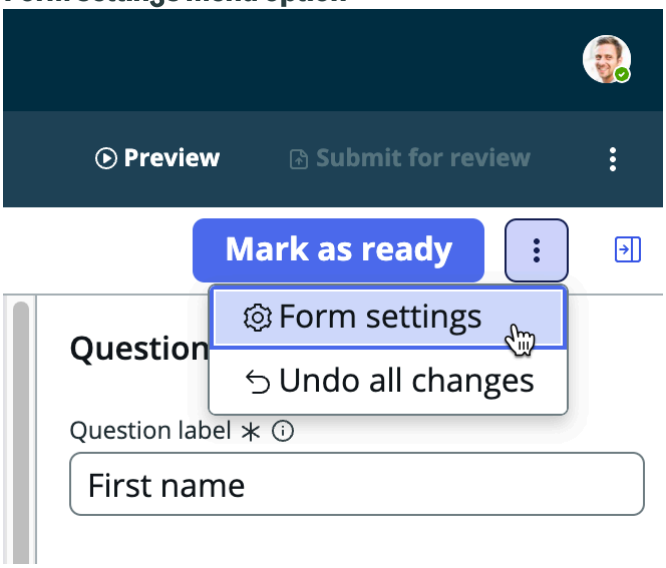
You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Check that you're editing the correct form in your app by selecting it from the **Request forms** tab.

5. Select the more actions icon ⋯.

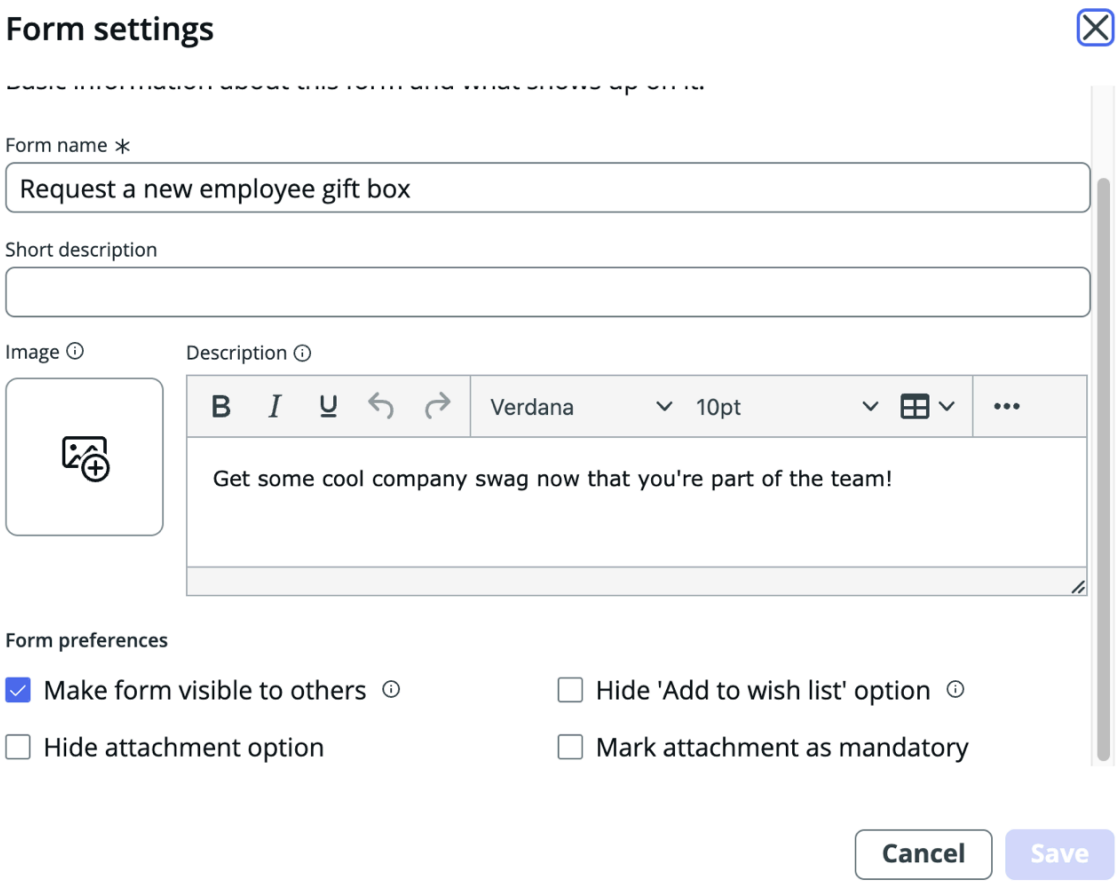
6. Select **Form settings**.

Form settings menu option



7. Update settings on the **General** tab.
For details on specific form settings, see Creator Studio form settings.

Form settings modal



8. Select the **Location** tab to update where the form appears in a catalog, how it's categorized, and which topics it appears for.

a. Select the edit icon (Edit) for the **Catalogs and categories** card.

b. Select the catalog that represents the business area the app will use.
For example, you could select a service catalog that contains software and laptop cables for an IT fulfillment app.

c. Expand the carat for each catalog to see its sub-catalogs.

d. Select items in the catalogs, as many as you need.

e. Select the **Apply** button to save your changes.

f. Select the edit icon (Edit) for the **Topics** card.

g. Choose the **Taxonomy** page where you want the form to appear, such as **Employee**.
Taxonomy is a method of categorization that Employee Center uses.

h. Select the topic(s) that represent the Employee Center areas where you want the form to appear.
For example, choose a topic that contains technology services, and expand its carat to see each of its sub-topics. Find out more about topics in Associate a catalog item with a taxonomy topic in Employee Center, and more about taxonomy, which is a categorization method, in Unified Taxonomy for Employee Center.

i. Select the topics where you want the form to appear, as many as you need.

j. Select the **Apply** button to save your changes.

9. Select the **Access** tab to change which roles and groups can view and submit the form.

a. Select the edit icon (Edit) to edit users that the form should be **Available for**.

b. Select the roles and groups that should have access to the form.

c. Select the **Apply** button to save your changes.

d. Select the edit icon (Edit) to edit users that the form should be **Not available for**.

e. Select the roles and groups that shouldn't have access to the form.
Work with your admin to restrict or provide access to the roles and groups for this setting in non-production and production environments. For more information, see Administering user access for deployed Creator Studio apps.

f. Select the **Apply** button to save your changes.

10. Select **Save all settings**.

Publish a form for your app in Creator Studio

Publishing forms once they're ready makes them available as catalog items in the production instance for published apps.

Before you begin
To publish a form, you must be given permission to work on the app.

About this task
After you publish a form, it's available in the specified catalog on the instance you're working on. However, you still need to deploy your app to the production instance for users to access the form. For more information, see Deploying your Creator Studio app.

Procedure
1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the application that contains the form you want to publish.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

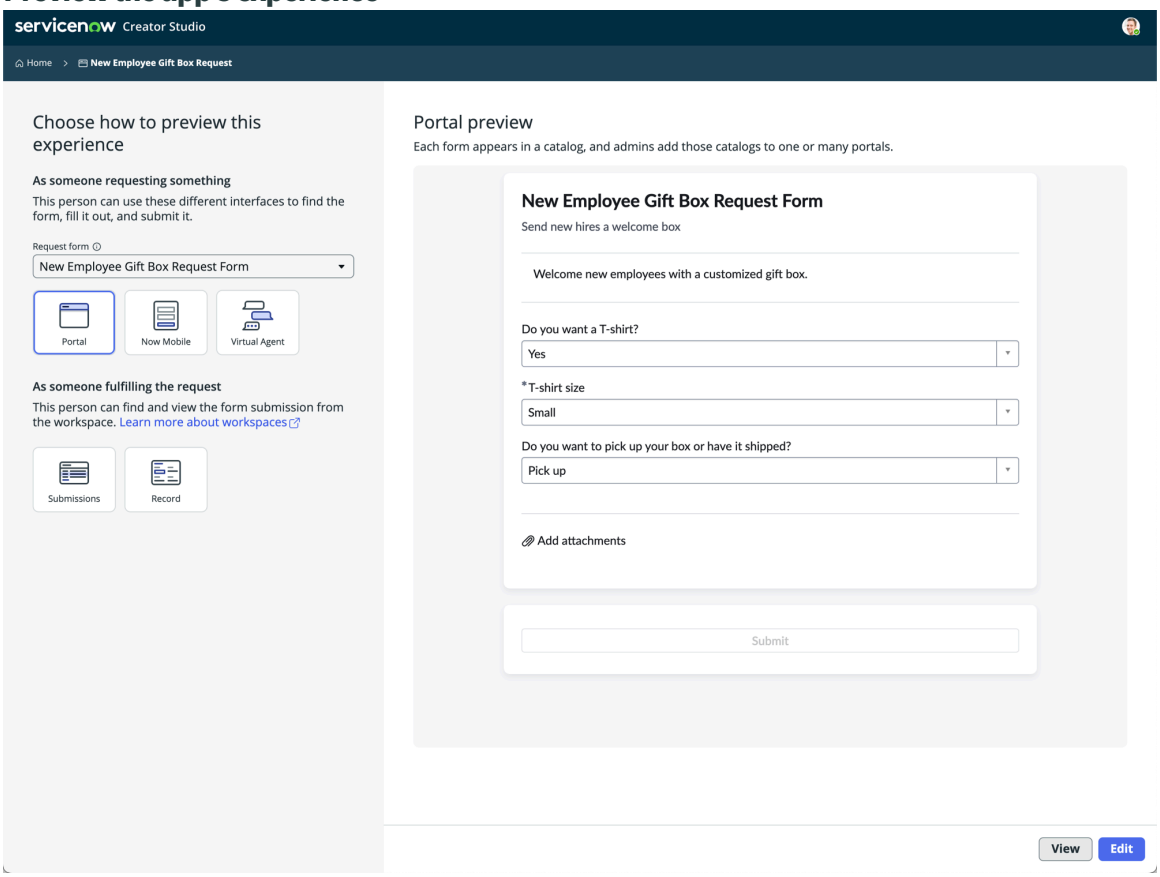
   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

   Note:
   Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

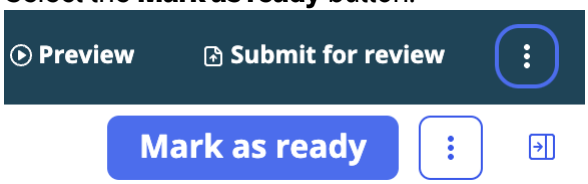
   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

Preview the app's experience



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Check that you're working on the correct form in your app by selecting it from the **Request forms** tab.
5. Select the **Mark as ready** button.



Result

The catalog item for the form is ready to be deployed with your app. Once the app is deployed, the form is available in the associated service catalog. If the form's app hasn't been deployed, you need to deploy it.

Hide a form from use in the ServiceNow AI Platform in Creator Studio

Hiding a catalog item for your app's form effectively makes the form inactive. Hidden forms are unavailable in both the app and the catalog it belongs to.

Before you begin

To hide a form, you must be given permission to work on the app.

About this task

Creator Studio doesn't let you delete forms. Instead, hide forms to ensure that workflows stay intact.

You can hide only forms that have already been published. For more information, see Deploying your Creator Studio app.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the form you want to hide.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

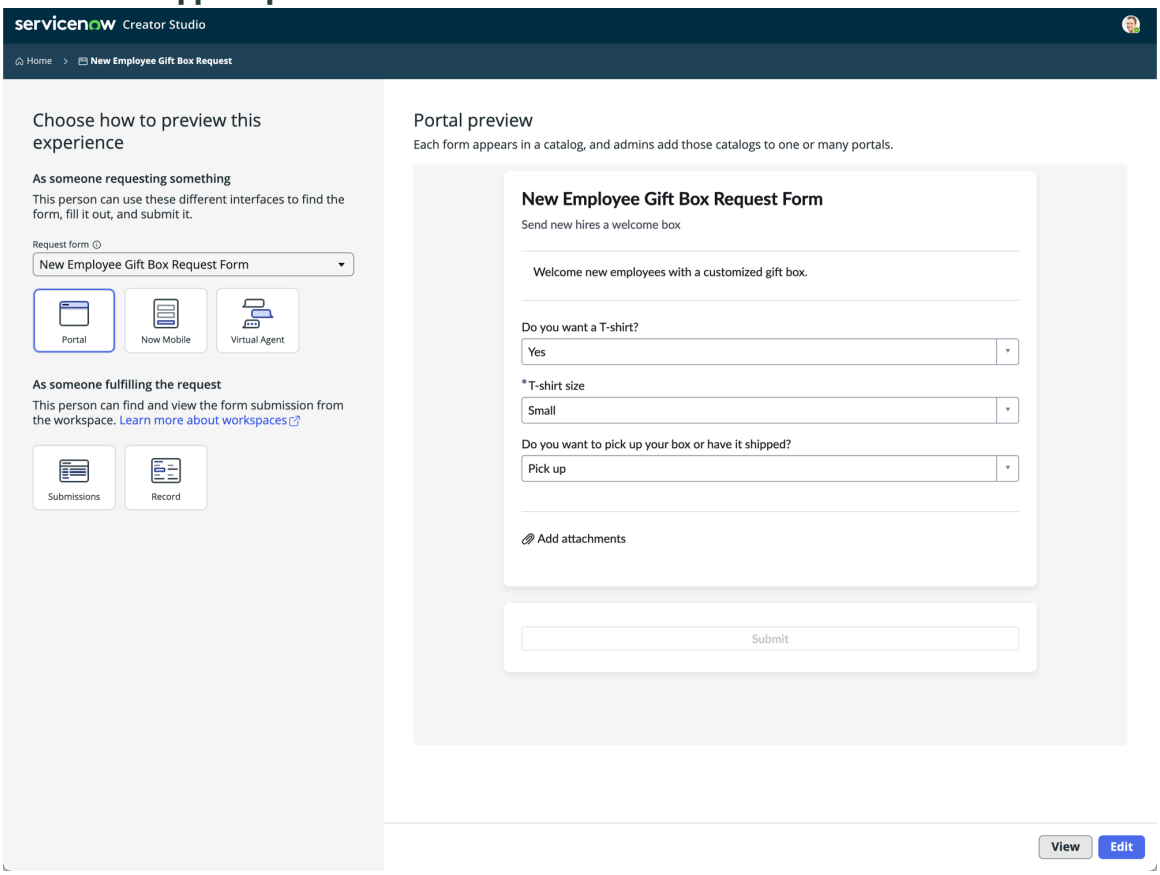
   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

   Note:
   Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

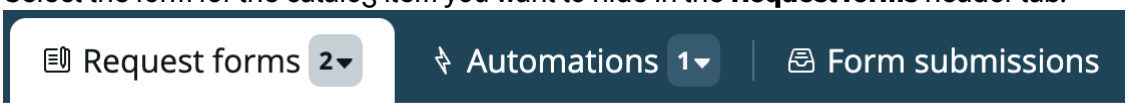
   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

Preview the app's experience



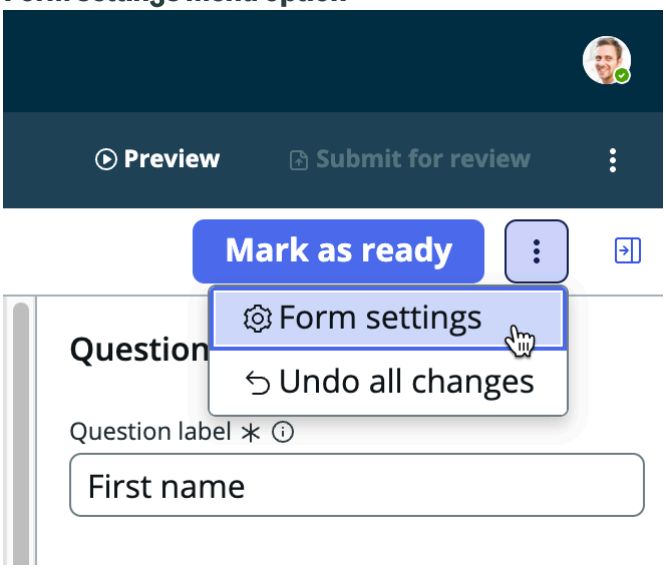
You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the form for the catalog item you want to hide in the **Request forms** header tab.



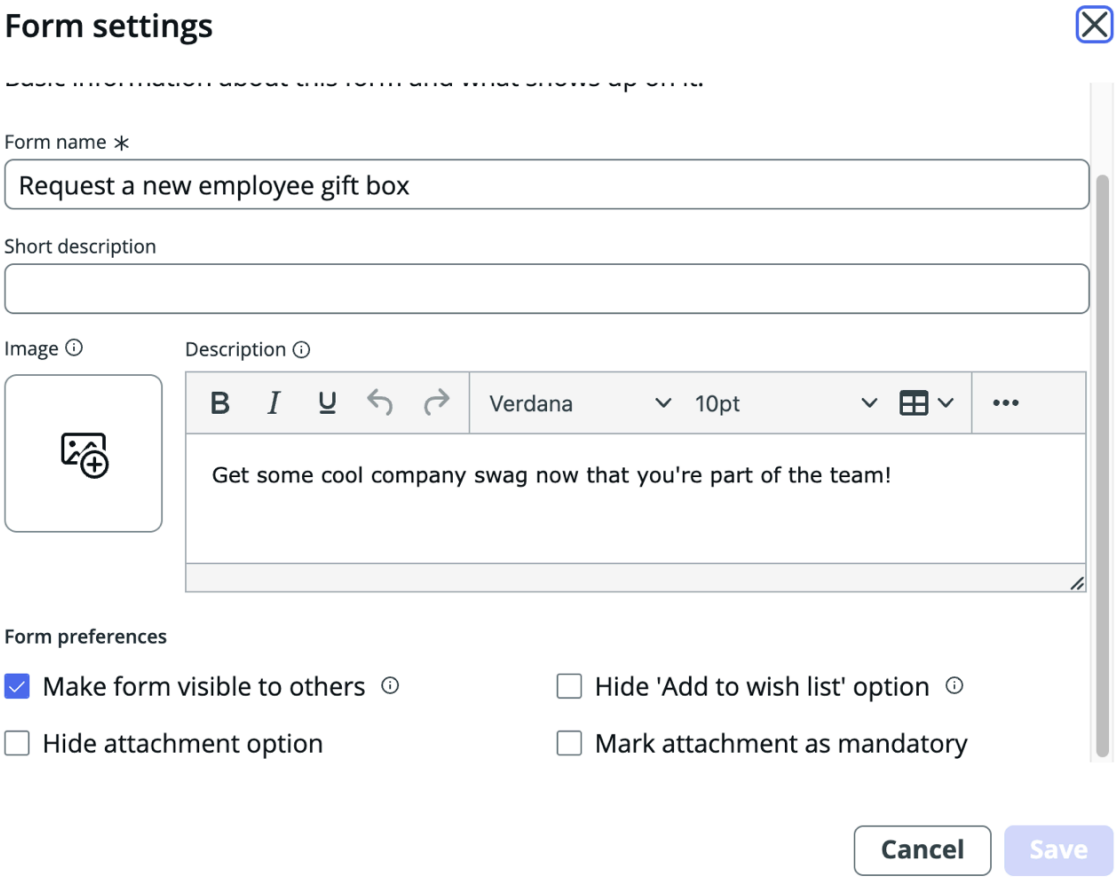
5. Select the more actions icon ( ).
6. Select **Form settings**.

Form settings menu option



7. De-select the **Make form visible to others** option.

Form settings modal



8. Select **Save**.

What to do next

You must re-deploy the app to hide the inactive form (catalog item) on the production instance.

Working with automation in Creator Studio

How do you simplify and streamline tasks for fulfillers? Use automation! For example, you can have a task assigned automatically to someone based on what type of request it is. We'll use playbooks to accomplish adding this automation to your app.

Summary:
After reading this section, you'll understand how to use automation to do the following things:

- Use playbooks to guide agents and fulfillers through processes from start to finish, improving the customer experience and the way tasks are carried out.
- Create a consistent process for your tasks or activities to be carried out.
- Consolidate business decisions and processes across the organization.

Note:
Because playbooks are based on forms, you should finish building out your app's forms before you start working on automation.

Playbooks are a set of activities that occur in order based on a trigger. Each activity is more like a step in a chain of steps. You can add multiple playbooks to an app if you need to.

Key terms:

Activity

Activities in a playbook complete automated tasks, such as obtaining approvals, assigning records, and sending email.

Automation

Tasks or requests moving through a workflow without manual intervention.

Playbook

A set of actions based on an initiating action called a trigger.

Record

A task or request that must be acted on. All rows in ServiceNow tables are individual records. Records have different states depending on what actions have been taken.

Trigger

The event that starts making the playbook run.

Workflow

The path a record takes from creation to completion.

What is automation?

Automation in Creator Studio enables you to create simplified playbooks, which are basic, automatic workflows. Simple playbooks consist of a trigger (such as a record changing states, or a user choosing a specific answer for a question) and an activity (such as the record being assigned to a new person). Playbooks enable you to add the following:

- Activities to your automation to define the workflow's path.
- Decisions to create different paths, or branches, depending on the decision's outcome.
- Custom activities defined by your admin or ServiceNow AI Platform owner.

Playbooks take the guess work out of assigning tasks and help users focus on the tasks and information that matter to their job. A well-designed playbook can do these things:

- Automatically start or trigger changes for different types of records, such as task assignments.
- Reuse activities and business decisions from other workflows you've already created.
- Clearly show the next steps that fulfillers must take to move to the next step of completing the record's life cycle.

There are several types of activities that you can add to playbooks that, when paired with decisions, remove the manual thinking behind what to do next when addressing tasks. Depending on your configuration, some of the activities you can add include:

- Request approval for a task
- Assign the task to someone
- Create a new task as a next step
- Send an email
- Choose a custom action configured by your admin

Note:
In addition to creating custom activities, your admin can also hide standard activities, so you may not see all of the above options.

You can also use a placeholder activity for more complex activities that must be configured outside of Creator Studio, or for another activity to be swapped in later. Complex activities are configured in a different tool called Workflow Studio.

What goes into building automation?

Automations in Creator Studio include the following parts.

Automation parts

Concept	Description
Playbook	An automatic workflow that guides users through tasks based on the record's status changes. Find out more about creating playbooks in Add an automated playbook to an app in Creator Studio.
Trigger	The event that specifies when the playbook should start running, such as when a form is submitted or updated to a specific status. Check out Edit the trigger for a playbook in Creator Studio for more information.
Activity	The thing that happens during the playbook, such as assigning a task or requiring approval.

Automation parts (continued)

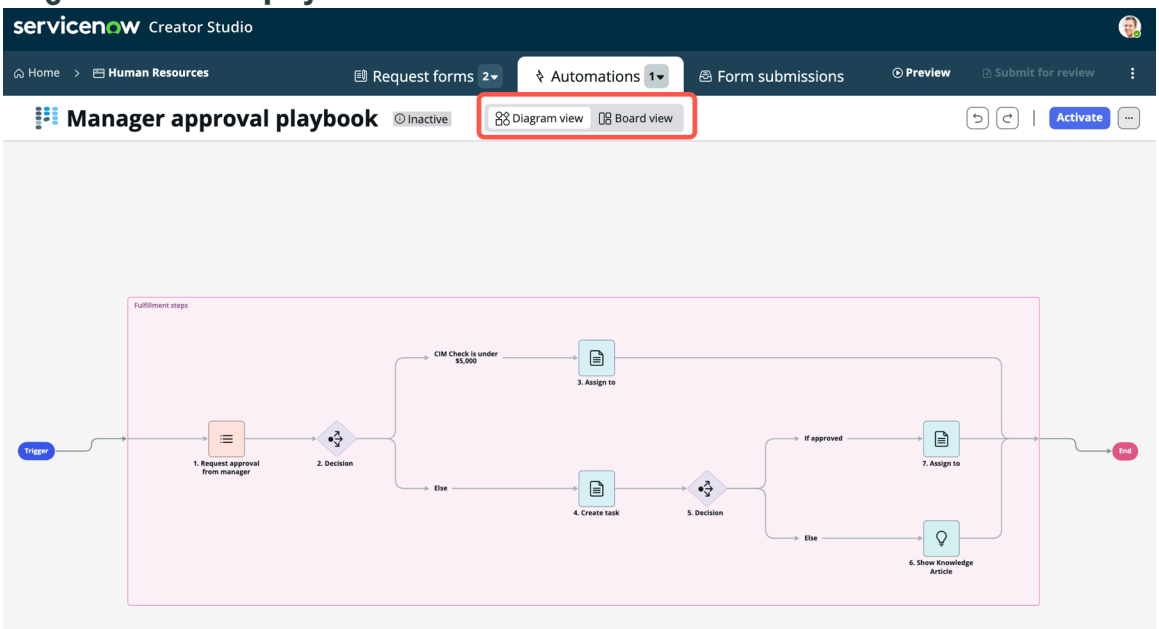
Concept	Description
	Note: If you're already familiar with optional activities in playbooks, that's great! However, to keep automations streamlined and simple, Creator Studio doesn't support optional activities. If you must create optional activities, you can add a placeholder activity in Creator Studio and then edit the placeholder in Workflow Studio or swap it out for another activity later in Creator Studio. Additionally, admins can create custom activities for you to include in a playbook. Learn how to add activities in Add activities to an app's playbook in Creator Studio.
Decision	A series of inputs, conditions, and results that create different branches, or conditional paths that users follow based on the decision's outcome. Get the scoop on adding decisions in Add a decision to an app's playbook in Creator Studio.
Branch	A distinct path from a decision's outcome, or what happens for each of the decision's possible choices. For more information, see Add a decision to an app's playbook in Creator Studio.
Parallel process	Branches for activities and stages that run in parallel to another branch of activities. Learn about parallel processes in Add a parallel process to an app's playbook in Creator Studio.
Connectors	Lines that connect activities and decisions in a playbook that enable you to add more activities, decisions, and parallel processes. You can drag connectors between activities to create parallel activities.

Board and Diagram views of a playbook

Creator Studio offers two ways of working with playbooks: the Board view and the Diagram view.

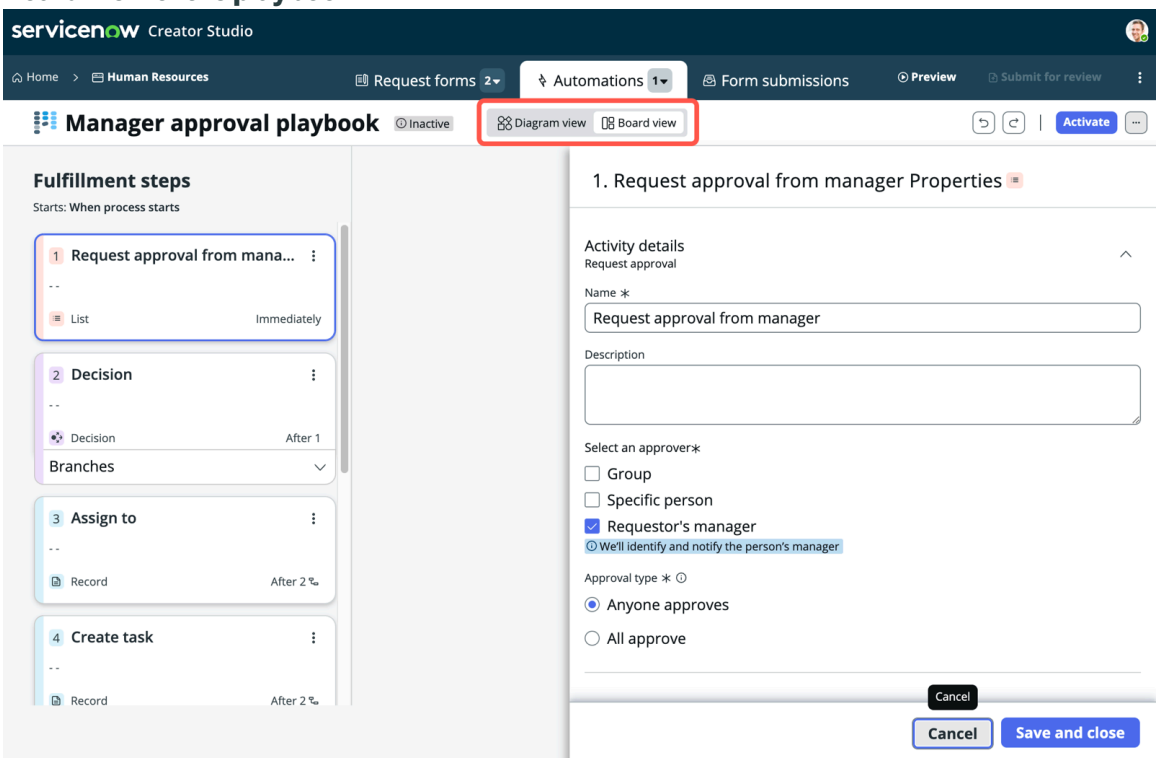
The Diagram view is a visually intuitive diagram that shows you the order that activities occur in the playbook. When you select an activity, such as the trigger or a decision, a modal pops up where you can edit its details. You must use the Diagram view to add decisions.

Diagram view of the playbook



The Board view is a more traditional layout, which shows each activity as a card in the navigation panel. When you select an activity, for example a task, its editable details appear in the canvas for you to work with them. You must use the Board view to rearrange activities.

Board view of the playbook



This help document will primarily give instructions using the Diagram view, with alternate directions on how to complete automation tasks in the Board view.

Where do playbooks run in the ServiceNow AI Platform?

Users work on requests in the Request App Workspace on the ServiceNow AI Platform, which lists a record for each request. The playbooks run on the specified records in the app's workspace category.

Specifically, the **Catalog tasks** tab of the record details walks users through the activities they must do to complete the task and close the record.

Workflow for creating automations in Creator Studio

Provide your organization's fulfillers with guidance when addressing records generated from the app by adding automated playbooks to it.

Before you begin

Note:
Because playbooks are based on forms, you should finish building out your app's forms before you start working on automation.

To work with automations, you must be given permission to work on the app.

Procedure

1. Create an app.
   If you have an existing playbook that's close to what you want to create, you can duplicate and edit it, which may be faster than creating an entirely new playbook. For more information, see Copy an automated playbook in Creator Studio.
2. Add an automated playbook to the app.
   For more information, see Add an automated playbook to an app in Creator Studio.
3. Add activities to the playbook.
   For more information, see Add activities to an app's playbook in Creator Studio.
4. Create different branches of the playbook by adding decisions to it.
   For more information, see Add a decision to an app's playbook in Creator Studio.
5. **Optional:** Create any parallel processes to run at the same time in the playbook.
   For more information, see Add a parallel process to an app's playbook in Creator Studio.
6. Make any additional changes to the playbook's trigger.
   For more information, see Edit the trigger for a playbook in Creator Studio.
7. Make any additional changes to the playbook settings.
   For more information, see Edit a playbook in Creator Studio.
8. Activate the playbook when it's ready.
   For more information, see Activate a playbook in Creator Studio.

Add an automated playbook to an app in Creator Studio

Create an automated playbook, which is a process that runs whenever a record is created or updated by the app's specified form.

Before you begin

Playbooks run on the records generated by catalog items you create for the app, so you must add forms to the app before you can add automation. For more information, see Working with forms in Creator Studio.

To add a playbook, you must be given permission to work on the app.

About this task

Note:
You can build a travel request app where people can ask for permission for different types of travel, which automatically routes the request to a manager for approval.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that you want to add automation to.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

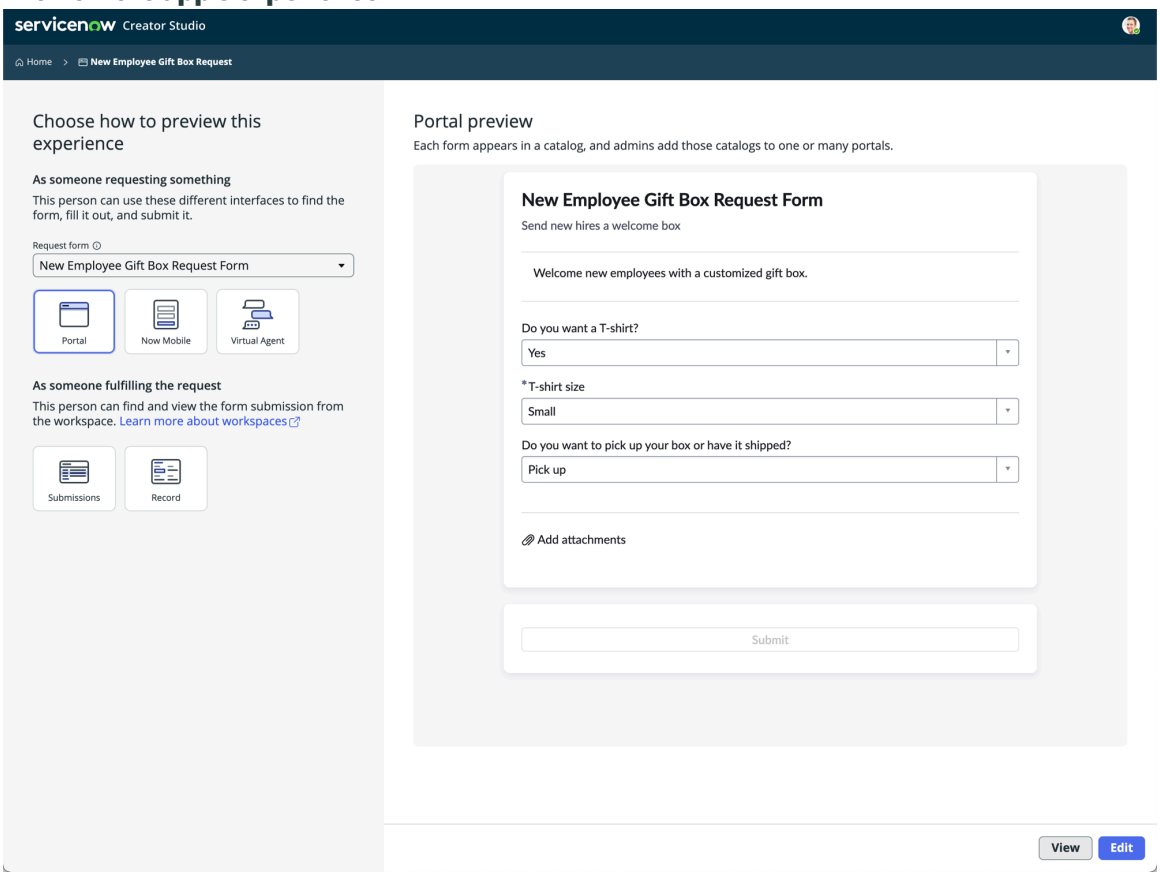
   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

   Note:
   Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

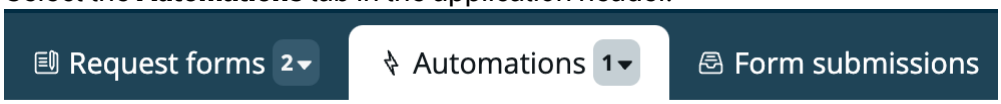
   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

Preview the app's experience



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the **Automations** tab in the application header.

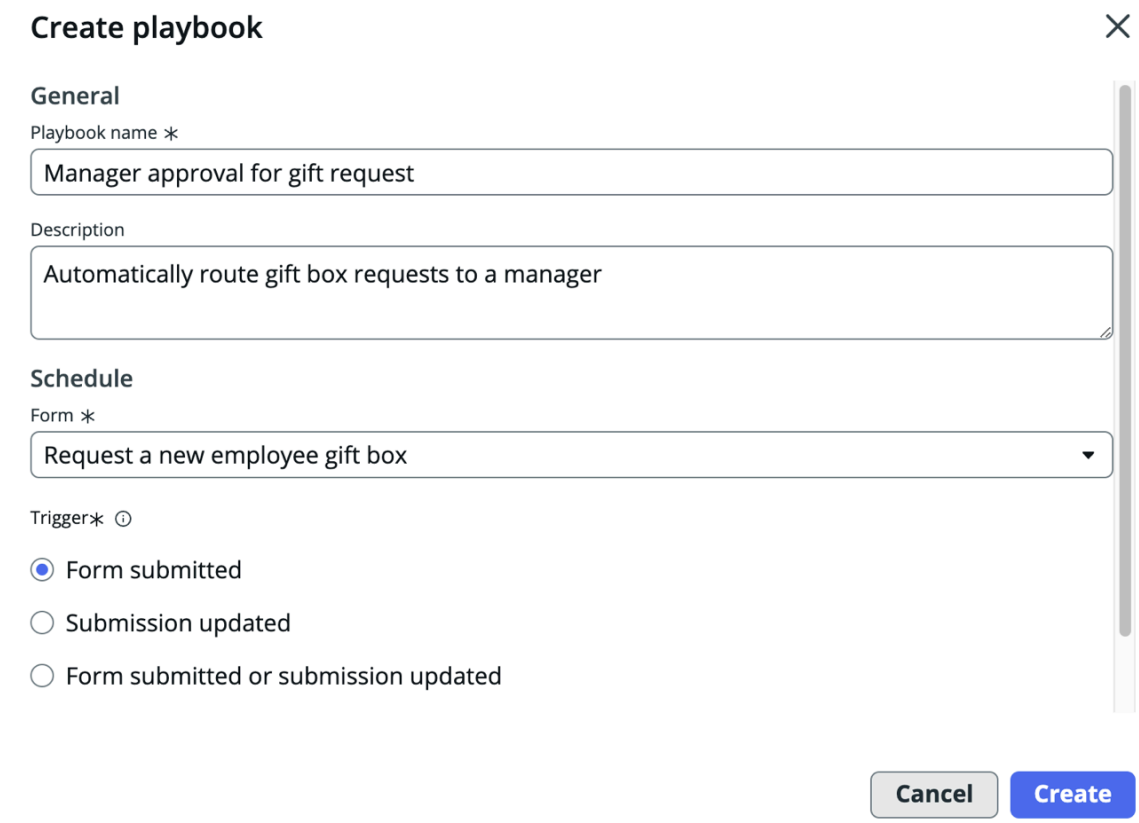


5. Select the **Create a playbook** button.
   If an automation already exists, select the **Automations** tab and then select **Add new playbook**.
6. Specify the playbook's General attributes in the Create playbook modal.

General playbook definition fields

Field	Description
Playbook name	Descriptive name for the playbook you're creating.
Description	Brief explanation of what the playbook does, for example, the end goal for the record type.

Create a playbook



7. Specify the Schedule for the playbook.

   a. Select the **Form** whose catalog item generates the record type that you want the playbook to run on.
   The table for the form you choose is always the app's task table, which is specified when the app is created.

   b. Select the type of **Trigger** that initiates the playbook.

Playbook trigger options

Trigger	Description
Form submitted	Start running the playbook when a user submits the form you chose.
Form updated	Start running the playbook when a user updates the form you chose.
Form submitted or updated	Start running the playbook when a user submits or updates the form you chose.

Note:
You can't change an playbook's trigger type after you finish creating the playbook. Instead, create a new playbook with a different trigger.

However, you can edit the trigger condition, such as making the playbook run conditionally based on a specific answer to a question. For more information, see Edit the trigger for a playbook in Creator Studio.

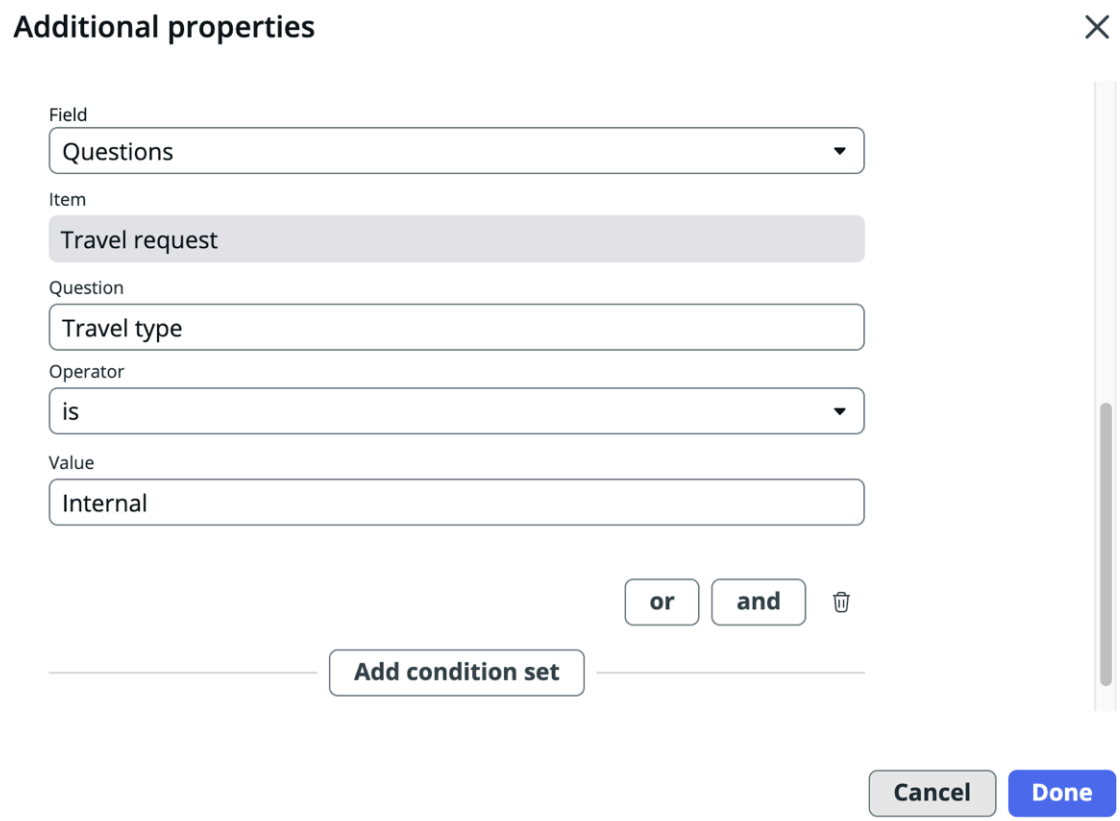
c. If you chose a trigger that includes a form being updated, specify how often that app should **Run your playbook**.
The options are:

- **Once**
- **For each unique change**
- **Only if not currently running**
- **For every update**

d. Specify the conditions that must be met for the playbook to begin running by selecting **Add condition set**.

- If you want to trigger the playbook based on the value of a column in a table, select the **Field** that you want to be the trigger, as well as its condition **Operator** and the specific trigger **Value**. For example, when a **Start date** is **after** the **Date** needed.
- If you want to trigger the playbook based on the response from a form, select **Questions** as the trigger **Field**. Then select the question you want in the **Question** field, the condition **Operator** and the answer's **Value**.

Question answer as trigger for an automation



Add as many conditions as you need. For more information, see Create a condition statement using the condition builder.

8. Select **Save**.

Result

Congrats:
Congratulations, you've created an automation!

What to do next

Next, you need to add activities to the playbook. For more information, see Add activities to an app's playbook in Creator Studio.

Copy an automated playbook in Creator Studio

Duplicate an existing playbook and make small changes to it, which may be faster than creating an entirely new automated playbook.

Before you begin

Because playbooks are based on forms, you should finish building out your app's forms before you start working on automation.

To copy a playbook, you must be given permission to work on the app.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app with the playbook you want to copy.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

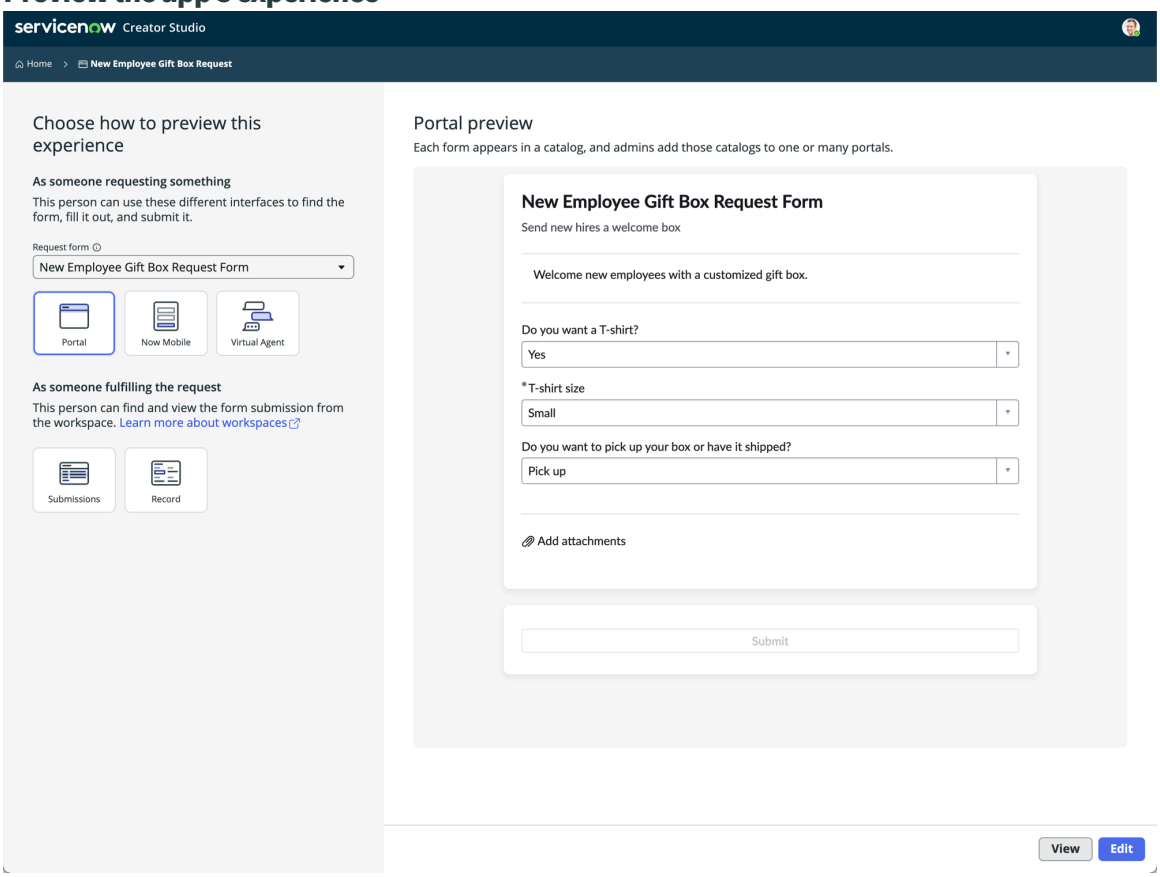
   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

   Note:
   Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

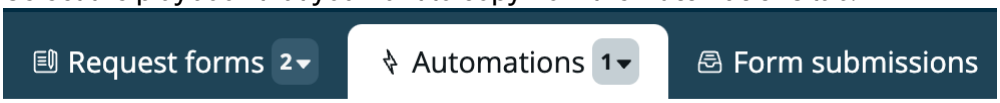
   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

Preview the app's experience



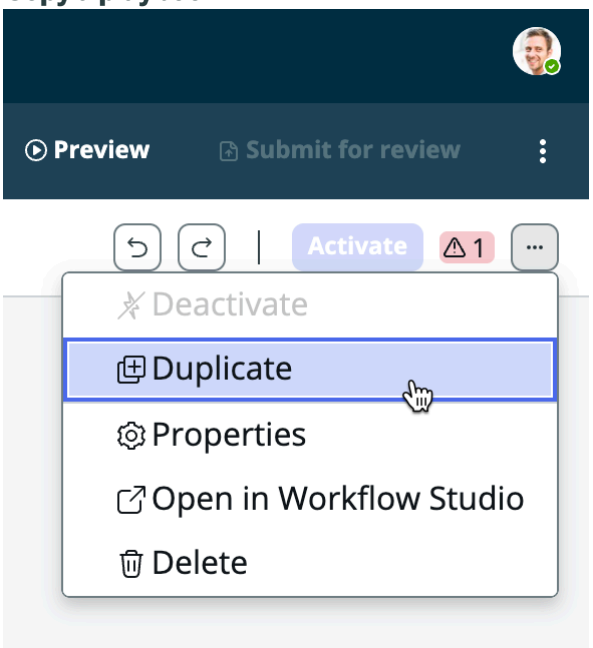
You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the **Automations** tab in the application header.
5. Select the playbook that you want to copy from the **Automations** tab.



6. Select the more actions menu icon ( ).
7. Select **Duplicate**.

Copy a playbook



8. Choose the **Duplicate** button in the confirmation modal.

Add activities to an app's playbook in Creator Studio

Add activities to an app's playbook to specify what the automation does to the designated record type. An activity defines what actually happens when a playbook executes.

Before you begin

To add activities to a playbook, you must be given permission to work on the app.

About this task

The activities that you can add to a playbook are limited by your administrator to ensure you use the correct ones for your organization. Your admin may have created some custom activities for you to choose from, or hidden some standard activities.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the playbook you want to add an activity to.

3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

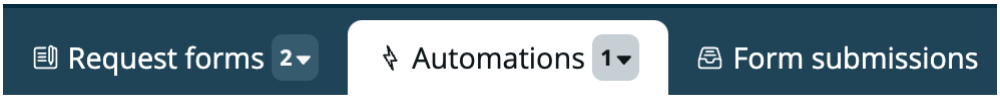
   > **Note:**
   > Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

   Preview the app's experience

   
   You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the **Automations** tab in the application header.
5. Check that you're editing the correct playbook in your app by selecting it from the **Automations** tab.



6. Select the add icon on the connector where you want to add an activity and choose the square **Add an activity** icon ( ) in the menu that pops up.

How to add an activity in Board and Diagram views

View	Steps
Diagram	**a.** Select the **+** icon in the stage. **b.** In the mini-picker, select the square icon ( ) to add an activity.
Board	Select **+ Add activity**.

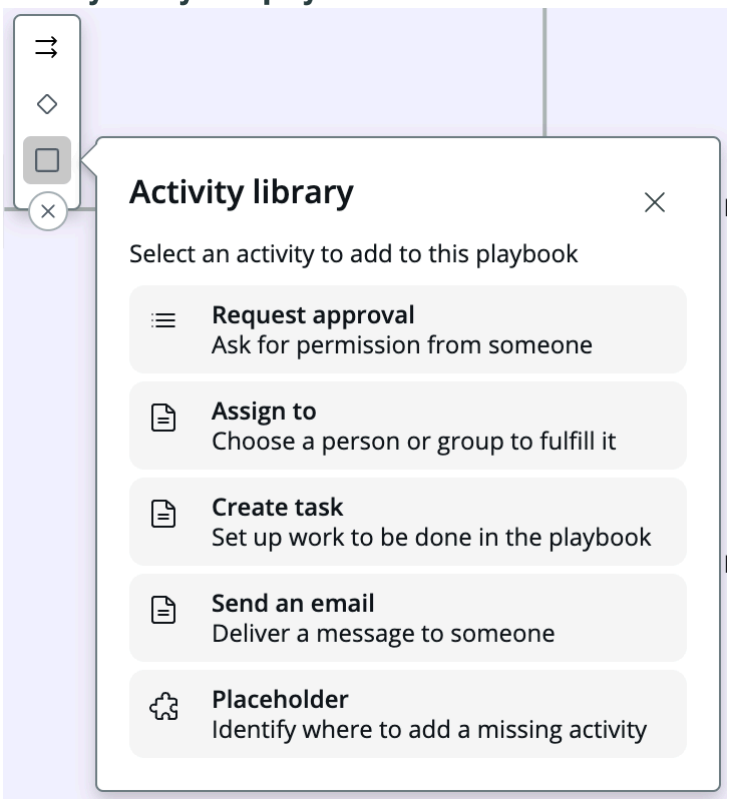
7. Choose the type of activity that you want from the Activity library pop-up.

Note:
In addition to the following standard activities, you may see some custom activities that your admin created.

Types of activities

Activity type	Description
Request approval	Ask someone for permission to accomplish a task.
Assign to	Choose a person who should fulfill the task.
Create task	Specify a process that must be done as part of the playbook.
Send an email	Send an email to one or more people. You can specify images and enrich text for the email that gets sent automatically.
Placeholder	Set an undefined activity to be specified later, or a more advanced activity such as an email notification, when an activity is completed. Placeholder activities don't have any logic assigned to them yet, and must be edited in Workflow Studio. Or, you can swap them out later for another type of activity in Creator Studio.

Activity library for a playbook



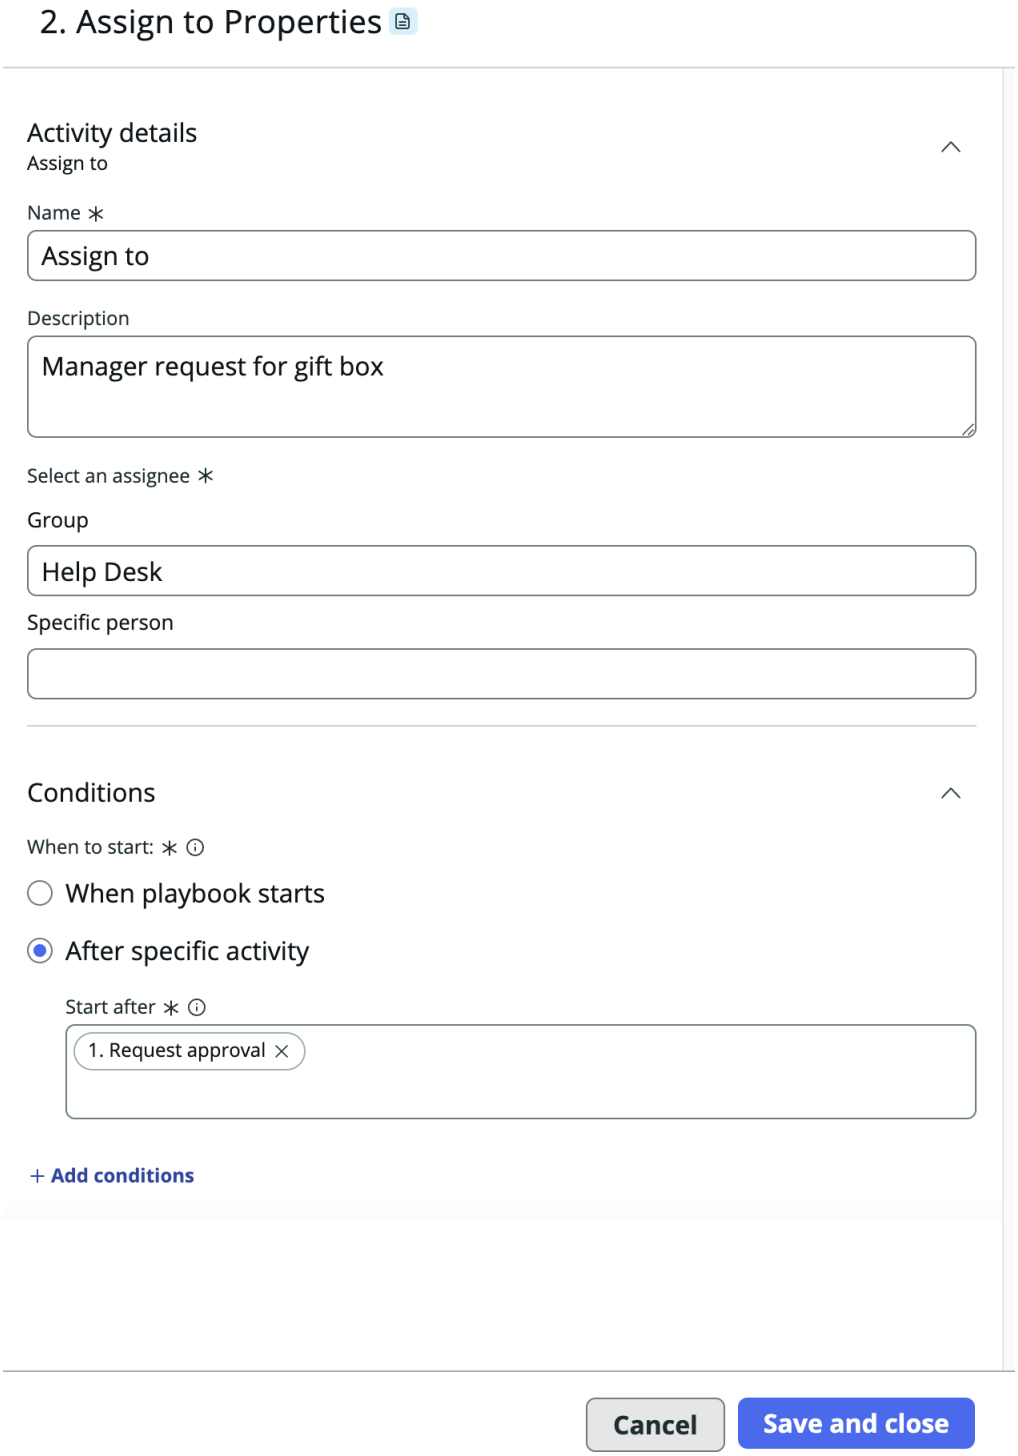
Your new activity and its Activity properties panel appear, where you define what the activity is.

8. Enter the basic details for the activity.

General activity details

Field	Description
Name	Unique, user-facing name for your activity, which appears to agents and fulfillers while the playbook is running.
Description	Optional details about what the activity accomplishes.

Activity details panel



9. If needed, specify the approver or assignee in the **Select an approver** or **Select an assignee** fields.
   Approvers and assignees are the person or people who must approve the task, or who the task gets assigned to. The options are:

- **Group**: Enter one or more user groups in the field that appears. For example, `App engine Admins`.
- **Specific person**: Enter the person's name as it appears on the ServiceNow AI Platform. If you entered a group, you can select only from users in the specified group.
- **Requester's manager**: (Request approval activities only) Automatically routes the approval to the manager of the person who's making the request.

10. Enter details for specific types of activities.

a. For Request approval activities only, specify the **Approval type**.
Approval type defines whether a single approver is needed or if everyone must approve the request. The options are:

- **Anyone approves**: Only one of the specified approvers must approve the request.
- **All approve**: Every one of the specified approvers must approve the request.

  If you select this option and specified a group, all members of the group must approve the request.

b. For Create task activities, specify the **Priority**.
The options are:

- **Critical**
- **High**
- **Moderate**
- **Low**
- **Planning**

c. For Send an email activities, specify the recipients and contents of the email.

- Enter the name (for ServiceNow AI Platform users) or email address for people who should receive the email in the **To** and **Cc** fields.

  Select the **Requester** option for the **To** or **Cc** fields to include the person who made the request in the email's recipients.

- Enter the email's subject in the **Subject** field.
- Enter the body of the email in the textbox. Select the additional toolbar buttons icon () to display more formatting options. For example, you can add images, tables, and links to the email.

11. Select at what point the activity should start running in the **When to start** field of the Conditions section.
The options are:

- **When** *`playbook`* **starts**: The approval request runs when the trigger occurs, which is the form's record being created or updated.
- **After specific activity**: The approval request runs after one or more activities run, which you must specify in the **Starts after** field. You can select only activities that occur sequentially before the activity you're working on.

  Note:
  This option isn't available for the first activity in a playbook.

12. **Optional:** Define any extra conditions that must be met for the activity to happen by selecting **+ Add conditions**.
    Use the condition builder that appears to specify any other things that must happen for the activity to run. For more information, see Create a condition statement using the condition builder.
13. Select the **Save and close** button to finish setting up your activity.

What to do next

Continue adding activities and decisions, as well as connectors and parallel processes if needed, to finish creating your playbook. For more information on decisions, see Add a decision to an app's playbook in Creator Studio.

Add a decision to an app's playbook in Creator Studio

Add decisions, which are if/then conditions, to define branches, or different paths of an automation's playbook in Creator Studio.

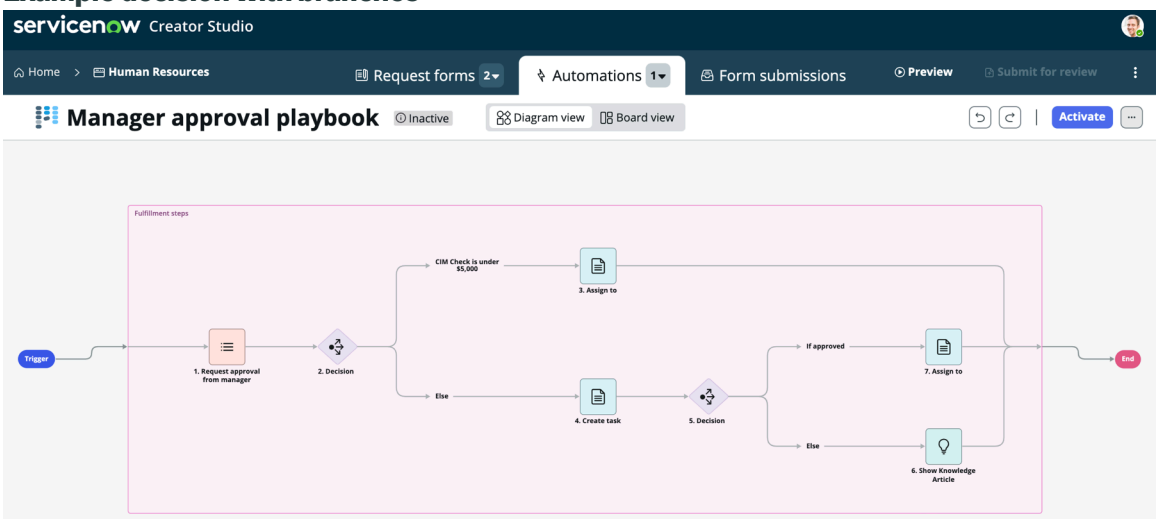
Before you begin

To add decisions to a playbook, you must be given permission to work on the app.

About this task

Each decision should have at least two branches, with each branch representing a possible outcome for the decision. The second branch can be the ELSE branch, which is required. The ELSE branch will be followed when all other conditions on other branches are false. Think of the else branch as the catch-all case for the decision.

Example decision with branches



Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the playbook you want to add a decision to.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

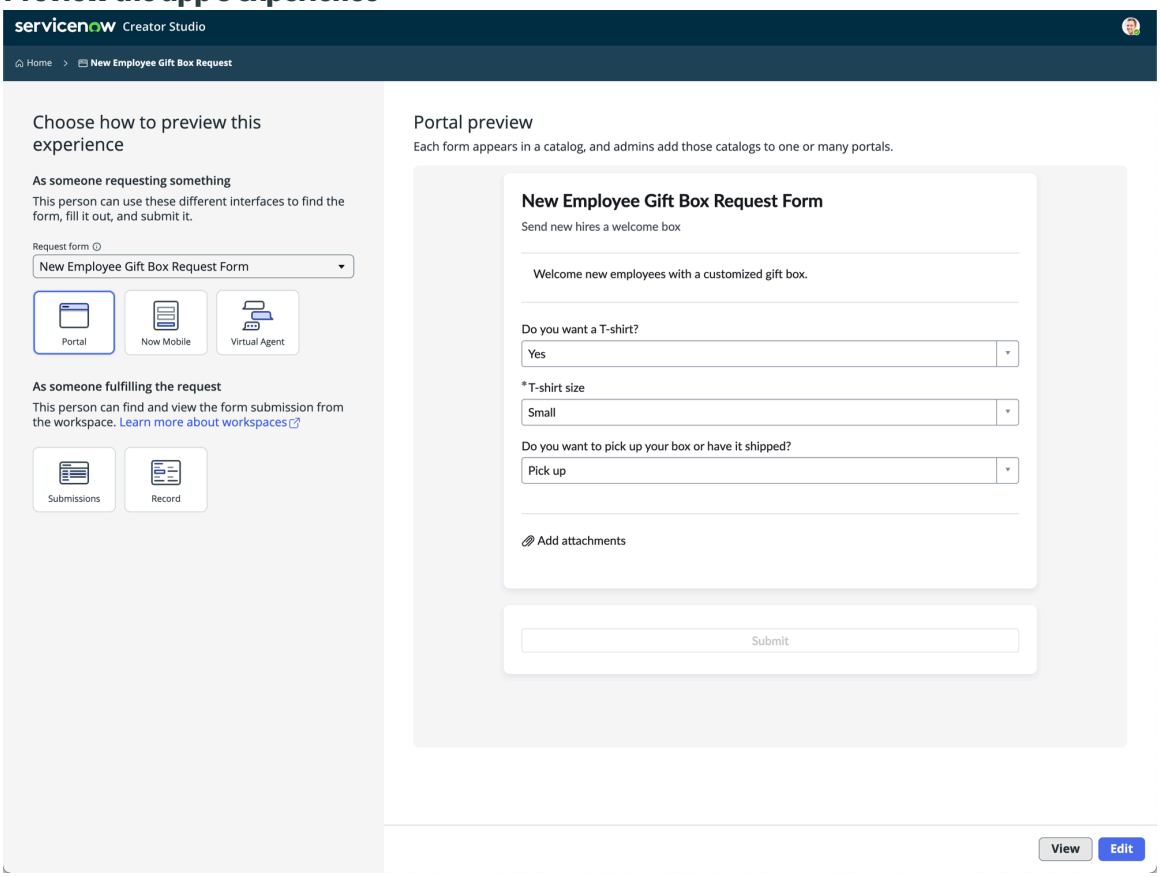
   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)

- **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

> **Note:**
> Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

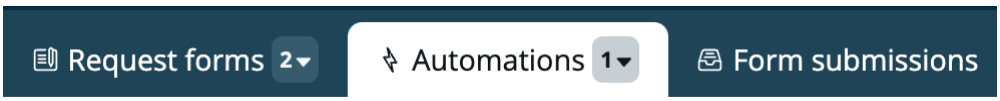
The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

Preview the app's experience



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the **Automations** tab in the application header.
5. Check that you're editing the correct playbook in your app by selecting it from the **Automations** tab.



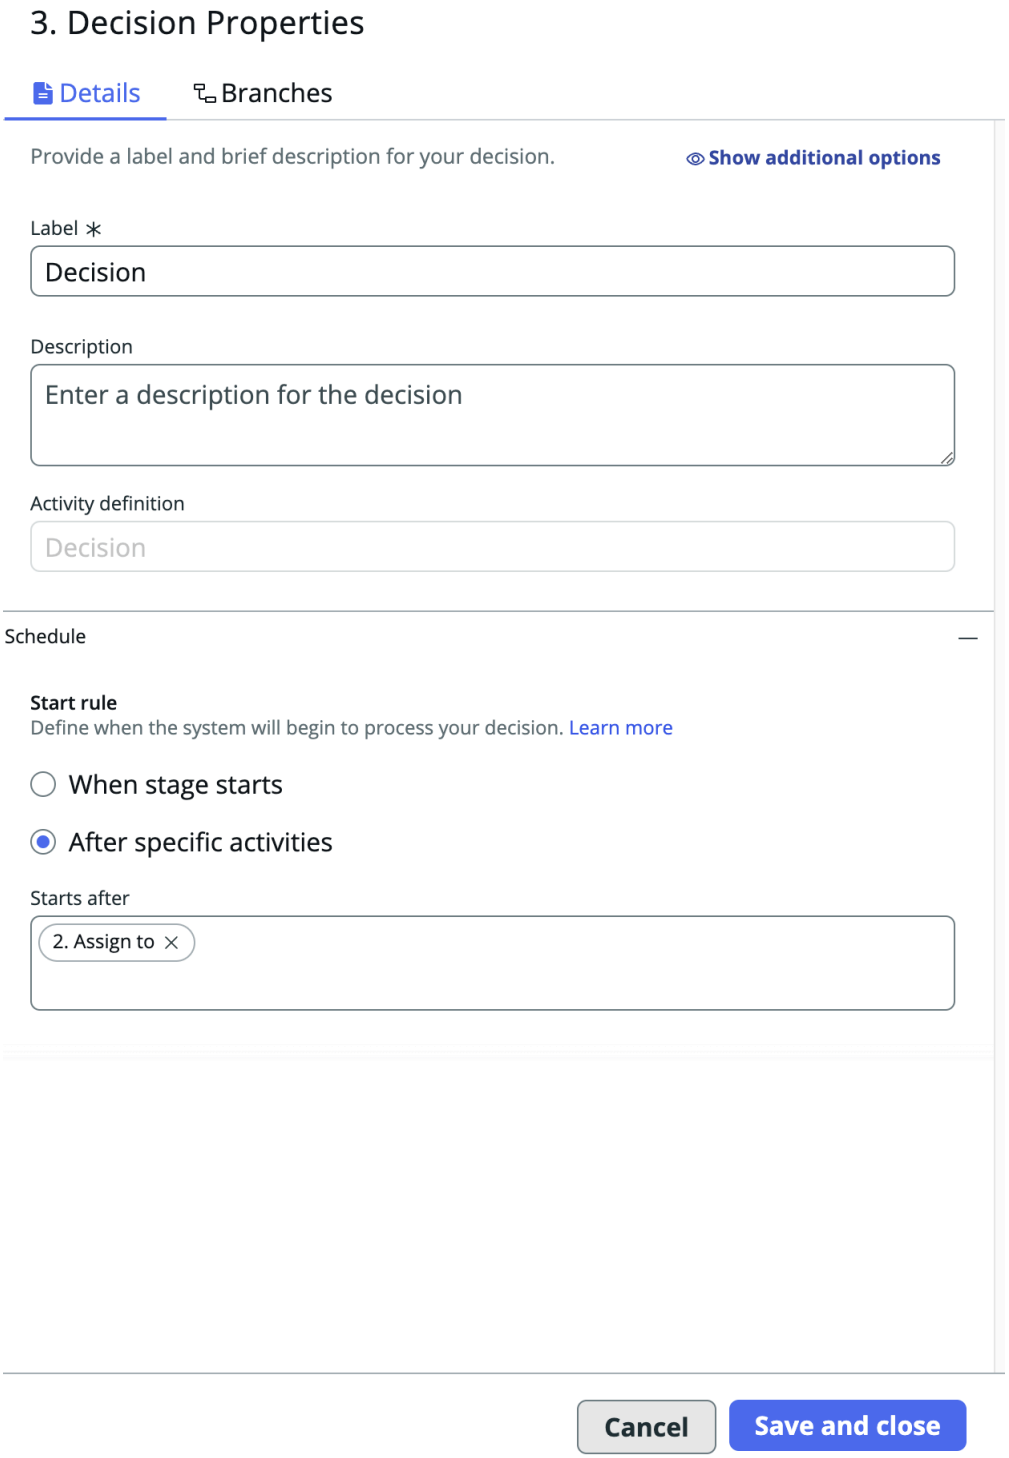
6. Select the add icon ( ) on the connector here you want to add a decision and choose the diamond-shaped **Add a decision** icon ( ) in the menu that pops up.
   You must be in the Diagram view to add a decision.

7. Specify the decision's basic attributes on the **Details** tab of the Decision properties panel that appears.

Decision basic options

Field	Description
Playbook name	Unique, user-facing name for the decisions, which appears to agents and fulfillers while the playbook is running.
Description	Optional details about what the decision accomplishes.

Playbook decision properties



8. Define the decision's schedule.

Decision schedule options

Field	Description
Start rule	Choose when you want your activity to start running. The options are:

Field	Description
	○ **When stage starts**: The decision starts running as soon as the stage starts running, which is when your playbook is triggered. ○ **After specific activities**: The decision starts running after the specified activities have finished running.
Starts after	Select the activity that must finish running for the decision to happen. This field is editable only if you selected to start the rule **After specific activities**. You can choose only activities that happen before this decision in the playbook.

9. **Optional:** Specify more scheduling conditions for the decision, such as whether there's a delay, by selecting **Show additional options**.

Decision schedule additional options

Field	Description
Display order	Order in which this activity occurs during a playbook run.
Start with delay	Toggle to specify that the ServiceNow AI Platform waits for a duration of time before running the decision after the start rule is met. For more information on how to specify the delay duration, see Start with delay input properties.
Restart rules	What the decision does when a playbook is restarted. The options are: ○ **Skip on restart**: Skip this decision when the playbook run is due to a restart. ○ **Run always**: Always run this decision, including first runs. ○ **Skip on first run**: Skip this decision during the first run. For more information, see Restart a playbook.

10. Create the conditions for each branch, or possible outcome for the decision on the **Branches** tab of the Decision properties panel.

    a. Enter a name for the branch in the **Branch label** field.

    b. Select the **Add condition** button and specify what conditions should be met for the branch to take effect.
    For more information, see Create a condition statement using the condition builder.

    c. **Optional:** Select the **Add new branch** button and add as many branches as needed.

d. If you add two or more branches, select how you want your decision activity to run the different branches.

Branch processing instructions

Option	Description
Process any & all branches that are true	The app processes all branches with conditions that are met.
Process only the first one that is true	The app processes only the first listed branch with conditions met. If you select this option, drag the branch that you want processed first to the top.

e. **Optional:** Adjust the order of branches as needed by dragging them into a new position.

11. Select **Save and close**.

Add a parallel process to an app's playbook in Creator Studio

Create parallel processes in Creator Studio to make things happen in your app at the same time.

Before you begin

To add a parallel process to a playbook, you must be given permission to work on the app.

About this task

Activities on a process's parallel branches run at the same time as other specified parallel activities. Unlike decision activities, the activities and stages on a parallel can run on the same conditions as other branches.

Procedure

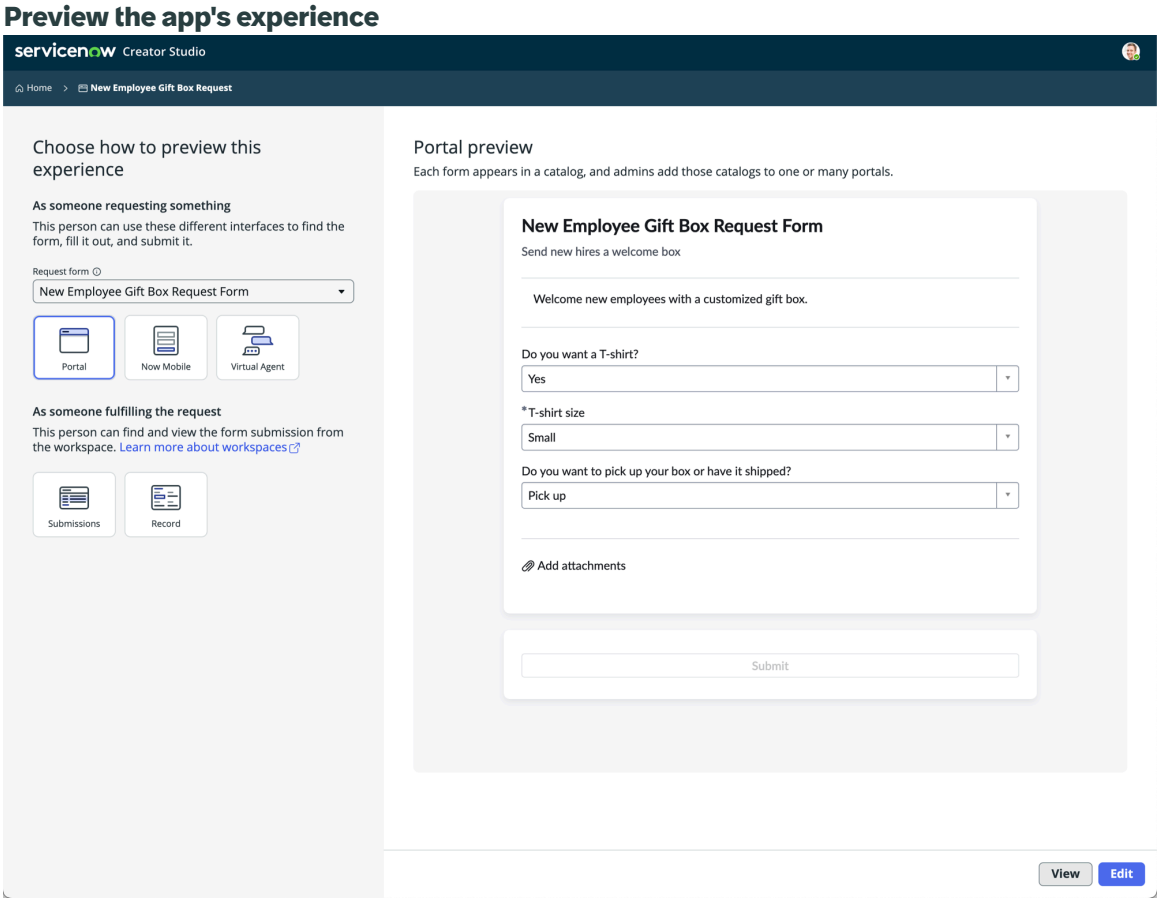
1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the playbook you want to add a parallel process to.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

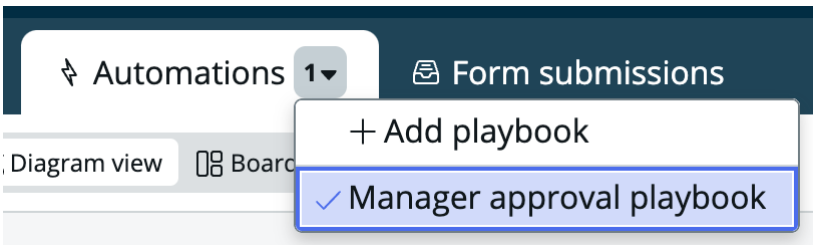
   Note:
   Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.



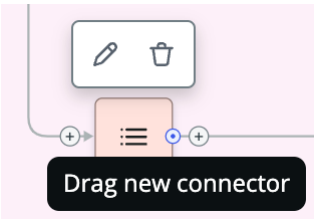
You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the **Automations** tab in the application header.
5. Check that you're editing the correct playbook in your app by selecting it from the **Automations** tab.



6. Choose one of the following ways to add a parallel branch in the diagram view.
   - Select the add icon ( ) and choose the **Add a parallel path** icon ( ) in the menu that pops up.
   - Select the Drag new connecter dot icon ( ) for the parallel process's starting activity and drag it to the activity or decision that should be the end point of the parallel process.

Note:
If you can't see the Drag new connector dot icon, you might need to hover over the activity to see it.



7. Add activities to the parallel branch as needed.
   For more information, see Add activities to an app's playbook in Creator Studio.
8. If you want to have several activities happen in a parallel process as soon as the playbook is triggered, complete the following steps.
   a. Display the Board view.
   b. For each activity that should be happen in parallel when the playbook is triggered, select the activity's card and set the **When to start** field to **When playbook starts**.
   c. Select the **Save and close** button.

Edit the trigger for a playbook in Creator Studio

Define the trigger for a playbook in Creator Studio to specify what makes the playbook start running.

Before you begin

The trigger initiates a playbook to run on one of the app's forms. For example, when a user selects a specific answer to a question, the playbook begins to run. The form you select must already be configured for you to select it for the trigger.

To edit the trigger for a playbook, you must be given permission to work on the app.

About this task

Note:
You can't change a playbook's trigger (whether the form is submitted or updated to initiate the playbook) or how frequently it should run after you create the playbook. Instead, create a new playbook with a different trigger.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the playbook you want to add actions to.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

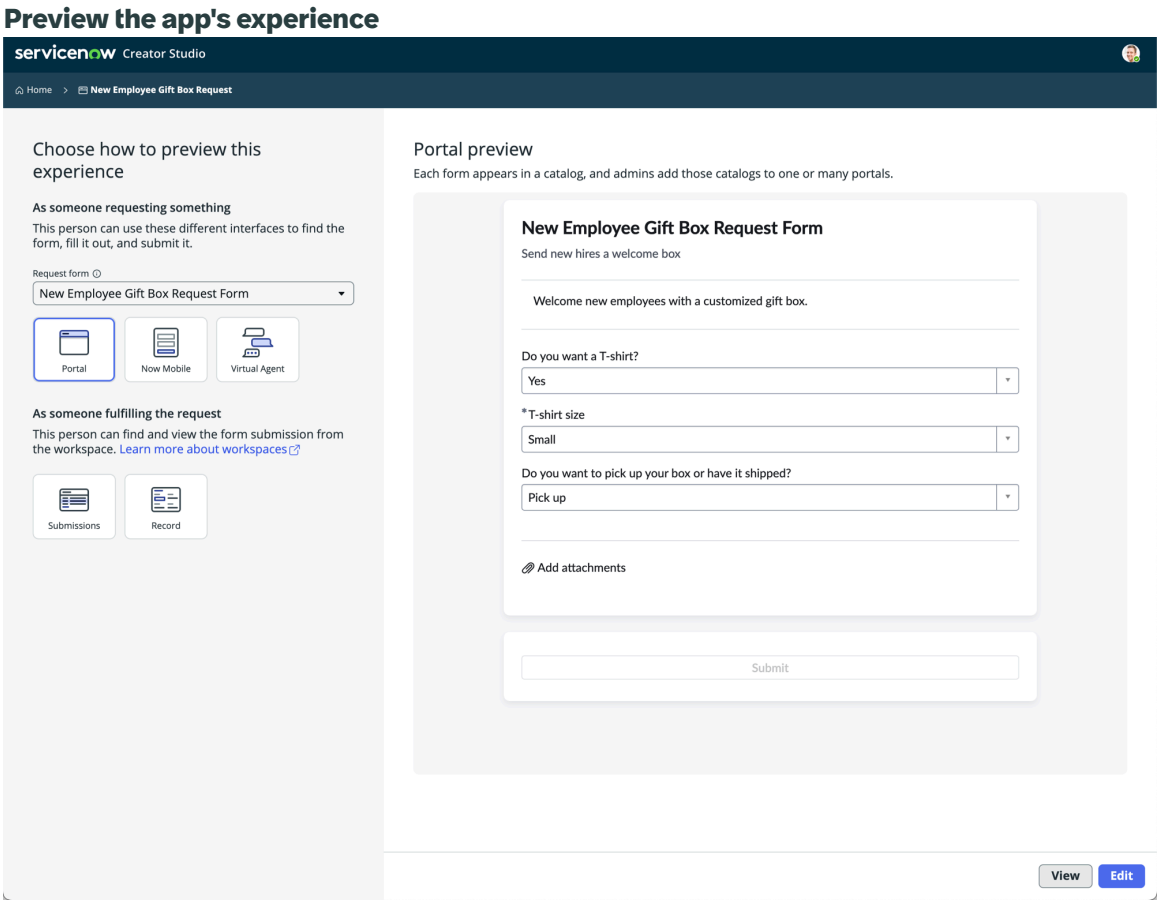
   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)

- **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

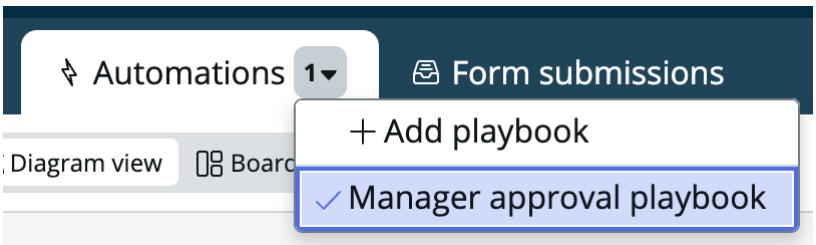
> **Note:**
> Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the **Automations** tab in the application header.
5. Check that you're editing the correct playbook in your app by selecting it from the **Automations** tab.



6. Select the **Trigger** (Trigger).

The Additional properties modal appears, where you can edit some of the trigger's settings.

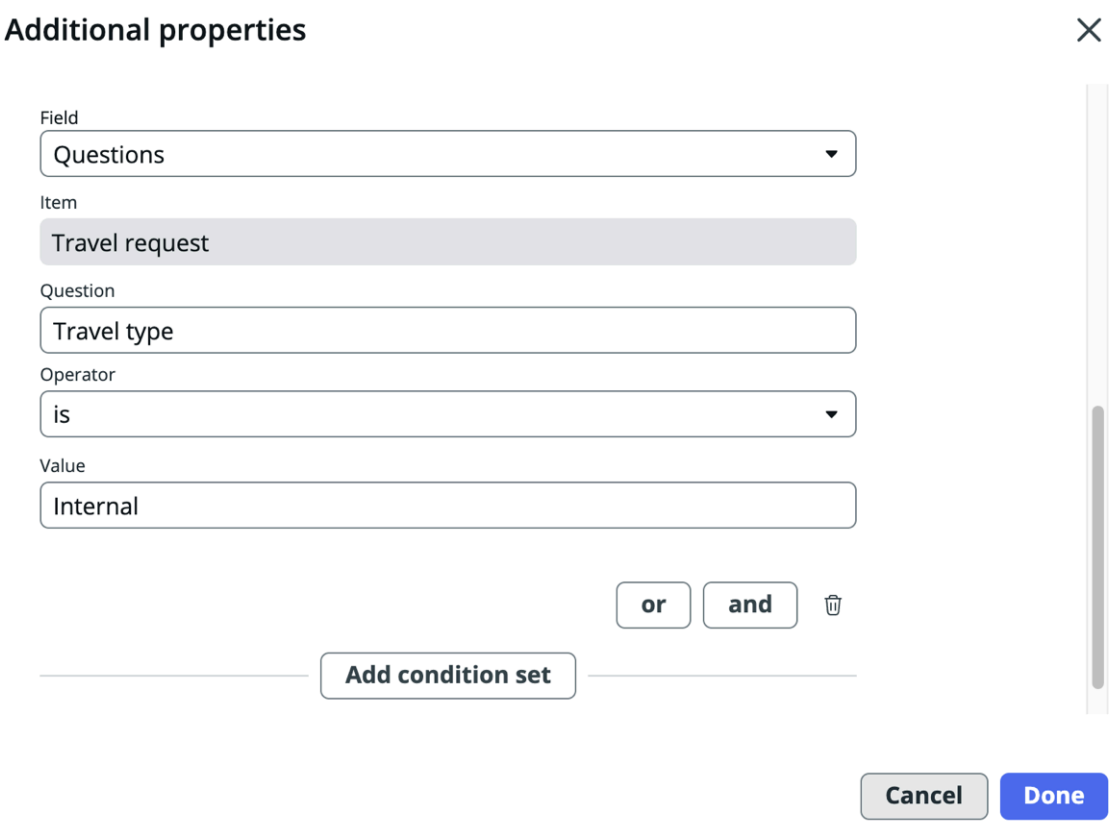
7. Make any changes to the trigger's general attributes.

General playbook definition fields

Field	Description
Playbook name	Descriptive name for the playbook you're editing.
Description	Brief explanation of what the playbook does, for example, the end goal for the record type.

8. If necessary, change the **Form** whose catalog item generates the record type that you want the playbook to run on.
9. Change the conditions that must be met for the playbook to begin running by selecting **Add condition set**.
   - If you want to trigger the playbook based on the value of a column in a table, select the **Field** that you want to be the trigger, as well as its condition **Operator** and the specific trigger **Value**. For example, when a **Start date** is **after** the **Date** needed.
   - If you want to trigger the playbook based on the response from a form, select **Questions** as the trigger **Field**. Then select the question you want in the **Question** field, the condition **Operator** and the answer's **Value**.

Question answer as trigger for an automation



Add as many conditions as you need. For more information, see Create a condition statement using the condition builder.

10. Save your changes by selecting the **Done** button.

Edit a playbook in Creator Studio

Update a playbook to change its settings, or rearrange or remove tasks, to make it work for your app.

Before you begin

To edit a playbook, you must be given permission to work on the app.

About this task

Note:

Not all items that can be added to playbooks are supported in Creator Studio, for example, notifications.

If you want to add complex, unsupported items to a playbook (such as optional activities, multiple stages, or data pills from previous activities), you must open and edit that playbook in Workflow Studio. After you edit a playbook in Workflow Studio, you can't edit it in Creator Studio. However, you can still work on the rest of the app in Creator Studio.

Procedure

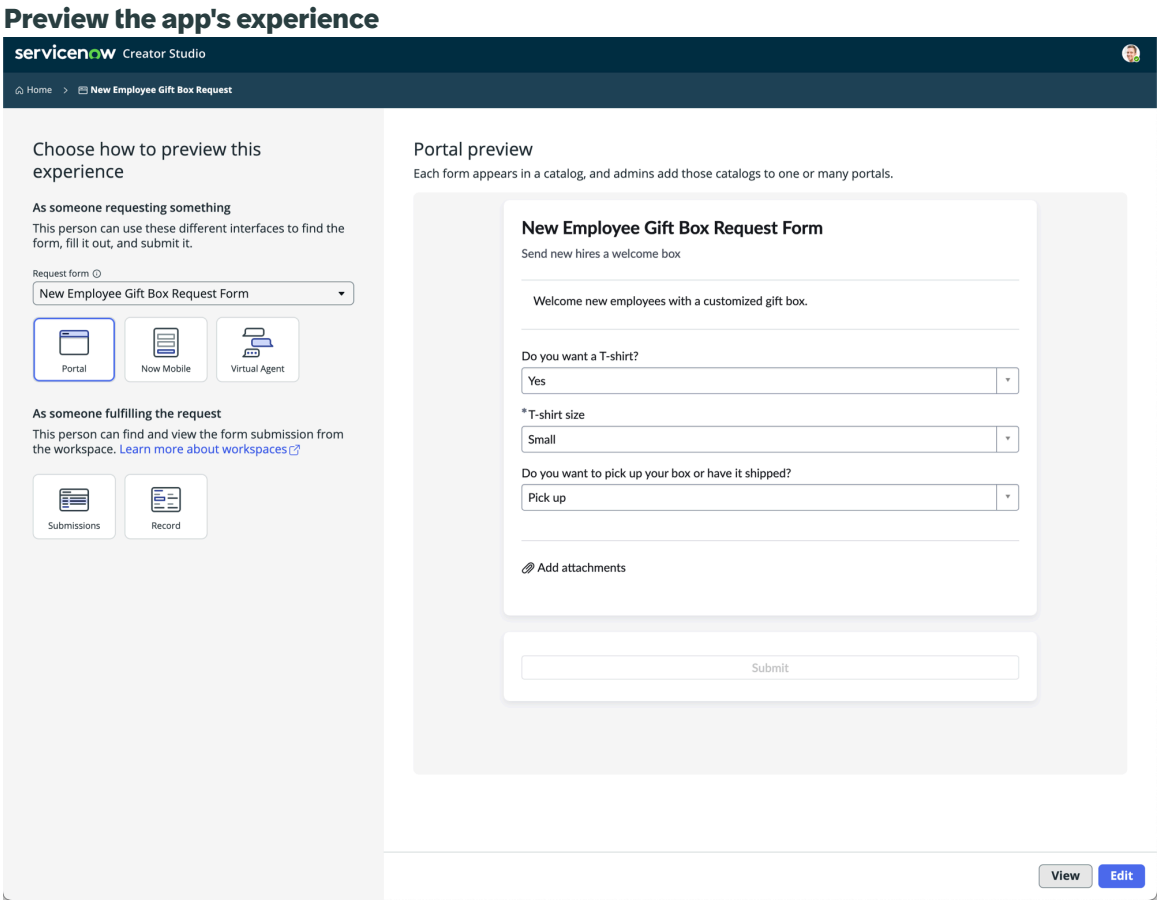
1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the playbook you want to edit.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

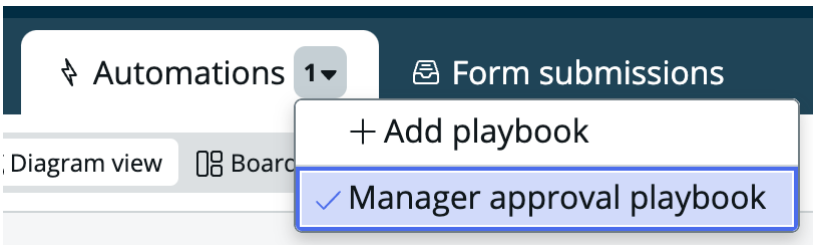
     Note:
     Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

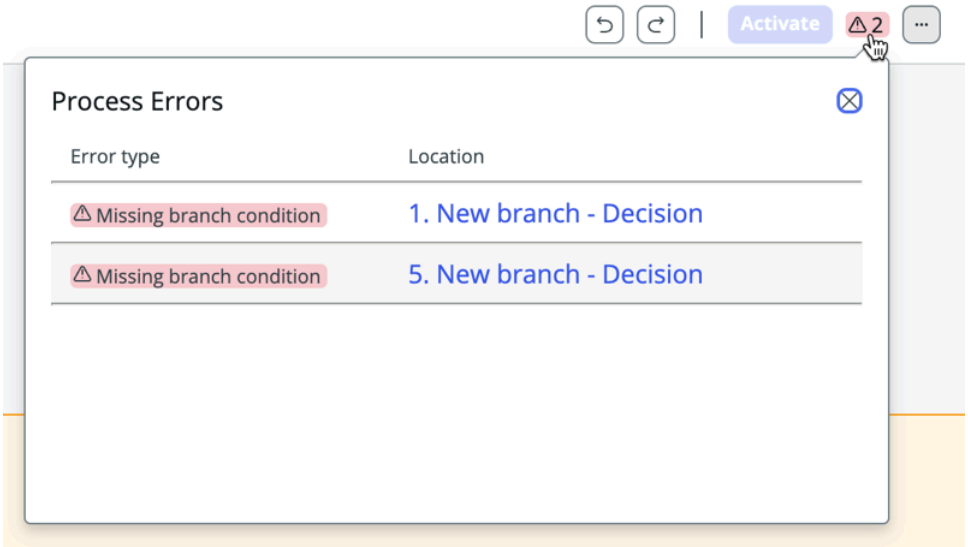


You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the **Automations** tab in the application header.
5. Check that you're editing the correct playbook in your app by selecting it from the **Automations** tab.



6. Address any errors in the playbook's logic by selecting the error message icon.
In the error tray that appears, you can open the properties to fix each error by selecting the **Location** link.



7. Edit the playbook's settings.

   a. Select the more actions icon (···) and select **Properties**.

   b. Update any of the settings.

   > **Note:**
   > You can't change a playbook's trigger once it's created. Instead, add a new playbook with a different trigger.

   c. Select the **Done** button.

8. Rearrange the order of tasks as needed.

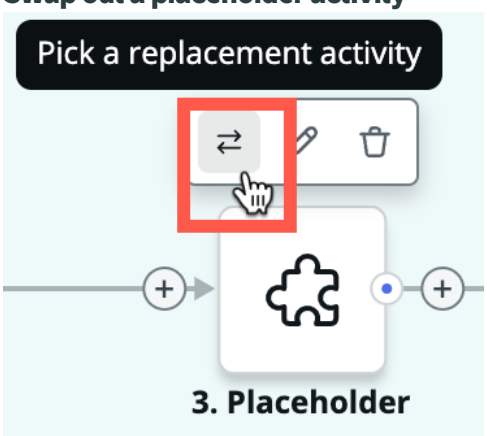
   a. Display the **Board view** for the playbook.

   b. Drag the cards for each activity into the order that you want.
   Creator Studio automatically saves the changes.

9. Swap a placeholder activity if you want to replace it with another activity type.

   a. Hover over the placeholder activity and select the replace activity icon (⇄) to directly open the activity picker.

Swap out a placeholder activity



b. Select the new activity from the activity picker.

c. Optional: Update the **Label** and **Description** as needed, or any of the other properties of the activity.
For more information, see Add activities to an app's playbook in Creator Studio.

10. Delete any unnecessary activities by hovering over the activity and selecting the delete icon ( ).

11. Make any advanced edits in Workflow Studio by selecting the more actions icon ( ) and selecting **Open in Workflow Studio**.

Activate a playbook in Creator Studio

Activating a playbook means that it will run when its related form is created or updated on your non-production, development instance. However, the app must still be deployed to production.

Before you begin

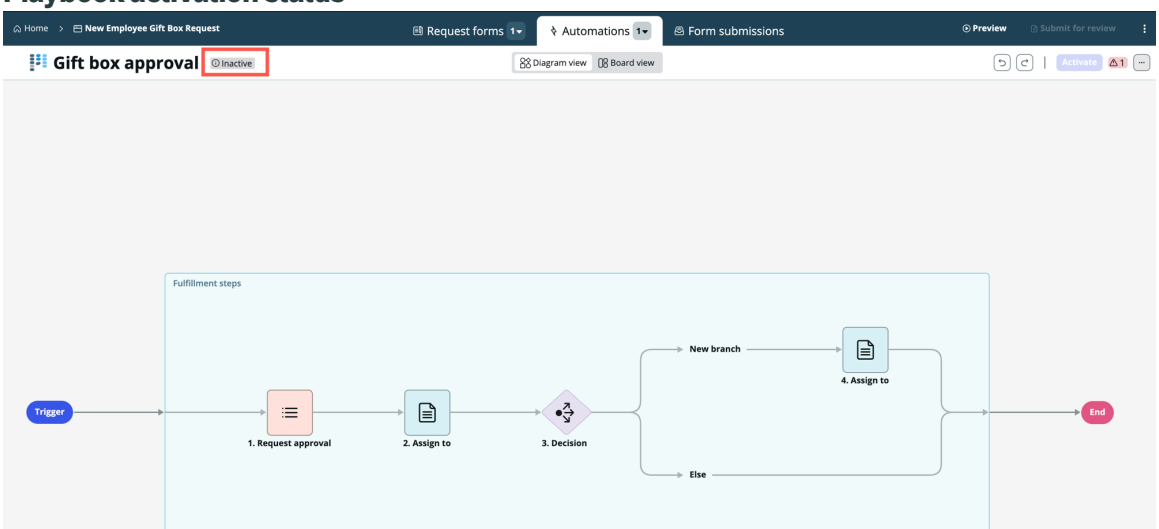
You must resolve any errors in the playbook before you can activate it.

To activate a playbook, you must be given permission to work on the app.

About this task

You can check the activation status of a playbook at any time in the **Automations** tab header.

Playbook activation status



If you don't activate a playbook and its app is deployed to production, the automation won't run on the applicable records. However, your App Engine admin can activate the deployed playbook for you.

Procedure

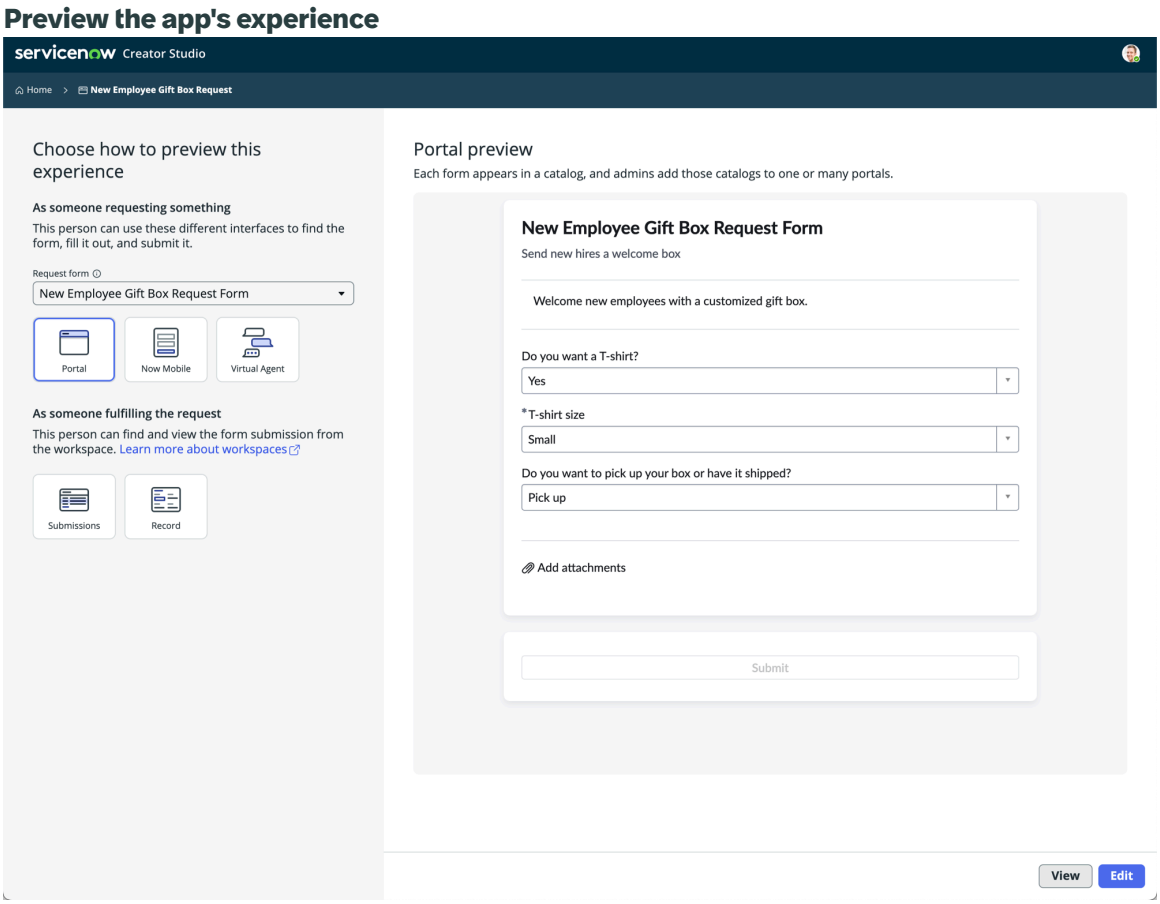
1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the playbook you want to activate.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

- **Portal** (see a preview of how it'll appear on a desktop website)
- **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
- **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

> **Note:**
> Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

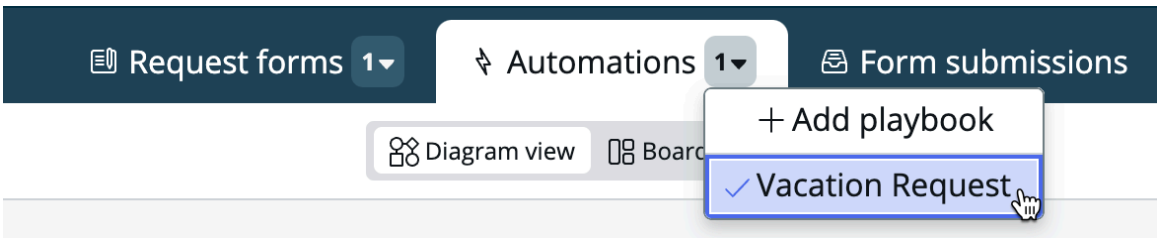
The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

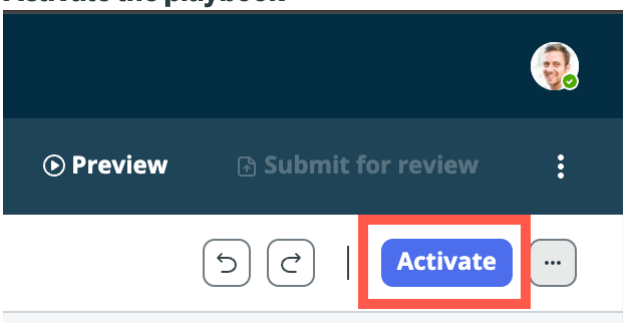
4. Select the **Automations** tab in the application header.
5. Check that you're activating the correct playbook in your app by selecting it from the **Automations** tab.

Select automation



6. Select the **Activate** button.

Activate the playbook



Result

The status displayed in **Automations** tab header updates from **Inactive** to **Saving** to **Active**, informing you of when changes are made.

The playbook is ready to be deployed with your app. Once the app is deployed, the form is available in the associated service catalog. If the form's app hasn't been deployed, you need to deploy it.

Delete a playbook in Creator Studio

Delete a playbook to remove it from the app completely.

Before you begin

To delete a playbook, you must be given permission to work on the app.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the playbook you want to delete.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

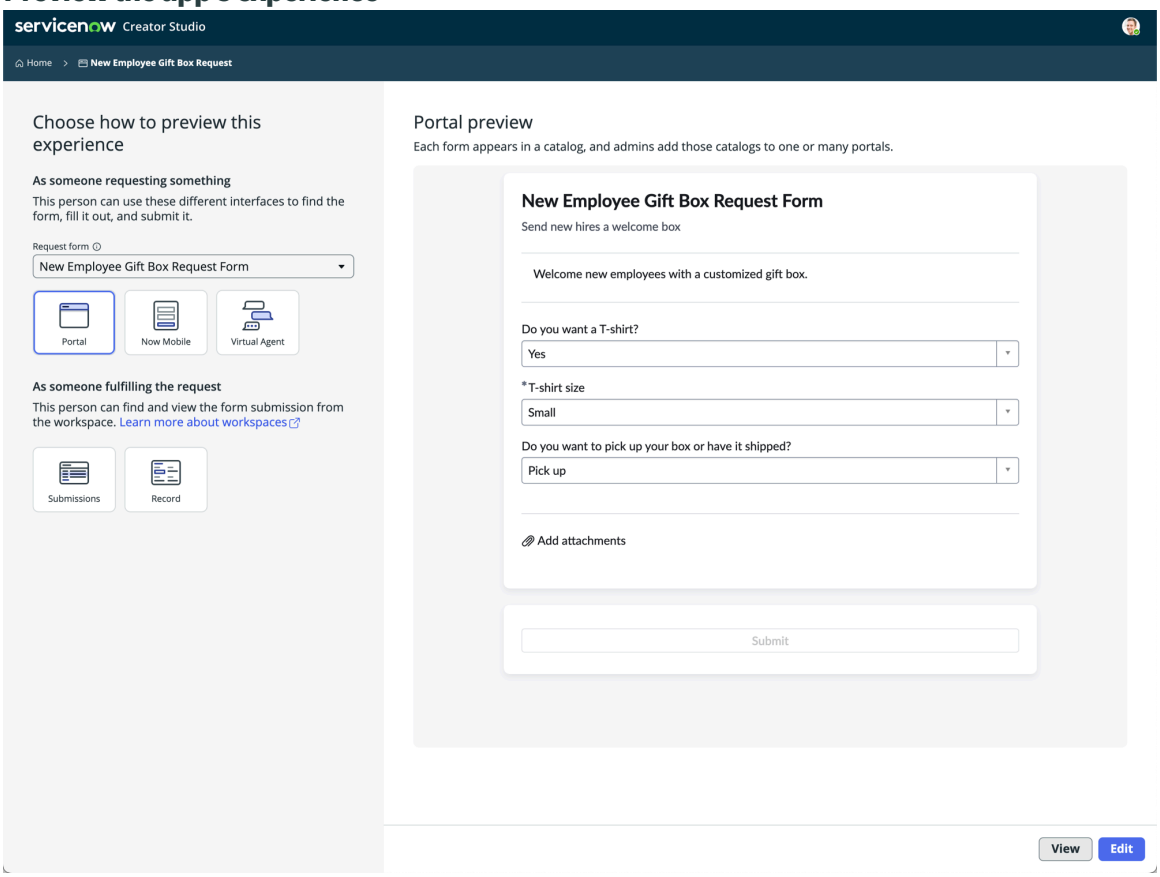
   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)

- **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

> **Note:**
> Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

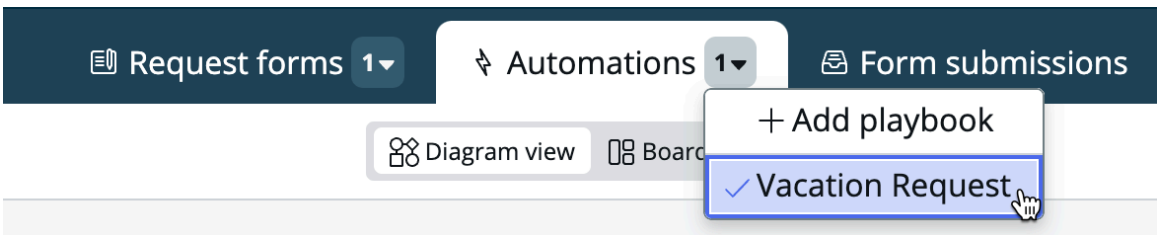
Preview the app's experience



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

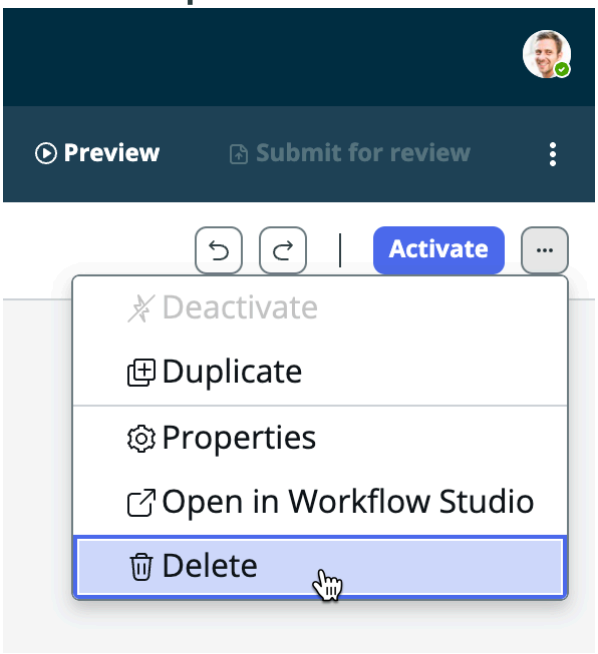
4. Select the **Automations** tab in the application header.
5. Check that you're deleting the correct playbook in your app by selecting it from the **Automations** tab.

Select automation



6. Select the more actions icon ( ).
7. Select **Delete**.

Delete menu option



8. On the confirmation modal, select the **Delete** button.

Working with form submission workspaces in Creator Studio

So, you've built your app, and people are submitting requests through it, that's great! However, you might be wondering where those requests go after they're submitted. The short answer is they live in a form submission Workspace, which you can customize in Creator Studio to suit your needs.

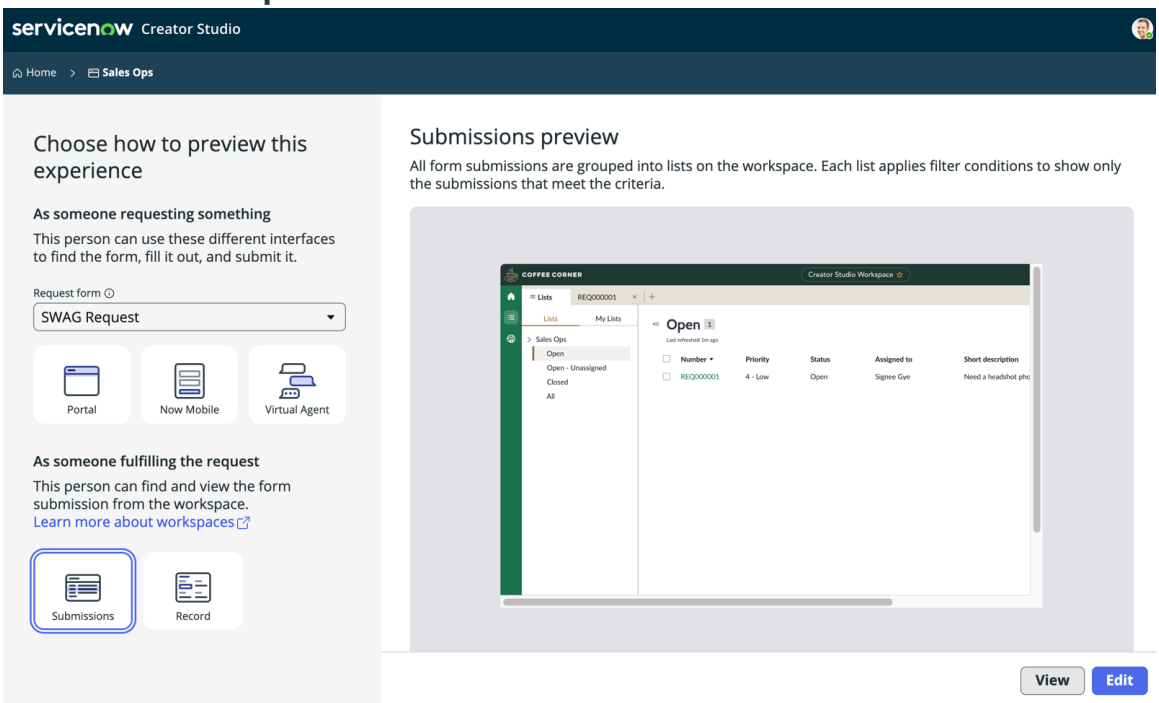
A little more about workspaces

The Request App Workspace holds form submissions that come in from each of your apps. Fulfillers (remember, these are the people who work on requests) can access the workspace through the ServiceNow AI Platform and see submissions for all the apps they're assigned to.

Each app that you build in Creator Studio has its own category in the Request App Workspace, regardless of how many forms or automations it has.

As the app owner, you're responsible for the look and feel of the workspace that the app's fulfillers use. Thankfully, the workspace should be ready to use out-of-the-box, but you can also customize it on the **Form submissions** tab of your app in Creator Studio.

Form customization preview



When you open the **Form submissions** tab, you'll see some filtered lists that appear in the default workspace. These filtered lists (**Open**, **Open – Unassigned**, **Closed**, and **All**) are intended to give fulfillers a quick view of all the form submissions. You can add more filtered lists as needed, for example, you could add a filtered list for each of the app's forms or for canceled requests.

If it would help your fulfillers to have additional categories, you must ask your admin to add them using the List Category [sys_ux_list_category] table on the ServiceNow AI Platform.

Creating lists to support multiple forms

When fulfillers open the workspace to view an app's form submissions, the default "Open" list displays all open requests made through the app. However, if you have multiple forms in your app, fulfillers might find it easier to have separate "Open" lists for each form in the app. In that case, you should create different lists for each separate form and name them after the forms. Find out how in Add a filtered list to a workspace in Creator Studio.

Alternatively, fulfillers can use the "My lists" feature in Workspace to create custom lists that fit their needs. Tell them how to by checking out Create My Lists in workspace.

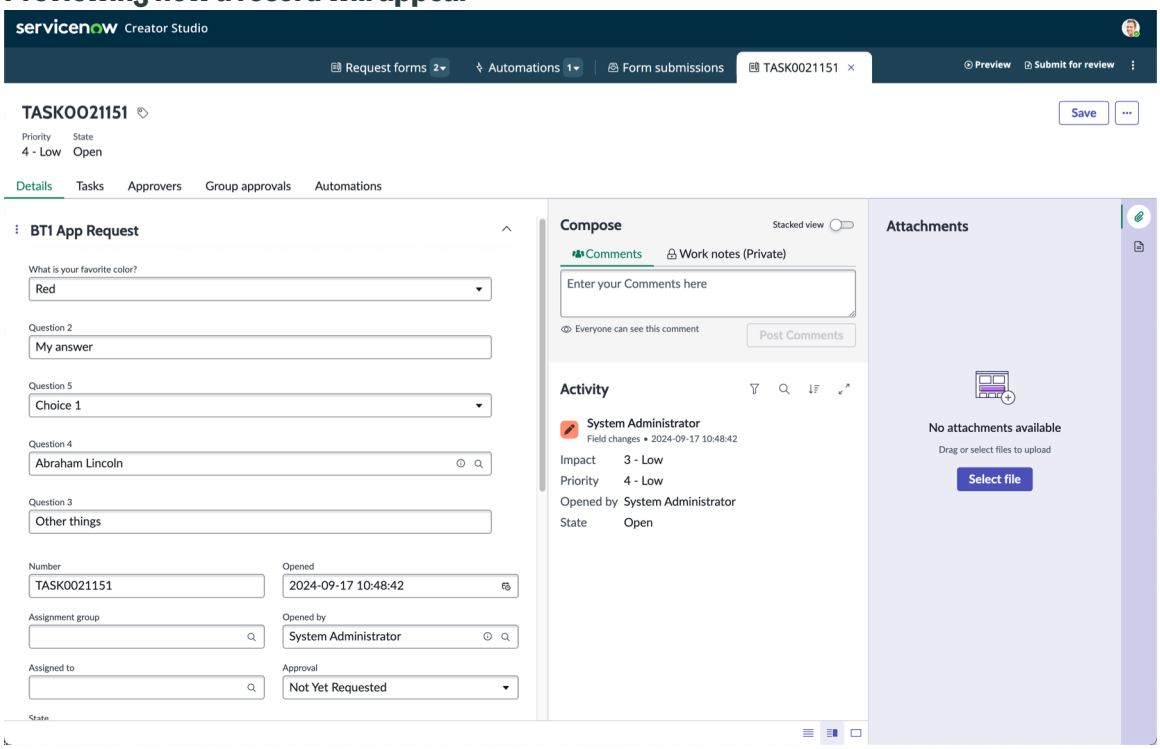
How fulfillers access submitted forms in Workspace

Fulfillers access the default workspace on the ServiceNow AI Platform by going to **All** > **App Engine** > **Request App Workspace**. The Request App Workspace displays a category for each app with filtered lists of records, both default and any extra that you added. Fulfillers then select a record to view the details of the request and make updates as needed.

Note:
You can't access the Request App Workspace as the owner of an app, though you can access it if you also have an admin or the applicable agent role. The app's agent role is <app scope>.agent, for example, x_snc_app_name.agent.

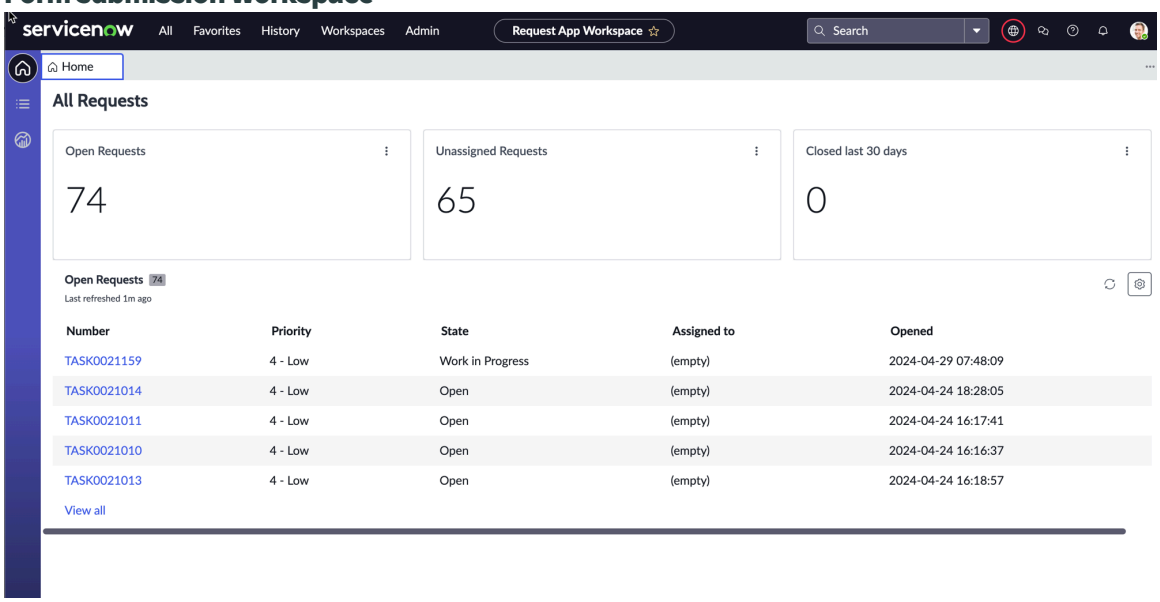
You can also preview and interact with how records will appear in the Request App Workspace directly within Creator Studio.

Previewing how a record will appear



What fulfillers can see in the Request App Workspace depends on their permissions. For example, admins can see workspace categories for all apps built in Creator Studio. However, most users see only the workspace category for their particular app.

Form submission workspace



When fulfillers view a record for an individual request in the workspace, the **Catalog tasks** tab displays the playbook that you configured in Creator Studio.

Fulfillers or admins may also want to monitor the app's performance as requests come in. This is where the Analytics Center in the Request App Workspace is helpful! On the **Analytics** tab, each app has its own analytics dashboard that shows applicable data, like how many open requests you have or what tasks are related to the app. There's a lot of helpful information here. Find out more about working with data in Analytics Center.

Add a filtered list to a workspace in Creator Studio

Create custom filtered lists in an app's workspace to view records that meet specific conditions. For example, if your app has multiple forms, you can create a list for each form by filtering on the record type.

Before you begin

To add a list to a workspace, you must be given permission to work on the app.

About this task

Note:
You can create a filtered list to display open records assigned to a specific user, or all requests that have been cancelled.

Procedure

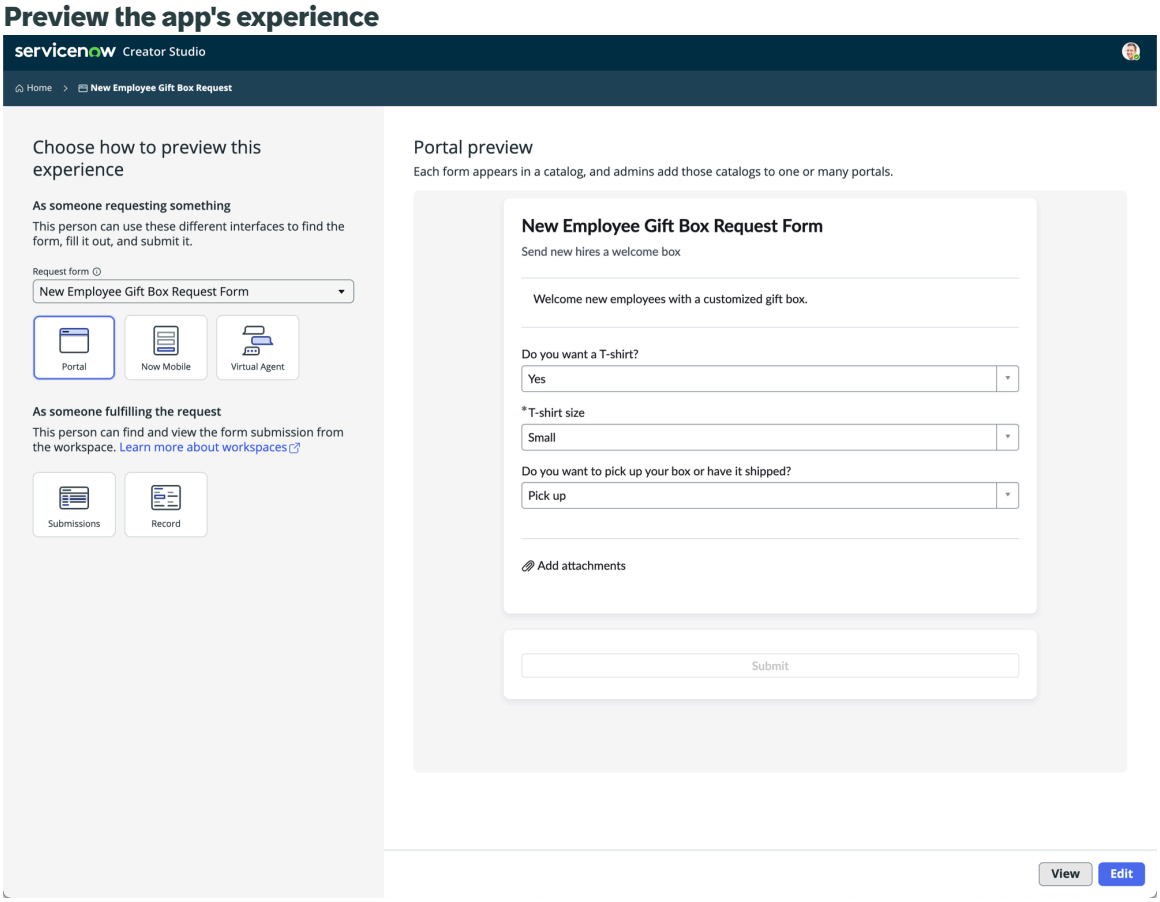
1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the workspace you want to add a list to.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

     Note:
     Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

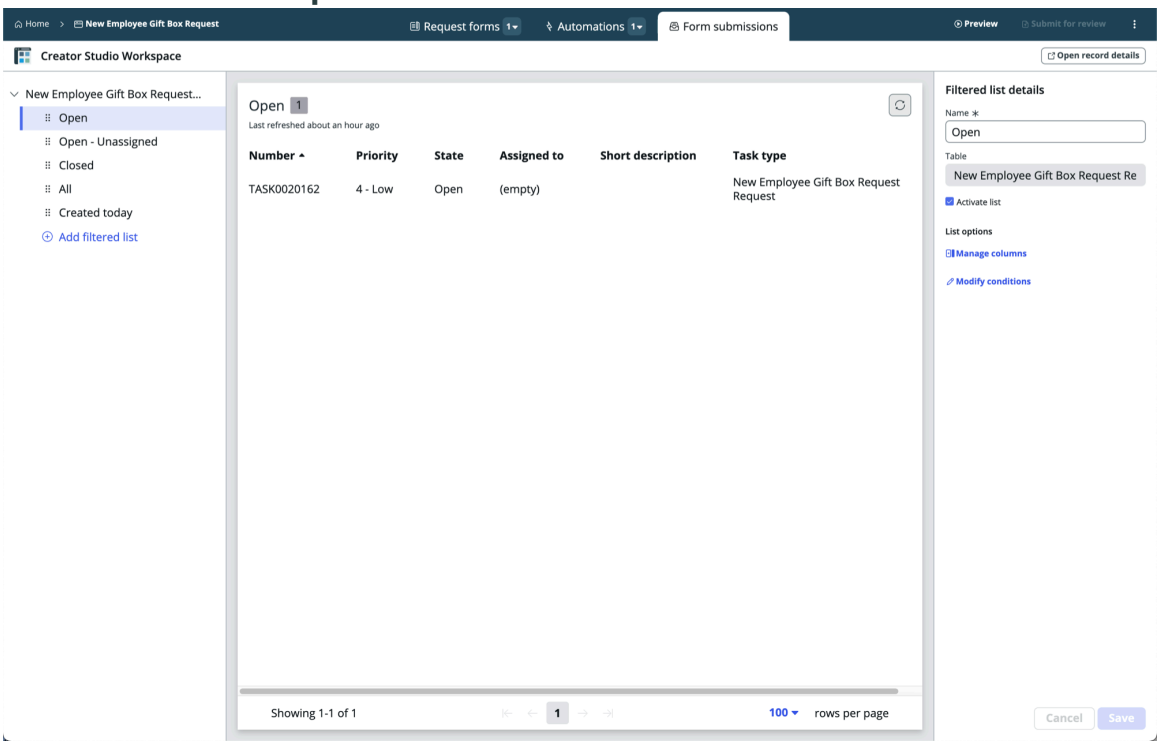
   The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

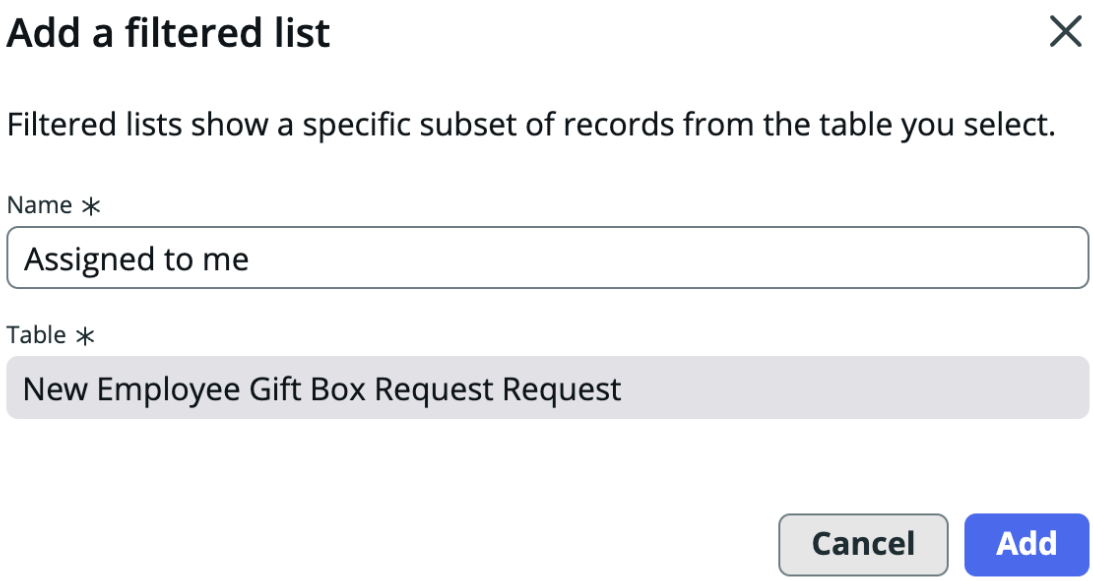
4. Select the **Form submissions** tab in the application header.

Form submission workspace in Creator Studio



5. Select **Add a filtered list**.

Add a filtered list



6. Enter a **Name** for the new list in the modal that appears.

   Choose a name to help users easily identify their category in the workspace, such as `HR timeoff requests`.

   Note:
   You can't change the table for the workspace, as it's linked to the app.

7. Select the **Add** button.
   The new list appears under the category, with its details appearing in the Filtered list details panel.
8. Select **Apply conditions** in the Filtered list details panel and use the condition builder to specify what types of records the list should contain, selecting **Apply** when you're done. For example, you can select **Urgency** as the field and **High** as the value to have the list show only urgent records. For more information, see Create a condition statement using the condition builder.

   For example, the following conditions specify open and closed requests:

   - `Active is true` specifies only open records.
   - `Active is false` specifies only closed records.
9. **Optional:** Change which columns appear and the order they're displayed in by selecting **Manage columns**.
   a. Move columns from **Available columns** to **Selected columns** in the Manage columns dialog box.
   b. Drag to rearrange the columns.
   c. Select **Apply**.
10. Ensure that the **Activate list** option is selected.

Result
Your new list will appear in the Request App Workspace after your admin deploys it!

Customize an app's workspace in Creator Studio

Make changes to the app's workspace category where fulfillers review submitted requests from apps built in Creator Studio to adjust how it appears. For example, you can rearrange columns in its lists and customize how the record generated by the request app looks.

Before you begin
To customize how the form submission workspace appears, you must be given permission to work on the app.

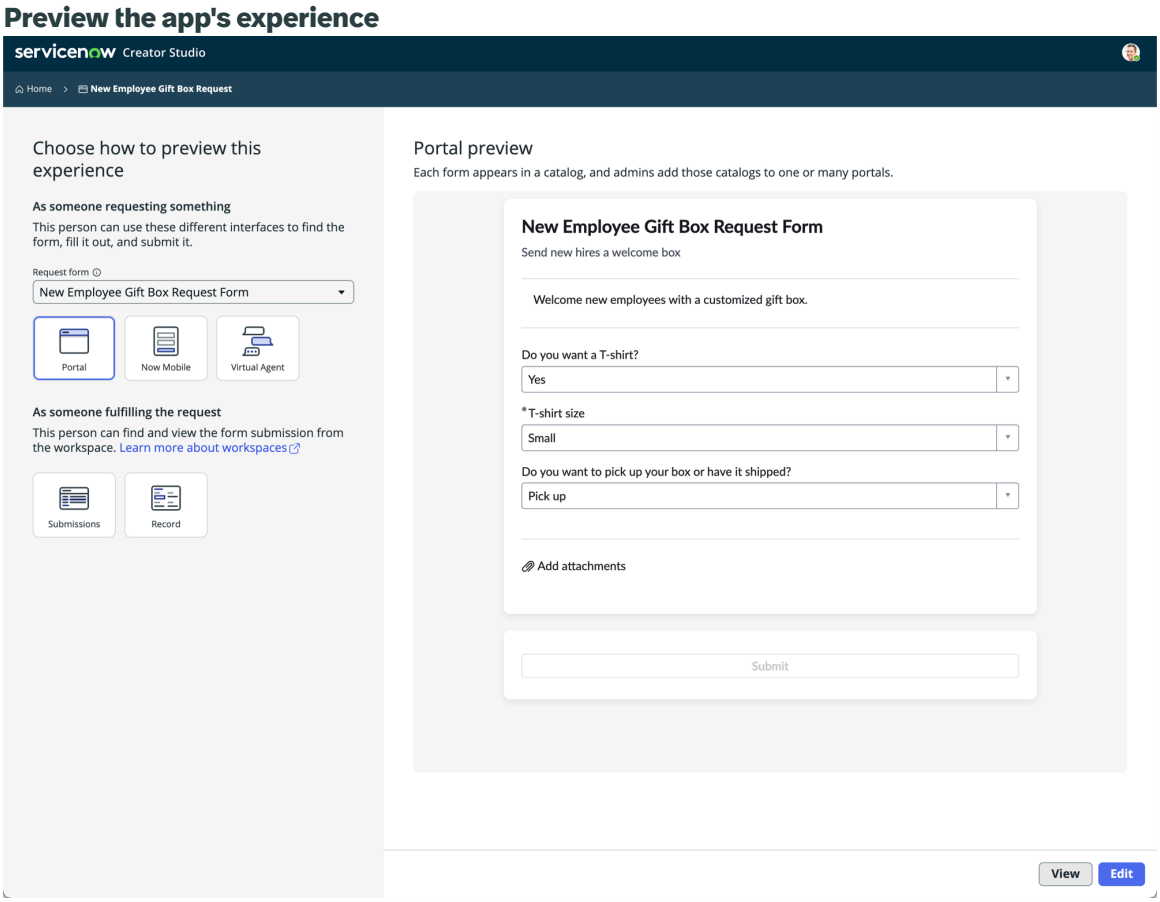
Procedure
1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the form submission workspace you want to edit.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)
   - **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

   Note:
   Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

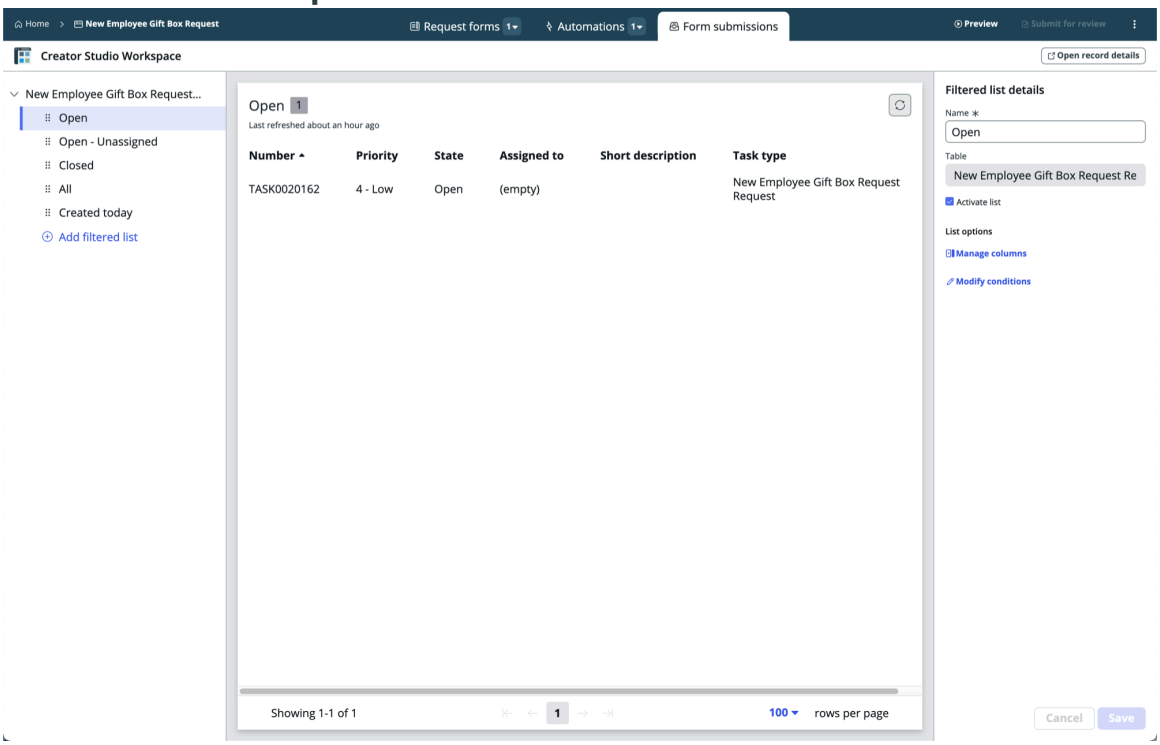
The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the **Form submissions** tab in the application header.

Form submission workspace in Creator Studio



5. Make the edits that you need to customize the workspace.

Edits you can make to a workspace

Update	Process
Edit the name of a filtered list	**a.** Select the list in the list navigation panel. **b.** Update the **Name** of the list in the Filtered list details panel that appears. **c.** Select **Save**.
Manage columns to change which columns appear and the order they're displayed in	**a.** Move columns from **Available columns** to **Selected columns** in the Manage columns dialog box. **b.** Drag to rearrange the columns. **c.** Save the update by selecting the **Apply** button.
Update the types of records that appear in a list	For example, you can select **Urgency** as the field and **High** as the value to have the list show only urgent records. For more information, see Create a condition statement using the condition builder.

Update	Process
	a. Select **Modify conditions** in the Filtered list details panel. **b.** Use the condition builder to update what types of records the list should contain. **c.** Save the update by selecting the **Apply** button.
Delete a list	**a.** Hover over the list you want to delete in the list navigation panel. **b.** Select the delete icon that appears ( ). **c.** Confirm the deletion in the modal that appears by selecting the **Delete** button.

6. Select the **Save** button in the Filtered list details panel to ensure all updates are saved.

Change the layout of an app's record in Creator Studio

Adjust how the records that your app generates will look, such as the order in which fields appear.

Before you begin

To change the layout of an app's record in the form submission workspace, you must be given permission to work on the app.

About this task

All columns of the app's Task table are available as fields on the record page, though you may want to adjust them. For example, you may want to move the **Priority** field to appear more visibly on the record so fulfillers can tell how important the request is. You could then build an automated playbook that runs when the priority changes to high.

Note:
You can't edit UI policies or make more advanced edits to the form in Creator Studio. To make advanced edits, open the record in Table Builder. For more information, see Forms in Table Builder.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the form submissions workspace you want to edit.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

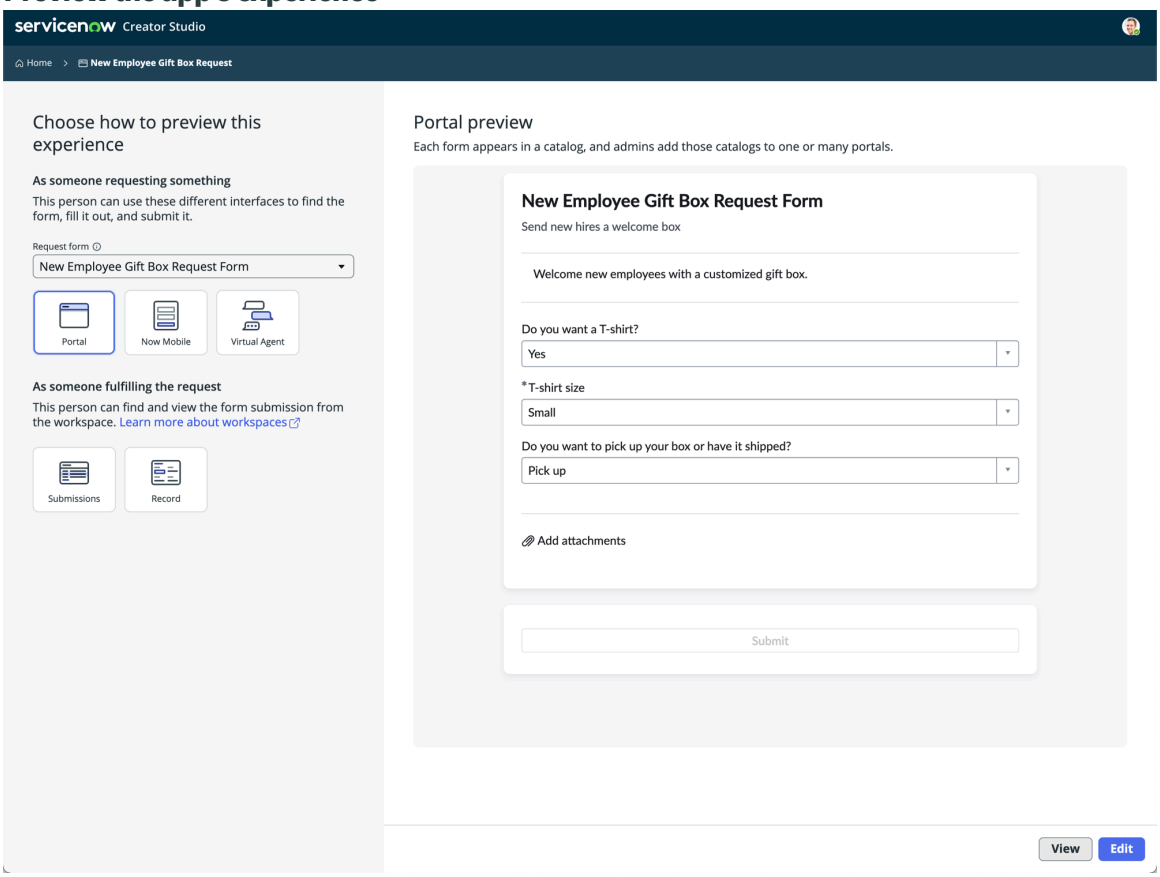
   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)

- **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

> **Note:**
> Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

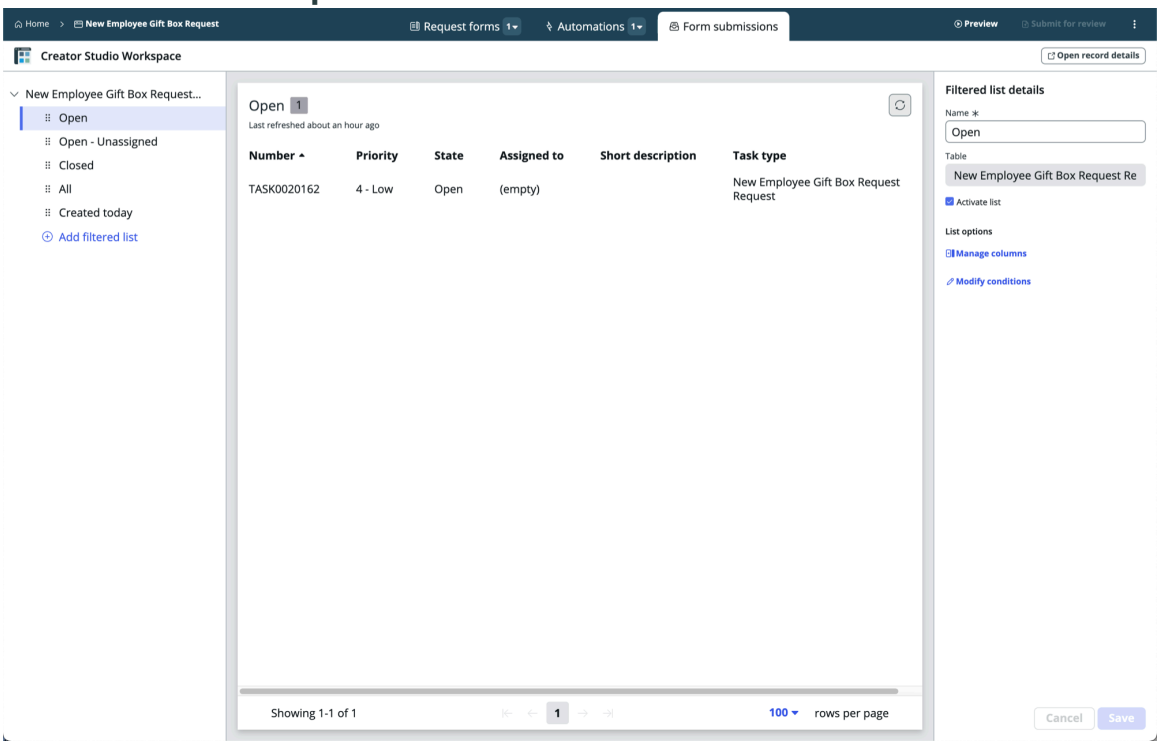
Preview the app's experience



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

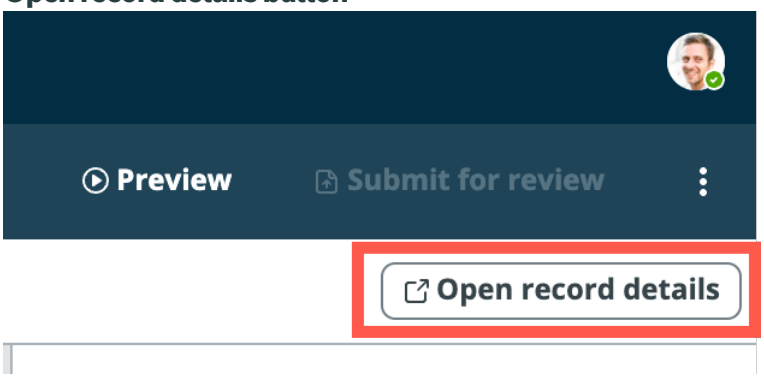
4. Select the **Form submissions** tab in the application header.

Form submission workspace in Creator Studio



5. Select the **Open record details** button.

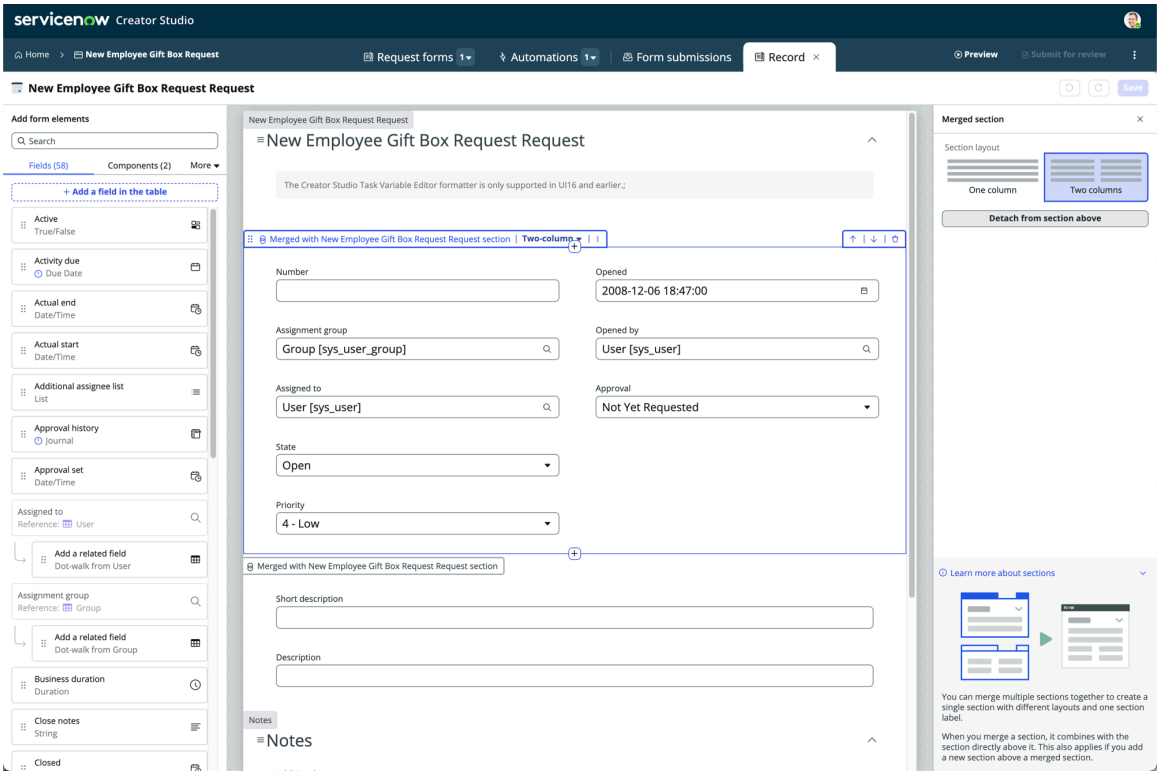
Open record details button



The Record details appear in a new **Record** application tab.

6. Make any additional changes to how the record appears, such as moving the fields around. Check out Important Task table fields for a list of the most commonly used fields that you can work with and their definitions.

Record details



7. Select **Save**.

What to do next

After you're done customizing how the app's records will appear, you can check out how they'll look in the Request App Workspace while remaining in Creator Studio. For more information, see Preview how an app's records appear.

Preview how an app's records appear

You can preview and interact with records generated by your app directly in Creator Studio, which mimics what the fullfiller sees in the Request App Workspace.

Before you begin

You can customize how the record will appear before testing it in a preview. For more information, see Change the layout of an app's record in Creator Studio.

To preview how an app's record will appear in the form submission workspace, you must be given permission to work on the app.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that contains the form submissions workspace you want to edit.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

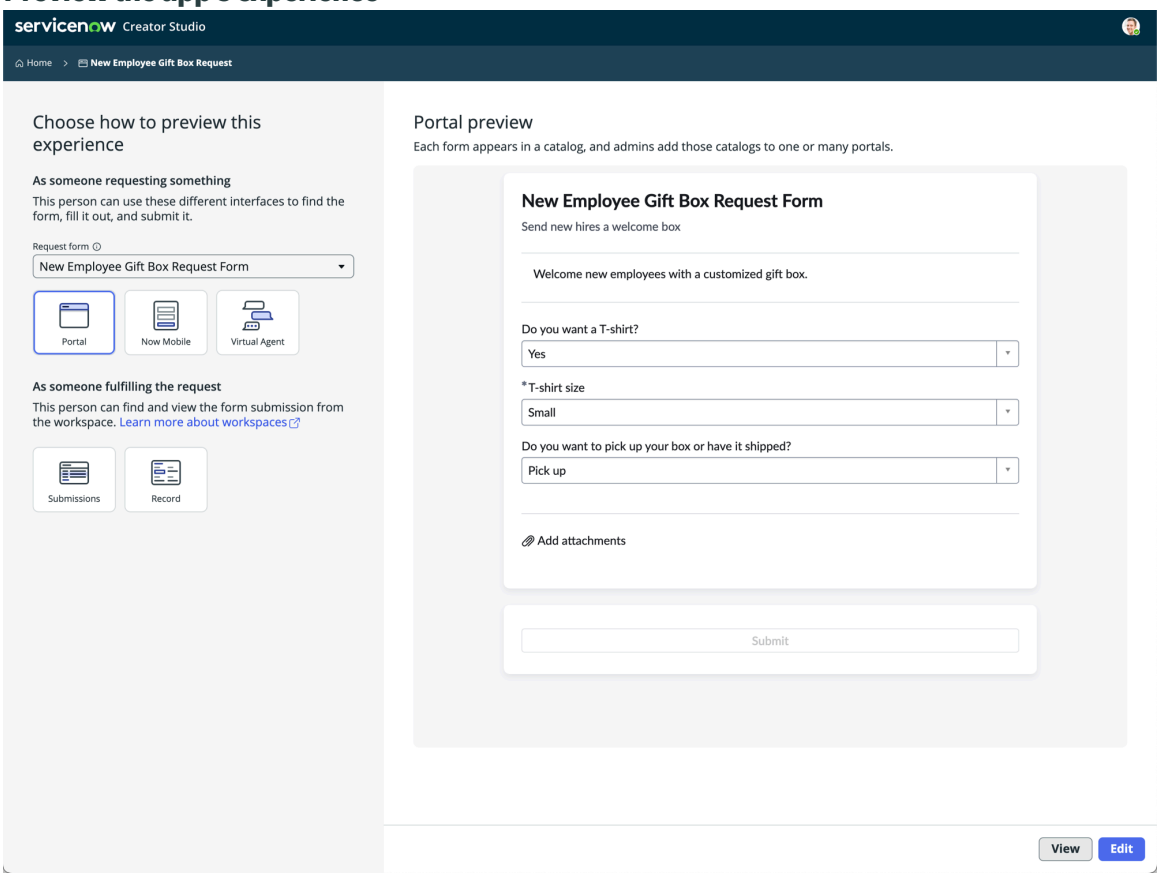
   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)

- **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

> **Note:**
> Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

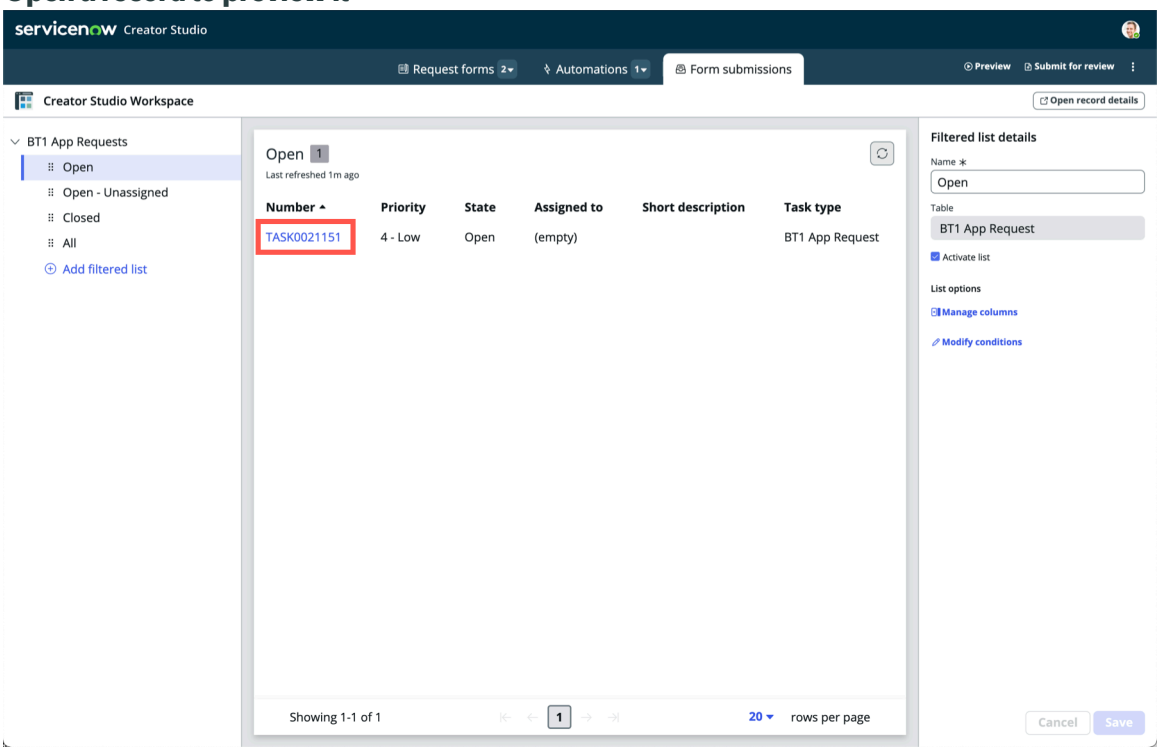
Preview the app's experience



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

4. Select the **Form submissions** tab in the application header.
5. Select a filtered list that contains a record, such as the *Open* records list.
6. Preview a record by selecting it in the canvas.

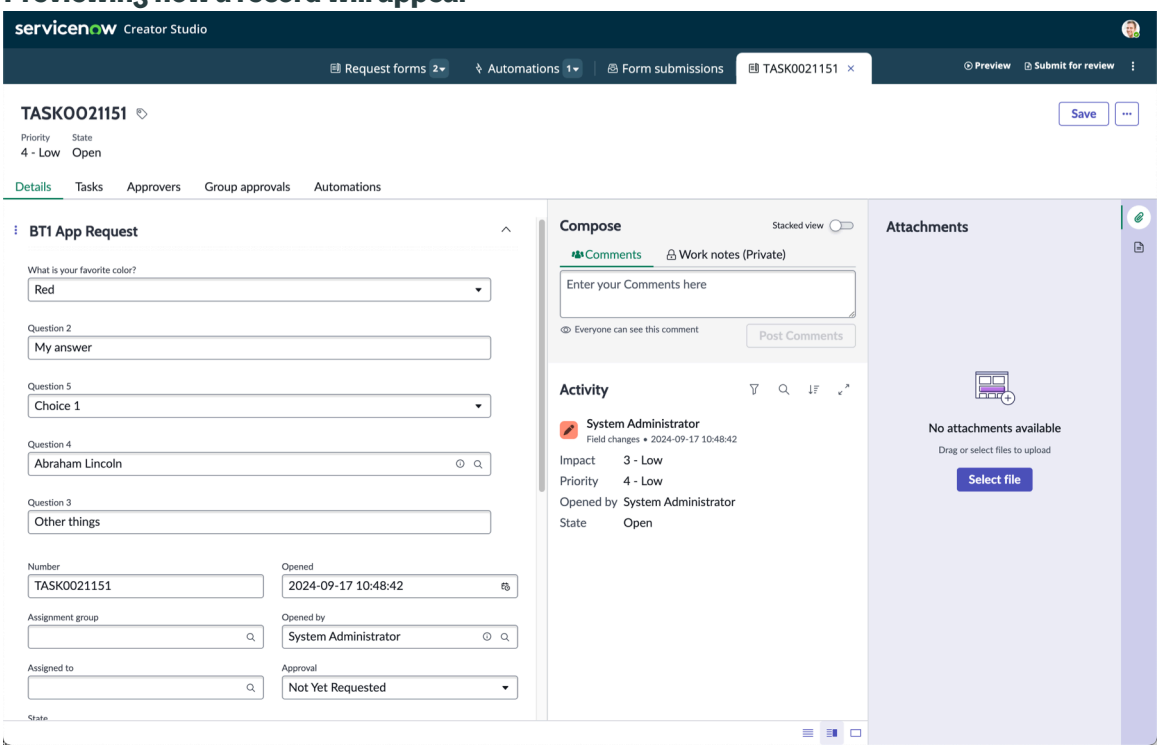
Open a record to preview it



The record opens in a new tab within Creator Studio.

7. Play with the record to see how its parts will appear.
   For example, you can select the record's **Approvers** tab to view how its approvers list will appear.

Previewing how a record will appear



Result
If you don't like what you see, you can tweak the record's appearance. Find out how in Change the layout of an app's record in Creator Studio.

Deploying your Creator Studio app

Congrats, you've built your app and are ready to share the first version of it with the world. That's great! Deployment is the next step in the process.

Deployment is a term that describes the process of an app moving from a non-production instance like development or QA through to production. Production is the instance that your customers see, or your "live" instance. To kick this process off, you should build your app in a non-production instance, and request that an admin deploy it to a production instance when you're ready.

Deploying an app automatically publishes the app, as well as all of the published forms and activated playbooks that you include, to a production instance.

Deployment uses pipelines configured in Pipelines and Deployments. If you don't have a pipeline configured, the Creator Studio home page alerts you and suggests you ask an admin to set it up for you.

The ServiceNow AI Platform uses the Application Repository to move apps between instances, so release notes and a version number are required. Find out more in App versioning and release notes for Creator Studio apps.

Requesting app deployment to production

You should test your app and all of its published forms and activated playbooks on a non-production instance. Once it's ready, you can submit the app for deployment to production. For more information, see Request deployment for your app from Creator Studio to production.

Apps aren't deployed directly from Creator Studio. Instead, your admin uses Pipelines and Deployments. Admins should check out Managing deployments using pipelines in AEMC.

Deploying forms and automation with the app

You may feel some hesitation at this point, perhaps wondering if your app is actually ready. Well, you can take small steps and include only the forms and activated playbooks that you want in your deployment request.

When you submit an app for deployment, all of the app's published forms and activated playbooks are available to be deployed. When you request deployment though, you can specify:

- Published forms that you don't want to appear in the catalog after the app is deployed to production.
- Activated playbooks that you don't want to appear when users view records generated by the app after it's deployed to production.

If you don't activate a playbook and its app is deployed to production, the automation won't run on the applicable records. However, your App Engine admin can activate the deployed playbook for you.

Assigning users to a deployed app

Your app is officially published and ready to be used, congratulations! But, who gets to use it, and do they have access? Your admin gets to take charge here.

After your admin deploys the app to production, the admin must assign users and groups that can access the app. That is, you can't assign user access in the deployment/publishing process. See I've built my app in Creator Studio, now what? to find out more about where to access published parts of your app.

App versioning and release notes for Creator Studio apps

Each deployed version of an app must have a version number and release notes, which helps administrators track app usage and changes.

App version number

The version number enables admins to track which version of the app is deployed to each instance. Follow your organization's versioning guidelines, or use the x.y.z format, where x = major update, y = minor update, and z = patch.

Creator Studio automatically updates the next version when you update a deployed app, for example from 1.0.0 to 1.1.0 and then to 1.2.0.

App release notes

The release notes help admins track what the changes are between app versions. When submitting your app for deployment, specify information that helps people understand differences between app versions.

Request deployment for your app from Creator Studio to production

After you've tested your app's forms, playbooks, and workspace category on a non-production instance, for example a development instance, deploy it to a production instance so users can access it.

Before you begin

Your admin must set up a deployment pipeline before you can submit your app for review. Contact your admin if you need a pipeline configured.

To request that your app is deployed to production, you must be given permission to work on the app.

About this task

You can't cancel the review cycle after you submit an app for deployment review, so make sure that your app is ready to go.

Procedure

1. Go to **All** > **App Engine** > **Creator Studio** to see all the apps on the Creator Studio home page.
2. Open the app that you want to deploy to production.
3. Select to **Preview** how different forms appear in various experiences, or select the **View** or **Edit** button to view or edit the application experience.

   Select different previewing options if you want to make sure that you've selected the correct application and see how it will appear in the following formats:

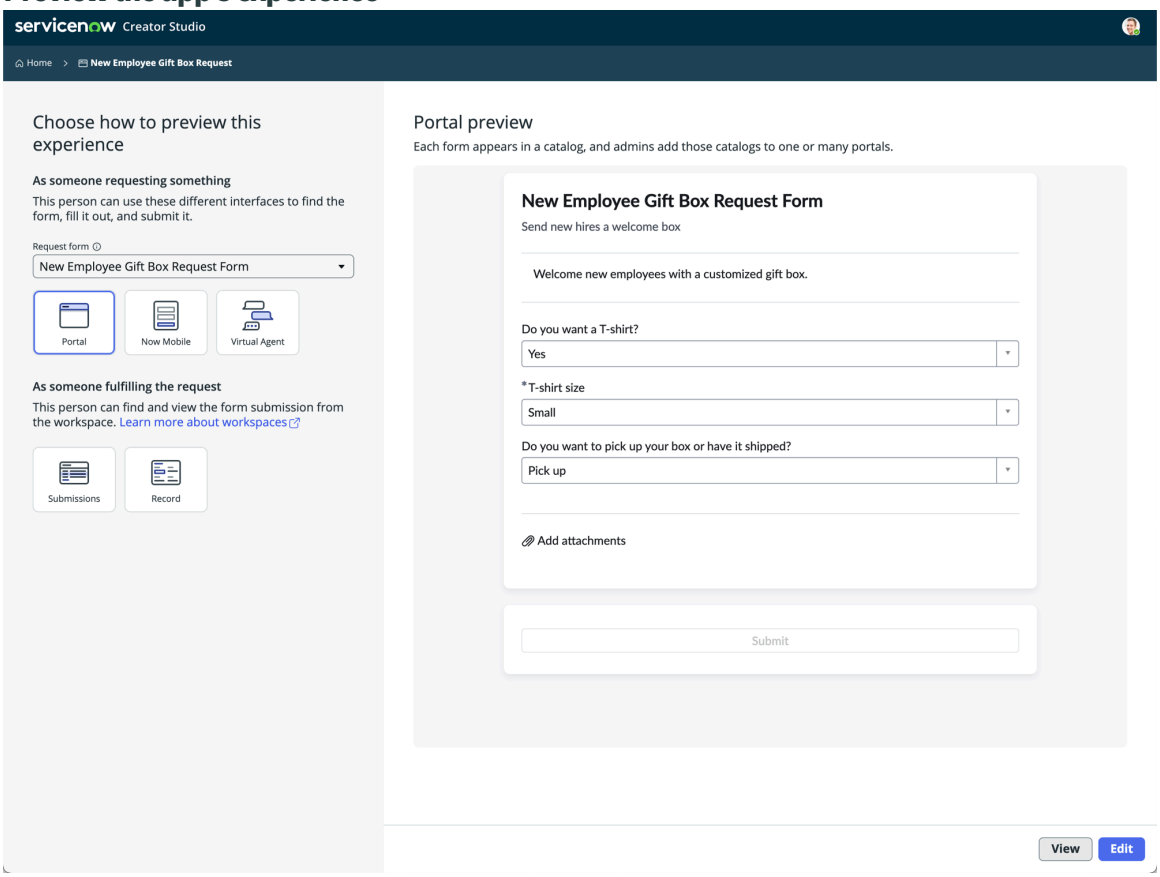
   - **Portal** (see a preview of how it'll appear on a desktop website)
   - **Now Mobile** (see a preview of how it'll appear on a mobile phone or device)

- **Virtual agent** (see a representation of how it'll appear on a chatbot interface)

> **Note:**
> Your organization should have the correct plugins installed to see how the form will appear in Virtual Agent. If you're interested, ask your admin and see Catalog builder preview topic conversation for more information on previewing forms and their catalog items in Virtual Agent.

The **View** button displays forms that have been published and doesn't explicitly create a new draft form for development. The **Edit** button takes you to a development form, for example, a new draft version of a form that's already been published.

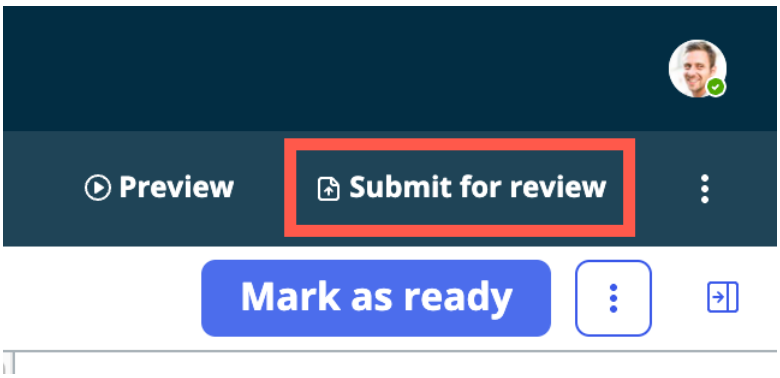
Preview the app's experience



You can also check out a representation of how the form submissions workspace will appear by selecting the **Submissions** preview, as well as the records your app generates for it (by selecting the **Record** preview).

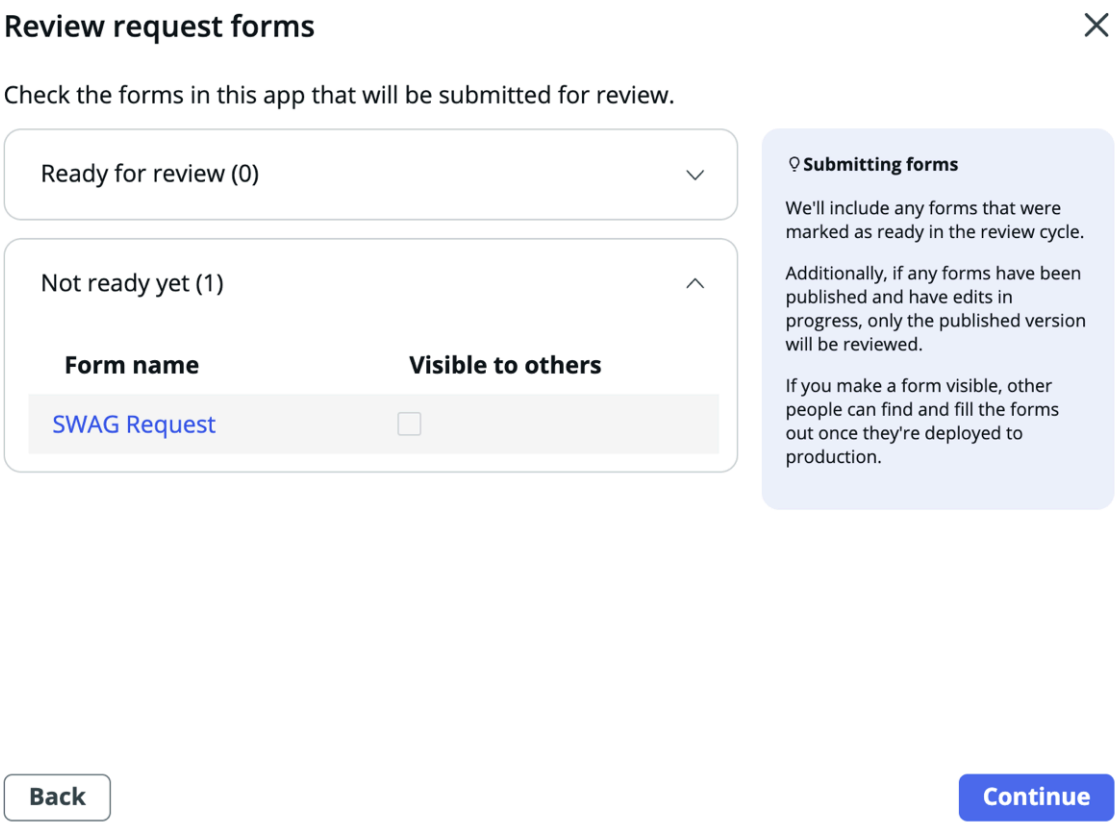
4. In the application header, select **Submit for review**.

Submit for review



5. Select **Continue** on the Submit app for review modal.
6. Now you need to choose which published forms are visible to users in the catalog. In the Ready for review section of the Review request forms modal, select which of the app's published forms that you want to be available after the app is deployed selecting the **Visible to others** option.

Review request forms for deployment



7. Select **Continue** when you're happy with the forms being deployed to production.
8. Next, you must decide which of the app's activated playbooks will run on production after the app is deployed. In the Review playbooks modal, select the **Run on production** option for each playbook that you want to run on records that the app generates.

Note:
If you can't select a playbook, you need to go back to the **Automations** tab of Creator Studio and activate it. If you need a refresher on that, check out Activate a playbook in Creator Studio.

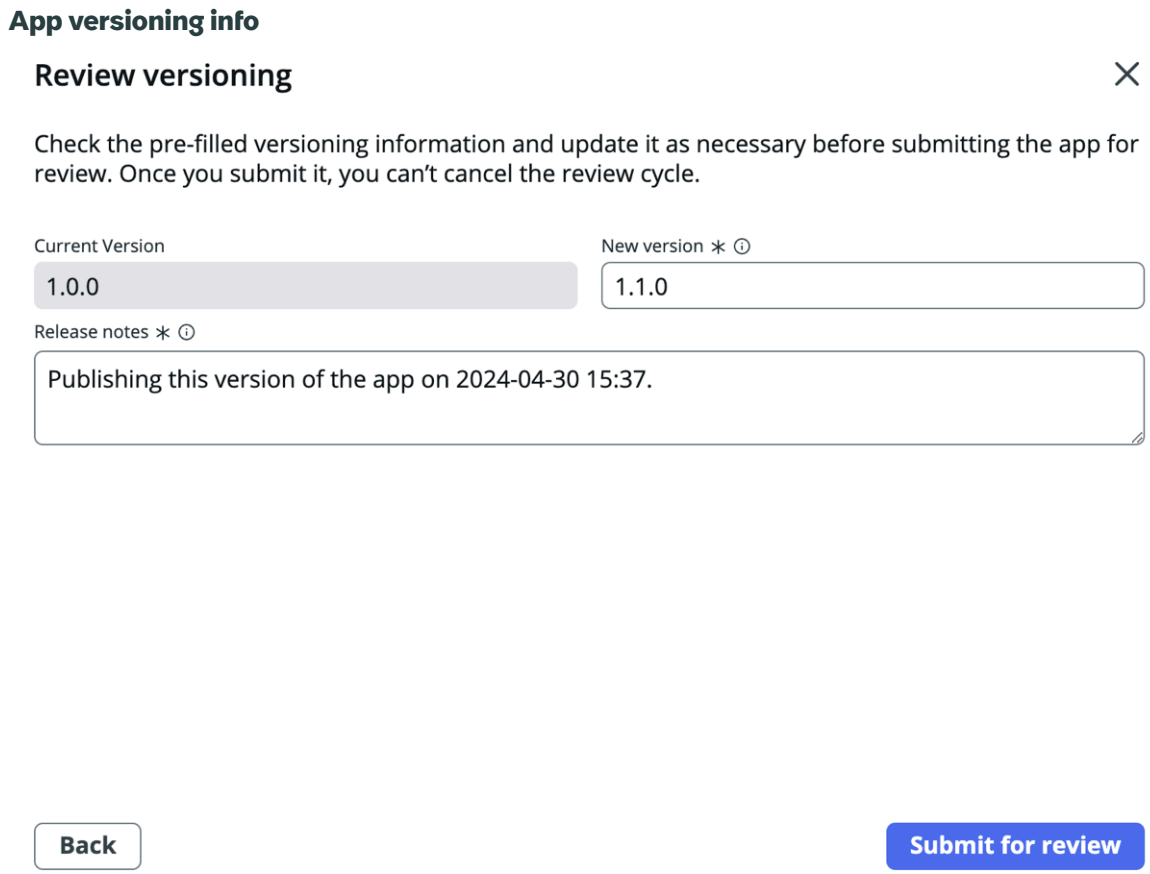
Unactivated playbooks still get deployed to production with the app, they just won't run on the records unless your admin activates them on production or redeploys the app with the playbook activated.

9. Select **Continue** when you're happy with the playbooks being deployed to run on production.
10. Finally, make sure that all the release details for the published app are correct.

Versioning options for deployment

Field	Description
New version	Version number of the app you're requesting for deployment. Creator Studio automatically generates an updated version number, but you can change it. Follow your organization's versioning guidelines, or use the x.y.z format, where x = major update, y = minor update, and z = patch.
Release notes	Details on what's changed in this new version of the app, or a general description of what the app does if this is its first version.

Read more about this step of requesting deployment in App versioning and release notes for Creator Studio apps.



11. Select **Submit for review** when everything is correct and ready for your admin to review and deploy.

Result
Woohoo! Your app is ready to be reviewed for deployment.

What to do next
Your admin uses Pipelines and Deployments to deploy the app to production. You can still make changes to the app after it's been deployed, you'll just need to request re-deployment when it's ready.

If you're an admin, check out Managing deployments using pipelines in AEMC for the scoop on deploying apps.

I've built my app in Creator Studio, now what?

You've added forms and automation to your app, and customized the form submission workspace. Now what?

What happens after I submit my app for review?

When you finish creating your app and select to **Submit for review**, your admin gets a deployment request. They then review your app deployment request and move the app to production.

After the app is deployed to production, the forms are available on the ServiceNow AI Platform.

Where do I find my app after it's deployed?

After deployment, your app lives as forms in the Service Catalog and categories you specified when creating the forms.

Users can access those forms directly in Service Catalog, as well as Service Portal and Employee Center.

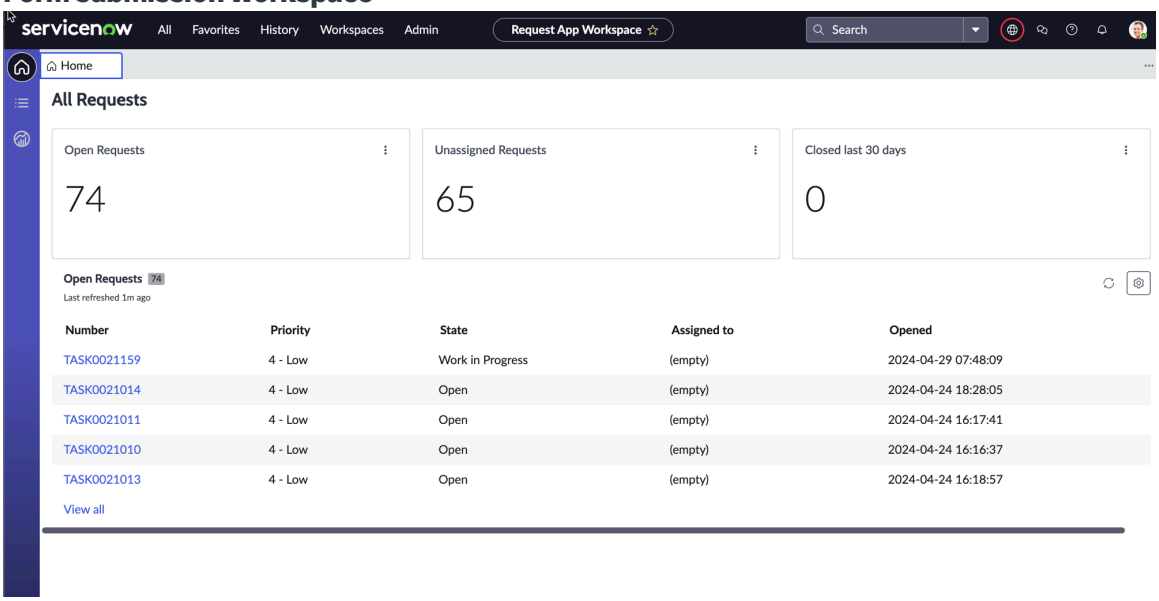
If you associate the app's form with one or more topics, the form will appear in the relevant, dynamically created topic pages in Employee Center. Find out more about topics in Associate a catalog item with a taxonomy topic in Employee Center, and more about taxonomy, which is a categorization method, in Unified Taxonomy for Employee Center.

Where do fulfillers work on submitted forms?

Fulfillers access the default workspace on the ServiceNow AI Platform by going to **All** > **App Engine** > **Request App Workspace**. The Request App Workspace displays a category for each app with filtered lists of records, both default and any extra that you added. Fulfillers then select a record to view the details of the request and make updates as needed.

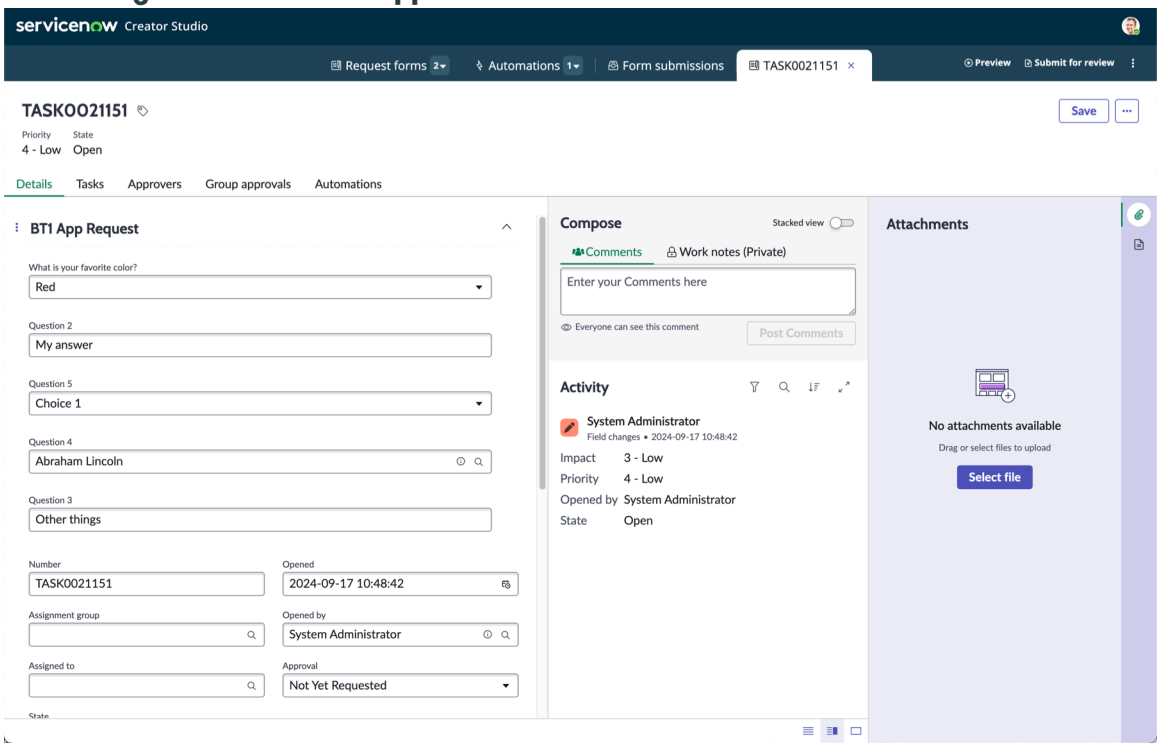
Note:
You can't access the Request App Workspace as the owner of an app, though you can access it if you also have an admin or the applicable agent role. The app's agent role is <app scope>.agent, for example, x_snc_app_name.agent.

Form submission workspace



You can also preview and interact with how records will appear in the Request App Workspace directly within Creator Studio.

Previewing how a record will appear



Can I continue developing my app in other ServiceNow AI Platform builders?

You can open Creator Studio apps in other builders. For example, open it in App Engine Studio to add more experiences or complex automations.

Get help and check out the FAQs

Got more questions? Take a look at the Creator Studio FAQs on the Community site !

You can also watch a quick video on how to contact your admin and check out some helpful resources.

Closing requests and app notifications in Creator Studio

The records that your app creates when a form is completed are not automatically closed, and some notifications are not automatic and must be configured.

Closing requests generated by Creator Studio apps

After an app's automation is done and the request is fulfilled, users must manually close the request record in the Request App Workspace. When fulfillers manually close the request, the ServiceNow AI Platform emails the person who made the request to notify them that the request is closed.

Additionally, you can create a playbook in the app to automatically email the requester when their request is closed. For more information, see Add activities to an app's playbook in Creator Studio.

Default notifications for apps built with Creator Studio

Apps created in Creator Studio send the following notifications by default.

Default app notifications

Event	Recipient	Trigger
Request opened	User who opened the request from the app	Record in the app's Task table is created
Request assigned to user	User the request is assigned to	Record in the app's Task table is created or updated
Request assigned to group	All users in the group that the request is assigned to	Record in the app's Task table is created or updated
Request closed*	User who opened the request	Record is updated any closed stated, such as Complete or Cancelled

*Remember, request records must be manually closed.

For more information on notifications from the ServiceNow AI Platform, see Receive notifications.

Notifications Creator Studio sends about building apps

Default app notifications

Event	Recipient
A Creator Studio Restricted User submits a new app request	App Engine Admin group
The requested app is approved and created by the admin	Creator Studio Restricted User who requested app creation
The app creation request has been fulfilled	App Engine Admin group

Creator Studio reference

Find details on the parts of building apps in Creator Studio, such as descriptions of all possible types of questions or layout options for forms.

Creator Studio form settings

You can edit the settings for an app's form in Creator Studio at any time. For example, to change who can access it.

General form settings

The **General** tab defines the form's basic information and how things appear on it.

General tab for app settings

Field	Description
Form name	Name of the form. Apps can have multiple forms. If you want to edit the settings for a different form, select that form in the **Request forms** tab.

General tab for app settings (continued)

Field	Description
Short description	Brief description of what the form is used for. For example, "Laptop request form."
Image	Image to appear on the form. Select the logo and navigate to a JPG, PNG, or SVG file to upload.
Description	Informative reason why people should use the form. You can include content like videos, images, and links to other sources of information, such as knowledge base articles.
Make form visible to others	Option to have the form available outside of the app, for example, in the specified catalogs. You can edit this option only for forms that have been published. **Note:** You can also specify whether the form is visible after deployment when you're ready to deploy your app. Find out how in Request deployment for your app from Creator Studio to production.
Hide "Add to wish list" option	Option to prevent users from favoriting the form on their wish list. Favoriting a form makes it easier to find.
Hide attachment option	Option to prevent users from adding attachments to the form.
Mark attachment as mandatory	Option to require attachments on the form. If you select the **Hide attachment option** setting, you can't select this setting.

Uneditable form settings

After you create the app, its **Template** can't be edited. If you want to change it, create a new form using a different catalog template. The **Record submission table** is automatically generated, and can't be changed.

Catalog location form settings

Location settings define where the form appears in a catalog, how it's categorized, and what topics it appears for. You must select the edit icon (Edit) to make changes to the catalog and topic settings.

Select the catalog that represents the business area the app will use. For example, you could select a service catalog that contains software and laptop cables for an IT fulfillment app. Expand the carat for each catalog to see its sub-catalogs. Then select as many items in the catalogs as you need.

If you associate the app's form with one or more topics, the form will appear in the relevant, dynamically created topic pages in Employee Center. Find out more about topics in Associate a

catalog item with a taxonomy topic in Employee Center, and more about taxonomy, which is a categorization method, in Unified Taxonomy for Employee Center.

User access form settings

Select the edit icon (Edit) to define access for roles and groups for the following:

- **Available for**: Search for and select roles and groups that can access the form.
- **Not available for**: Search for and select roles and groups that can't access the form.

Available question types in Creator Studio

Build apps using different types of questions on a form in Creator Studio.

You get to pick the questions to ask requesters. Creator Studio provides two types of questions you can ask:

- **General questions** are where you give requesters an empty box to write a short answer (think name or email) or a list of choices to pick from (like a dropdown menu or those little circles you fill in).
- **Reference-based questions** are where you provide a list of choices that you define in a table.

The type of question you select from the **Content type** field in the Question details panel changes the question's settings that appear.

Types of general questions

General question type form elements

Content type	Description
Short answer (Single-line text)	Single-line question.
Multi-line text	Longer option that provides space for a question multiple lines in length.
Dropdown	Question with a list of pre-defined answers that users select from a dropdown menu. Users can select only one answer.
Radio button	Question with list of pre-defined answers that users select from radio buttons. Users can select only one answer.
Check box	True or false question that users answer by selecting the relevant check box. **Note:** If you put two checkbox questions side-by-side on a form, they make a section. You can't add other types of questions to that section.
Yes/No	Question where users select Yes or No as their answer.
Date	Question where the answer is a date that users must select from a calendar.

General question type form elements (continued)

Content type	Description
Date and time	Question where the answer is a date and time that users must specify.
Question set	Preconfigured questions that you can't change. Admins create question sets in Service Catalog. For more information, see Service catalog variable sets. **Note:** • You can't change an existing question into a question set. To include a question set on a form, you must newly add it to the form. • If you put two checkbox questions side-by-side on a form, they make a section. You can't add other types of questions to that section.

Types of reference-based question types

Reference-based questions pull their possible values from the table that you must designate as the **Source table**.

Reference-based question form elements

Content type	Description
Record choices	Question where the answers are retrieved from an additional specified table when the filter conditions, which you must also define, are met. Use this question on a form that references data from another form, such as a form that uses the Incident table. "Choose the related incident" is an example Record choices question, which could use a filtered list of incidents as possible answer selections.
Field choices	Question where the answers are retrieved from a field on the specified table when the filter conditions, which you must also define, are met. For example, you could create a Field choices question for a table with a "Country" field, which the user could then use to select their country.

Reference-based question form elements (continued)

Content type	Description
Multi-select	Question where users can select multiple answers that are retrieved from the specified table when the filter conditions, which you must also define, are met. Use this question on a form that references data from multiple other forms, such as a form that pulls answers from multiple separate Incident tables.

Question details

Depending on the type of question you add to a form, you must specify some of the following details.

Question type details

Field	Description	Available for
Question label	Question or statement that says what the question is asking.	All question types
Help text	Additional information that appears as a tooltip to guide the user when they hover over the information icon.	All question types
Show questions on form	Hide the question from the form by leaving this option unselected.	All question types
Mark as required	Option to make the question required before the user can submit the form.	All question types
Mark as read-only	Option to make the question read-only. You can use this option to associate data with the form behind the scenes by adding it to the app's Task table. For example, if you don't automatically pull the user's role into the form's Task table, you could create a single-line text question where the default value is their role (such as Sales) and then hide it. You could even hide the question from the form to make the data exchange invisible to the user.	All question types

Question type details (continued)

Field	Description	Available for
Default value	Value that's auto-populated in the question's answer when the form is opened. For reference-based questions where you designate a source table, you must use an asterisk (`*`) as a wildcard when searching for values in the **Default value** field. For example, if the question references the User table and you're looking for Abel Tuter, entering `Tuter` won't find that user but entering `*Tuter` will.	All question types
Choices	Customizable answers to the question, which you can drag to rearrange in a new order.	• Dropdown • Radio button
Include "None" as a choice	Option to include **None** as a possible answer to the question.	• Dropdown • Radio button • Field choices
Default to the first choice	Option to display the first choice as the possible answer when the user sees the question.	Radio button
Source table	Table location that provides data for answers to the question.	• Record choices • Field choices • Multi-select
Field	Field in the specified source table that possible answers are retrieved from.	Field choices
Filter conditions	Conditions that must be met to view certain choices. Select **Add condition** and use the condition builder to create the filter. For more information, see Condition builder.	• Record choices • Field choices • Multi-select

Layout options for forms in Creator Studio

Adjust how your form, which creates a catalog item, appears in Creator Studio using layout options.

Layout options enable you to design a form by dragging them from the Form elements panel to the form canvas. You can also drag layout options to rearrange them.

Note:
To edit or delete a section, you must hover over the section name and then select **Section** to see the section details in the properties panel, as well as the delete icon.

Selecting a section

Layout options

Element	Description	Details
One-column section	Section with optional header (label) where all questions in that section of the form appear in a single column.	• Specify a **Section label** to give the section a header. • Select **Show section label on form** to display the section header.
Two-column section	Section with optional header (label) where all questions in that section of the form appear in two columns.	• Specify a **Section label** to give the section a header. • Select **Show section label on form** to display the section header.
Divider line	Displays a line between questions or sections.	N/A
Heading	Displays header text, such as a question or a statement based on what type of information you're asking the user to provide on the form.	Specify header text in the **Name** field.
Rich text	Displays longer text that you can enhance with options like links, different fonts, and bullets and tables.	Use the rich text editor to enhance any supplemental text with the following typographic formatting: • Bold/Italics/Underlining • Font face and size

Layout options (continued)

Element	Description	Details
		• Font and background color • Tables • Links • Images • Source code to include scripting • Alignment • Bulleted list • Numbered list

Creator Studio glossary

Learn about the terms and concepts used in Creator Studio.

activity

Activities in a playbook complete automated tasks, such as obtaining approvals, assigning records, and sending email.

automation

Tasks or requests moving through a workflow without manual intervention.

board view

A traditional layout of viewing a playbook, which shows each activity as a card in the navigation panel. When you select an activity, for example a task, its editable details appear in the canvas for you to work with them.

catalog

A collection of items that represent all the items a requester can ask for.

collaboration descriptor

Level of collaborative access assigned to a developer. The collaboration descriptor that someone is assigned determines if they can assign, manage, and monitor delegated development permissions. For example, people who are Owners of an app can do more than people with the Editor collaboration type.

delegated development

A collaborative process that enables developers to invite other people into apps so they can co-create and develop the app together.

deployment

The process of an app moving from a non-production instance like development or QA through to production. Production is the instance that your customers see, or your “live” instance.

diagram view

A visually intuitive diagram that shows you the order that activities occur in the playbook. When you select an activity, such as the trigger or a decision, a modal pops up where you can edit its details.

dynamic behavior

A form for a catalog item can use dynamic behavior to automatically update based on how users answer a question. For example, if a user says they don't want lunch for an event they're attending, you can make a **Meal preference** field disappear.

> **Note:**
> Dynamic behaviors are also called Catalog UI Policies.

extend a table

When you create a table based off an existing table. Extending a table means the new table inherits the parent (extended) table's columns, as well as its business logic. Apps built in Creator Studio extend the Request Task table.

field

A field in Creator Studio is a column on the related Task table. Ii you're using condition builder, a field is either a column on the table or a question from the form.

form

A content page that displays fields and values for a single record from a database table.

form template

A pre-defined set of questions arranged on a form provided by Creator Studio.

fulfiller

Someone who works on requests. Fulfillers may also approve or deny requests, depending on any approval automation for the app.

item

Something a requester can ask for, such as new computer equipment or time off work. Each item requires its own form in Creator Studio.

playbook

A set of automated activities that occur based on a trigger, for example, sending an email when a request is approved. Think of playbooks as pre-programmed workflows that kick in after a form is submitted. They are like if/then statements: If this happens, then that will happen.

record

A task or request that needs to be acted on. All rows in your app's tables are individual records. Records have different states depending on what actions have been taken.

reference-based question

Question on a form that retrieves its possible answers from the table you define.

release notes

Information about what's included in each new version of the deployed app, which helps admins track what the changes are between app versions.

requester

Someone requesting something, like a piece of equipment or permission to do something, such as take time off work.

target table

The table where apps created in Creator Studio store their requests.

trigger

The event that makes an automated playbook begin running. For example, submitting a request automatically assigns it to a manager.

version number

A number assigned to the app that increases with each subsequent time it's deployed.

Workflow

A sequence of activities to automate processes in applications.

Building low-code applications

Create and manage custom applications in a simple, low-code environment.

ServiceNow Studio

Use ServiceNow Studio to build apps and app files with integrated tools, access and edit metadata in scoped and global apps, and package app changes for deployment, all in one powerful development tool.

App Engine Studio

Use App Engine Studio for guided, low-code development to build a custom app from scratch or with a template.

Creator Studio

Use Creator Studio to quickly create a request/fulfill app based on Service Catalog using helpful templates.

ERP Data Hub

Use ERP Data Hub to connect to an ERP (Enterprise Resource Planning) system, create an ERP model, and extract data from the ERP system, such as sales orders, data records, and purchase documents. You can then use the ERP data when building low-code apps on the ServiceNow AI Platform.

ERP Customization Mining

Use ERP Customization Mining to find the custom applications in your ERP system for platform migration, such as from SAP to the ServiceNow AI Platform.

ServiceNow CLI

ServiceNow CLI enables you to create custom commands to manage applications from your local system's command line.

Which builder should I use to create an app?

Types of builders

Want to build an app easily, without code?

Creator Studio specializes in helping you craft request-fulfillment applications without writing code. For example, an application to request office supplies by filling out a form, and someone approves or denies your request. For more information, see Exploring Creator Studio.

Need a more general app but still want low-code options?

App Engine Studio lets you build a broader range of apps than Creator Studio without being a programming pro. For more information, see Exploring App Engine Studio.

Are you a developer who wants more control in a centralized user interface?

Build apps smarter and deliver them faster with the new ServiceNow Studio. ServiceNow Studio empowers platform developers with a modern, unified environment for building on the ServiceNow AI Platform. ServiceNow Studio features streamlined navigation to applications and metadata, integrated low-code tools, efficient tracking and packaging of development work that accelerates development processes and enhances productivity. For more information, see Exploring ServiceNow Studio.

Are you a developer who wants to use industry-standard development tools and processes?

The ServiceNow IDE and ServiceNow SDK support developing applications in source code with ServiceNow Fluent, creating JavaScript modules, and using third-party libraries. ServiceNow Fluent is a domain-specific programming language for creating application metadata in code.

The ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform. The ServiceNow SDK uses Visual Studio Code Desktop locally. For more information, see Building applications in source code.

Related applications and features

Exploring decision tables

Use Decision Builder to create and manage decision tables. Embed business logic into a series of if-then decision rules.

ServiceNow Studio

ServiceNow Studio gives developers access to app development builders and tools, all in one place.

Flows in Workflow Studio

Workflow Studio automates processes and repetitive work to improve efficiency and experience.

Table Builder

Use Table Builder to design tables, forms, and flows visually using a single user interface.

UI Builder

Use UI Builder to build web user interfaces for CSM Configurable Workspace, App Engine Studio generated workspaces and portals, or custom web experiences using Next Experience Components and custom web components.

Workflow Studio

Integrate workflow authoring, configuring, and monitoring into a single page experience.

Workspace Builder

Workspace Builder for App Engine enables you to create a custom workspace from App Engine Studio (AES) quickly and efficiently.

Build apps using App Engine Studio

ServiceNow® App Engine Studio (AES) is a guided, low-code tool for developing rich web applications to store information, automate business processes, and solve business problems. Work that was once assigned to administrators can now be delegated to employees with little to no training using AES.

This video shows a visual overview of the app creation process using App Engine Studio.

App Engine Studio overview

Get started

By delegating development to citizen developers in your organization, administrators are freed up to address more strategic, system-wide priorities. AES can help you do the following:

- Build powerful apps quickly to fit any business need by using a suite of development tools, including guided workflows and templates.
- Create experiences users love with Catalog Builder, Workflow Studio, Workspace Builder, Mobile App Builder, and other integrated tools.
- Scale apps without sprawl with straightforward governance and tools that support both citizen and pro developers, such as App Engine Management Center (AEMC).

Exploring App Engine Studio

Learn how you can use the low-code app development tool, App Engine Studio (AES), to build powerful applications using guided setup, predefined templates, and workflows.

This video shows a visual overview of the app creation process using App Engine Studio.

App Engine Studio overview

App Engine Studio users

Users

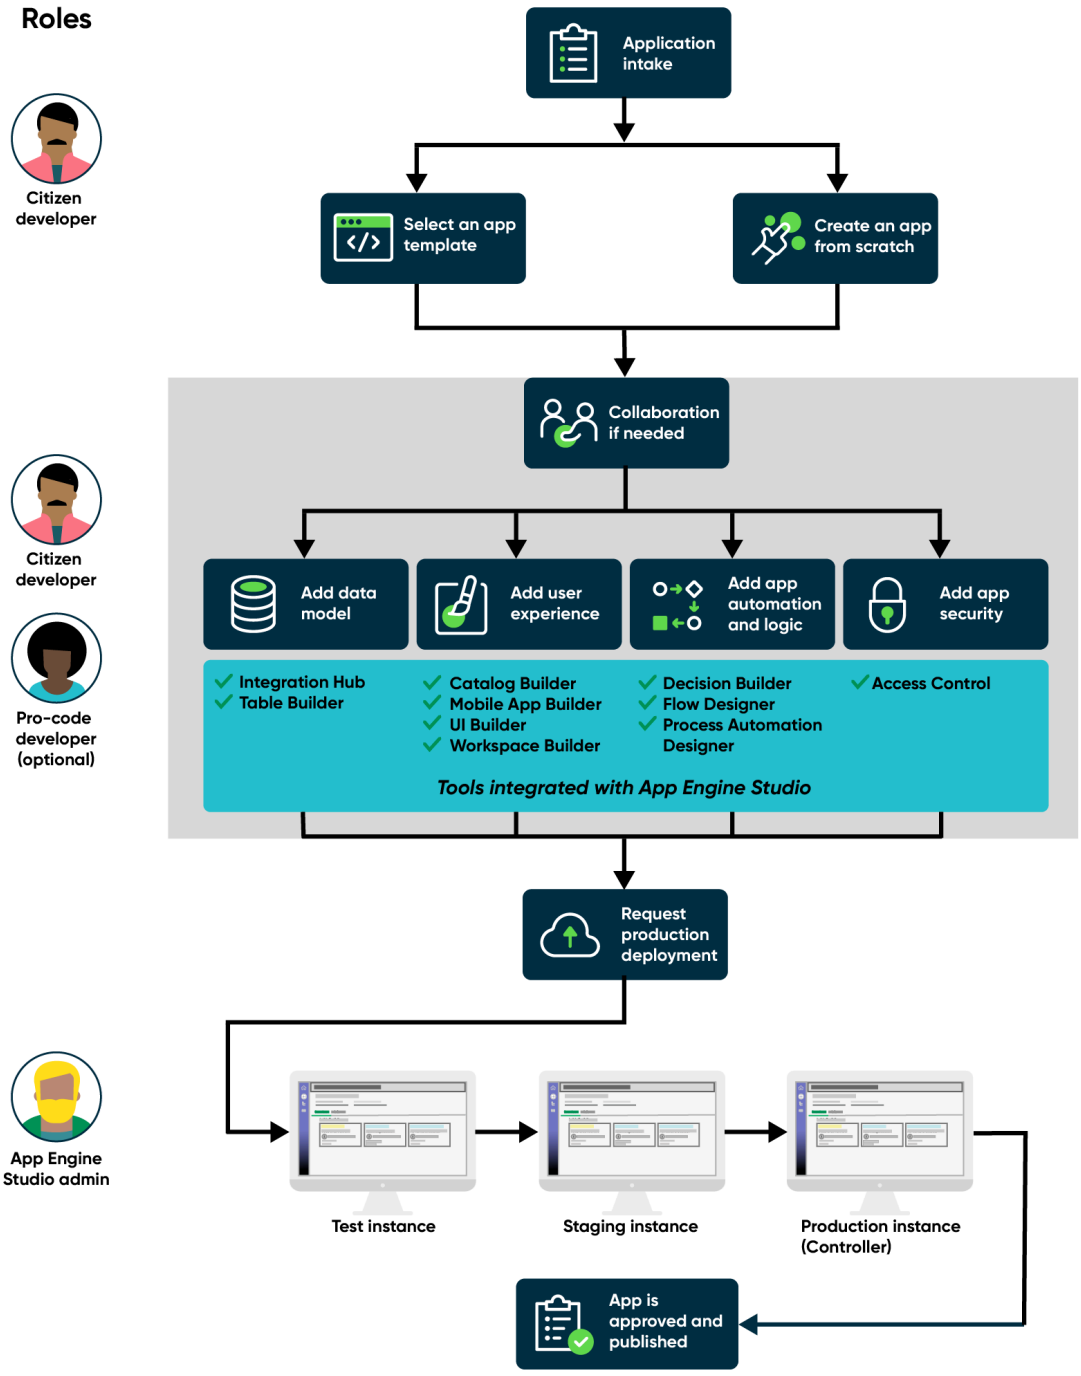
User	Description
Citizen developer	Citizen developers without programming experience can efficiently create applications on a simplified low-code, no-code platform that uses graphical interfaces and templates. The lower barrier to entry means developers of all skill levels can build applications.
Pro-code developer	Pro-code developers are familiar with using programming languages to build applications.
App Engine Studio admin	App Engine Studio admins manage the processes related to application development in AES. They review new application ideas, manage application development and deployment, and manage collaborator access, usually in the App Engine Management Center.

Workflow to create apps using App Engine Studio

The following illustration describes the basic tasks involved in creating an app using App Engine Studio. For detailed instructions, see Building apps in App Engine Studio.

Note:
Select the image to enlarge it.

Application creation process using AES



The workflow for creating apps in App Engine Studio is as follows:

1. As a citizen developer, you submit your plan for an app through Application Intake for approval and development in AES.
2. The AES admin reviews the intake request. If it's rejected, that closes out the request. But you can always update your idea and submit a new request.
3. When the request is approved, you must decide whether to create your app using a predefined template, or to create it from scratch. You should explore the available templates. They can save you lots of time.
4. Then you must determine whether you have the resources to build the app on your own. If you need help, you can request collaboration, or the AES admin can assign a collaborating developer.
5. If you use a template, the base system app is created automatically, with a basic data model, user experiences, automated workflows, and security roles. For more

Get to know AES

AES is designed to address enterprise low-code development needs by putting the power of the ServiceNow AI Platform in the hands of low-code developers. Guidance-driven flows and easy-to-customize templates help citizen developers to come up to speed quickly.

Regardless of their skill level, citizen developers become more productive using AES. Whether you're building a custom app from scratch or using a template, the simplified low-code experience in AES speeds up development on the ServiceNow AI Platform.

Key features of the AES include:

- **Guided experience for first-time users:** AES features a guided experience that orients developers, making it easy to navigate the environment. The first time you use the guidance, you're stepped linearly through the entire process of creating an application. After that, the guidance displays assistance related to what you're working on. You can hide the guidance by selecting **Don't show me this again** and exiting the pop-up.
- **App templates:** App templates simplify the app development process. Using templates based on proven use cases gives developers the ability to create powerful apps without the learning curve.

- **Guardrails:** Citizen developers receive tooltips and recommendations along the way, keeping them on track. Submitting apps for approvals also ensures quality.
- **Collaboration:** Developers of all skill levels can seamlessly collaborate on app development in AES's low-code environment.
- **Integrated tools:** Why work with multiple low-code tools when AES integrates with several? From designing tables to building catalogs and creating custom flows, AES has it all.

App Engine Studio benefits

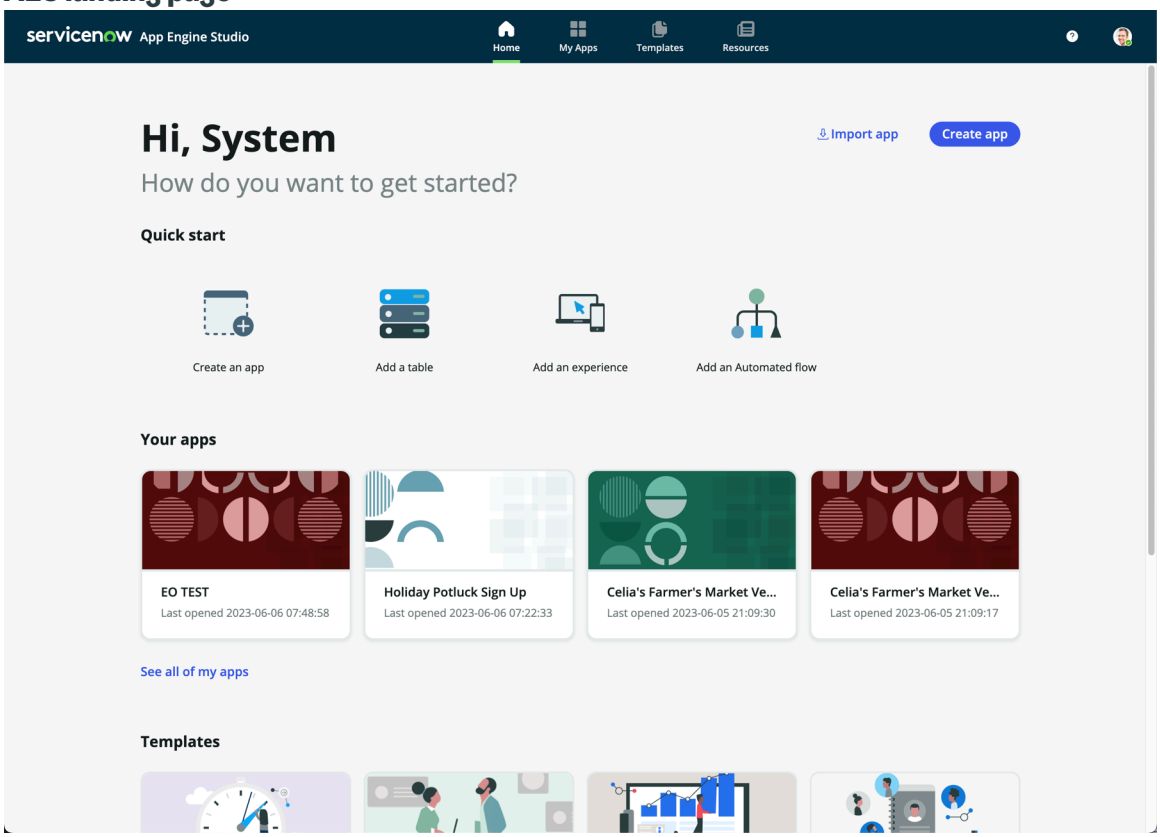
App Engine Studio provides the following benefits.

Benefit	Feature	Role
Submit ideas for an app, which admins then approve.	Submit your idea for app development	Citizen developer
Use templates for standard application types, such as procurement portal or time off request, as a starting point to create and customize new apps quickly.	Create your app using an application template	Citizen developer
Access multiple development tools in one interface, such as Table Builder and Workspace Builder.	Integrated development tools for AES	Citizen developer
Scale development while maintaining process to review and test applications before deployment.	Managing app development using the App Engine Management Center	Administrator

Accelerate your low-code development with AES

Using App Engine Studio's low-code development environment, citizen developers can quickly build high-quality apps. Citizen developers are individuals in your organization who aren’t experienced programmers, but who are subject matter experts with ideas for creating apps. With an approved idea in hand, a citizen developer chooses an app template, fills in a few parameters, and AES builds the app. The resulting application includes data, experiences, logic and automation, and security, all of which can be customized to your organization's needs.

AES landing page



Apps created from a template can be easily modified to meet the requirements defined by the citizen developer, or new apps can be created from scratch.

You can perform the following tasks to customize apps created using AES.

Task	Description
Create your data foundation easily	App Engine Studio templates contain default data tables that include everything you must deliver base system app functionality. Using the Table Builder app included with AES, you can edit or add new tables, add and delete columns, change table types, and more. You can also import existing data from spreadsheets, making it easy to automate existing manual spreadsheet-driven workflows.
Deliver great experiences	Experiences are role-based user interfaces that end users access to interact with your app. AES includes several distinct experience types, including configurable workspaces, portals, catalog items, and mobile experiences. You can add an experience by following a few simple steps. For example, you can quickly create a workspace by adding a name and description, a URL, and the roles that can access the workspace. Then you can tailor the workspace experience to the needs of your organization using the Workspace Builder tool within AES. More advanced configurations can be edited in UI Builder.
Automate your apps with workflow templates	AES templates include a set of powerful digital workflows that you can use to simplify the user experience, increase productivity, and strengthen your business processes.

Task	Description
	Simply choose from a list of common automation activities, and let the wizard quickly guide you through configuring the workflow. To adapt template-generated workflows to your needs, launch the Workflow Studio app to edit workflows.
Keep your apps secure	You can maintain control over who uses your apps by adding roles in AES. The app templates include predefined roles, giving you a head-start on security. You can add or delete existing roles, or create roles to meet your security needs.

Scale development while maintaining oversight

App Engine Studio lets you scale development across your organization while establishing and maintaining guardrails. You can control access to AES. You can also review apps created by your citizen developers before they're moved through your pipeline and published to your production environment. This review process gives you confidence to ensure the quality of the apps you create, release, and deploy.

What to explore next

To learn more about configuring and using App Engine Studio, see:

- Configuring App Engine Studio and related apps
- Building apps in App Engine Studio
- App Engine Studio reference

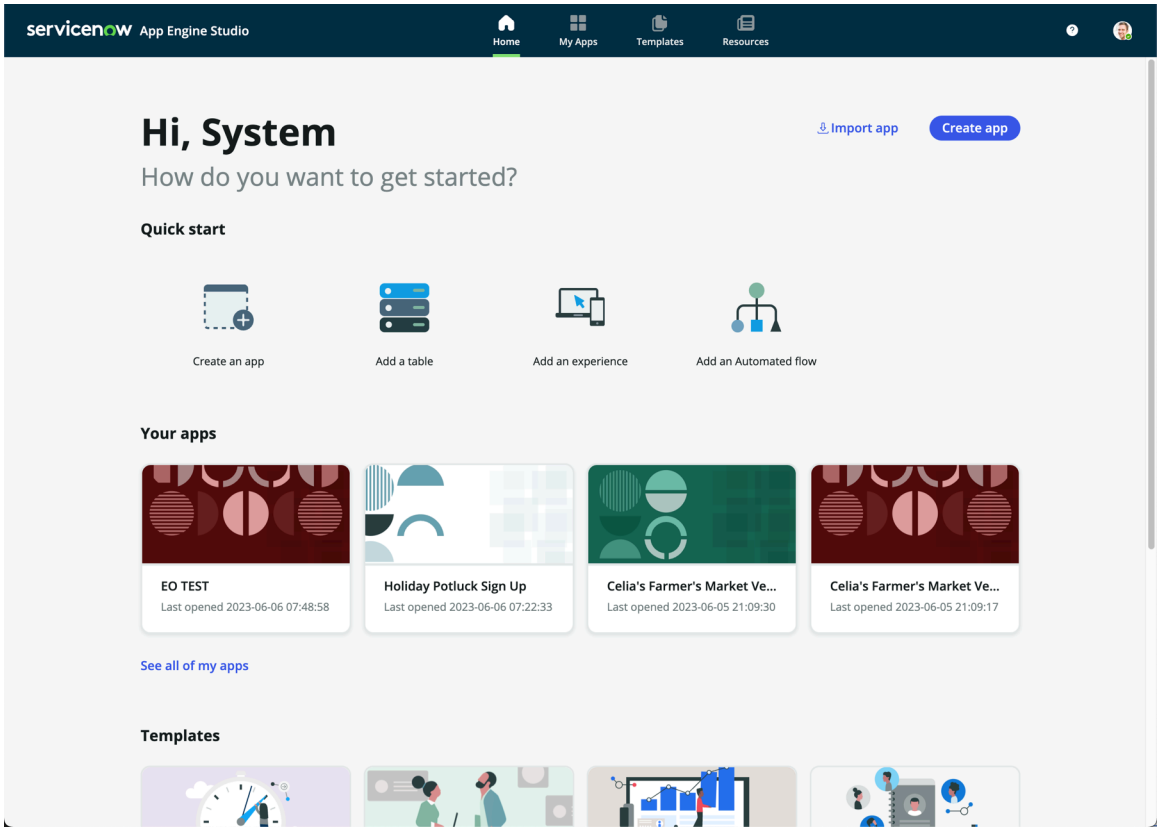
AES user interface

Learn about the App Engine Studio (AES) user interface.

AES is a web user interface that lets you build custom applications for your organization. You can build applications using templates which can be customized to fit your organizations needs.

App Engine Studio home

The App Engine Studio home page provides easy access to creating apps, viewing your app, quick start actions, and templates.



Use the top navigation bar to view your apps, access app templates, and find help resources. You can also access the help center by selecting the in the top right.

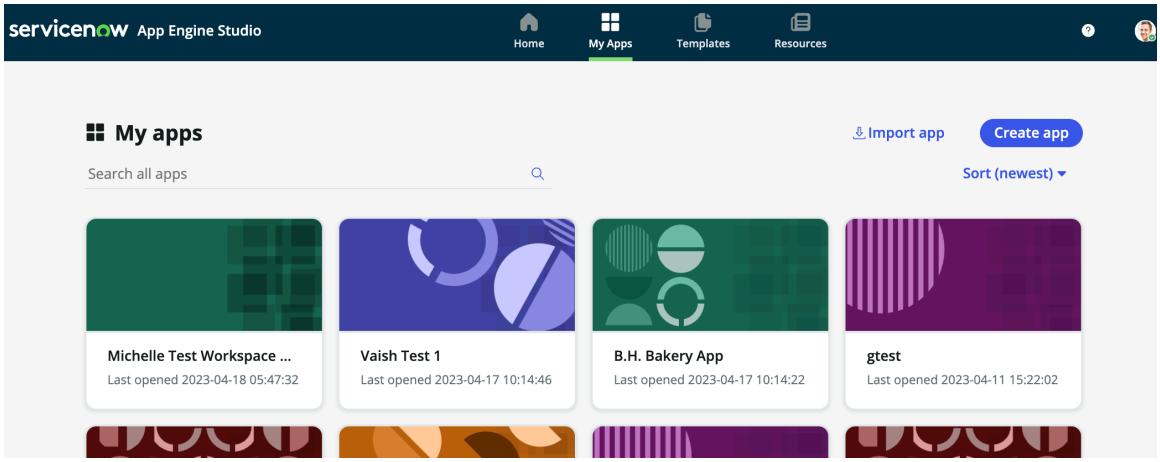
Users can access the following in AES:

- Create app — Create an application from scratch.
- Quick start — Links to add objects to apps, browse app templates, and learn more about the App Engine Studio tools.
- My recent apps — A list of applications you have accessed recently using App Engine Studio.
- Templates — A list of templates you can use to create an application with preconfigured data, experience, logic and automation, and security.

> **Note:**
> If you're in the App Engine Studio User Limited group, you won't see any templates on this tab.

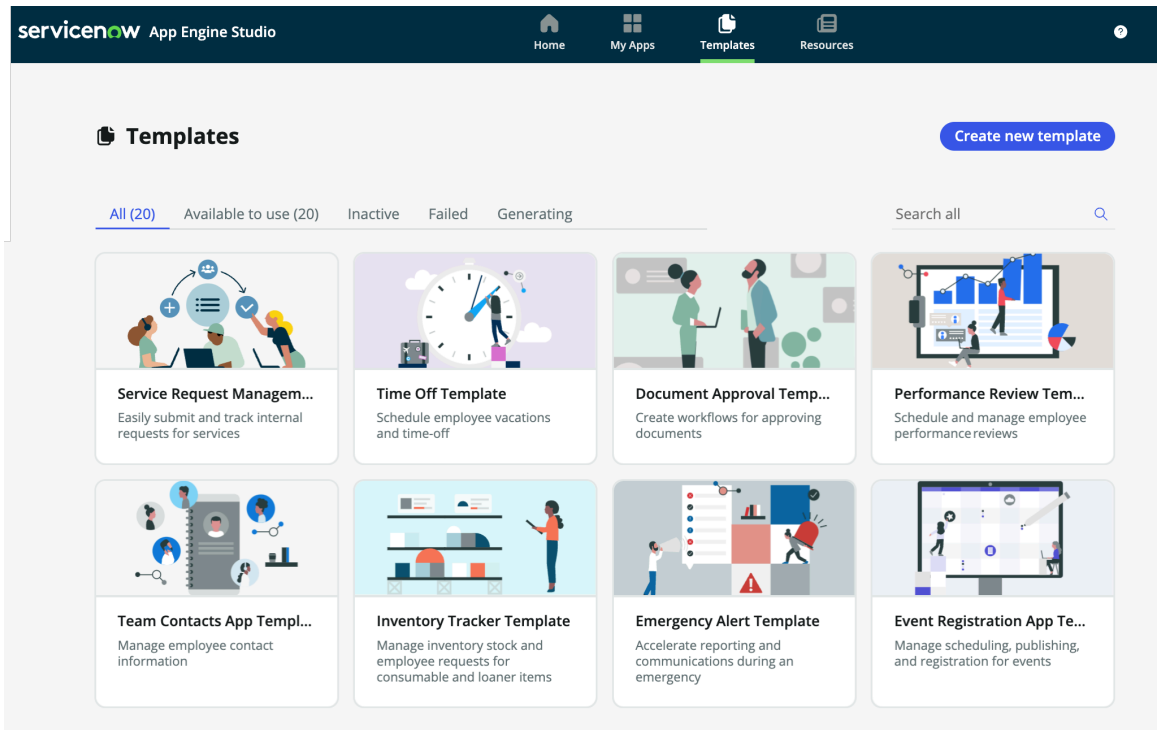
My Apps tab

View and search the applications you created.



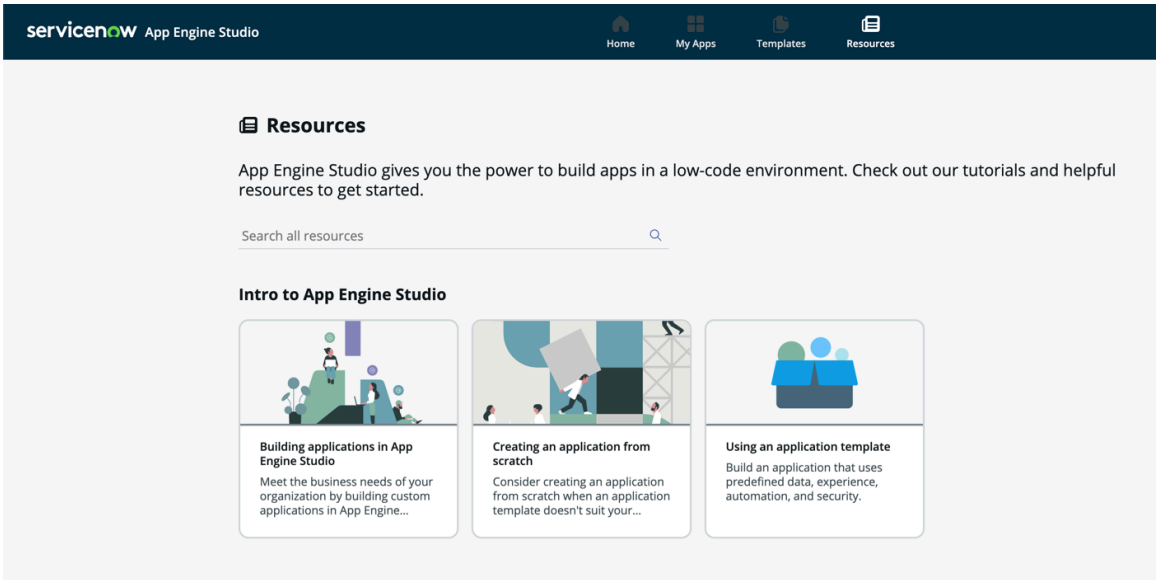
Templates tab

Provides a list of available app templates.



Resources tab

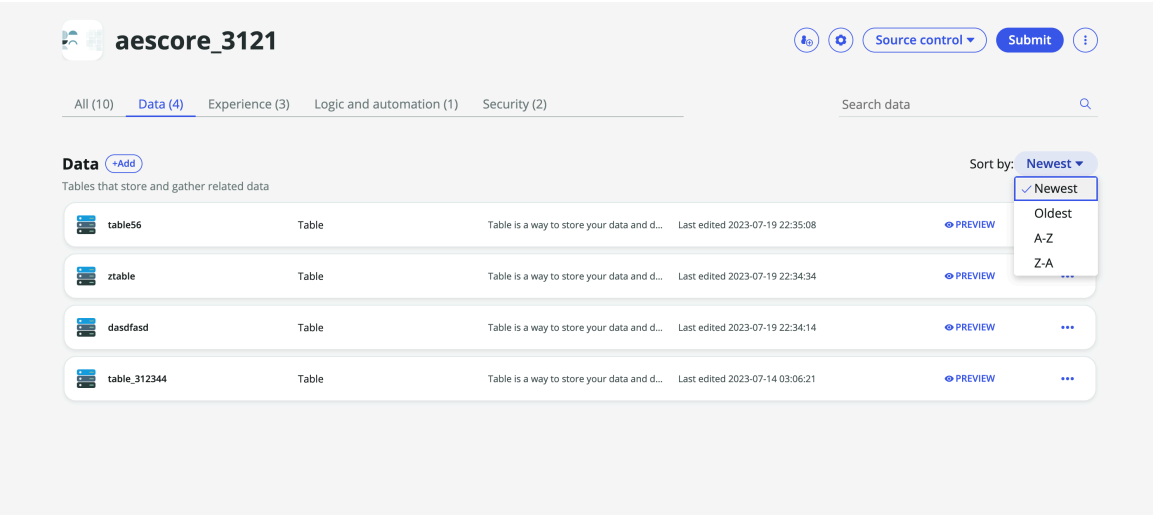
View tutorials and helpful resources to get started in AES.



App Home

Add data, experience, logic and automation, and security to your app from the app home.

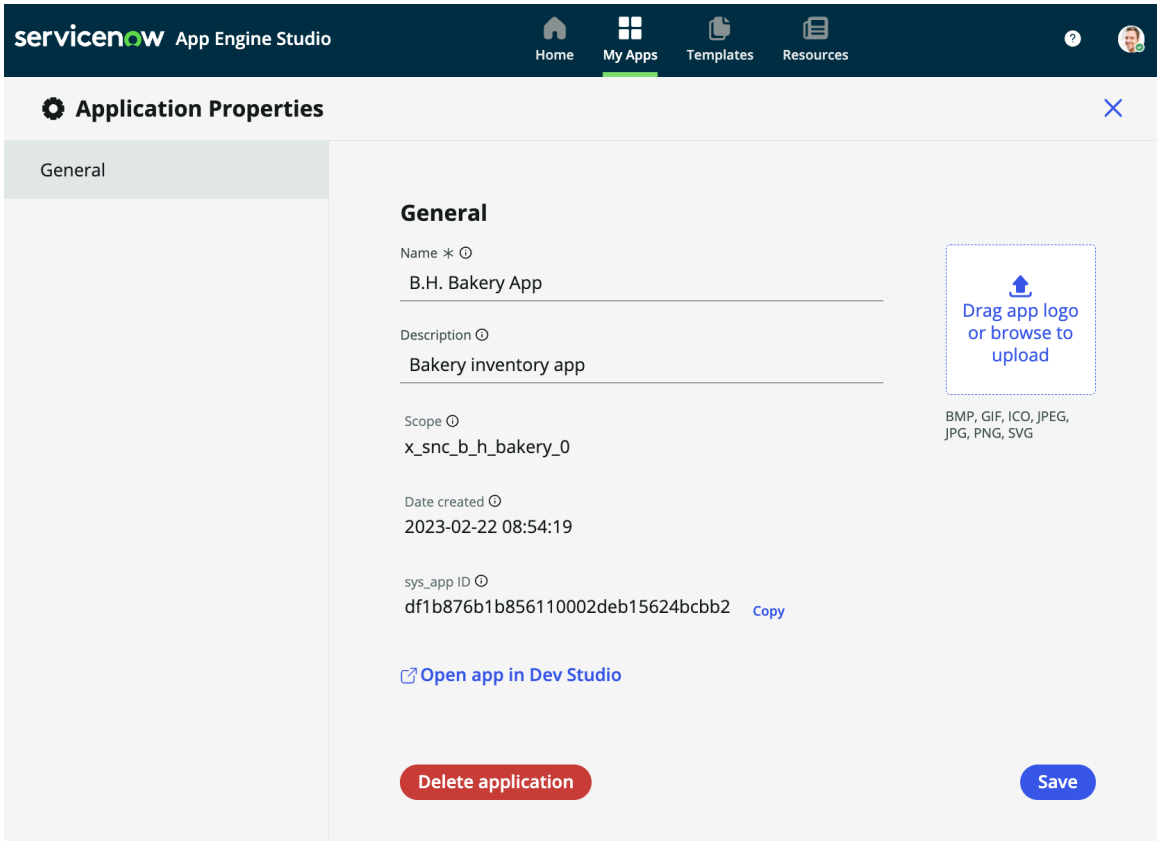
Note:
When viewing an app home page in AES, if you tab to a section (such as tables or experiences) with more than three items, the **Sort by** option enables you to display them alphabetically or temporally, by **Newest** or **Oldest**.



Some objects require access depending on your role. You can request access by selecting **Contact your system administrator** to become a delegated developer. For more information on the delegated developer role, see Delegate developers using AES.

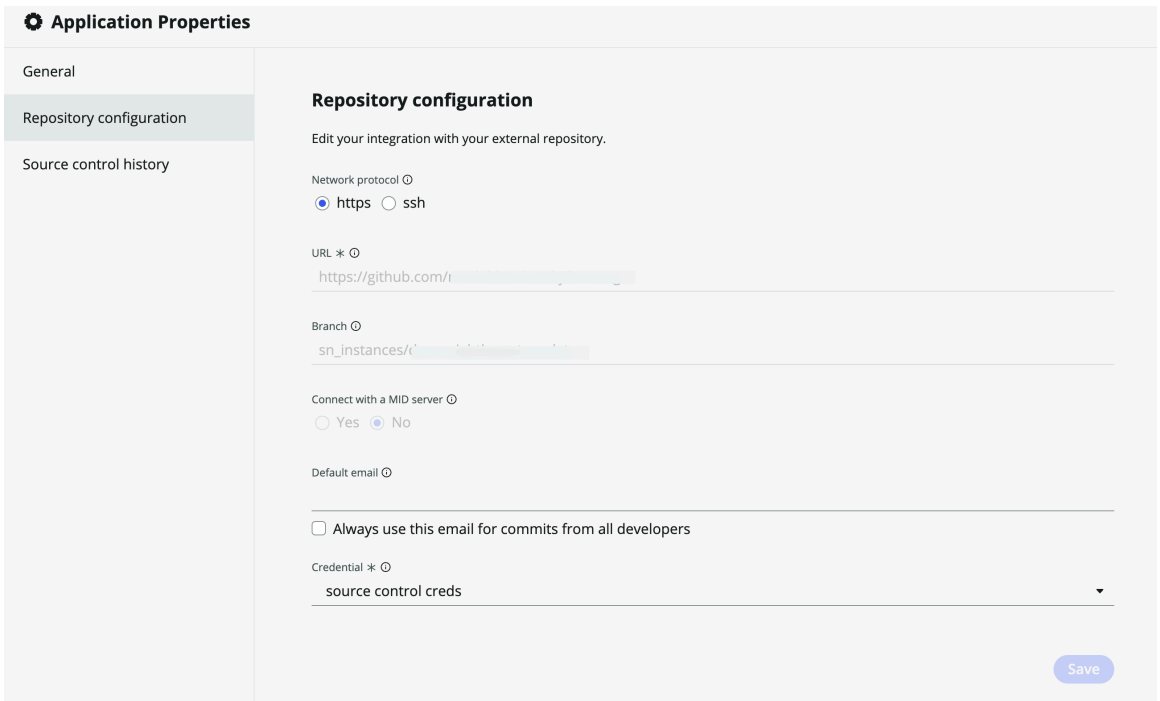
Application properties

View general settings of your application such as the name, description, and logo. You can also open your application in ServiceNow Studio or delete your application.



Repository configuration

View and edit the source control repository settings for your application.



Use App Engine instead of customization

App Engine development tools, such as App Engine Studio, offer an excellent alternative to customizing existing applications on the ServiceNow AI Platform.

When your company needs to add new functionality to the ServiceNow AI Platform, you can customize existing applications, such as IT Service Management (ITSM), or create a new application using App Engine developer products, such as App Engine Studio, Creator Studio, or ServiceNow Studio. A simple guideline for which path to choose is:

- If the customization extends the intended purpose of the application, it works better to customize. For example, you can add IT functionality to ITSM.
- If the customization doesn't extend the intended purpose of the application, it works better to create a new application using App Engine developer products. For example, do not repurpose the ITSM workflow to add a travel request workflow.

Examples of when to use App Engine

ServiceNow products work best when they're used as they were intended. If you find yourself heavily customizing an application to repurpose it, a better plan is to create a new application using App Engine developer products.

The following scenarios demonstrate where creating a new application works better than heavily customizing an existing ServiceNow application:

- Your company has a business process that augments existing product functionality but doesn't follow the same workflow exactly.
- You have a novel use case for an app that doesn't align with any product workflow.
- You have a use case that could be built by heavily customizing an out-of-the-box application, but it doesn't align with what the existing application was intended to do.

Let's dive deeper into the last use case.

Issues with repurposing existing products

ServiceNow applications come with roles, processes, and flows that are specially tailored to their use case. For example, ITSM apps help with IT users, IT issues, IT reports, and IT cases.

You might have an idea for an app that's similar to but doesn't exactly align with ITSM. Because ITSM gives you a starting point, you might be tempted to customize ITSM to add the new functionality. For example, ITSM tracks IT issues, and a travel app you want to create might track travel requests. While the workflows sound similar, in fact, they use very different data, different user interfaces, and the details of each workflow vary greatly. Rather than heavily customize ITSM to repurpose it, a better plan is to use App Engine developer products for the following reasons:

- Combining two workflows creates conflicts.
- Customizing applications has implications.

Combining two workflows creates conflicts

In the ITSM example, the repurposing of ITSM to include a travel workflow uses different data, different tables, different roles, and different workflows than ITSM. As ITSM, ITSM customizations, and the travel workflow grow over time:

- Their features will continue to diverge.
- Adding new functionality or fixing problems in one workflow might adversely impact the other.
- The performance of ITSM may suffer.
- The code base will grow and the two purposes of ITSM will make troubleshooting more difficult.
- Quality engineers will require two different testing frameworks.

All these issues may cause unnecessary complications, poorer performance, upgrade delays, and software problems.

Customizing applications has implications

The ServiceNow AI Platform is built to embrace customization and configuration. The ServiceNow AI Platform is flexible enough to fit your company's business needs. How you customize ServiceNow applications, however, can have significant impacts on ServiceNow support, upgrading to future ServiceNow AI Platform versions, and the functionality of the platform.

Let's start by differentiating customization and configuration:

- Customization is any change made to the code that is part of the baseline installation of a ServiceNow instance. You use code to customize applications.
- Configuration is any change you make to the behavior of a product that does not touch the code in the baseline installation of a ServiceNow instance. You can use system properties, ServiceNow products, or code to configure an application.

The following are some of the implications that result from customizing applications:

- If you add code to an application, you own it whether or not it modifies the code in the baseline installation on a ServiceNow instance.
- The platform marks all customizations and skips them when you update to a new version of the platform. That means you are responsible for manually updating the customizations. This can have a significant impact on the time and resources required to update to new platform versions.
- The ServiceNow AI Platform uses a framework that supports applications in how they process tasks, how forms are rendered in multiple browsers, and the overall user experience. Introducing customizations can have unintended consequences on this framework.
- You own the burden of testing custom code and determining if it impacts platform functionality.
- ServiceNow Customer Support cannot troubleshoot custom code or issues caused by custom code.

Customization is one of the key features of the ServiceNow AI Platform. However, over-customizing an application to repurpose it is likely to generate technical debt, lengthen your upgrade cycle, and complicate future platform upgrades because the custom code may not easily migrate to new platform versions.

Conclusion

Customization and configuration are hallmarks of the ServiceNow AI Platform that enable your company to customize workflows to fit its specific needs. Proceed with these tasks in the following order:

1. Configure ServiceNow applications as much as you can before customizing them.
2. Customize an application only when it extends the intent of the application.
3. Use App Engine developer products, such as App Engine Studio, Creator Studio, and ServiceNow Studio, to create new applications rather than customizing an application to create functionality that doesn't align with its original purpose.

Customization vs. configuration with App Engine Studio

There are important differences between customizing and configuring ServiceNow applications. The ServiceNow platform is built to embrace customization and configuration, but how you do so can have significant impacts on ServiceNow support, upgrading to future ServiceNow platform versions, and the functionality of the ServiceNow platform.

The general rules around customization are:

- Customize an application only if it extends the original intent of the application. For example, add IT functionality to ITSM but don't add a travel workflow. Instead of over-customizing an application, create a new application using App Engine products, such as App Engine Studio, Creator Studio, or ServiceNow Studio.
- Configure as much as you can before customizing an application.
- If you add code or make other modifications to out-of-the-box functionality, you own them.

What is configuration

Configuration is the process of using ServiceNow built-in tools and features to modify an application's behavior without making changes to flows or the code that is part of the baseline installation on a ServiceNow instance.

Configuration can take the form of using ServiceNow built-in tools to add tables and more, setting instance-wide parameters, as well as using code to extend an application's functionality to meet business needs as long as the code does not modify the baseline code installation. The entire platform is designed for you to add configuration code.

If you add code, such as workflow scripts, you own it, even if it doesn't alter the baseline code installation. That includes owning the impact it has on the entire ServiceNow platform. Issues that arise from added code are beyond the scope of ServiceNow support to debug.

Reverting a configuration should not require any change to the baseline code.

Configuration examples include:

- Forms: Configure tables, fields, data types, default values, and field dependencies to configure the data you capture and display.
- UI elements: Modify layouts, add related lists, add buttons, and change field names.
- Service Catalog: Configure portals where your customers can request catalog items such as service and product offerings.
- ACLs: Restrict unauthorized users from accessing forms and data.
- System property values: Modify the application's experience for all users.

What is customization

Customization is any change made to the flows or the code that is part of the baseline installation on a ServiceNow instance. You use ServiceNow products or code to customize applications.

If you add code, you own it, even if it doesn't alter the baseline installation. That includes owning the impact it has on the entire ServiceNow platform.

Customization examples include:

- Scripting: Customize ServiceNow through scripting using JavaScript. This includes creating client scripts, server-side scripts, and business rules with intricate logic that modify the baseline code.
- Custom tables: Develop custom tables to accommodate specialized data that doesn't fit within standard tables.
- Integration: Customize integration with external systems, such as APIs and web services, for seamless data exchange.

- Widgets and portals: Create custom widgets and portals to provide unique features and user experiences.
- Workflows: Create and modify workflows using Workflow Studio. Create and manage playbooks, flows, actions, decision tables, and integrations from one design environment to automate tasks. Upgrading to a new version of a flow requires reapplying your customizations.

Tools for customization and configuration

ServiceNow offers many tools and features, such as business rules, to modify the out-of-the-box behavior of ServiceNow applications. Whether they customize or configure an application depends on how they're used. Using these tools to modify the installed code base constitutes customization. Using these tools to add code that does not modify the flows, or the installed code base constitutes configuration. In both cases, you own the code you add as well as the impact it has on the ServiceNow platform.

ServiceNow tools include:

- UI Policies: Dynamically modify the visibility of fields and attributes on a form according to user inputs.
- Business rules: Automatically trigger actions based on specified conditions.
- UI Actions: Extend and customize forms and lists by adding buttons, context menu items, or other UI elements that perform specific actions when clicked.
- Client-side scripts: Scripts that execute within the user's browser when certain actions occur on a form or a UI page.
- Server-side scripts: Scripts that execute on the ServiceNow server or database, for example, to update record fields when a database query runs.

What is personalization

Personalization is when users use out-of-the-box application tools to modify an application's look and feel only for themselves. Admins can change the look and feel for all users and that is considered configuration. Personalization examples include a user choosing to use dark mode or choosing which table columns to display.

Personalization does not change the baseline code installation on a ServiceNow instance. So, personalization does not impact customer support or interfere with upgrades to new ServiceNow versions.

Ramifications of customizing ServiceNow products

The ServiceNow platform is extremely flexible and built to embrace customization and configuration to fulfill a wide range of business requirements. How you customize ServiceNow applications, however, can have significant impacts on ServiceNow support, upgrading to future ServiceNow platform versions, and the functionality of the platform. Instead of customizing ServiceNow applications, consider using App Engine development products, such as Creator Studio and ServiceNow Studio to create new applications.

The ServiceNow platform uses a framework that supports applications in how they process tasks, how forms are rendered in multiple browsers, and the overall user experience. ServiceNow relies on the framework's integrity to develop and provide support in a consistent manner. Customizations can impair this framework, change platform functionality, and impair workflows and upgradeability.

Customizations trigger the platform to create sys_update_xml records, which are stored in the Customer Update table. The platform marks all customizations and skips the customized records

when you update to a new version of the ServiceNow platform. That means you are responsible for manually updating the customizations. This can have a significant impact on the time and resources required to update to new platform versions.

Note:
The Customer Update table also contains modifications or additions to configuration metadata, for example, creating a new catalog item or a new workflow.

For more information, see the Customer Updates table. Note that the complexity of maintaining customizations dramatically increases as the number of customizations increases.

Customizing the installed code base can be costly, generate technical debt, lengthen your upgrade cycle, and complicate future platform upgrades because the custom code may not easily migrate to new platform versions. Custom code can change the standard functionality of the ServiceNow platform in unintended ways. Evaluate demands for customization carefully and only resort to customization where there is clear business value and no alternative. Wherever possible, avoid customization by using configuration instead.

If you customize a product:

- You are responsible for maintaining the customization going forward.
- Customer Service and Support will not support problems caused by custom code. If it is the cause of the problems, the support team will likely advise you to revert to the out-of-the-box code.

What is the Customer Service and Support stance on supporting customization

The ServiceNow Customer Service and Support stance on customization is if you add code, you own it and its consequences. Why? Customer Support is not privy to your custom business logic, doesn't know what the expected behavior should be, is unable to reproduce the issue on an out-of-the-box instance, and customer support engineers are not certified implementation specialists, so they are not certified to review customized code logic.

Alternatives to customization

If you have requirements and ideas for enhancements, instead of customizing the installed code base, you can:

- Use configuration instead of customization.
- Submit an Enhancement Request to the ServiceNow development team. Each request is evaluated and, if approved, will be incorporated into a future release.
- Create an app using App Engine developer products to handle desired functionality.

When to use App Engine developer products instead of customizing

When your company needs to add new functionality to the ServiceNow platform, you can customize existing applications, such as ITSM, or create a new application using App Engine developer products, such as Creator Studio or ServiceNow Studio. A simple guideline for which path to choose is:

- If the customization extends the intended purpose of the application, it works better to customize. For example, you can add IT functionality to ITSM.
- If the customization doesn't extend the intended purpose of the application, it works better to create a new application using App Engine developer products. For example, do not repurpose the ITSM workflow to create a travel request workflow.

For example, ITSM is designed to handle IT issues. To customize it to handle travel requests goes beyond the original intention of ITSM. Because IT and travel requests have different workflows, it's better to create a travel request app using App Engine developer tools, such as Creator Studio and ServiceNow Studio, instead of customizing ITSM.

For more information, see Build apps using App Engine Studio.

Examples of when to use App Engine developer products

ServiceNow products work best when they're used as they were intended. If you find yourself heavily customizing an application to repurpose it, a better plan is to create a new application using App Engine developer products.

The following scenarios demonstrate where creating a new application works better than heavily customizing an existing ServiceNow application:

- You have a novel use case for an app that doesn't align with any product workflow.
- You have a use case that could be built by heavily customizing an out-of-the-box application, but it doesn't align with what the existing application was intended to do.
- Your company has a user group or business process that should be separate from the OOTB product workflow.

Guidelines for customizing ServiceNow products

If you must make a customization, consider the following suggestions:

- Maximize configuration options first.
- Avoid copying objects. Instead, update objects in place wherever possible, except for Service Portal widgets and other items designated to be reused.
- Default to "add before edit." This means that you should, for example, add fields to forms rather than change the type of an existing field. Avoid using the same names as out-of-the-box objects, methods, or classes when adding them.
- Minimize the number of fields you add to a form. The more fields you have on a form, the longer it may take to load.
- Export original records as backups before customizing them. Keep track of their out-of-the-box sys_id's in case you must restore them in the future.
- Use scoped applications as your default for any new custom development.
- Document all customizations. Add comments explaining why you customized (including business justification). Review all comments before upgrading to determine if you can revert to out-of-the-box code.
- Create tests for all customizations. Write Automated Test Framework (ATF) tests for all customizations where possible.
- Use HealthScan regularly to identify unnecessary customizations.
- Customizations should be made to baseline objects where necessary so that conflict resolution and decision-making can be appropriately recorded in the updates. Hidden customizations may cause administrators to overlook updates in future assessments in case reverts or merges are necessary.
- Test your customization for all use cases. Include performance testing and the introduction of unintended consequences.
- Administrators are responsible for verifying that their customizations work after a ServiceNow platform upgrade, and for keeping track of what customizations are made.

Handling customizations when you upgrade

Customizations trigger the platform to create sys_update_xml records, which are stored in the Customer Updates table. These records are not updated during platform version upgrades. ServiceNow marks them as skipped records in the ServiceNow Upgrade Monitor. To make sure they're successfully ported to the upgraded instance, you must manually process the skipped changes. For more information, see the Customer Updates table.

Assuming you've documented all your customizations—including the business justification—take your documented inventory and compare it with the skipped records identified in the Upgrade Monitor. After filtering out low-risk changes that have resulted in skipped records (for example, field labels or form layouts), you'll need to decide whether to:

- Retain each customization
- Revert to out-of-the-box
- Merge your customization with the base system to resolve conflicts

Integrated development tools for AES

App Engine Studio (AES) provides instant access to several tools available in the ServiceNow AI Platform development suite.

As you create apps using App Engine Studio, you can extend their capabilities with these powerful development tools.

App Engine Studio development tools and features

Tool	Description	Reference
Access Control	Work with access control and roles for the application.	See Add application security.
Catalog Builder	Add record producer catalog items in a guided tool for building a Service Catalog.	See Add a standard catalog item.
Decision tables in Workflow Studio	Add decision rules to decouple decision logic from code using decision tables.	See Add a decision.
Email notifications	Create and edit email notifications that are automatically sent when a record is created or updated. Email notifications are also used as a reference in flows or can be triggered by an event.	See Add an email notification.
ERP Data Hub	Build an ERP (Enterprise Resource Planning) data model and extract data from your ERP system.	See ERP Data Hub.

App Engine Studio development tools and features (continued)

Tool	Description	Reference
ERP Customization Mining (ERP-CM)	Identify all of the customizations in your ERP system.	See ERP Customization Mining (ERP-CM).
Flows in Workflow Studio	Add flows to automate application processes.	See Add a flow from scratch.
Integration Hub - Import	Import and map data into existing tables.	See Create a data integration.
Mobile App Builder	Add mobile experiences.	See Add a mobile experience.
Process Automation Designer	Edit cross-functional processes and consolidate them into automated task-oriented views.	See Edit a process.
Table Builder	Work with data models in a tabular format. Table Builder is exclusive to App Engine Studio and necessary for creating apps.	See Create a blank table.
UI Builder	Edit workspace and portal experiences using a highly configurable UI development tool.	See Add a workspace and Add a portal.
Workspace Builder	Quickly build custom workspaces to give users a service desk-like experience to manage tickets.	See the following topics: • Building workspaces in AES • Configure a workspace in Workspace Builder • Configure workspace settings in Workspace Builder • Configure a workspace home page in Workspace Builder • Configure a record page for a workspace in Workspace Builder

App Engine Studio Community

App Engine and App Engine Studio

ServiceNow® App Engine Studio (AES) is a development tool for creators of varying skill levels to build applications that meet the immediate needs of your organization. The App Engine Enterprise version includes App Engine Studio (AES) for building low-code apps.

Streamline app development with App Engine

App Engine Starter and Enterprise versions

App Engine Starter is included in all products (that is, it's free). To access additional features outside of App Engine Starter, you need a paid App Engine Enterprise license.

The App Engine Enterprise version enables users to act as a Fulfiller for unlimited custom apps and unlimited custom tables. Customer entitlements may vary depending on the type of App Engine subscription purchased. Contact your account team or your company's ServiceNow admin for entitlement confirmation.

For a full list of App Engine products, see the ServiceNow product site.

Additional information on App Engine

Learn more about App Engine	Additional ServiceNow resources
ServiceNow provides several additional resources on App Engine.	 App Engine Enterprise purchase overview and version comparison

Learning plan for getting started with App Engine Studio

ServiceNow provides citizen developers with several quick training modules for getting started building low-code apps in App Engine Studio (AES).

The ServiceNow Developers site provides numerous resources for developing apps in AES.

Use the following learning modules to quickly explore ways to build apps.

ServiceNow Developers site learning modules

Course	Description
Build My First App Engine Studio Application	Create an application to track a collection using AES. The application will be secure, automated, and provide an engaging user experience.
Create an App and Data Model	Create an application from scratch with AES, including the data model used by the application. The data model is a foundation for learning how to add user experiences, logic and automation, and security to your application in other learning modules.

ServiceNow Developers site learning modules (continued)

Course	Description
Create Record Producer User Experiences	Create record producer catalog items in AES. Users can submit a request or create a task using Service Catalog items in Service Portal.
Create Workspace User Experiences	Create a workspace to report on and manage data in an application created with AES.
Create Mobile User Experiences	Create and test a mobile experience in AES that enable users to access applications from anywhere.
Automate Processes with Flows	Create flows in AES to automate business processes. Flows reduce human error, improve efficiency, and make apps work better.
Secure Apps and Data	Use AES to secure an application by creating roles, assigning the roles to users, and testing user access to application data.

Additional learning resources

Learn more about application development
You can learn about How citizen developers cook up innovation on the ServiceNow blog.
For more information about defining cross-scope access to an application resource and approving or denying requests, see Define cross-scope access to an application resource.

Configuring App Engine Studio and related apps

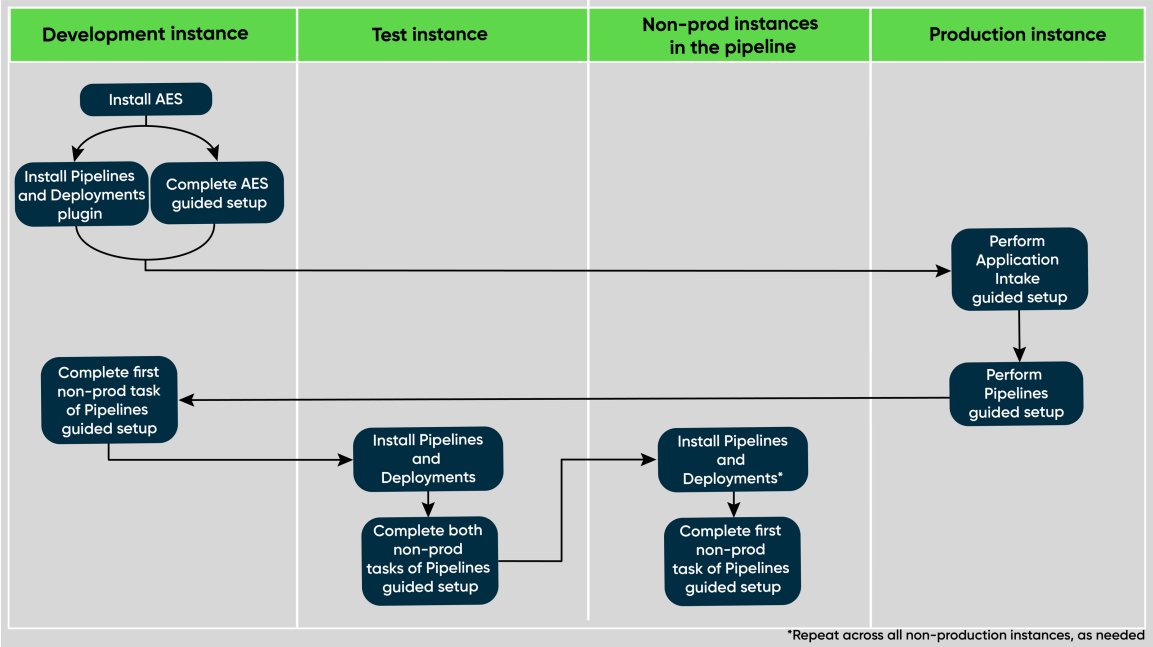
App Engine Studio (AES) guided setup walks you through the implementation process, one step at a time. As you finish each setup procedure, you're prompted to begin the next one.

When you have finished configuring AES, you have the option of configuring other products related to AES:

- App Engine Management Center (AEMC)
- Application Intake
- Pipelines and Deployments

Each of these products has its own guided setup. If you have already configured one or more of the products and you are prompted to configure it again, you can simply ignore that instruction. The following diagram illustrates the preferred method for implementing AES and associated applications:

AES implementation



AES implementation usually follows these steps.

1. On a development instance, install AES and the Pipelines and Deployments plugin. For more information, see Installing App Engine Studio.
2. Complete the AES guided setup. For more information, see Configure App Engine Studio.
3. On your production instance:
   a. Complete the Application Intake guided setup. For more information, see Configure Application Intake.
   b. Complete the Pipelines and Deployments guided setup. For more information, see Configure Pipelines and Deployments.
4. On a development instance, complete the first non-production task of the Pipelines and Deployments guided setup.
5. On your test instance, install Pipelines and Deployments.
6. Complete both non-production tasks of the Pipelines and Deployments guided setup on the test instance.
7. In all the other non-production instances in your pipeline:
   a. Install Pipelines and Deployments.
   b. Complete the first non-prod tasks of the Pipelines and Deployments guided setup.
8. Repeat step 7 across all non-production instances, as needed.
9. Install the AEMC plugin on each instance in your pipeline. For more information, see Configure the App Engine Management Center.

   AEMC allows admins to manage app development from intake through production on your production instance.

Note:
If you plan on cloning your production instance to one or more non-production instances, you should also install the AES product on your production instance prior to cloning. For more information, see System clone and Cloning instances with AES.

AES and domain separation

Domain separation is unsupported for App Engine Studio (AES). Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

Related topics

Domain separation for service providers

Installing App Engine Studio

You can install the App Engine Studio (AES) application (com.snc.app-engine-studio) if you have the admin role. The application installs related ServiceNow® Store applications and plugins if they are not already installed.

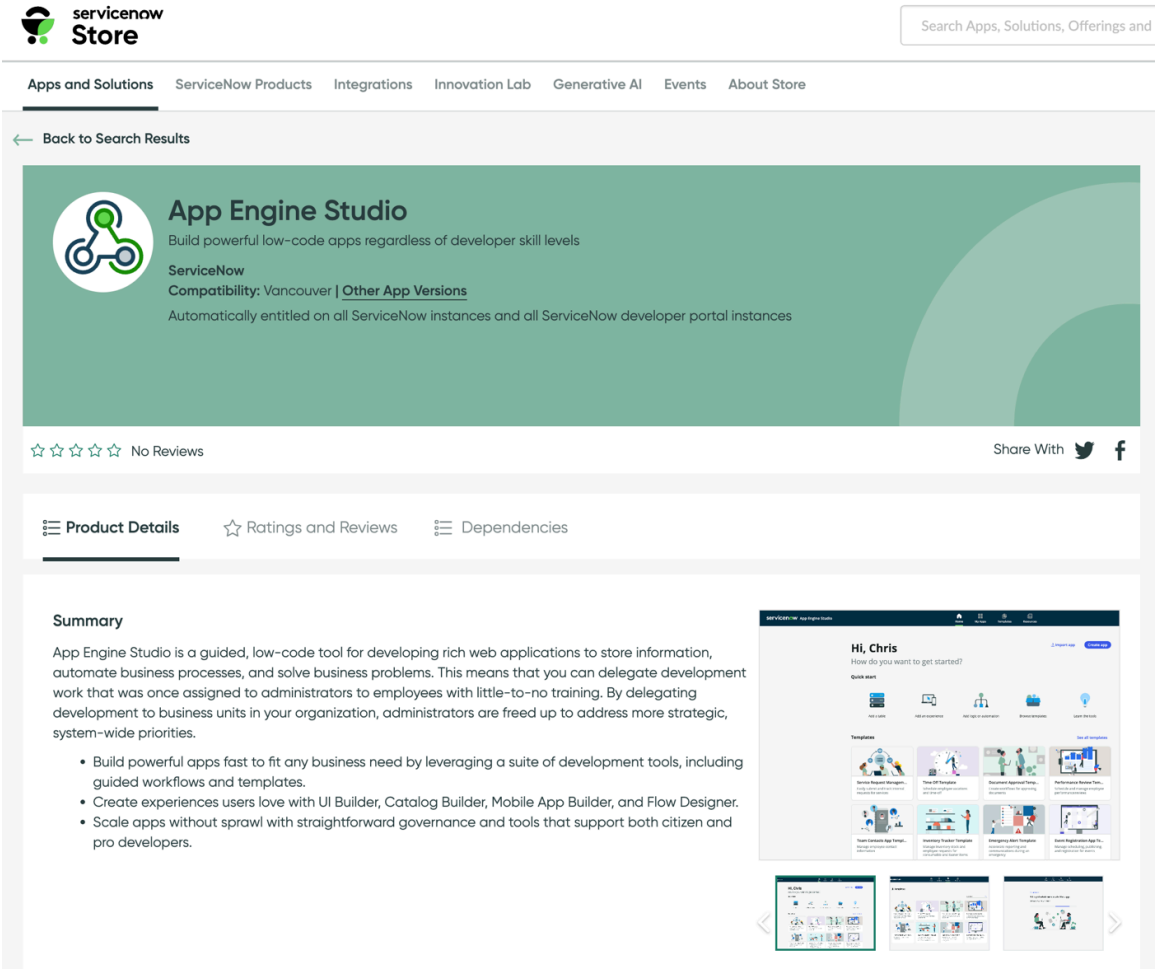
Trial version of AES

To try AES before purchasing a license, you can install it on a personal developer instance (PDI). For more information about PDIs, see Personal developer instance guide. To obtain a PDI, see the ServiceNow Developer Site.

Note:
An App Engine Studio subscription is required to install on a production or non-production instance. For more information, contact your ServiceNow representative.

Using the ServiceNow Store to install AES

The ServiceNow Store enables you to download core products and applications. A product contains one or more applications that are licensed as a group. For example, App Engine Studio is a product that contains numerous tools and applications within it, such as Table Builder and Mobile App Builder. If you install the basic AES application and not the full AES product, you won't get its full suite of features and tools.



Check that the application and all of its associated ServiceNow Store applications have valid ServiceNow entitlements. For more information, see Get entitlement for AES apps.

When you install AES, you also install the following related items:

- Roles and groups
- Tables
- Plugins

For more information, see Components installed with AES.

Installation workflow for AES

The following is an overview of the tasks that you must perform to install AES for the first time:

1. Develop your instance strategy for AES.
2. Get entitlement for AES to ensure you have a license.
3. Install AES (the full product, not the application) from the ServiceNow Store. App Engine Studio is a product that contains numerous tools and applications within it, such as Table Builder and Mobile App Builder. If you install the basic AES application and not the full AES product, you won't get its full suite of features and tools.
4. Install the AES integrations and plugins.

Alternatively, you can update existing AES installations by doing the following:

- Update a previously installed AES version
- Upgrade your AES instance to the next family release

Learn more about AES installation	Additional ServiceNow resources
ServiceNow provides several additional resources on installing and administering App Engine Studio.	App Engine Studio release notes ServiceNow Community site ServiceNow University Introduction to App Engine Studio for Citizen Developers course

AES instance strategy

You should install App Engine Studio (AES) on all ServiceNow instances where users will develop applications.

You will need to establish your company's instance strategy for AES. Some of the decisions you will need to make include:

- Whether you want to allow anyone within your company to have access to AES to start building apps.
- Whether you want to grant access to a select group of people.
- Whether you want to grant access on a case-by-case basis by setting up a form where individuals can complete information about the app that they are looking to build. IT then decides whether to give those individuals access to build that app.

A non-production instance that is similarly configured to your production instance may be the best candidate for your test environment. You can then more accurately find issues that may arise if the application is deployed to production.

Note:
If you plan on cloning your production instance to one or more non-production instances, you should also install the AES product on your production instance prior to cloning. For more information, see System clone and Cloning instances with AES.

After you have established your instance strategy, you must also establish and automate your approval or review process. AES is a product that runs on your non-production environment. For an organization with multiple non-production environments, you will need to decide which non-production environment AES will run on. You must also determine which pipeline to use for promoting apps from a particular non-production instance to your test instance, and then

finally to production where the app will be running live. For more information, see Pipelines and Deployments.

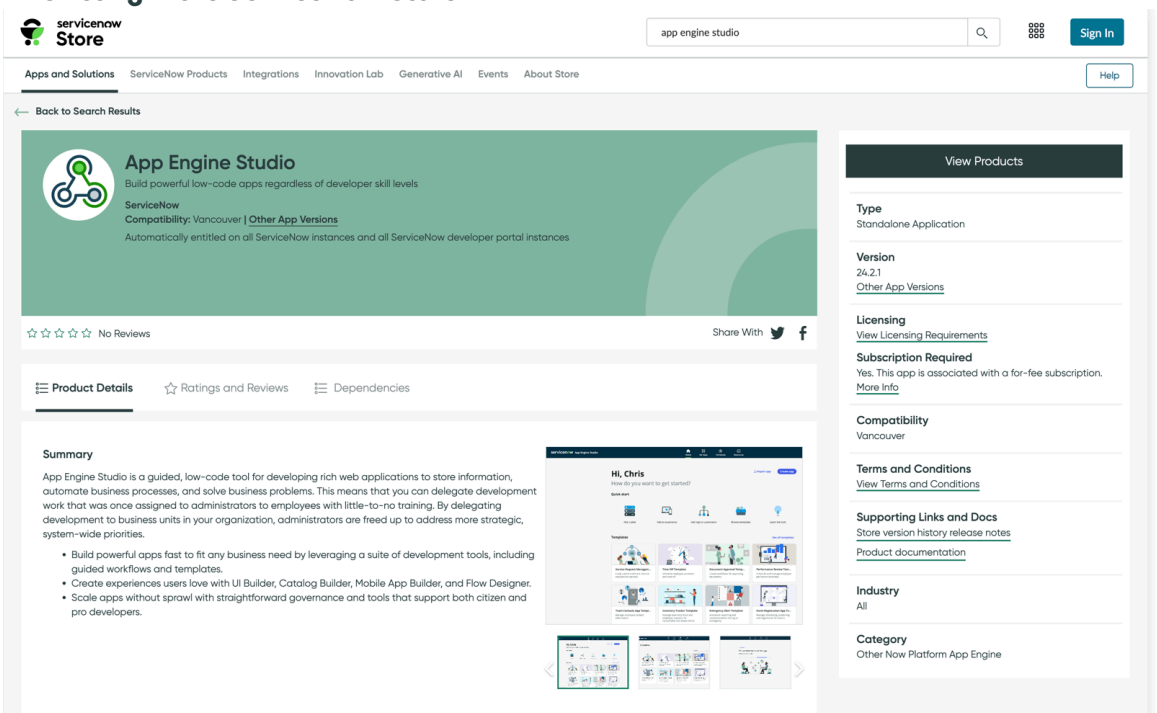
AES and the ServiceNow Store

App Engine Studio (AES) enables you to obtain new and updated features more rapidly. Before you can use AES, you must verify that you have entitlement to it, meaning that you have valid licenses to use it. Then, you can install AES and its plugins from the ServiceNow Store.

Request apps on the Store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

AES listing in the ServiceNow Store



Methods for installing AES

The process you use to obtain AES depends on whether you are installing AES for the first time, updating a version of AES that you previously installed from the ServiceNow Store, or upgrading from one family release to the next one.

Get entitlement for AES apps

Install App Engine Studio (AES) by verifying that the application or the product and its associated applications have valid ServiceNow entitlements. An entitlement means you have a license to install the product.

This video shows you how to perform the following procedure.

Get entitlement for AES apps

Before you begin

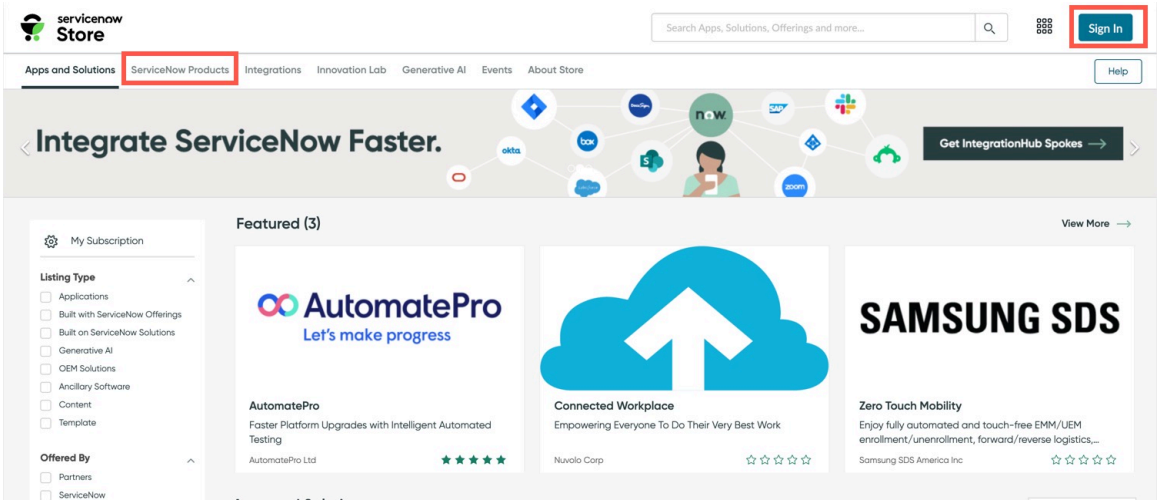
Note:
An App Engine Studio subscription is required to install on a production or non-production instance. For more information, contact your ServiceNow representative.

Individuals performing entitlement must have a Now Support account and have permission to request applications for the instances under consideration.

Role required: admin

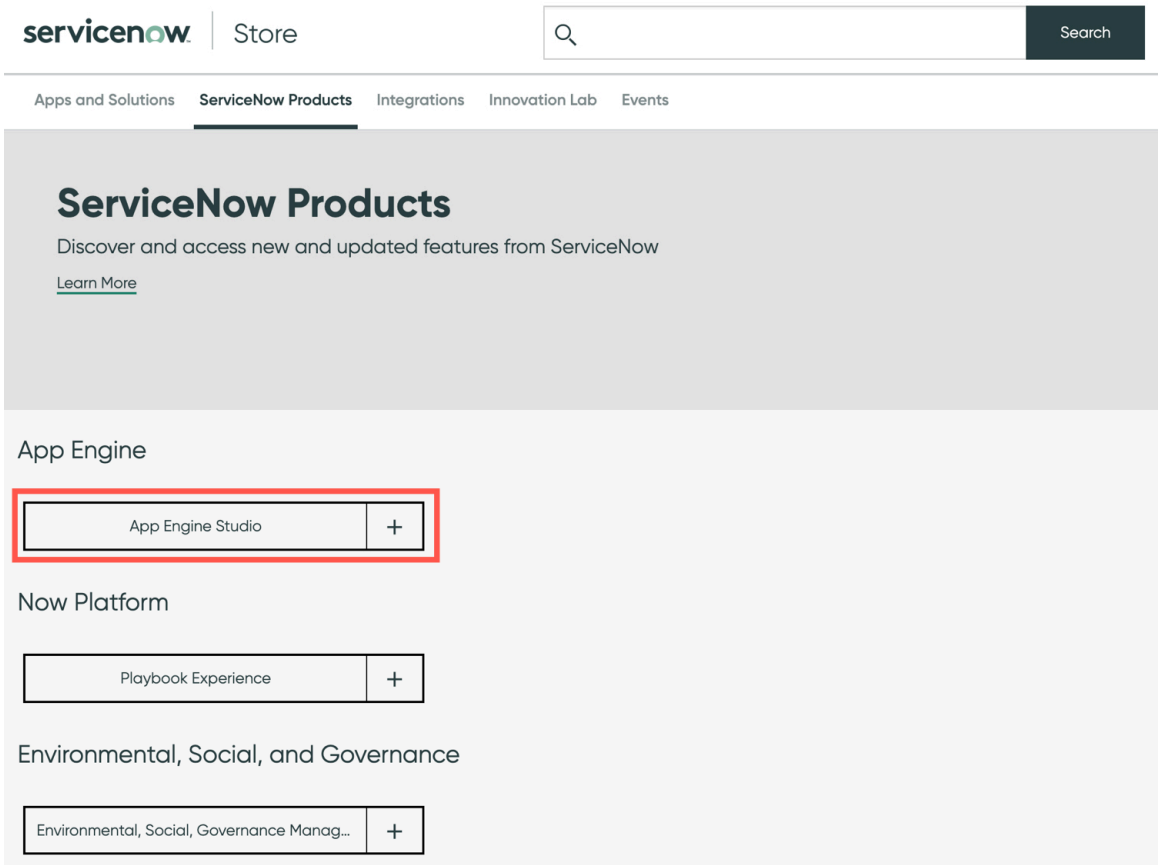
Procedure

1. Navigate to the ServiceNow Store.
2. Select **Sign In** and log in using your Now Support credentials.



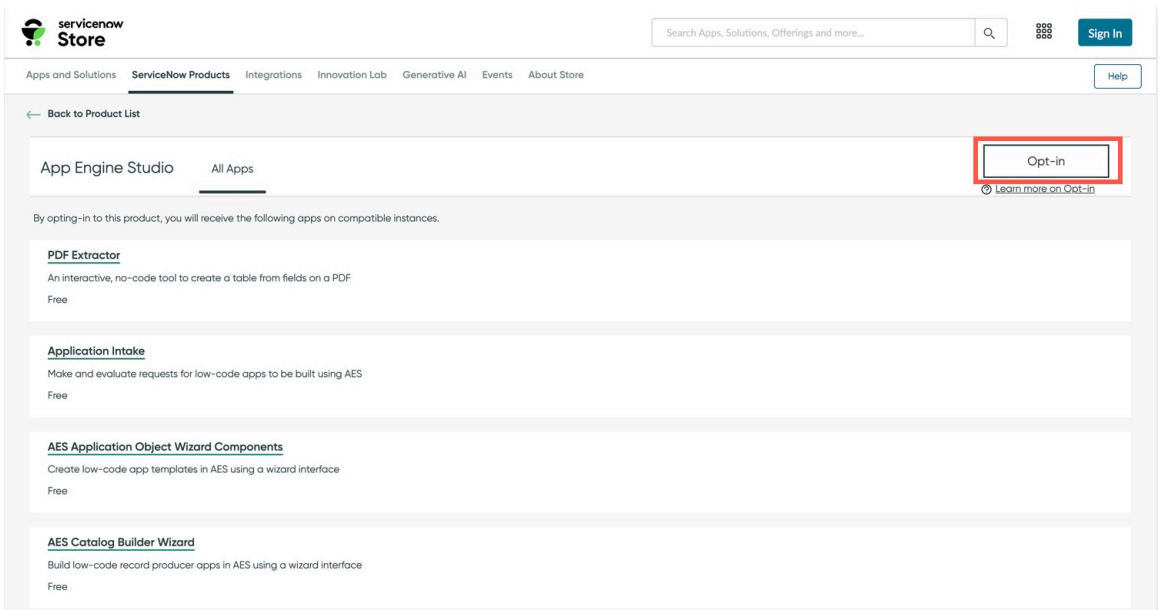
Integrations and other types of content appear on the **Certified Apps** tab.

3. Select the **ServiceNow Products** tab to view all available ServiceNow products.



4. Select **App Engine Studio**.

> **Note:**
> When you have obtained entitlement to the core product, the applications listed under it are also entitled.



The page lists all the applications that are associated with the AES product you're entitling.

5. Verify that you have entitlement to the product and applications by selecting **Opt-in**.

Note:
The **Opt-in** button is not available unless you purchased an AES subscription.

6. When the ServiceNow Store prompts you to read and accept the ServiceNow terms and conditions, select the check box and select **Accept**.

   Opting in to entitlement is a one-time process for each product.

   A check mark appears next to the product name, and the **Manage Entitlement** button appears. The button indicates that you are subscribed to the product and its associated applications.

7. Change the instances affected by the entitled applications by selecting the **Manage Entitlement** button and then specifying one of the following options:
   - **Remove all existing entitlements**
   - **Entitle all instances**
   - **Entitle selected instances**

Result
Install and activate AES. Navigate to **All** > **My Company Applications** and select App Engine Studio.

Install AES from the ServiceNow Store for the first time

Install App Engine Studio (AES) from the ServiceNow Store for the first time. The installation involves several easy steps. Some steps are performed on the ServiceNow Store and some in your ServiceNow AI Platform instance.

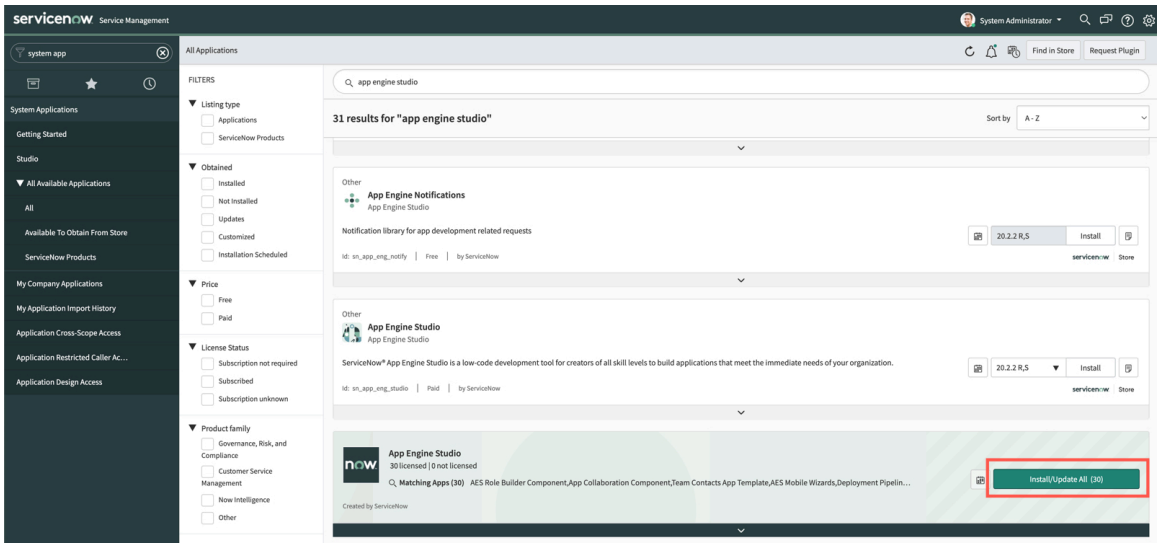
Before you begin
Role required: admin

About this task
The ServiceNow Store enables you to download core products and applications. A product contains one or more applications that are licensed as a group. For example, App Engine Studio is a product that contains numerous tools and applications within it, such as Table Builder and Mobile App Builder. If you install the basic AES application and not the full AES product, you won't get its full suite of features and tools.

For a list of all dependencies and tools installed with the AES product, see the listing in the ServiceNow Store.

Procedure
1. In the ServiceNow Store, ensure that you have entitlements (or licenses) to the product and its dependent applications.
2. Install AES from the ServiceNow Store.
3. Run the installation on your instance, and accept all the plugins.

Result



Install the AES product and integrations

Install the App Engine Studio (AES) product to ensure you get all the dependencies, integrations, and tools, such as templates and builders.

Before you begin

Store installation requires a Now Support account. You must also have permission to request applications for the instances you're supporting.

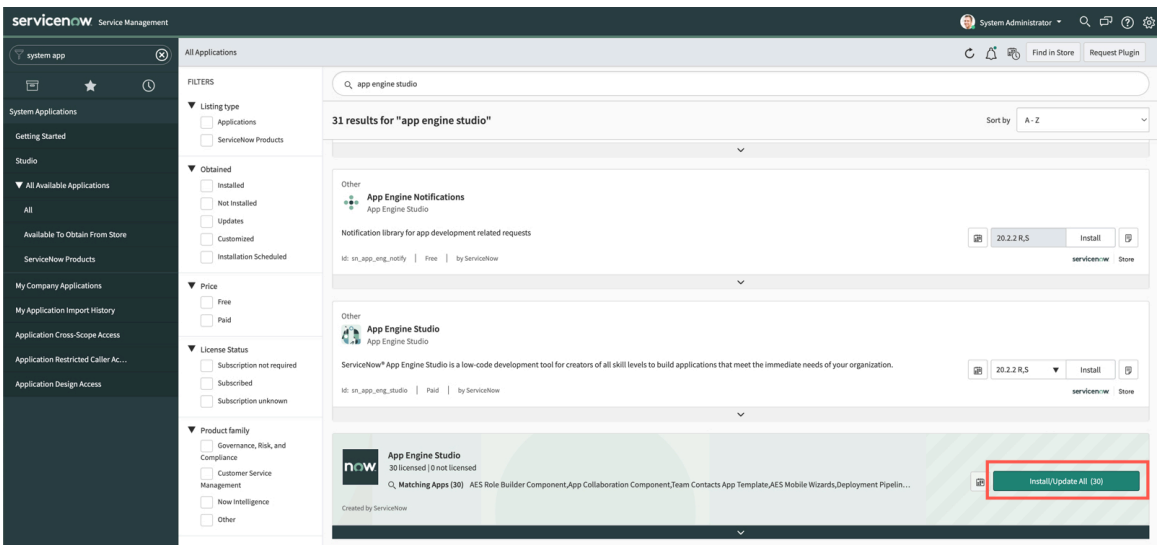
Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Locate the App Engine Studio product (not the application), and select **Install**.

   Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

   Note:
   You must select the AES product, not the application.



3. On the Install dialog box, review the list of applications and dependencies to install.
   Dependent plugins and applications are listed if they will be installed, are currently installed, or need to be installed. If any plugins or applications must be installed, you must install them before you can install App Engine Studio.
4. **Optional:** If demo data is available and you want to install it, select the **Load demo data** check box.
   Demo data comprises the sample records that describe application features for the common use cases. Load the demo data when you first install the application on a development or test instance.
5. Select **Install**.

Result
App Engine Studio is installed on your instance.

Update a previously installed AES version

If you previously installed App Engine Studio (AES) from the ServiceNow Store and if a new version is available, then update the version in your instance.

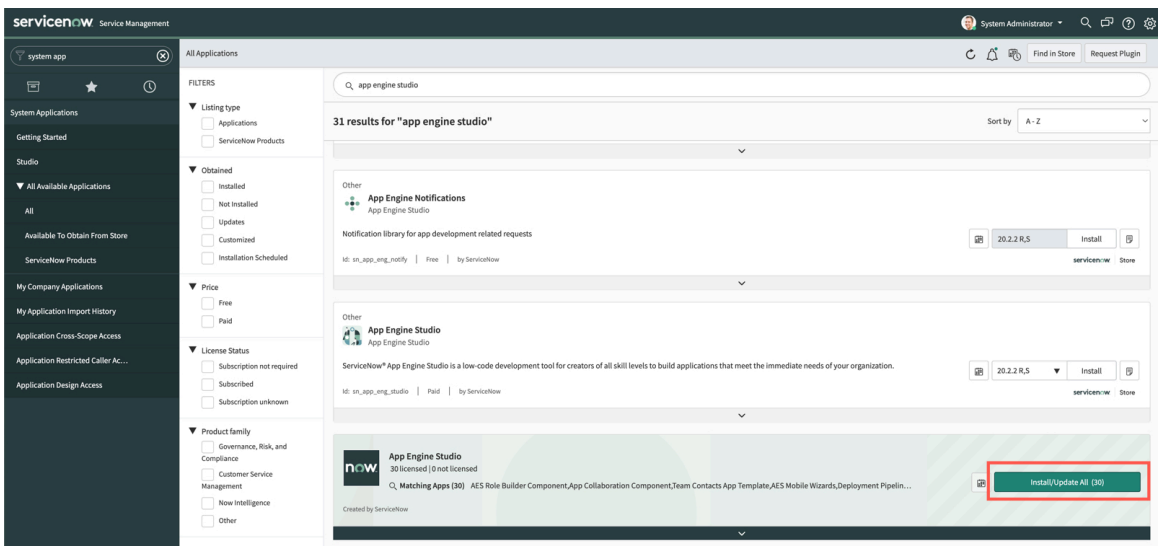
Before you begin

Note:
There should be no changes to the underlying applications or code bases when updating AES.

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Search for `App Engine Studio`.



3. Select the version that you want to update to, and select **Update** or **Install/Update All**.

Result
App Engine Studio automatically updates on the instance.

Upgrade your AES instance to the next family release

If you are currently running a family release (Rome, for example) and want to upgrade App Engine Studio (AES) to the next release, you don't need to acquire the applications from the ServiceNow Store.

The application is automatically updated when the platform is updated to the minimum required version.

Components installed with AES

Several types of components are installed with activation of the App Engine Studio (AES) plugin, including tables and user roles.

Note:
The Application Files table lists the components that are installed with this application. For instructions on how to access this table, see Find components installed with an application.

Roles installed

Role title [name]	Description	Contains roles
App Engine Studio admin [app_engine_admin]	Administers AES, including users, app configuration, and other management tasks. This role is assigned automatically to users in the App Engine Studio Admins group.	• sn_request_read • sn_request_write • sn_app_eng_studio.user
App Engine Studio app template admin [app_template_admin]	Administers the use, sharing, and activation or deactivation of templates. This role is assigned by an admin to individual users. For more information, see Manage template access.	• app-template-author • app-template-runner • flow-designer • flow-operator
App Engine Studio user [sn_app_eng_studio.user]	Builds applications in App Engine Studio. This role is assigned automatically to users in the App Engine Studio Users group. For more information, see Grant user access to AES.	• catalog_builder_editor • app_template_runner • sn_g_app_creator.app_creator

Tables installed

Table	Description
App Details [sn_app_eng_studio_app_details]	Details about the operations that a developer used to create an application in App Engine Studio. This table is updated automatically as developers build applications in App Engine Studio.
Applications in Projects [sn_app_eng_studio_project_application_m2m]	Applications that a developer creates in App Engine Studio. This table is updated automatically as developers build applications in App Engine Studio.
Environment [sn_pipeline_environment]	Instances that you use for the developing, testing, or launching an application. You update this table as you define environments for App Engine Studio.
Deployment Request [sn_deploy_pipeline_deployment_request]	Requests to review and publish an application that a developer created in App Engine Studio. From the deployment request form, a reviewer can deploy the application to different environments, accept or reject an application, and send feedback to a developer. For more information, see Managing app deployments using Pipelines and Deployments.
Pipeline [sn_pipeline_pipeline]	Configurations for deploying applications to different environments. There can be only one active pipeline at a time. You update this table as you create a pipeline for the deployment of applications from App Engine Studio. For more information, see Managing app deployments using Pipelines and Deployments.
Project [sn_app_eng_studio_project]	Details about App Engine Studio development sessions. A project is created automatically when a developer creates an application in App Engine Studio. This table is updated automatically as developers build applications in App Engine Studio.
Resources Content [sn_app_eng_studio_resources_content]	Help resources that a developer can access in App Engine Studio. This table includes configurations to support the default user experience for App Engine Studio.

Table	Description
Resources Content Topic [sn_app_eng_studio_resources_content_topic]	Categorizations of help resources in App Engine Studio. This table includes configurations to support the default user experience for App Engine Studio.
Taxonomy [sn_app_eng_studio_taxonomy]	Application files that a developer creates in App Engine Studio. This table is updated automatically as developers build applications in App Engine Studio.
Taxonomy Category [sn_app_eng_studio_taxonomy_category]	Categorizations for application files in App Engine Studio. By default, application files are categorized as data, experience, logic and automation, or security. This table includes configurations to support the default user experience for App Engine Studio.
Taxonomy Details [sn_app_eng_studio_taxonomy_details]	Details about application files that a developer creates in App Engine Studio. This table includes configurations to support the default user experience for App Engine Studio.

Note:
The following data preservers are added for tables related to pipelines:

- Environment
- Pipeline
- Pipeline Environment Order
- Pipeline Types

The data preservers prevent records in these tables from being overwritten during cloning on a non-production instance. For more information, see Data preservation on cloning target instances.

Configure App Engine Studio

App Engine Studio (AES) guided setup provides a sequence of tasks that help you configure AES on your ServiceNow instance.

App Engine Studio must be installed on the instances where you expect to be developing your applications. In earlier versions, you were required to install AES on all instances in your pipeline.

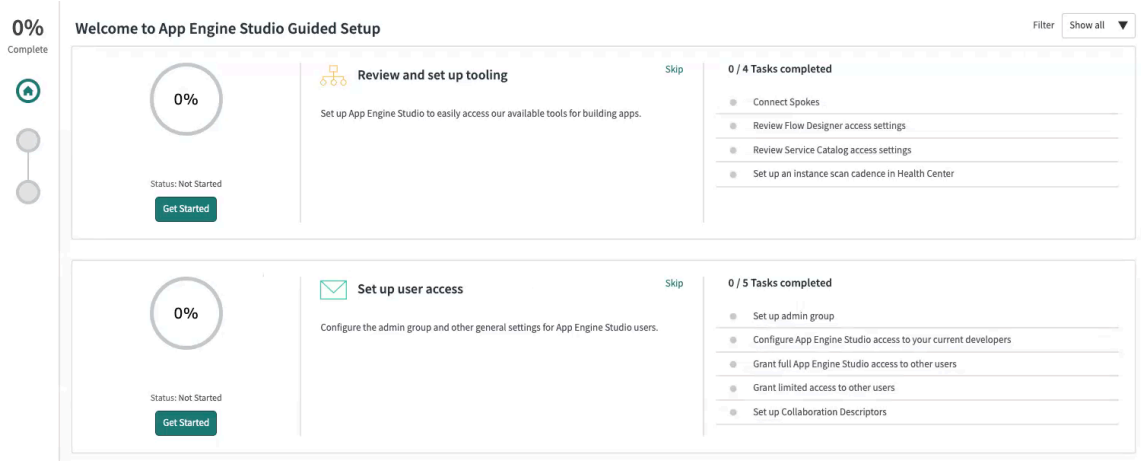
If you plan on cloning your production instance to one or more non-production instances, you should also install the AES product on your production instance prior to cloning. For more information, see System clone.

Learn more about AES configuration	Additional ServiceNow resources
ServiceNow provides several additional resources on configuring and administering App Engine Studio.	App Engine Studio release notes ServiceNow Community site App Engine Studio video on adding security

Guided setup to configure AES

To open App Engine Studio guided setup, navigate to **All** > **App Engine** > **App Engine Studio** > **Configuration** > **Guided Setup**.

The landing page provides information on the different tools and user access. Select the **Get Started** button in the top, right corner to start your configuration.



The App Engine Studio Guided Setup page provides a list of different categories. Select the **Get Started** button under each category to start configuring App Engine Studio.

Note:
If you have previously started any of the guided setup tasks, and then exited without completing them, the **Get Started** button is labeled **Continue**.

For detailed instructions on any of the tasks initiated from guided setup, see the Perform AES configuration tasks.

Configure AES personas and roles

The responsibilities of your staff are controlled by roles assigned to each member. Personas aren't explicitly part of App Engine Studio (AES) but administrators assign roles to give team members permission to configure or use AES.

Low-code/citizen developer

Low-code/citizen developers are tech savvy and interested in creating apps. Though they might not have formal coding or app development training, citizen developers can submit ideas for new apps and, if approved, build them using AES.

App Engine Studio admin

App Engine Studio admins manage all processes related to app development in AES. They review new app ideas, manage app development and deployment, and manage collaborators, usually in the App Engine Management Center.

App template admin

The app template admin makes sure that the right people have access to appropriate predefined and custom templates for app development in App Engine Studio.

App template author

The app template author creates and edits custom app templates in App Engine Studio and can share them with other users or groups.

Security admin

The security admin creates and modifies roles and access control lists for apps. This role is set on the platform level, and it is required for making updates to roles in App Engine Studio.

System administrator

The system administrator has access to all system features, functions, and data, regardless of security constraints. Grant this privilege carefully. If you have sensitive information, such as HR records, that you must protect, create a custom admin role for that area and train a person who is authorized to see those records to act as the administrator.

Professional ServiceNow developer

Professional ServiceNow developers can work in App Engine Studio, usually as collaborators with citizen developers. Because of their coding knowledge and development background, though, they're more likely to build and customize apps on the ServiceNow AI Platform, using more complex building tools.

Personas for AES

Persona	Roles required	Responsibilities
Low-code/citizen developer	App Engine Studio Users group (sn_app_eng_studio.user)	• Submit requests for new custom applications to build in App Engine Studio. • Understand ServiceNow and application development best practices. • Build and test applications in App Engine Studio.

Personas for AES (continued)

Persona	Roles required	Responsibilities
		• Submit App Engine Studio applications for IT review. • Maintain and change the application during its life cycle if determined during the intake process.
	App Engine Studio User Limited group (sn_app_eng_studio.user)	• Collaborate with other users on applications they've been given permission to see. • Submit App Engine Studio applications for IT review. • Understand ServiceNow and application development best practices. **Note:** Users in the App Engine Studio User Limited group can't create new apps.
App Engine Studio admin group	• atf_test_designer • scan_admin • app_engine_admin	• Manage App Engine Studio processes and properties. • Review and approve/reject submitted application requests based on intake guardrails defined by the system administrator. • Provision App Engine Studio user access. • Review submitted App Engine Studio applications. • Manage deployment requests. • Manage promotion of App Engine Studio applications across instances. • Execute ATF tests/suites in testing instances. • Ensure instance scans run with proper definitions.

Personas for AES (continued)

Persona	Roles required	Responsibilities
		• Collaborate with the system administrator to resolve application conflicts that arise on the platform.
App template admin	app_template_admin	• Control access to custom and predefined templates. • Activate and deactivate templates. • Share templates globally or with users and groups.
App template author	app_template_author	• Create and edit custom templates in App Engine Studio. • Share custom templates with users or groups.
Security admin	security_admin	• Create and modify roles and access control lists. • Required for making updates to roles in App Engine Studio.
System administrator	Admin	• Install and configure App Engine Studio and its dependent apps. • Define environments. • Configure pipelines. • Provision access to the App Engine Studio administrator group. • Upgrade the App Engine Studio application, when applicable. • Define guardrails for which AES administrators can approve or reject application intake requests. • Collaborate with professional ServiceNow developers to create

Personas for AES (continued)

Persona	Roles required	Responsibilities
		instance scan definitions for the platform. • Collaborate with AES administrators to resolve application conflicts that arise on the platform.
Professional ServiceNow developer	• atf_test_admin • delegated_developer • scan_admin • sn_app_eng_studio.user	• Build and test applications in ServiceNow Studio and App Engine Studio • Collaborate with citizen developers on an as-needed basis to deliver applications in App Engine Studio, including the following tasks: ○ Ensuring application development and organizational best practices are followed by citizen developers. ○ Helping with review and testing of submitted App Engine Studio applications. ○ Building complex configurations involving UI Builder, Mobile App Builder, Workflow Studio, or other builder tools. • Create ATF tests/suites for applications. • Collaborate with a system administrator to create instance scan definitions for the platform.

Perform AES configuration tasks

As you work through the App Engine Studio (AES) guided setup, you must perform different configuration tasks.

Setting up environments, tools, and user access

The tasks for configuring App Engine Studio are listed below, along with links to detailed instructions for completing them.

App Engine Studio configuration tasks

Task	Description
Install App Engine Studio in your development instances.	You can install the App Engine Studio application (com.snc.app-engine-studio) if you have the admin role. The application installs related ServiceNow® Store applications and plugins if they are not already installed. For detailed instructions, see Installing App Engine Studio.
Set up instance credentials.	For each instance that you're using, create a Connections and Credentials alias. Ensure that the alias type is **Credential**, not **Connection and Credential**. For detailed instructions, see Set up instance credentials.
Activate Playbooks.	You can edit processes in App Engine Studio, but you must activate Playbooks for App Engine Studio and enable the **Process Automation Designer for App Engine [com.glide.pad.license]** plugin to get started. For more information, see Activate playbooks.
Set up IntegrationHub spokes.	Activate spokes to enhance your Workflow Studio and App Engine Studio experience with integration-specific content. The following spokes are available for use with App Engine Studio. • Gmail spoke • Google Sheets spoke • Jira spoke • Microsoft 365 Excel spoke • Microsoft Teams spoke • Slack spoke • Twilio spoke • X Spoke (formerly Twitter Spoke) • Zoom spoke
Review access settings for Flow Designer in your development instance.	Enable your developers to use the editing capabilities that best suit them. For detailed instructions, see Review Flow Designer access settings.
Review access settings for Catalog Builder.	Enable your developers to add items to the appropriate catalogs and categories. For detailed instructions, see Review Catalog Builder access settings.

App Engine Studio configuration tasks (continued)

Task	Description
Set up an instance scan cadence in Health Center.	Schedule regular scans of your instance so that you can identify possible issues that arise from application development in App Engine Studio. For detailed instructions, see Set up an instance scan cadence in Health Center.
In your production instance, add users to the App Engine Studio Admin group.	Add members to the group so they can review app- and deployment-related requests. Also, define a contact email address for the group. For detailed instructions, see Add users to the App Engine Admin group.
In your development instance, add developers to the App Engine Studio Users group.	Enable developers in your organization to build applications in App Engine Studio. For detailed instructions, see Grant user access to AES.
In your development instance, add users to the App Engine Studio User Limited group.	Enable developers in your organization to collaborate on applications that someone else created in App Engine Studio. For detailed instructions, see Grant user access to AES.
Set up collaboration descriptors.	Set up custom collaboration descriptors in the global scope for use in App Engine Studio. For detailed instructions, see Set up custom collaboration descriptors.
In your non-production instance, specify an app template admin.	Grant the app_template_admin role to users who will manage template activation, deactivation, and sharing in App Engine Studio. For detailed instructions, see Manage template access.

Learn more about AES configuration	Additional ServiceNow resources
ServiceNow provides several additional resources on configuring and administering App Engine Studio.	 App Engine Studio release notes

Learn more about AES configuration	Additional ServiceNow resources
	 ServiceNow Community site
	 App Engine Studio video on adding security

Add users to the App Engine Admin group

Add users to the App Engine Admin group in your production instance to give them administrative rights to App Engine Studio (AES). You must also identify a contact email address for the group. After you configure the email address of the App Engine Admin group, members can receive notifications for app development-related requests, including app intake requests.

Before you begin
Role required: admin

About this task
If you are not using pipelines, you must also add users to the App Engine Admin group in your development instance.

Procedure
1. Navigate to **All** > **User Administration** > **Groups**.
2. Open the App Engine Admins group.
3. Select the **Group Members** related list and select **Edit**.
4. Select one or more names in the **Collection** list.
5. Enter a contact email address for the group.
6. Select **Add**.
7. Select **Save**.

Grant user access to AES

Control who has access to build applications in App Engine Studio (AES) by adding users to AES Users group or the AES User Limited group.

Before you begin
Role required: user_admin or admin

About this task
Grant access to build applications in AES by adding users to the App Engine Studio Users group in your organization's development instance. Each group member is automatically assigned the sn_app_eng_studio.user role.

To restrict access so that users can work in App Engine Studio but not create apps or see templates, add users to the App Engine Studio User Limited group.

For more information about the differences between the App Engine Studio Users group and the App Engine Studio User Limited group, see Configure AES personas and roles.

Procedure

1. Navigate to **All** > **User Administration** > **Groups**.
2. Add users by selecting either the **App Engine Studio Users** group or the **App Engine Studio User Limited** group.
   a. In the Group Members related list, select **Edit**.
   b. On the Edit Members page, move each developer from **Collection** to **Group Members List**.
   c. Select **Save**.
   d. On the group record, select **Update**.

Related topics

Components installed with AES

Manage template access

Control who has access to templates in App Engine Studio (AES) using the app_template_admin role. App template admins activate and deactivate templates and grant other users access to share their templates.

Before you begin
Role required: admin

About this task
An administrator grants the app_template_admin role to users who will manage template activation, deactivation, and sharing. This role should be granted on non-production instances where App Engine Studio users author and use templates.

To create apps and work with templates in AES, users must be an admin or in the App Engine Studio Users group. If they are in the AES User Limited group, they can only edit existing apps, not create new ones.

Procedure

1. Navigate to **All** > **User Administration** > **Users**.
2. Select the user you want to give the app_template_admin role to.
3. On the Roles related list, select **Edit**.
4. Move **app_template_admin** from the **Collection** list to the **Roles list**.
5. Select **Save**.

Set up custom collaboration descriptors

Customize the set of development collaborators you list in App Engine Studio (AES) using Guided Setup.

Before you begin
Role required: admin

About this task
Owner and Editor collaboration descriptors are provided out of the box in AES and have special capabilities. Development permissions included in each descriptor can be configured to your

platform needs. You can create custom descriptors as well, in the global scope, so they can be used in AES.

Note:
You should create collaboration descriptors in addition to Owner and Editor in the global scope. If you want collaboration descriptors to appear and be used in AES, you should also set them to `standard = TRUE`. AES doesn't support collaboration descriptors that are created in custom scopes, and non-standard collaboration descriptors don't render in AES.

Admins or delegated developers who invite collaborators can use these descriptors to delegate different types of work.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio** > **Guided Setup**.
2. Select **Get Started**.

   Note:
   If you have previously started any of the guided setup tasks, and then exited without completing them, the **Get Started** button is labeled **Continue**.

3. In the Set up user access section, select **Set up Collaboration Descriptors**.
4. In the Set up Collaboration Descriptors section, select **Configure**
5. Select **New**.
6. Give the new app collaboration descriptor a name and description.
7. Select **Submit**.

What to do next

Further customize collaborator permissions in App Engine Studio. For more information, see Change collaborator permissions.

Delegate developers using AES

Delegated development enables designated users without a system admin role to develop or deploy applications on the ServiceNow AI Platform. This enables administrators and delegated developers to work together to deliver custom applications through App Engine Studio (AES).

After an administrator reviews a request, they delegate the development work by providing a link to the developer that opens App Engine Studio in your organization's development environment. The administrator can:

- Send the link directly to a developer via email
- Post the link on a portal page
- Create a catalog item for delegated developers to request App Engine Studio access

Delegated developer role in AES

The delegated developer role enables an admin to elevate user permissions to a dedicated role with specific access for App Engine Studio.

A delegated developer has more permissions than a user, but less than an admin. The delegated developers each have their own permissions.

An admin may have several delegated developers, each with their own set of permissions. For example, you may want a designated developer for developing a time-off request, and another developer with separate permissions for creating support tickets.

Some AES features may be inaccessible to the delegated developer, depending on permissions. Your role enables you to access, edit, and add objects. If a feature of App Engine Studio is unavailable to you, contact your system administrator.

For more information about delegated development and permissions, see Delegated development and deployment.

Restricted ability to create apps

In addition to delegated development, admins can define whether AES users can create apps or only work on existing apps.

- Grant access to build applications in AES by adding users to the App Engine Studio Users group in your organization's development instance. Each group member is automatically assigned the sn_app_eng_studio.user role.
- To restrict access so that users can work in App Engine Studio but not create apps or see templates, add users to the App Engine Studio User Limited group.

AES integration with a Git source control repository

Enable application developers to integrate App Engine Studio (AES) with a Git source control repository to save and manage multiple versions of an application from a non-production instance.

Linking an application to source control enables all application developers on a non-production instance to:

- Import applications from a Git repository.
- Pull and apply remote changes from a Git repository.
- Commit all local changes on the instance to a Git repository.
- Create tags to permanently link to a given version of an application.
- Create branches to maintain multiple versions of an application simultaneously.

Integration requirements

To link an application to source control:

- The user must have the admin role.
- The non-production instance must have network access to the Git repository.
- Each application must be within its own Git repository.
- The repository user credentials must grant read and write access.

Note:
All application developers on the instance share a single set of credentials per repository.

Options available from App Engine Studio

After linking an application to source control, application developers can use App Engine Studio to manage the repository. From App Engine Studio, developers can:

- Edit the application repository credentials.
- Commit all local changes on the instance.
- Apply remote changes from the repository.
- Create a branch.
- Switch branches.
- Import an application from a remote repository.

Source control integration does not support managing applications on a production instance. Instead, you can manage applications on a production instance using the application repository, an update set, or App Engine Studio. For more information about managing applications on a production instance, see Application sharing.

Options available from a Git repository

The ServiceNow platform offers limited support for modifying linked application files outside of an instance. From Git, developers can:

- Move application files to a different Git directory structure.
- Edit application files outside of App Engine Studio.

The system generates a properties text file called `sn_source_control.properties` at the root level of the repository. To move application files to a different Git directory structure, application developers can set the *`path`* parameter to specify the subfolder path containing their application files. For example, if you moved your application to the `src/app` subfolder, set the *`path`* to `path=src/app`.

The system generates a `checksum.txt` file in the Git repository to determine if any application files have been changed outside of App Engine Studio. When the checksum value from the file matches the current checksum value, the integration skips the validation and sanitization process. When the checksum values do not match, the integration validates and sanitizes the application files as part of the source control operation. The sanitization process:

- Creates upgrade log entries for each sanitization action taken.
- Removes unsupported folders and files from the repository.
- Aborts all source control operations when a system application file fails XML schema validation. For example, if a database dictionary record fails XML schema validation, the system aborts all operations.
- Skips the current source control operation when a non-system application file fails XML schema validation.

The Git integration sanitizes only content within the application path listed in the `sn_source_control.properties` file. Repository content outside the application path is ignored.

MID Server support

Use an existing MID Server to connect to a source control repository. Connecting an application through a MID Server enables access to repositories behind a firewall.

Source control role permissions

For more information on roles and collaborators, see Application collaboration.

Link an application or application-customization to source control

Linking an application or application-customization to source control allows application developers to manage changes in App Engine Studio (AES) from a Git repository.

Before you begin

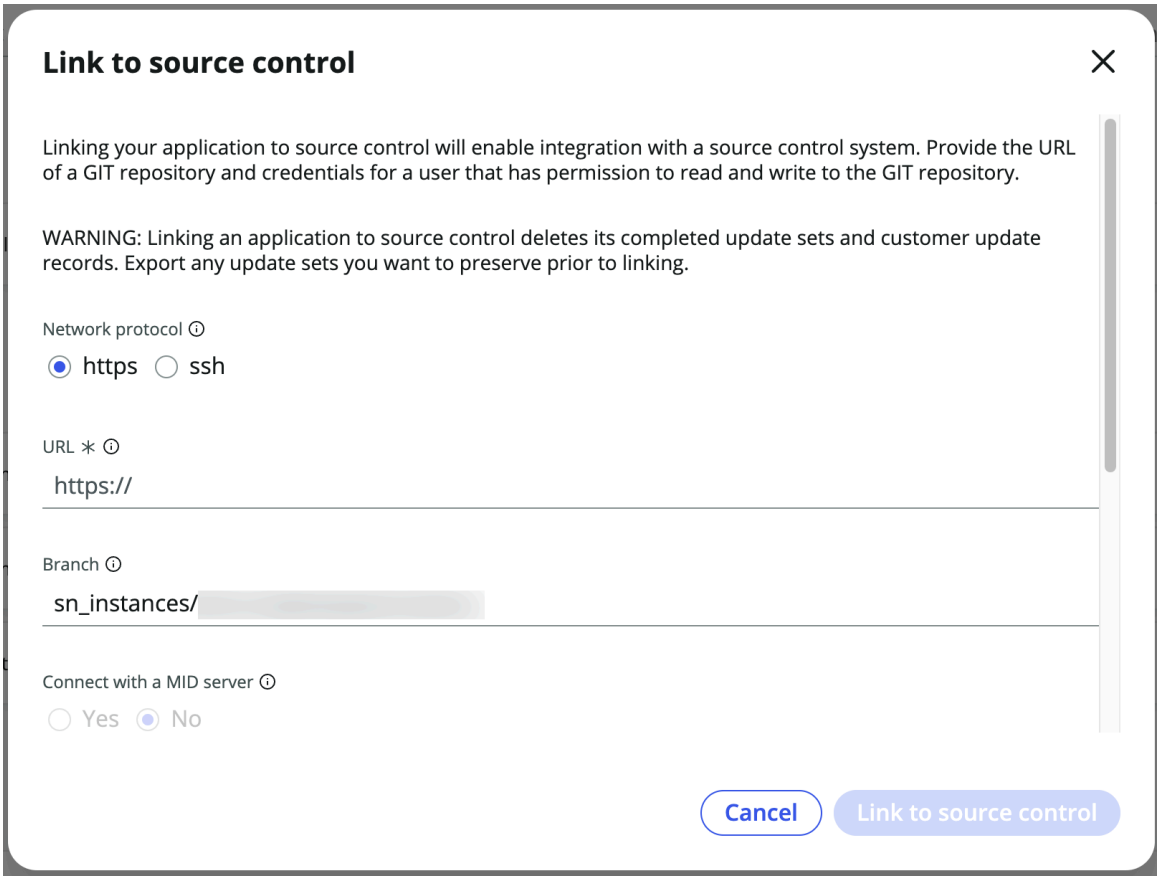
- Learn more about Manage customizations to applications.
- Create a dedicated Git repository for the application. For increased security, enable multi-factor authentication for the Git repository.
- Generate an access token that the source control integration can use instead of a password and multi-factor authentication passkey while creating a Credential record. Search for personal access token on GitHub or GitLab.
- Restrict permissions on the access token to allow read and write access to the Git repository.
- Verify that the non-production instance has network access to the Git repository.
- Ensure that users add the email address to their respective Users Table (ServiceNow sys_user) records that they use in their commits to the Git repository.
- Role required: admin

About this task

The source control integration does not support linking to an application or customization on a production instance. Instead, install applications on a production instance from the application repository, an update set, or the App Engine Studio.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select **Source control** > **Link to source control**.
   App Engine Studio displays the Link to source control dialog box.



4. Enter the connection details for the Git repository.

Source control connection details

Field	Description
Network protocol	Https or SSH credential type that enables secure channel data exchange.
URL	The URL to the Git repository where you want to save application files. For SSH protocol, use command to generate private key `ssh-keygen -t rsa -m PEM -b 4096 -C "email@address"`. **Note:** If the Git repo URL for SSH provided by your Git server does not work, check with your Git server owner or provider for the correct URL. There may be additional specifications such as scheme protocol prefixes, port numbers, and so on, required for your Git repo URL to function.
Branch	The repository branch to work on within the application. **Note:** This branch is used for commits. The default branch is set to "main" if it is not already set in the remote repository. If there is no default branch on the remote git repository, the instance creates a new default branch with the name "main". This is configured using the `glide.source_control.git_default_branch` system property.

Field	Description
MID Server Name	The name of the existing MID Server to link through. **Note:** Use a separate MID Server to prevent conflicts with Discovery activities. Be sure that the MID server user can create files to the sys_attachment table and that the table can accept files of the “bundle” type. Linking or an application through a MID Server enables access to repositories behind a firewall. See MID Server for more information.
Default email	The committer email address is defined by the sys_user record if available. But if a committer's sys_user record email field is empty, the system generates an alternate email (username@instancename.service-now.com). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.
Credential	The credential to be used with the selected protocol. See Getting started with credentials to learn more about creating credentials. **Note:** If you select the SSH network protocol, enter a valid credential of the SSH private key type. If you select the https protocol, enter a valid credential of the Basic Auth credentials type.
Commit Comment	An optional description of the repository or application.

Note:
All application developers on the instance share a single set of repository credentials.

5. Select **Link to source control**.
   The system validates the connection and user credentials and displays a success message.

   All application developers on the instance can use the linked Git repository to manage changes.

MID Server

Getting started with credentials

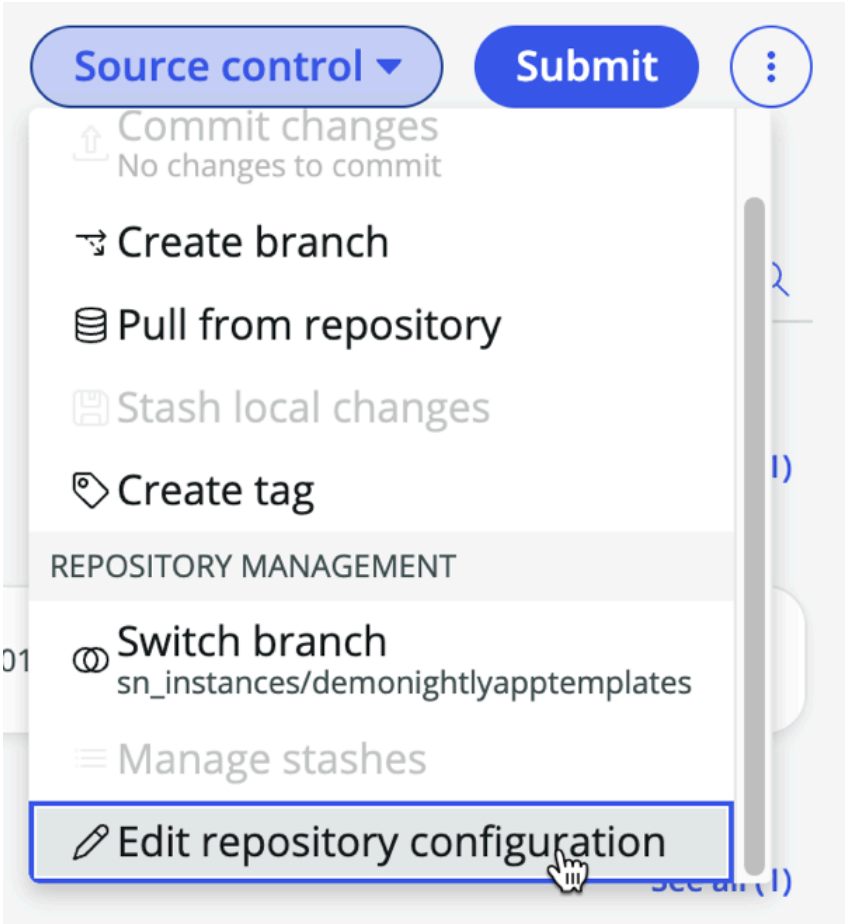
Edit a Git repository configuration

You can edit a Git repository's integration with App Engine Studio (AES) to change the network protocol selection, credentials or other field entries.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select **Source control** > **Edit repository configuration**.

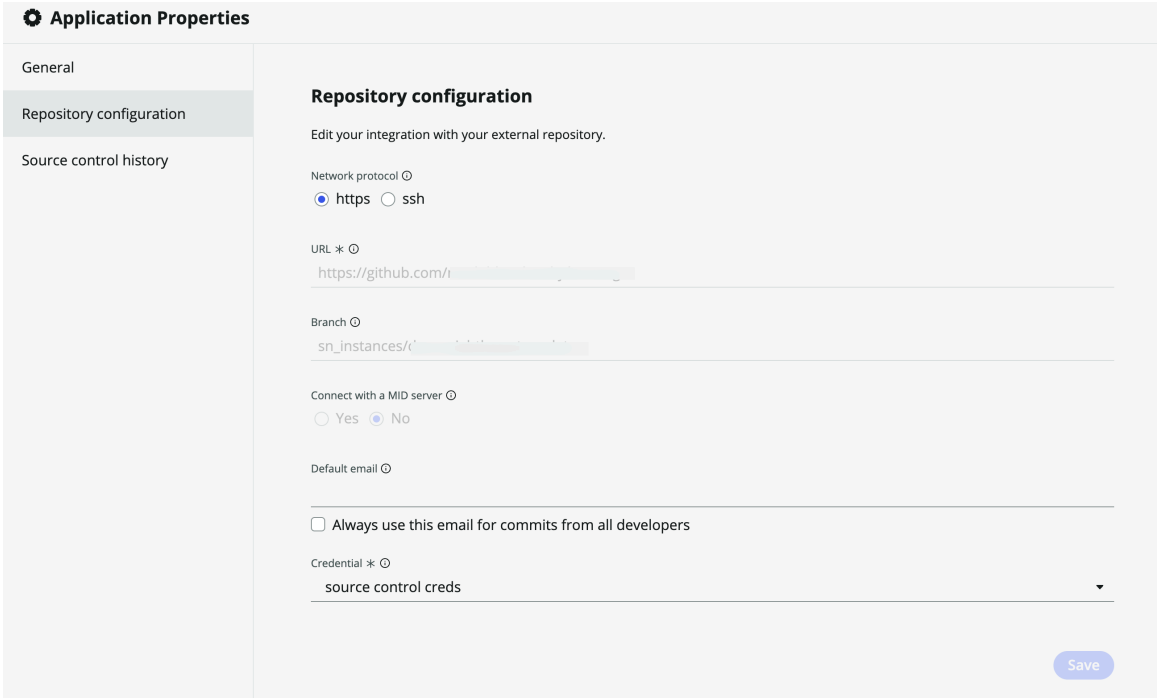


4. On the form, fill in the fields.

Repository configuration fields

Field	Definition
Network protocol	Protocol for source control, either **https** or **ssh**.
URL	URL address of your repository.
Branch	Current branch for the repository.
Connect with a MID server	Whether or not to use a MID server connection, which enables access to repositories behind a firewall. **Note:** If you have no MID server name, you can select a new one from the drop-down list. If you choose a new MID server, in the **Source control** menu before making any further source control operations to avoid errors.
Default email	Email address for the committer, which is defined by the sys_user record, if available.

Field	Definition
	If a committer's sys_user record email field is empty, the system generates an alternate email (username@instancename.service-now.com). You can also enter a default email address and change it later by selecting the **Always use this email for commits from all developers** check box.
Credential	Saved credentials to use for the source control connection. All application developers on the instance share a single set of credentials per repository. For information on working with credentials, see Getting started with credentials.



5. Select **Save**.

Configure the App Engine Management Center

Use the App Engine Management Center (AEMC) guided setup to step through the initial configuration of the Application Intake and Pipelines and Deployments applications. The Application Intake guided setup is optional, but if you want to use AEMC, the Pipelines and Deployments guided setup is required.

Before you begin

Ensure that AEMC is installed on your production instance and all of your non-production instances (development, test, and the like).

Role required: admin

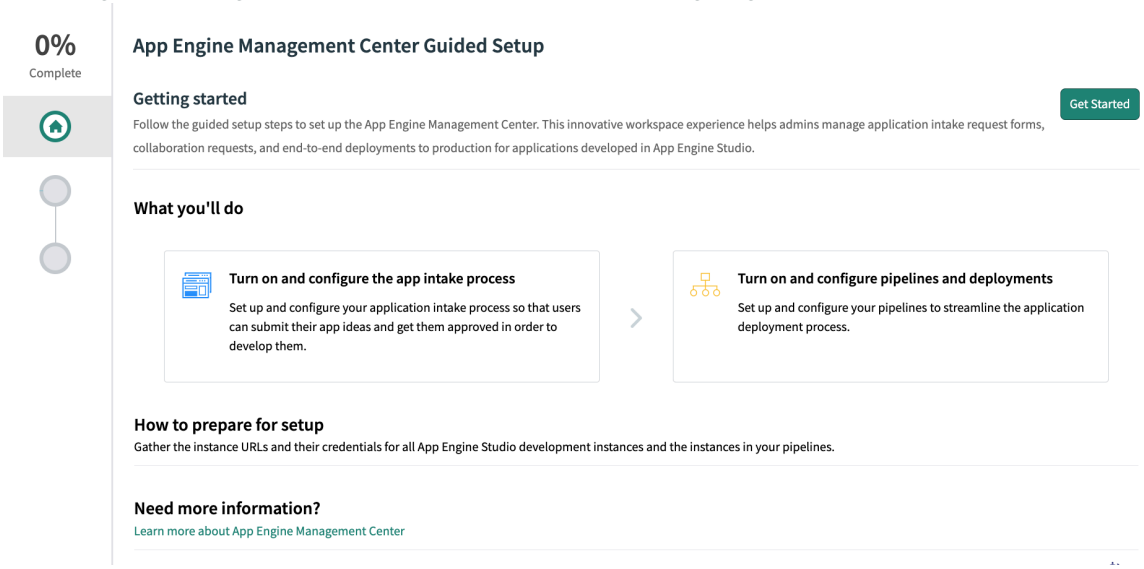
About this task

Essentially, the AEMC guided setup contains the guided setup steps for both the Application Intake and Pipelines and Deployments applications. If you have already configured one or both of these applications, you can skip those steps of the guided setup.

Procedure

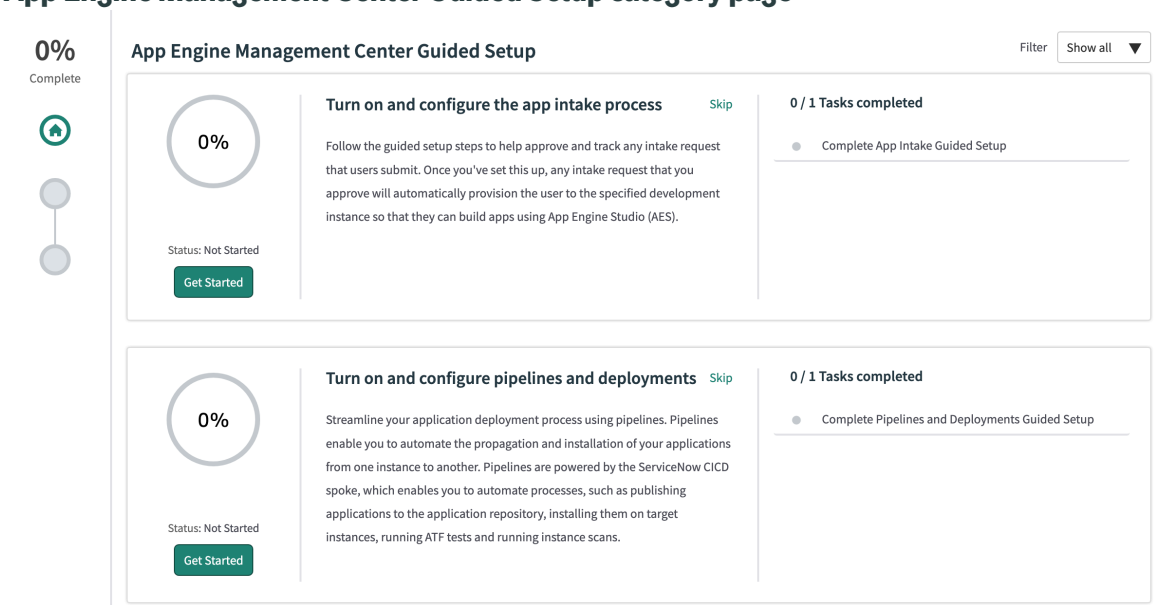
1. In your production instance, navigate to **All** > **App Engine** > **Administration** > **Guided Setup**.
   The landing page provides information on the two applications that you must configure, Application Intake and Pipelines and Deployments.

App Engine Management Center Guided Setup landing page



2. Initiate guided setup by selecting **Get Started**.
   The App Engine Management Center guided setup category page provides a list of different categories of tasks that you must complete before you can use AEMC.

App Engine Management Center Guided Setup category page



Note:
If you have previously started any of the guided setup tasks, and then exited without completing them, the **Get Started** button is labeled **Continue**.

3. Select the first **Get Started** button to initiate the Application Intake Guided Setup.
   There are several Application Intake configuration tasks you must complete.
   a. Activate the Apply for Citizen Development catalog item.
   b. Add users to the App Engine Admin group.
   c. Create development environment records.
   When you've completed all of the tasks in this category, the Category screen reopens.
4. Select the next **Get Started** button to initiate the Pipelines and Deployments Guided Setup.
   There are several Pipelines and Deployments configuration tasks you must complete.

   On your production instance:

   a. Configure environment credentials.
   b. Configure your pipeline environments.
   c. Configure your pipeline.
   d. Add users to the App Engine Admin group.
   e. Add ATF and instance scan suites for testing.

   > **Note:**
   > You can add ATF and instance scan suites for testing only if you've already created them and set up your testing instance. If you have not done this yet, you must come back to this step.

   f. Enable Change Management integration.
   g. Configure properties to integrate Change Management.

   On your testing instance:

   a. Configure environment credentials.
   b. Configure your controller instance.
   c. Enable Automated Test Framework (ATF) properties.
   d. Configure Automated Test Framework (ATF) suite.
   e. Configure Instance Scan suite.

   On your other, non-production instances:

   a. Configure environment credentials.
   b. Configure your controller instance.
   When you have completed the tasks in the second category, the Category page reappears.
   You have completed guided setup for App Engine Management Center.
5. **Optional:** Configure additional properties used to control system behavior in AEMC.

Test App Engine Management Center functionality on a non-production instance

Test App Engine Management Center (AEMC) on a non-production instance to confirm that everything is working as expected before moving to production.

Before you begin
Role required: admin

About this task
To test AEMC and pipelines before you proceed to a production environment, pick two non-production instances for testing purposes. Follow the Pipelines and Deployments guided setup

as if one of those non-production instances is a production instance. Because the system doesn't verify that the instance type on the environment record is actually a production instance, you can set the instance type to **Production** for the second non-production instance.

Procedure

1. Begin the Pipelines and Deployments Guided setup tasks as detailed in Pipelines and Deployments configuration tasks.
2. When you begin the tasks to configure your pipeline environments, select one of your non-production instances and designate it as a production instance in the pipeline environment record.
   For more information on the usual process, see Configure your pipeline environments.
3. Test AEMC and your pipeline functionality.
4. When you're done testing, change the **Instance type** of the non-production pipeline environment record to the correct type of instance.

Configure Application Intake

Use the App Engine Studio (AES) Application Intake guided setup to step through the initial configuration of the Application Intake application. Detailed instructions for each step are provided in subsequent sections of the product documentation.

Before you begin

Before you can use Application Intake to submit application ideas, you must ensure that the App Engine Studio application is installed.

Role required: admin

About this task

Application Intake guided setup provides a sequence of tasks that help you configure the Application Intake app on the ServiceNow AI Platform. For more information on each task, see Application Intake configuration tasks.

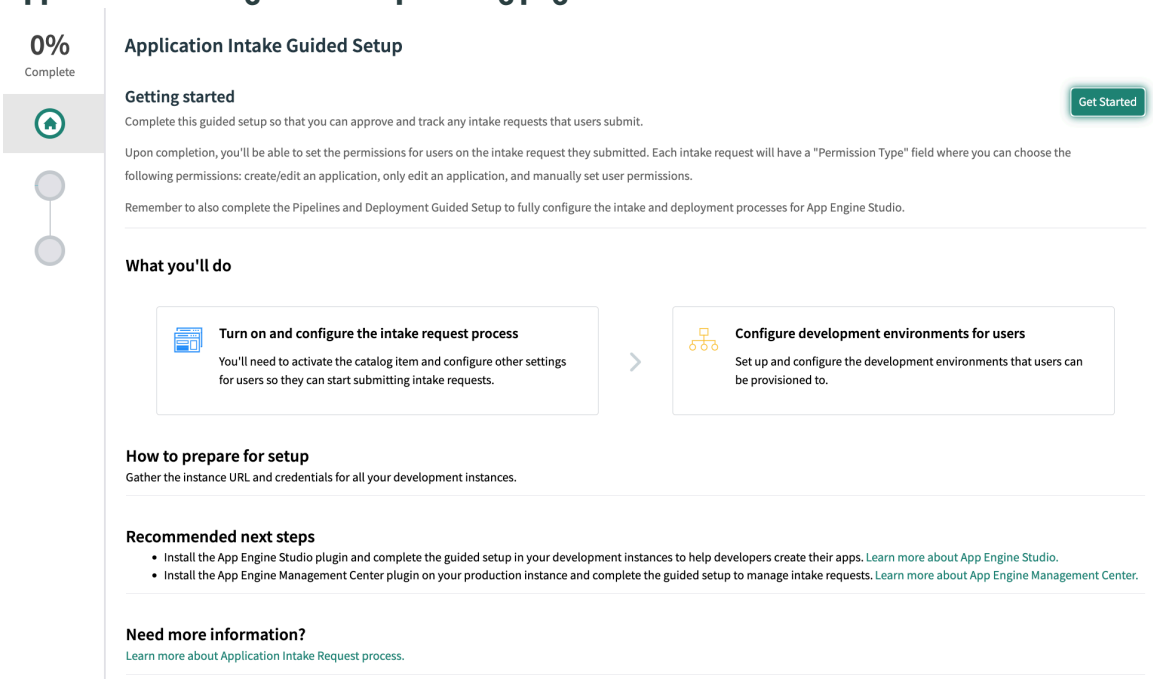
For general information about guided setup, see Guided setup .

Procedure

1. Navigate to **All** > **App Engine** > **Application Intake** > **Guided Setup**.

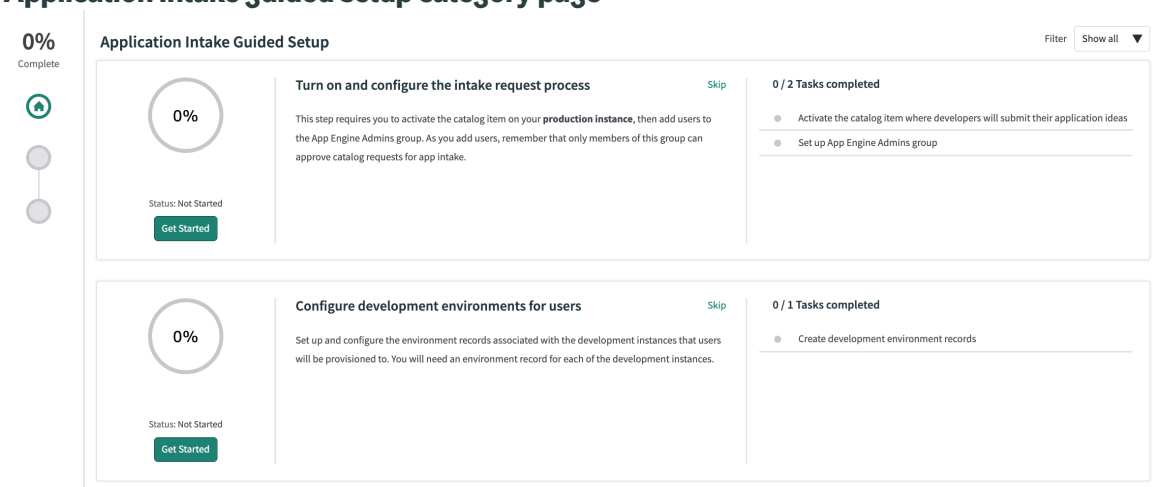
   The landing page provides information on the different categories, tools, and user access.

Application Intake guided setup landing page



2. To initiate guided setup, select **Get Started**.
   The Application Intake Guided Setup page provides a list of different tasks you must complete before you can use Application Intake to submit requests.

Application Intake guided setup category page



Note:
If you have previously started any of the guided setup tasks, and then exited without completed them, the **Get Started** button is labeled **Continue**.

3. Select the first **Get Started** button to initiate the Application Intake Guided Setup.
   There are several Application Intake configuration tasks you must complete.
   a. Activate the Apply for Citizen Development catalog item.
   b. Add users to the App Engine Admin group.
   When you've completed all of the tasks in this category, the Category screen reopens.
4. Select the next **Get Started** button to begin performing tasks for configuring development environments for your users.

On your production instance, Create development environment records for each development instance that you want to provision users to. This process allows your production instance to connect to your development instances.

Note:
If these records have already been set up in the Pipelines and Deployments Guided Setup, you can skip this step. When you have completed the tasks in the second category, the Category screen reappears.

Congratulations! You have completed guided setup for Application Intake.

Application Intake configuration tasks

As you work through the App Engine Studio (AES) Application Intake guided setup, you must perform different configuration tasks.

Activating and configuring the intake request process, and setting up development environments

The tasks for configuring Application Intake are listed below, along with links to detailed instructions for completing them.

Application Intake configuration tasks

Task	Description
Activate the catalog item where developers will submit their application ideas	Activate the Apply for Citizen Development catalog item so that citizen developers can submit their ideas for applications. For detailed instructions, see Activate the Apply for Citizen Development catalog item.
Set up the Apply for Citizen Development catalog item	For quick setup and use, use the predefined Apply for Citizen Development catalog item in Catalog Builder. To customize your app intake form, either update the Apply for Citizen Development catalog item, or use the AES App Intake template as a starting point and add questions and fields as needed. For detailed instructions, see Customize the App Intake form in Catalog Builder.
Add users to the App Engine Admins group	Add users to the App Engine Admin group. After the email address of the App Engine Admin group is configured, members can receive notifications for app development-related requests, including application intake requests. **Note:** If you already added users on the production instance using AES guided setup or Configure Pipelines and Deployments guided setup, you can skip this step. For detailed instructions, see Add users to the App Engine Admin group.
Create development environment records	On your production instance, create an environment record of type "Development" for each development instance that you want

Application Intake configuration tasks (continued)

Task	Description
	to provision users to. This will allow your production instance to connect to your development instances. **Note:** If these records have already been set up in the Pipelines and Deployments Guided Setup, you can skip this step. For detailed instructions, see Configure your pipeline environments.

When you have completed Application Intake guided setup, proceed to Pipelines and Deployments guided setup to fully configure App Engine Studio.

Activate the Apply for Citizen Development catalog item

Enable citizen developers to submit their ideas for applications by activating the Apply for Citizen Development catalog item. This is the first step in configuring the App Engine Studio (AES) Application Intake app.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **App Engine** > **Application Intake** > **Guided Setup**.
   For more information, see Configure App Engine Studio.
2. Either start the process or continue with a process in progress.
   - To start the process, select **Get Started**.
   - If you previously completed one or more of the tasks, select **Continue**.
3. In the **Turn on and configure the intake request process** section, select **Get Started**.
4. In the **Activate the catalog item where developers will submit their application ideas** section, select **Configure**.
5. In the Apply for Citizen Development catalog item record, select the **Active** check box.
6. Select **Update**.
7. Close the browser window and return to the Application Intake guided setup.

Customize the App Intake form in Catalog Builder

Create a custom app intake experience for your organization by editing the fields and questions on the App Engine Studio (AES) App Intake form in Catalog Builder.

Before you begin
Role required: admin

About this task
The Out of the Box variables associated with this catalog item are set to read-only. To edit the App Intake form, you must create a copy of the existing **Apply for Citizen Development** catalog item. Then, disable the original catalog item, and continue editing the **Copy of Apply for Citizen Development** catalog item. For more information, see Copy a catalog item.

Procedure

1. Navigate to **All** > **Service Catalog** > **Catalog Builder**.
2. On the **Catalog Items** tab, select the copy of the **Apply for Citizen Development** item you created.
3. Select **Edit**.
4. Define the questions on the App Intake form on the **Questions** tab.
5. Edit any other settings on the form that you want to change.
6. On the **Review and submit** tab, review the form preview and make any needed corrections by selecting **Preview**.
7. Save your changes.
   - To save your changes without submitting the form, select **Save**.
   - To submit the form, select **Submit**.

Change the order of the questions in the App Intake form

Customize the App Intake form by changing the order in which questions appear.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **Service Catalog** > **Catalog Builder**.
2. On the **Catalog Items** tab, select **Apply for Citizen Development** from the list of catalog items.
3. Select **Edit**.
4. On the **Questions** tab, point to the question you want to move.
5. On the left side of the question, select the Row drag and drop gripper icon (⠿) and drag the question to a new position.

Define dynamic behavior for an existing App Intake form question

Define dynamic behavior for a question on the App Intake form based on answers to other questions.

Before you begin
Role required: admin

About this task
Sometimes, if a user gives a specific answer to one question on the App Intake form, you might need a follow-up question to gather more information. For example, if you ask if they have taken any ServiceNow training, and the answer is "no", the user goes to the next visible question. If the answer is "yes", another question appears asking which training courses they have completed. Use the following steps to define this type of dynamic behavior.

Procedure

1. Navigate to **All** > **Service Catalog** > **Catalog Builder**.
2. On the **Catalog Items** tab, select **Apply for Citizen Development** from the list of catalog items.
3. Select **Edit**.

4. On the **Questions** tab, point to the question you want to update.
5. Select the Add dynamic behavior icon ( ) next to the question that you want to update.
6. Select **Define new behavior**.
7. On the **Actions** tab, specify the behavior of the question when certain conditions are met.

Actions tab

Field	Description
Specify the behavior of this question when the trigger conditions are met	
Make the question mandatory	Specifies how the dynamic behavior setting affects the mandatory state of the field, with the following options: ○ No action ○ Yes ○ No
Make the question visible	Specifies how the dynamic behavior setting affects the visible state of the field, with the following options: ○ No action ○ Yes ○ No
Make the question read-only	Specifies how the dynamic behavior setting affects the read-only state of the field, with the following options: ○ No action ○ Yes ○ No
Clear value	Option to clear the question value.

8. On the **Conditions** tab, specify the conditions that trigger the action on the question. For more information about building condition statements, see Condition builder.
9. On the **Settings** tab, specify the scenarios where the behavior setting applies.

Settings tab

Field	Description
Applicability	
Scenarios where this dynamic behavior applies	
Applies when the item is being requested	Option to specify if the dynamic behavior applies when the item is being requested.
Applies while viewing the catalog tasks after the request is submitted	Option to specify if the dynamic behavior applies while viewing the catalog tasks after the request is submitted.

Field	Description
Applies while viewing the requested item record after the request is submitted	Option to specify if the dynamic behavior applies while viewing the submitted record.

10. Select **Add behavior**.

Deactivate a question from the App Intake form

Deactivate a question from the App Intake form if it's no longer needed.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Service Catalog** > **Catalog Builder**.
2. On the **Catalog Items** tab, select **Apply for Citizen Development** from the list of catalog items.
3. Select **Edit**.
4. On the **Questions** tab, point to the question you want to remove.
5. Remove the question from the form by selecting the Deactivate question icon ( ).
6. Select **Deactivate**.

Manage user groups for Application Intake

Control which user groups are available for admins to give Creator Studio and App Engine Studio app development permissions to during the Application Intake process. These groups are managed on the User Groups Permission Types [sn_app_intake_permission_type] table.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **sn_app_intake_permission_type.list**.
2. Select a record in the list to update it.
3. On the group record, change the status of the **Active** option to control whether the group is available in the Application Intake guided setup.

What to do next

Confirm that you see the correct active groups in an application request in App Engine Management Center.

Configure Pipelines and Deployments

Use the App Engine Studio (AES) Pipelines and Deployments guided setup to step through the initial configuration of Pipelines and Deployments. Detailed instructions for each step are provided in subsequent sections of the product documentation.

Before you begin

Role required: admin

About this task

The Pipelines and Deployments guided setup provides a sequence of tasks that help you configure Pipelines and Deployments on the ServiceNow AI Platform. For more information on each task, see Pipelines and Deployments configuration tasks.

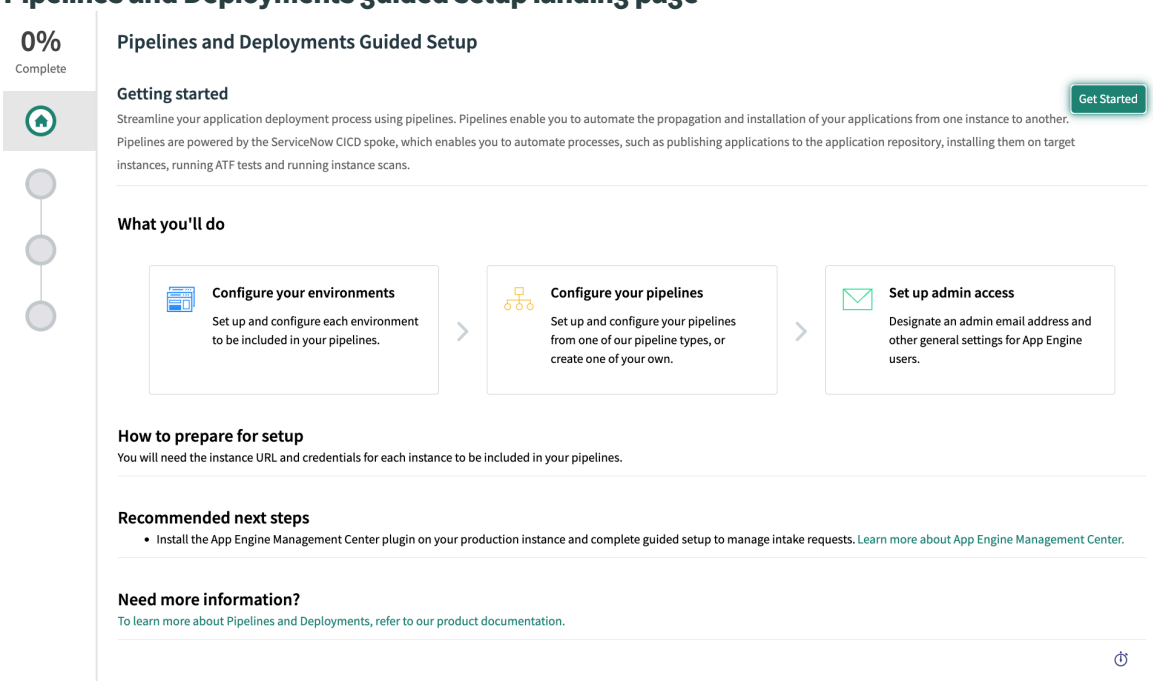
For general information about guided setup, see Using guided setup.

Procedure

1. Navigate to **All** > **App Engine** > **Pipelines and Deployments** > **Guided Setup**.

   The landing page provides information on the different categories, tools, and user access.

Pipelines and Deployments guided setup landing page

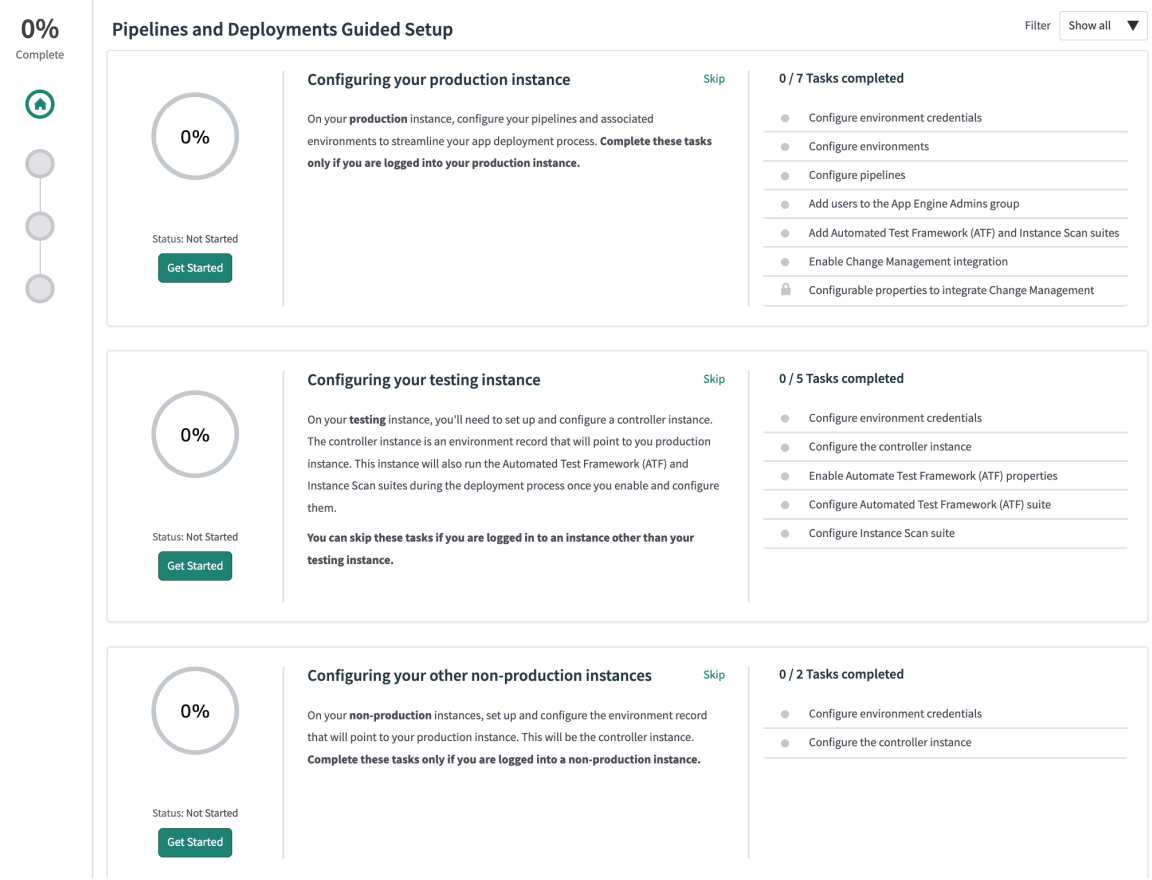


2. To initiate guided setup, select **Get Started**.

   The Pipelines and Deployments Guided Setup category page provides a list of different categories of tasks you must complete before you can use Pipelines and Deployments.

> **Note:**
> If you have previously started any of the guided setup tasks, and then exited without completed them, the **Get Started** button will be labeled **Continue**.

Pipelines and Deployments guided setup category page



Important:
Please be aware that each of the categories of tasks shown here are to be performed on different environments in your pipeline.

3. Select the first **Get Started** button to begin performing configuration tasks on your production environment.
   a. Configure environment credentials.
   b. Configure your pipeline environments.
   c. Configure your pipeline.
   d. Add users to the App Engine Admin group.
   e. Add ATF and instance scan suites for testing.

      Note:
      You can add ATF and instance scan suites for testing only if you've already created them and set up your testing instance. If you have not done this yet, you must come back to this step.

   f. Enable Change Management integration.
   g. Configure properties to integrate Change Management.

   When you have completed all of the tasks in this category, the Guided Setup screen reappears.

4. Select the next **Get Started** button to begin performing configuration tasks on your testing environment.
   a. Configure environment credentials.
   b. Configure your controller instance.
   c. Enable Automated Test Framework (ATF) properties.
   d. Configure Automated Test Framework (ATF) suite.
   e. Configure Instance Scan suite.

   When you have completed all of the tasks in this category, the Guided Setup screen reappears.

5. Select the last **Get Started** button to begin performing tasks for all of the other non-production (that is, test, development, staging, and so forth) instances in your pipeline.
   a. Configure environment credentials.
   b. Configure your controller instance.
   Congratulations! You have completed guided setup for the Pipelines and Deployments application.

Pipelines and Deployments configuration tasks

As you work through the Pipelines and Deployments guided setup, you must perform different configuration tasks on each of your instances.

Setting up environments, pipeline records, and user access

The tasks for configuring Pipelines and Deployments are listed below, along with links to detailed instructions for completing them. These tasks build on each other, so it's important to complete them in the sequence listed in the Guided Setup.

Pipelines and Deployments configuration tasks

Instance	Task	Description
Production	Configure environment credentials.	Configure credentials for each instance in your pipeline so that the flows used by AEMC can access the instances in your pipelines. For more information, see Configure environment credentials.
	Configure environments.	Set up your production and non-production (that is, development, test, and/or staging) environments by adding the URLs and credentials used to access each instance. For more information, see Configure your pipeline environments.
	Configure pipelines.	Set up and configure each pipeline by naming the pipeline, identifying each of the environments associated with the pipeline, and specifying the order in which apps are deployed between the environments in that pipeline.

Pipelines and Deployments configuration tasks (continued)

Instance	Task	Description
		For more information, see Configure your pipeline.
	Add users to the App Engine admin group.	Add users involved with this flow of tasks to the App Engine admin group. **Note:** If already added users on the production instance using AES guided setup or Configure Application Intake guided setup, you can skip this step. For more information, see Add users to the App Engine Admin group.
	Add Automated Test Framework (ATF) and Instance Scan suites.	Add your customized test suites as part of an application deployment in addition to the instance scan and ATF testing suites that are standard in AEMC. For more information, see Add ATF and instance scan suites for testing.
	Enable Change Management integration	Connect an existing Change Management program with AEMC so that deployments through the pipeline to the production environment are automatically scheduled based on the Change request state and planned change window. For more information, see Enable Change Management integration.
	Configure properties to integrate Change Management	Change requests and configuration items (CIs) are created using specifications set up in your existing Change Management program. If you want to change the change model, change template, or CI creation subflows used during app deployments, you must configure these properties during Guided Setup. For more information, see Configure properties to integrate Change Management.
Testing	Configure environment credentials	For more information, see Configure environment credentials.
	Configure the controller instance	Identify the controller instance that contains the pipeline deployment flows, as well as all of the data associated with the pipeline. As each instance completes its assigned tasks, it communicates with

Pipelines and Deployments configuration tasks (continued)

Instance	Task	Description
		the controller instance to determine where the next stage of deployment takes place. **Note:** Your production instance should be identified as the controller. For more information, see Configure your controller instance.
	Enable ATF properties on instances of type Testing.	Enable system properties that allow the ATF suite to run during the deployment process. If you do not enable these properties, a warning displays during the deployment process, but you can continue with the deployment. **Note:** If you plan on cloning your production instance to one or more non-production instances, you should either create a data preserver for these settings or enable these settings on your production instance. For more information, see System clone. For more information, see Enable Automated Test Framework (ATF) properties.
	Configure Automated Test Framework (ATF) suite	For more information, see Test your apps with the ATF.
	Configure Instance Scan suite	For more information, see Configuring Instance Scan.
Non-production instances that aren't of type Testing	Configure environment credentials	For more information, see Configure environment credentials.
	Configure the controller instance in your non-production instances	For more information, see Configure properties to integrate Change Management.

Configure environment credentials

Configure credentials in your production instance so that the flows used by the App Engine Management Center (AEMC) can access different instances.

Before you begin

You must use a functional user account with admin permissions to create the credentials for use in your pipelines. This user account should have the following characteristics:

- It should not be associated with a person in your organization.
- It should not need its password reset regularly.
- It should be controlled by your administrator.
- It should have admin privileges on all instances in the pipeline.

You can create a new functional user account specifically for pipeline credentials, or use one that you have previously created with these characteristics. Either way, this user account must be created before you can create the pipeline credentials. For more information about creating this user, see Create a user.

Role required: admin

About this task

Create the pipeline credentials with a functional user account that you created on the Users [sys_users] table. For example, you create a user account called Pipeline Runner and give it admin permissions. This account user name and password are used to set up the credential record.

Procedure

1. Navigate to **All** > **Connections & Credentials** > **Connection & Credential Aliases**.
2. Select **New**.
3. On the form, change the **Type** to **Credential**.
   Changing the type removes several fields from the form.
4. On the form, fill in the remaining fields.

Field	Description
Name	Unique name for the credential record. For example, Pipeline Credentials.
Application	Scope the record is being created in, which should be **Global**.
ID	Unique ID for the credential record. This field populates automatically based on the name. IDs are written in the form [scope_name.credential_name], unless the application is in the Global scope, then the ID is just the credential name.

5. Select **Submit**.
   The Connections & Credentials Aliases table reopens.
6. Open the credential that you created to add credential records to it.
7. On the **Credentials** tab, select **New**.
8. In the **What kind of Credentials would you like to create?** list, select **Basic Auth Credentials**.

   Note:
   If you want to use OAuth credentials in your pipelines instead, see Configure OAuth credentials for use in Pipelines and Deployments.

9. On the form, fill in the fields.

Field	Description
Name	Unique name for the basic auth credential record. For example, Pipeline Credentials.
Order	Order in which the flows you're using read the credential records. For example, if you have multiple credentials for backups, order them like 100, 200, 300, and so on. Flows read from the top of the list.
User name	User name for the functional account. For example, pipeline.runner.
Password	Password for the functional user account.
Active	Option to make the record active.
Credential alias	Alias for the record, repeated from the credential record ID. The alias exists so that only certain users can see what the user name and password are. When flows execute, they use the credential alias so they can install the apps.

10. Select **Submit**.
11. Repeat this process on each non-production instance in your pipeline.
    For the credential record, use the user name and password that the pipeline should use to access the production instance.

Configure OAuth credentials for use in Pipelines and Deployments

Use OAuth credentials in your pipelines to add another level of security to your pipeline. This task helps you create and configure OAuth credentials for use in your pipelines.

Before you begin

In the top right corner of your instance, make sure you set the application scope to **Global**. Open all your instances (development, test, production, and the like) in separate browser tabs. The following tasks lay out the steps for a three-instance environment. However, if you use any other non-production instances (stage, and the like), there are steps that detail where you may need to repeat a task on that instance.

Role required: admin

About this task

Creating and connecting OAuth credentials consists of several tasks that must be completed in the order laid out. Pay close attention to make sure you're in the correct instance for each step. For more information, see OAuth 2.0 .

Procedure

1. Complete all of the steps under Create OAuth API endpoints for external clients on the specified instances.
2. Complete all of the steps under Create third-party OAuth provider records on the specified instances.
3. Complete all of the steps under Use OAuth to create pipeline credentials on the specified instances.

What to do next

When you Configure your pipeline environments, make sure you select the correct instance credential records for the instance you're configuring.

Create OAuth API endpoints for external clients

Create OAuth API endpoints to enable your controller instance to have two-way communication with your non-production instances. Follow and complete each step carefully on the specified instances before moving on to create your third-party OAuth provider records.

Demonstration of how to create OAuth API endpoints for external clients

Before you begin

In the top right corner of your instance, make sure you set the application scope to **Global**.

Open all of your instances (development, test, production, and the like) in separate browser tabs.

Role required: admin

About this task

To create OAuth API endpoints for external clients and use OAuth in your pipelines, you must create several records, each on different instances in your pipeline. Begin on your production instance, which should be your controller instance.

Procedure

1. On your production instance, navigate to **All** > **System OAuth** > **Application Registry**.
2. Select **New**.
3. Select **Create an OAuth API endpoint for external clients**.
4. On the form, fill in the fields.

Application Registries form

Field	Action
Name	Enter `Pipeline Controller Client`.
Redirect URLs	**a.** Unlock the field. **b.** Enter the URL for your production, development, and test instances, each with `oauth_redirect.do` after the backslash. **c.** Lock the field. Separate each of the three URLs with a comma and a space. For example: `https://<production instance`

Field	Action
	`name>.service-now.com/oauth_redirect.do, https://<development instance name>.service-now.com/oauth_redirect.do, https://<test instance name>.service-now.com/oauth_redirect.do.`

5. Select **Submit**.

> **Important:**
> Complete the next steps on your development instance.

6. On your development instance, navigate to **All** > **System OAuth** > **Application Registry**.
7. Select **New**.
8. Select **Create an OAuth API endpoint for external clients**.
9. On the form, fill in the fields.

Application Registries form

Field	Action
Name	Enter `Pipeline Development Client`.
Redirect URLs	**a.** Unlock the field. **b.** Enter the URL for your production and development instances, each with `oauth_redirect.do` after the backslash. **c.** Lock the field. Separate the two URLs with a comma and a space. For example: `https://<production instance name>.service-now.com/oauth_redirect.do, https://<development instance name>.service-now.com/oauth_redirect.do.`

10. Select **Submit**.

> **Important:**
> Complete the next steps on your test instance.

11. On your test instance, navigate to **All** > **System OAuth** > **Application Registry**.
12. Select **New**.
13. Select **Create an OAuth API endpoint for external clients**.
14. On the form, fill in the fields.

Application Registries form

Field	Action
Name	Enter `Pipeline Test Client`.
Redirect URLs	**a.** Unlock the field. **b.** Enter the URL for your production and test instances, each with `oauth_redirect.do` after the backslash. **c.** Lock the field. Separate the two URLs with a comma and a space. For example: `https://<production instance name>.service-now.com/oauth_redirect.do, https://<test instance name>.service-now.com/oauth_redirect.do`.

15. Select **Submit**.
16. **Optional:** Repeat this process from steps 11–15 for any other non-production instances (staging, and the like) you have.

What to do next

Follow the steps in Create third-party OAuth provider records on the specified instances.

Create third-party OAuth provider records

Create third-party OAuth provider records to enable each of your instances to access the API endpoints you've created.

Before you begin

Complete the tasks in Create OAuth API endpoints for external clients.

In the top right corner of your instance, make sure you set the application scope to **Global**.

Open all of your instances (development, test, production, and the like) in separate browser tabs. Begin the steps below on the production instance.

Role required: admin

Procedure

1. On your production instance, navigate to **All** > **System OAuth** > **Application Registry**.
   You must create three records here, one for each of the three instances (development, test, and production). If you have any additional non-production instances (staging, and the like), create a record for each of those following the method shown here.

   Demonstration of how to create the first three records on your production instance
2. Select **New**.
3. Select **Connect to a third party OAuth Provider** to create a record for your development instance.

4. On the form, fill in the fields.

Application Registries form

Field	Action
Name	Enter `Dev Instance Connection`.
Client ID	**a.** On your development instance, open the Application Registry list (**All** > **System OAuth** > **Application Registry**). **b.** Open the **Pipeline Development Client** record. **c.** Copy the **Client ID**. **d.** On your production instance, paste the Client ID from your development instance into the **Client ID** field.
Client Secret	**a.** On your development instance, open the Application Registry list (**All** > **System OAuth** > **Application Registry**). **b.** Open the **Pipeline Development Client** record. **c.** Unlock the **Client Secret** field and copy the text. **d.** On your production instance, paste the Client Secret from your development instance in the **Client Secret** field.
Default Grant type	Change to **Authorization code**.
Authorization URL	**a.** Unlock the field. **b.** Enter the URL for your development instance followed by `oauth_auth.do`. **c.** Lock the field. For example: `https://<development instance name>.service-now.com/oauth_auth.do`.
Token URL	**a.** Unlock the field. **b.** Enter the URL for your development instance followed by `oauth_token.do`. **c.** Lock the field. For example: `https://<development instance name>.service-now.com/oauth_token.do`.

5. Select **Submit**.
6. Select **New**.
7. Select **Connect to a third party OAuth Provider** to create a record for your test instance.

8. On the form, fill in the fields.

Application Registries form

Field	Action
Name	Enter `Test Instance Connection`.
Client ID	**a.** On your test instance, open the Application Registry list (**All** > **System OAuth** > **Application Registry**). **b.** Open the **Pipeline Test Client** record. **c.** Copy the **Client ID**. **d.** On your production instance, paste the Client ID from your test instance into the **Client ID** field.
Client Secret	**a.** On your test instance, open the Application Registry list (**All** > **System OAuth** > **Application Registry**). **b.** Open the **Pipeline Test Client** record. **c.** Unlock the **Client Secret** field and copy the text. **d.** On your production instance, paste the Client Secret from your test instance in the **Client Secret** field.
Default Grant type	Change to **Authorization code**.
Authorization URL	**a.** Unlock the field. **b.** Enter the URL for your test instance followed by `oauth_auth.do`. **c.** Lock the field. For example: `https://<test instance name>.service-now.com/oauth_auth.do`.
Token URL	**a.** Unlock the field. **b.** Enter the URL for your test instance followed by `oauth_token.do`. **c.** Lock the field. For example: `https://<test instance name>.service-now.com/oauth_token.do`.

9. Select **Submit**.
10. On the Application Registry list, select the **Pipeline Controller Client** record.
11. Copy the **Client ID** and paste it somewhere like a notes application.
12. Unlock the **Client Secret** field, copy the text, and paste it in a note with the Client ID.
13. Go back to the Application Registry list and select **New**.

14. Select **Connect to a third party OAuth Provider** to create a record for your production instance.
15. On the form, fill in the fields.

Application Registries form

Field	Action
Name	Enter `Prod Instance Connection`.
Client ID	**a.** Copy the **Client ID** that you noted down. **b.** Paste the Client ID into the **Client ID** field.
Client Secret	**a.** Copy the **Client Secret** that you noted down. **b.** Unlock the **Client Secret** field, and paste the text in the field.
Default Grant type	Change to **Authorization code**.
Authorization URL	**a.** Unlock the field. **b.** Enter the URL for your production instance followed by `oauth_auth.do`. **c.** Lock the field. For example: `https://<production instance name>.service-now.com/oauth_auth.do`.
Token URL	**a.** Unlock the field. **b.** Enter the URL for your production instance followed by `oauth_token.do`. **c.** Lock the field. For example: `https://<production instance name>.service-now.com/oauth_token.do`.

16. Select **Submit**.

> **Important:**
> Complete the next steps on your development instance.

17. On your development instance, navigate to **All** > **System OAuth** > **Application Registry**.

    Demonstration of how to create records for your production instance on both your development and test instances

18. Select **New**.
19. Select **Connect to a third party OAuth Provider** to create a record for your production instance.
20. On the form, fill in the fields.

Application Registries form

Field	Action
Name	Enter `Prod Instance Connection`.
Client ID	**a.** Copy the **Client ID** that you noted down. **b.** Paste the Client ID into the **Client ID** field.
Client Secret	**a.** Copy the **Client Secret** that you noted down. **b.** Unlock the **Client Secret** field, and paste the text in the field.
Default Grant type	Change to **Authorization code**.
Authorization URL	**a.** Unlock the field. **b.** Enter the URL for your production instance followed by `oauth_auth.do`. **c.** Lock the field. For example: `https://<production instance name>.service-now.com/oauth_auth.do`.
Token URL	**a.** Unlock the field. **b.** Enter the URL for your production instance followed by `oauth_token.do`. **c.** Lock the field. For example: `https://<production instance name>.service-now.com/oauth_token.do`.

21. Select **Submit**.

> **Important:**
> Complete the next steps on your test instance.

22. On your test instance, navigate to **All** > **System OAuth** > **Application Registry**.
23. Select **New**.
24. Select **Connect to a third party OAuth Provider** to create a record for your production instance.
25. On the form, fill in the fields.

Application Registries form

Field	Action
Name	Enter `Prod Instance Connection`.
Client ID	**a.** Copy the **Client ID** that you noted down. **b.** Paste the Client ID into the **Client ID** field.

Field	Action
Client Secret	**a.** Copy the **Client Secret** that you noted down. **b.** Unlock the **Client Secret** field, and paste the text in the field.
Default Grant type	Change to **Authorization code**.
Authorization URL	**a.** Unlock the field. **b.** Enter the URL for your production instance followed by `oauth_auth.do` **c.** Lock the field. For example: `https://<production instance name>.service-now.com/oauth_auth.do`.
Token URL	**a.** Unlock the field. **b.** Enter the URL for your production instance followed by `oauth_token.do` **c.** Lock the field. For example: `https://<production instance name>.service-now.com/oauth_token.do`.

26. Select **Submit**.
27. **Optional:** Repeat steps 22–26 for any other non-production instances that you have (staging, and the like).

What to do next

Now that you've completed the pre-work for using OAuth, complete all the steps in Use OAuth to create pipeline credentials on the specified instances.

Use OAuth to create pipeline credentials

Create credential records on each of your instances to enable OAuth use in your pipeline.

Before you begin

Complete the tasks in Create OAuth API endpoints for external clients and Create third-party OAuth provider records.

In the top right corner of your instance, make sure you set the application scope to **Global**.

Open all of your instances (development, test, production, and the like) in separate browser tabs.

Role required: admin

About this task

To configure credentials correctly, you must create records for each of your production and non-production instances on your production instance. Then, you must create a record for your production instance on each of your non-production instances connecting them all together. Use the videos in each section to follow along with the steps. Begin on your production instance.

Procedure

1. On your production instance, navigate to **All** > **Connections & Credentials** > **Connection & Credential Aliases**.
   Create credential records on your production instance
2. Select **New**.
3. Change the **Type** to **Credential**.
4. In the **Name** field, enter `Pipeline Dev OAuth`.
5. Select **Submit**.
6. Reopen the record you just created (Pipeline Dev OAuth).
7. On the Credentials related list, select **New**.
8. Select **OAuth 2.0 Credentials**.
9. On the form, fill in the fields.

OAuth 2.0 Credentials form

Field	Action
Name	Enter `Dev OAuth`.
OAuth Entity Profile	Search for and select the **Dev Instance Connection default profile**.

10. Select **Submit**.
11. Reopen the **Dev OAuth** credential record.
    An expected error appears, directing you to verify the OAuth configuration and select **Get OAuth Token** to request a new token.
12. Under Related Links, select **Get OAuth Token**.
    A development instance opens requesting to connect to your ServiceNow account.
13. Select **Allow**.
14. Go back to the Connection & Credential Aliases list (**All** > **Connections & Credentials** > **Connection & Credential Aliases**).
15. Select **New**.
16. Change the **Type** to **Credential**.
17. In the **Name** field, enter `Pipeline Test OAuth`.
18. Select **Submit**.
19. Reopen the record you just created (Pipeline Test OAuth).
20. On the Credentials related list, select **New**.
21. Select **OAuth 2.0 Credentials**.
22. On the form, fill in the fields.

OAuth 2.0 Credentials form

Field	Action
Name	Enter `Test OAuth`.

Field	Action
OAuth Entity Profile	Search for and select the **Test Instance Connection default profile**.

23. Select **Submit**.
24. Reopen the Test OAuth credential record.
    An expected error appears, directing you to verify the OAuth configuration and select **Get OAuth Token** to request a new token.
25. Under Related Links, select **Get OAuth Token**.
    A test instance opens requesting to connect to your ServiceNow account.
26. Select **Allow**.
27. Go back to the Connection & Credential Aliases list (**All** > **Connections & Credentials** > **Connection & Credential Aliases**).
28. Select **New**.
29. Change the **Type** to **Credential**.
30. In the **Name** field, enter `Pipeline Prod OAuth`.
31. Select **Submit**.
32. Reopen the record you just created (Pipeline Prod OAuth).
33. On the Credentials related list, select **New**.
34. Select **OAuth 2.0 Credentials**.
35. On the form, fill in the fields.

OAuth 2.0 Credentials form

Field	Action
Name	Enter `Prod OAuth`.
OAuth Entity Profile	Search for and select the **Prod Instance Connection default profile**.

36. Select **Submit**.
37. Reopen the Prod OAuth credential record.
    An expected error appears, directing you to verify the OAuth configuration and select **Get OAuth Token** to request a new token.
38. Under Related Links, select **Get OAuth Token**.
    A production instance opens requesting to connect to your ServiceNow account.
39. Select **Allow**.
40. **Optional:** If you have any other non-production instances (staging, etc.), create a credential record for each of them on your production instance using the methods above.

> **Important:**
> After you've completed the steps above on your production instance, follow the steps below to create one credential record on each of your non-production instances connecting them to your production instance. Complete the next steps on your development instance.

41. On your development instance, navigate to **All** > **Connections & Credentials** > **Connection & Credential Aliases**.
    Create a credential record on your development instance and connect it to production.
42. Select **New** to create a record to connect your development instance to production.
43. Change the **Type** to **Credential**.
44. In the **Name** field, enter `Pipeline Prod OAuth`.
45. Select **Submit**.
46. Reopen the record you just created (Pipeline Prod OAuth).
47. On the Credentials related list, select **New**.
48. Select **OAuth 2.0 Credentials**.
49. On the form, fill in the fields.

OAuth 2.0 Credentials form

Field	Action
Name	Enter `Prod OAuth`.
OAuth Entity Profile	Search for and select the **Prod Instance Connection default profile**.

50. Select **Submit**.
51. Reopen the Prod OAuth credential record.
    An expected error appears, directing you to verify the OAuth configuration and select **Get OAuth Token** to request a new token.
52. Under Related Links, select **Get OAuth Token**.
    A production instance opens requesting to connect to your ServiceNow account.
53. Select **Allow**.

> **Important:**
> Complete the next steps on your test instance.

54. On your test instance, navigate to **All** > **Connections & Credentials** > **Connection & Credential Aliases**.
    Create a credential record on your test instance and connect it to production.
55. Select **New** to create a record to connect your test instance to production.
56. Change the **Type** to **Credential**.
57. In the **Name** field, enter `Pipeline Prod OAuth`.
58. Select **Submit**.
59. Reopen the record you just created (Pipeline Prod OAuth).
60. On the Credentials related list, select **New**.
61. Select **OAuth 2.0 Credentials**.
62. On the form, fill in the fields.

OAuth 2.0 Credentials form

Field	Action
Name	Enter `Prod OAuth`.
OAuth Entity Profile	Search for and select the **Prod Instance Connection default profile**.

63. Select **Submit**.
64. Reopen the Prod OAuth credential record.
    An expected error appears, directing you to verify the OAuth configuration and select **Get OAuth Token** to request a new token.
65. Under Related Links, select **Get OAuth Token**.
    A production instance opens requesting to connect to your ServiceNow account.
66. Select **Allow**.
67. **Optional:** If you have any other non-production instances (staging, etc.), create a credential record on that instance for production using steps 54-66.

What to do next

Now that you've created all of the credential records connecting your instances, you can use those records to configure your pipeline environments. For more information, see Configure your pipeline environments.

Configure your pipeline environments

Set up your App Engine Studio (AES) production and non-production (for example, development, test, and/or staging) environments by adding the URLs and credentials used to access each instance.

Before you begin

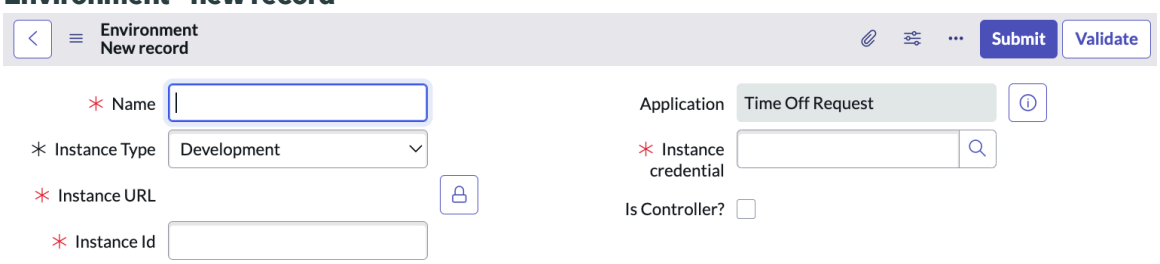
Role required: admin

> **Note:**
> Only users with the System Administrator (admin) role can define instance credentials for environments. Users with the App Engine Administrator [sn_app_eng_notify.app_engine_admin] role can view environment records; however, the **Instance credential** field is not visible.

Procedure

1. In your production instance, navigate to **All** > **App Engine** > **Pipelines and Deployments** > **Environments**.
2. Select **New**.

Environment - new record



3. On the form, fill in the fields.

Environment form

Field	Description
Name	Name of the environment. Enter a name that distinguishes the instance as a development, test, or production environment. For example, if you're defining a development environment, you could include `Dev` in the name.
Instance Type	The type of environment you are defining: ○ Sandbox ○ Development ○ Testing ○ Staging ○ Production
Instance URL	Web address of your ServiceNow instance.
Instance ID	The instance_id sys_property for the instance. **Note:** The Instance ID is automatically generated when you complete all of the other fields and select **Validate**.
Application	Application scope of the environment.
Instance credential	Authentication data related to the instance that you're configuring as an environment. **Note:** If you are using OAuth 2.0 credentials, select the appropriate credential for the instance record. For example, on your development instance record, select the OAuth Dev credential, and for your test instance record, select the OAuth Test credential.
Is Controller?	Identifies if this instance is a controller. This should be selected for the production environment record where you plan to manage deployment requests. For more information, see Configure your controller instance.

4. Select **Submit**.
5. Repeat the previous steps as you define each remaining environment in your pipeline. For example, if you defined a production environment, repeat the procedure again to define a development environment. Then repeat the procedure once more to define a test environment.

Configure your pipeline

Configure your App Engine Studio (AES) pipeline so that your administrator can quickly move an application from one environment to another.

Before you begin

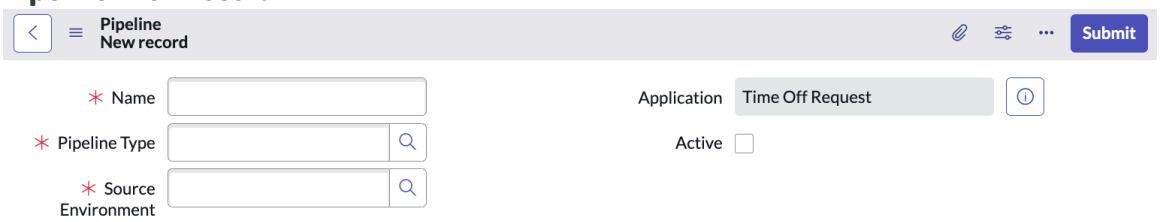
You must create all of your pipeline environment records before completing these steps. For more information, see Configure your pipeline environments.

Role required: admin or app_engine_admin

Procedure

1. In your production instance, navigate to **All** > **App Engine** > **Pipelines and Deployments** > **Pipelines**.
2. Select **New**.

Pipeline - new record



3. On the form, fill in the fields.

Pipeline form

Field	Description
Name	Name of the pipeline. Enter a name that distinguishes this pipeline from other pipelines.
Pipeline Type	The type of pipeline you are defining. The most common use case for pipelines is to select Application Deployment; however, you can define other types as needed.
Source Environment	The environment for this pipeline, usually the development environment.
Application	Application scope of the pipeline.
Active	Select the check box to activate this pipeline.

4. Select **Submit**.
5. Reopen the pipeline record you just created.
6. In the Pipeline Environments Order section, select the environments in the pipeline, excluding the **Source Environment**, and specify the order in which apps should be deployed through the pipeline.
7. Select **Update**.

Configure your controller instance

You must identify one of the instances in your App Engine Studio (AES) pipeline as the controller instance. All communication between the instances in your pipeline, including the deployment order for applications in the pipeline, takes place in the controller instance.

Before you begin

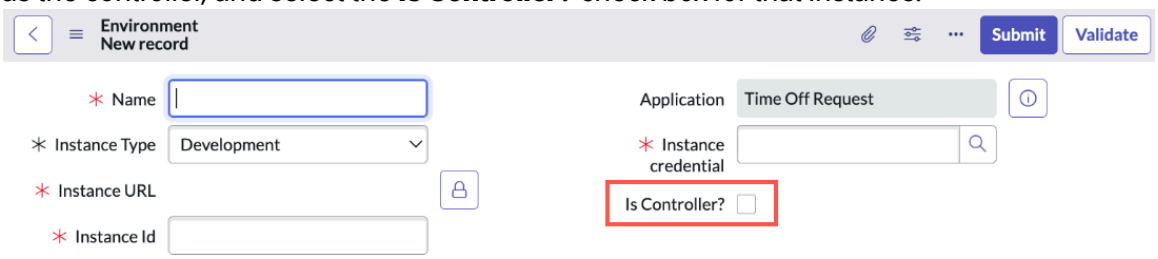
Role required: admin

About this task

Typically, your production instance should be identified as the controller instance. All request and approval records are stored on your controller instance.

Procedure

1. Navigate to **All** > **App Engine** > **Pipelines and Deployments** > **Environments**.
2. When you are configuring your pipeline environments, decide which instance you want to use as the controller, and select the **Is Controller?** check box for that instance.



3. Select **Save**.
   When the workflow for the pipeline runs, the non-production instances communicate with the controller instance to determine to which instance the app should next be deployed.

Add ATF and instance scan suites for testing

Add your customized test suites as part of an application deployment in addition to the instance scan and Automated Test Framework (ATF) testing suites that are standard in AEMC.

Before you begin

Because the ATF and instance scan suites exist only on testing instances, you must have your pipeline set up to complete this task. For more information, see Configure your pipeline environments.

Role required: admin

Procedure

1. On your production instance, navigate to **All** > **App Engine** > **Pipelines and Deployments** > **Scan Suites**.
2. If this is the first time you are looking at this table, select **Populate default suites** to load the instance and ATF scan suites that ServiceNow provides.
3. Add a new scan suite by selecting **New**.
4. On the form, fill in the fields.

Scan Suite form

Field	Description
Suite	Table with all the ATF and Instance scan suites that exists on your testing instance.
Error severity	Error options that indicate the severity of a scan suite not passing testing.
Instance Type	Type of instance the scan suite will run on. This field should be set to **Testing**.

5. Select **Submit**.
   The suites you add will run on apps installed on the instance you selected during testing.

Enable Automated Test Framework (ATF) properties

The App Engine Studio (AES) Pipelines and Deployments app includes an Application Test Framework (ATF) suite called the Application Deployment Test Suite. Two system properties control whether the test runs automatically whenever an app is deployed to a Test environment.

Before you begin
Role required: admin

About this task
The tests in the Application Deployment Test Suite can be run on production instances; however, the flows included in the base system run only on non-production (Test) instances. Additionally, the tests should run only on an instance defined with an **Instance Type** of **Testing**. For more information, see Configure your pipeline environments.

> **Note:**
> If you plan on cloning your production instance to one or more non-production instances, you should either create a data preserver for these settings or enable these settings on your production instance. For more information, see System clone.

Procedure

1. Navigate to the System Properties table by typing `sys_properties.list` in the navigation filter and pressing **Enter**.
2. Locate the following two properties:
   - sn_atf.runner.enabled
   - sn_atf.schedule.enabled
3. If you want these tests to run automatically on non-production instances whenever an app is deployed to a Test instance, open each property record, change the **Value** field to true, and select **Update**.

Enable Change Management integration

Enable Change Management integration with AEMC so that deployments through the pipeline to the production environment are automatically scheduled based on the Change request state and planned change window.

Before you begin
Role required: admin

About this task
This task can be completed within the Guided Setup system. This task opens within Guided Setup when you select **Configure**. If you prefer, you can follow the instructions below to access the same configuration task outside of the Guided Setup.

Procedure

1. Navigate to the System Properties table by typing `sys_properties.list` in the navigation filter and pressing **Enter**.
2. Locate the following property: sn_deploy_pipeline.change_management.enabled.
3. Connect your existing Change Management processes to AEMC by changing the **Value** field to `true`.

4. Select **Update**.
5. In the Pipelines and Deployments Guided Setup, select **Mark Complete**.
   Marking the enablement step complete enables you to configure properties related to Change Management integration including the change model, change template, and CI creation subflow. For more information, see Configure properties to integrate Change Management.

Configure properties to integrate Change Management

Configure predefined properties through the Pipelines and Deployments Guided Setup to tailor your Change Management and AEMC integration to your company's needs. Configuring these properties is optional.

Configure the change model

Configure the change model you would like to use during application deployments. If not configured, the **Normal** change model is used by default.

Before you begin
Role required: admin

About this task
There are several change models you can use to tailor change activities and flows for specific use cases. For more information about each type of model, see Change models. Use the steps below to select which change model you would like to use during app deployments.

This task can be completed within the Guided Setup system. This task opens within Guided Setup when you select **Configure**. If you prefer, you can follow the instructions below to access the same configuration task outside of the Guided Setup.

Procedure
1. Navigate to the System Properties table by typing `sys_properties.list` in the navigation filter and pressing **Enter**.
2. Locate the following property: sn_deploy_pipeline.change_management.default.model.
   To change the value of this property, and therefore the model that's being used, you must identify the **sys_id** of the change model you want to switch to.
   a. Navigate to **All** > **Change** > **Administration** > **Change Models**.
   b. Select the Change model you want to make the default for app deployments (for example, **Standard**).
   c. Right-click in the header bar for the record, and select **Copy sys_id**.
3. In the **sn_deploy_pipeline.change_management.default.model** property, paste the sys_id you have copied into the **Value** field, replacing its current contents.
4. Select **Update**.
5. In the Pipelines and Deployments Guided Setup, in the **Configure Change Model** section, select **Mark Complete**.

Configure the change template

Configure the default change template used to create change requests during application deployments.

Before you begin
Role required: admin

About this task

There are several templates that you can choose from to use as the default template for creating change requests. For more information, see Create a change request template. Use the following steps to select which change template you would like to use during app deployments.

This task can be completed within the Guided Setup system. This task opens within Guided Setup when you select **Configure**. If you prefer, you can follow the instructions below to access the same configuration task outside of the Guided Setup.

Procedure

1. Navigate to the System Properties table by typing `sys_properties.list` in the navigation filter and pressing **Enter**.
2. Locate the following property: sn_deploy_pipeline.change_management.default.template.
   To change the value of this property, and therefore the default template used for change requests, you must identify the **sys_id** of the referenced template in the change template that you want to switch to.
   a. Navigate to **All** > **Change** > **Standard Change** > **All Templates**.
   b. Select the update personalized list icon ( ) from the list header.
   c. In the Available column, select **Template** and use the move icon ( ) to add it to the Selected column.
   d. Select **OK**.
   e. Select the value in the **Template** field of the change template that you want to make the default for app deployments.
   f. Right-click in the header bar for the template record and select **Copy sys_id**.
3. In the **sn_deploy_pipeline.change_management.default.template** property, paste the sys_id you have copied into the **Value** field, replacing its current contents.
4. Select **Update**.
5. In the Pipelines and Deployments Guided Setup, in the **Configure Change Template** section, select **Mark Complete**.

Configure CI creation subflow

Customize how Configuration Items (CIs) are created during application deployment using AEMC.

Before you begin

Role required: admin

About this task

By default, the **Create CMDB CI if not present** subflow will run automatically during deployment to create a CI if for your application if it doesn't exist. However, you can change how Configuration Items (CIs) are created during deployment by using the following steps.

Procedure

1. Navigate to the System Properties table by typing `sys_properties.list` in the navigation filter and pressing **Enter**.
2. Locate the following property:
   sn_deploy_pipeline.change_management.config_ci_creation_subflow.
   To change the value of this property, and therefore the template that's being used, you must identify the **sys_id** of the subflow you want to switch to.

a. Navigate to **All** > **Flow Designer**.

b. Select the **Subflows** tab.

c. In the **Name** column, search for and open `Template: Create CMDB CI if not present` or `Create CMDB CI if not present`.

d. Select the More Actions menu icon ( ), and select **Copy subflow**.

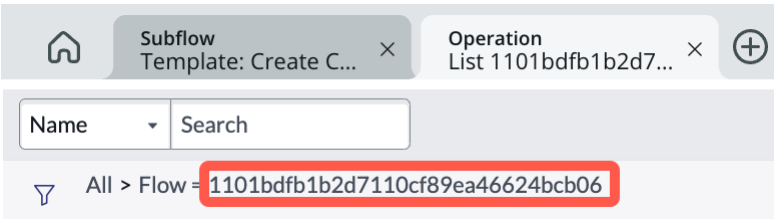
e. Enter a name for the subflow, and make sure the application is in the **Deployment Pipeline** scope.

f. Select **Copy**.

g. Modify the subflow, and select **Save**.

h. To find the sys_id of the subflow, select the More Actions menu icon ( ), and select **Executions**.

i. Copy the sys_id.
The sys_id is listed at the top of the page, after **All> Flow=**.



3. In the **sn_deploy_pipeline.change_management.config_ci_creation_subflow** property, paste the sys_id you have copied into the **Value** field, replacing its current contents.
4. Select **Update**.
5. In the Pipelines and Deployments Guided Setup, in the **Configure CI Creation Subflow** section, select **Mark Complete**.

Cloning instances with AES

Learn how to protect the data, tables, and templates you've created in App Engine Studio when using System Clone to copy instances from production to non-production.

Preserving data and tables when cloning

The following are requirements for cloning instances with AES:

1. Ensure that all of your AES plugins are installed across all instances.
2. If you're cloning a production instance, verify that you've set up a data preserver on the target instances to preserve the Automated Test Framework (ATF) and Instance Scan properties. For more information about data preservers, see Data preservation on cloning target instances.

> **Important:**
> By default, the ATF system property is disabled to prevent you from accidentally running these tests on a production system. Running ATF on a production instance is neither recommended nor supported due to the potential for data corruption or outages.

3. If you're collecting development and deployment data, the App Engine Management Center (AEMC) plugin must be installed on all instances.

Cloning data and tables from a production instance over a non-production instance can overwrite data in your non-production tables. To ensure that data isn't lost in development environments, create a cloning strategy for collaboration.

1. The following tables have data preservation to ensure that the tables are correctly cloned between instances:

   > **Note:**
   > For the following tables, preservation is for global scope only.

   - Collaboration Descriptor tables:
     - App Collaboration Descriptors (sys_appcollab_descriptor)
     - App Collaboration Descriptor Permissions (sys_appcollab_permission_m2m)
   - Collaboration Users and Groups tables:
     - App Collaboration Users (sys_appcollab_user)
     - App Collaboration Groups (sys_appcollab_group)

   The data preservation ensures data is retained on the tables in the development instances.
2. The following tables have clone exclusions:
   - Collaboration Descriptor tables:
     - App Collaboration Descriptors (sys_appcollab_descriptor)
     - App Collaboration Descriptor Permissions (sys_appcollab_permission_m2m)
   - Collaboration Users and Groups tables:
     - App Collaboration Users (sys_appcollab_user)
     - App Collaboration Groups (sys_appcollab_group)

   Clone exclusions ensure data from production instances isn't copied to development instances.
3. If AES is the only application using the Credentials table, consider creating data preservers for Credential Alias, Basic Auth, and Discovery credentials. Otherwise, you must ensure that these tables aren't overwritten when the production instance is cloned to non-production instances.
4. The following users must be reassigned their roles after cloning:
   - Users in the AES Users group
   - Users in the AES User Limited group
   - Users who have the sn_app_eng_studio.user role in non-production instances
5. After cloning, a **ReSync Collaborations Permissions** post-clone clean-up script runs automatically, so any applications that were the same on production and development instances are automatically have collaborators synced. Developers can resume development on them immediately.

Note:
The cloned instance must have the collaboration plugin enabled.

6. If some applications were backed up prior to cloning and retrieved after cloning, you can use the **Resync collaboration permissions** related link on the sys_app record to reassign users and groups to their appropriate delegated development permissions.
7. If a collaboration descriptor is no longer associated with a user or group after cloning (in the event that development apps were wiped out during cloning as they were not in the source instance), select the **Clean up records with empty references** related link to remove the unreferenced user or group from the collaboration table. You should run this UI action after the cloning is done and all preserved applications have been retrieved (with **Resync collaboration permissions** already run on them).

The following tables have data preservation to ensure that the tables are correctly cloned between instances:

- Pipeline Instance
- Request Authorization Key
- Deployment Request
- Deployment Environment Request

Preserving app templates when cloning

Admins must protect custom templates from being overwritten during the cloning process. Without protection, templates created in AES (both from existing applications and from scratch) are in danger of disappearing during a clone.

When you create a template in AES, a scoped app is automatically generated on the Custom Applications [sys_app.list] table in your instance. Though they have different contents, template applications and standard custom applications are treated similarly on the ServiceNow AI Platform. So, preserving app templates during a system clone works the same way as preserving an application.

To protect app templates on your non-production instances, follow the process in Preserve applications and customizations in development during a system clone.

More information on cloning and data preservation

See the following topics for more information on cloning and data preservation:

- For more information on using the System Clone tool, see System clone.
- For more information on data preservation, see Data preservation on cloning target instances.
- For more details on cloning instances with AES, see the App Engine Studio System Administrator Guide on ServiceNow University.

Building apps in App Engine Studio

Meet the business needs of your organization by building custom applications in App Engine Studio (AES).

App Engine Studio build process

At a high level, there are seven main steps for building a new application in App Engine Studio. Select each step to see more information.

Application building process

1. Plan your app development
2. Submit your idea for app development
3. Delegate developers using AES
4. Create your app or Generate your app with Now Assist for Creator
5. Collaborate with other developers

6. Submit your app for approval and publishing
7. Managing app deployments using Pipelines and Deployments

Considerations

There are several considerations to keep in mind as you build applications in App Engine Studio:

- You access App Engine Studio by navigating to **App Engine Studio** > **App Engine Studio** or with the following web address: `<instance-name>.service-now.com/now/appenginestudio`. If you don't have a working link, contact your administrator.
- When you navigate back and forth between different applications in App Engine Studio, the application scope changes accordingly.

Working with data, experiences, automation, and security

App Engine Studio enables you to add as many data tables, types of experiences, logic and automation, and security roles as needed. However, you do not need to add all four categories to your app if the app doesn't need them.

App creation tutorial

This tutorial series guides you through the entire process of building an application using the low-code tools available in the ServiceNow AI Platform.

If you want to build an application that can solve your business problems, the app creation tutorial is your guide to building an application from start to finish. The tutorial walks you through each step of app development, from planning to building and testing. You also learn to use the powerful low-code app development tool, App Engine Studio, and its suite of integrated tools to build and enhance applications easily.

The use case for our tutorial is simple: We want to create an application that automates the employee travel request process for an organization. To do so, we build the application step-by-step, including the data model, user experience, logic and automation, and security for the application.

Each step in the tutorial demonstrates one aspect of app development. You can follow along with the tutorial sequentially or skip to the steps most relevant to you. Use the app creation tutorial and related resources to build your own application.

Complete the tutorial

Step 1	Planning your application
Step 2	Create an app
Step 3	Building a data model
Step 4	Creating user experiences
Step 5	Adding logic and automation
Step 6	Test your application

Planning your application

Plan out your application before building it to streamline the development process.

When you want to build an application, the first thing you should do is develop a plan for the app. Planning involves outlining what the application does and identifying who will use the

application. By planning your application, you can better understand the purpose of your application and address potential issues before development begins.

This is the first step in the app creation tutorial. Follow along to develop a plan for an application that manages employee travel requests for an organization.

Step 1		Planning your application
Step 2		Create an app
Step 3		Building a data model
Step 4		Creating user experiences
Step 5		Adding logic and automation
Step 6		Test your application

https://player.vimeo.com/video/964898255?badge=0&autopause=0&player_id=0&app_id=58479

Video sections

Timestamp	Section
0:17	Identify the use case for your application.
0:21	Visualize the workflow for your application.
0:42	Outline the functional requirements for your app.

Step 1: Identify the use case for your application

Start by identifying the use case for your application. In our tutorial, we're creating an application to manage employee travel requests for an organization. The app automates the entire travel request process and involves users such as employees, managers, regional heads, and travel desk agents as needed.

Consider the problem that you aim to solve with your application. To determine if your use case is a good fit for the tools featured in this tutorial, see Plan your app development.

Step 2: Visualize the workflow for your application

Once you have identified the use case for your application, visualize the end-to-end workflow for the application. The end-to-end workflow is the sequence of actions an application follows to complete a task or process.

The following visualization demonstrates the end-to-end workflow for the employee travel request application in our tutorial:

To visualize the end-to-end workflow for your application, map out what your application does from start to finish. Include any loops that lead back to earlier steps in the workflow and any actions that cause you to exit the workflow.

Step 3: Outline the functional requirements for your app

It's also important to consider the functional requirements of your application. The functional requirements of an application include who uses the application, what tasks they perform in the app, and what data the app must collect to support these tasks.

Use the following prompts to outline the functional requirements for your application:

1. Identify the personas who use your application and consider what tasks they perform.

   In our tutorial, the personas who use the employee travel request application and their associated tasks are:

Persona	Tasks
Employees	Submit travel requests
Managers and regional heads	Approve or deny travel requests
Travel desk agents	Book travel and complete follow-up tasks

2. Determine the data that your application must collect.

   For example, the application in our tutorial must collect details about employees' travel requests, including:

   - Where the employee is traveling to and from
   - When the travel occurs
   - How much the travel costs

3. Choose the process or processes that you want to automate in the workflow for your application using logic and automation.

   Review the following table to see how we plan to use logic and automation in our tutorial application.

	What it does	Tutorial application example
Logic	Controls how and when certain actions occur in your application workflow.	Verifies that an employee's travel request is only forwarded to the travel desk after it has been approved by both the manager and the regional head.
Automation	Sets up automatic processes based on the logic that you define.	Updates the employee's travel request case status and sends email notifications whenever a travel request is rejected.

4. Consider the roles and permissions for your application.

   Roles determine whether users have access to application content. Permissions are the individual abilities that a user has within application content, such as creating, reading, updating, and deleting. You can determine the roles for your application and configure permissions for each role at a later step in the tutorial. For more information about roles in App Engine Studio, see Configure AES personas and roles.

5. Think about how you want to organize the data collected by your application.

   The data that your application collects is automatically stored in tables. You might want to organize the data across different tables, depending on the processes that your application completes. You can decide how you want to organize the data for your application a later step in the tutorial. For more information about data organization in App Engine Studio, see Create a data model for your application.

Next steps

Once you've developed a plan for your application, you can begin building the application in App Engine Studio. Proceed to the next step: Create an app.

Create an app

When you're ready to start building your application, begin creating your application in App Engine Studio.

Before you begin

Note:
To create apps in AES, you must be an admin or in the App Engine Studio Users group. If you are in the App Engine Studio User Limited group, you can only edit existing apps, not create new ones.

Role required: admin, sn_app_eng_studio.user

About this task

Once you've developed a plan for your application, you can start building it in App Engine Studio. App Engine Studio is a powerful tool that enables you to develop robust applications in a low-code environment.

This is the second step in the app creation tutorial. Follow along to create an application in App Engine Studio.

Step 1	✓	Planning your application
Step 2	○	Create an app
Step 3	○	Building a data model
Step 4	○	Creating user experiences
Step 5	○	Adding logic and automation
Step 6	○	Test your application

https://player.vimeo.com/video/953654187?badge=0&autopause=0&player_id=0&app_id=58479

Video sections

Timestamp	Section
0:06	Open App Engine Studio.
0:10	Create an application.
0:14	Name your application and provide additional details.
0:24	Review, add, and customize roles.
0:36	Go to your application dashboard.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. On the App Engine Studio home page, select **Create app**.
3. Enter a unique **Name** and **Description** for your application.
   We enter the following details for the application in our tutorial:

Field	Value
Name	`Travel request`
Description	`Enables employees to submit travel requests`

4. **Optional:** Upload a logo for your application by dragging an image into the **Drag app logo or browse to upload** field, or by selecting the field, selecting the image from your file directory, then selecting **Open**.

   Tip:
   You can add a logo for your application later using the **Application Properties** menu.

5. Select **Continue**.

6. Control who has access to content in your application by reviewing, adding, or customizing roles.
   By default, App Engine Studio provides admin and user roles. To add more roles to your application, select **Add a role**, and enter a name and description for the role.
   In our tutorial, we use the default roles and permissions. We don't add additional roles.
7. Select **Continue**.
8. On the summary screen, select **Go to app dashboard** to continue setting up your application.
   Your application dashboard displays each part of your application, including **Data**, **Experience**, **Logic and automation**, and **Security**. You'll configure these parts of your app in later steps of the tutorial.

Result

You've created an application in App Engine Studio. The application is empty and ready for configurations.

What to do next

Now that your application is created, you can start building the data model for the application. Proceed to the next step in the tutorial: Building a data model.

Building a data model

After creating an application, start building the data model for the application. Learn about what a data model is and how we build the data model for the tutorial application.

Once you have created an application in App Engine Studio, you can start configuring each part of the application. In our tutorial, we start with the data model for the application.

This is the third step in the app creation tutorial. In this step, you learn about data models and build the data model for the employee travel request application.

Step 1	✓	Planning your application
Step 2	✓	Create an app
Step 3	○	Building a data model
Step 4	○	Creating user experiences
Step 5	○	Adding logic and automation
Step 6	○	Test your application

Overview of data models

The data model for an application describes the data that the application reads and writes and how the data is stored. To build a data model, you can create tables to store the data for your application. Each table contains rows that represent individual records and columns that define the type of information within each record. You can create as many tables as needed for your application and define relationships between the tables.

For more information about building data models in App Engine Studio, see Create a data model for your application.

Tutorial data model

In our tutorial, the data model for our application stores information about employees' travel requests, such as where the employee is traveling to and how much the travel costs.

We build the data model for the application in our tutorial in three phases:

Phase 1	Create a data table
Phase 2	Configure a data table
Phase 3	Share data between tables

Next steps

Start building the data model for your application. Proceed to the next step Create a data table.

Create a data table

Create a table to store the data for your application.

Before you begin

Role required: admin, sn_app_eng_studio.user, or delegated developer

About this task

The first phase in building the data model for the employee travel request application is to create a table. In our tutorial, we create a blank table that extends the Task table.

Phase 1		Create a data table
Phase 2		Configure a data table
Phase 3		Share data between tables

This procedure covers the first part of the task demonstrated in the tutorial video. The rest of the procedure is outlined in the next topic Configure a data table.

Follow along to create a table for the employee travel request application.

https://player.vimeo.com/video/967024604?badge=0&autopause=0&player_id=0&app_id=58479

Video sections

Timestamp	Section
0:10	Create a data table.
0:14	Create a table by extending the Task table.

Video sections (continued)

Timestamp	Section
0:21	Define table properties.
0:33	Add permissions to your table.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. Select the travel request application.
3. On the application dashboard, select **+ Add** next to **Data**.
4. Select **Create a blank table**.
   A blank table enables you to create the fields, rows, and columns in your table from scratch. You can import existing data, such as spreadsheets or PDFs, to create the table for your application.
5. Select **Continue**.
6. Select **Create from an extensible table**.
   Extensible tables are tables with built-in capabilities and functionality that you can use to create new tables. If you don't want to create a table from an extensible table, you can create a table from scratch by selecting **Create new table**.
7. Select **Task** from the **Table** list.

   The Task table is one of the commonly extended tables in the ServiceNow AI Platform. The Task table includes built-in functionality for approvals and assignments, which we need for the table in our tutorial application.

8. Select **Continue**.
9. Define the properties of your new table.
   We define the following properties for the table in our tutorial:

Table properties

Field	Description	Tutorial table properties
Table label	Unique label to identify the table.	`Travel request`
Table name	Database name for the table. Auto-populates based on the **Table label** that you provided.	No action needed
Table name prefix	Database prefix for the table. Auto-populates based on the application that you created the table in.	No action needed
Make extensible	Option to enable other tables to share data from this table. For more information, see Table extension.	No action needed
Auto-number	Option to track table records with a unique number.	Select the check mark
Prefix	Abbreviated name of the table to append to the beginning of record numbers.	`TRA`
Starting number	Number to identify the first record created for your table.	No action needed
Number of digits	Maximum number of digits for the record number.	No action needed

10. Select **Continue**.
11. Control who has access to content in the table by adding permissions to each existing role, or creating new roles.

> **Note:**
> At least one role must have read access for you to be able to preview the table.

In our tutorial, we grant the following permissions to the admin and user roles.

Role	Permissions
Admin	**All**
User	○ **Create** ○ **Read**

12. Select **Continue** to add the roles to your new table.
13. Select **Edit table** to continue setting up your new table.

Result
You have created a table for your application.

What to do next
Complete the setup of your table by proceeding to the next phase: Configure a data table

Configure a data table

Configure a table to capture the necessary data for your application.

Before you begin
Role required: admin, sn_app_eng_studio.user, or delegated developer

About this task
The second phase in building the data model for the employee travel request application is to configure the table so that it collects the necessary data for employee travel requests, such as location, dates of travel, and estimated airfare.

Phase 1		Create a data table
Phase 2		Configure a data table
Phase 3		Share data between tables

This procedure covers the second part of the task demonstrated in the tutorial video. The first part of the procedure is outlined in the previous topic Create a data table.

Follow along to configure a table to store the necessary data for the employee travel request application.

https://player.vimeo.com/video/967024604?badge=0&autopause=0&player_id=0&app_id=58479

Video sections

Timestamp	Section
0:48	Begin editing your table.

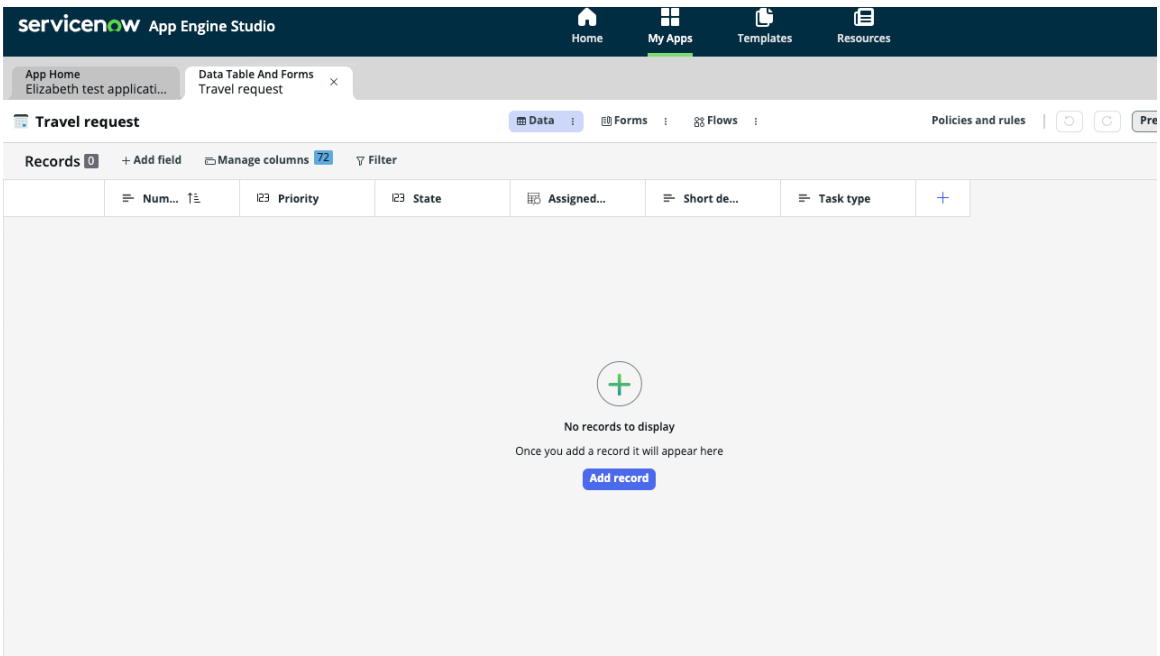
Video sections (continued)

Timestamp	Section
0:54	Add and configure fields in your table.
2:32	Change the data form layout.
2:39	Save your changes.

Procedure

1. Ensure that the employee travel request table is open.
   - To open a table from your instance home page, navigate to **All** > **App Engine** > **App Engine Studio**. Then select your application and select the table that you want to configure.
   - To open a table that you have just created, select **Edit table**.

   When your table is open, it appears in the canvas space.



2. Select **Forms** in the top ribbon to change your view to **Forms** view.

   Forms view enables you to create your table as a form. You can choose other views depending on the type of data that your table stores.

3. Remove any unnecessary fields from your table by hovering over the field, then selecting the delete field icon ( ).

> **Note:**
> When you create a table from an extended table, the table comes with preconfigured fields. You can choose to keep or remove any preconfigured fields in your own table.

In our tutorial, we remove the following fields:

- **Priority**
- **Configuration item**
- **Parent**
- **Assigned to**

4. Select **Save**.
5. Create new fields for your table.
   We must create several fields to collect details about employees' travel requests.

   a. Select **+ Add a field in the table** in the **Add form elements** panel.

   b. In the **Column label** field, enter `Departure Date`.

   > **Tip:**
   > The **Column name** field auto-populates based on the column label that you enter.

   c. In the **Type** field, select **Date**.

   d. **Optional:** To set additional properties for the field, select **Advanced settings**.
   We don't set additional properties for the fields in our tutorial. For more information about field types and advanced settings, see Field configuration in Table Builder.

   e. Select **Add**.

   f. **Optional:** Select **Add another one** to create additional fields.

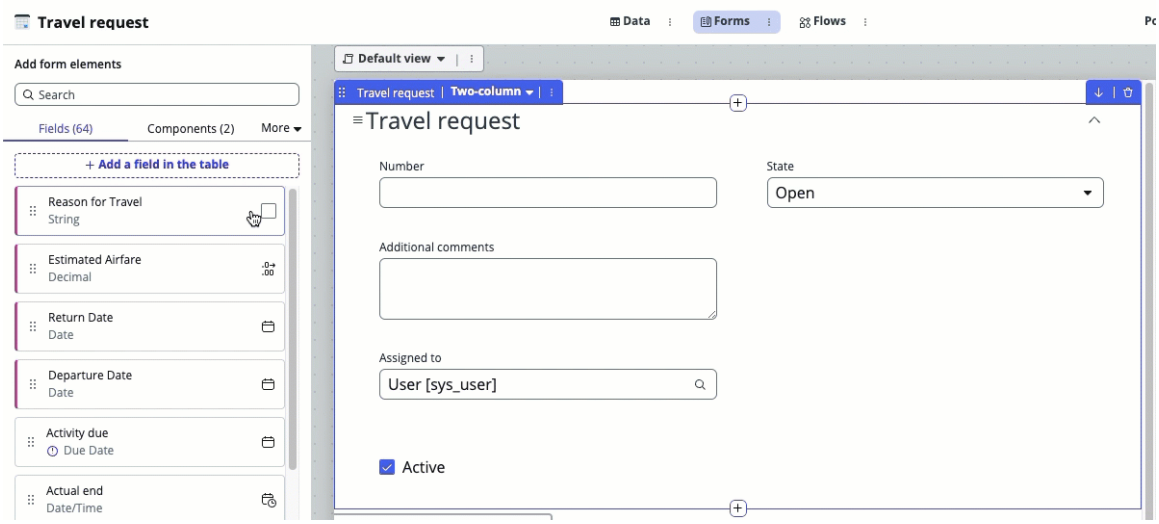
   g. Repeat the process in steps a-f to add as many fields as you need.
   We add more fields to collect additional information about employees' travel requests. The following table outlines the additional fields that we add to our table:

Column label	Type
`Return Date`	Date
`Estimated Airfare`	Decimal
`Reason for Travel`	String

   h. When you have added all of the new fields that you need, select **Done**.
   The fields that you have added will appear in the **Add form elements** panel.

   i. To add the fields to your form, select the fields, then drag them into the **Default view** panel with your existing fields.

Tip:
To add multiple fields to your table at once, hover over the field, select the check mark in each field, then drag the fields into the **Default view** panel.



6. Select **Save**.
7. Add pre-existing fields to your table.

   a. Search for the fields that you want to add by entering the names of the fields in the search bar.

   In our tutorial, we add the following fields to our table:

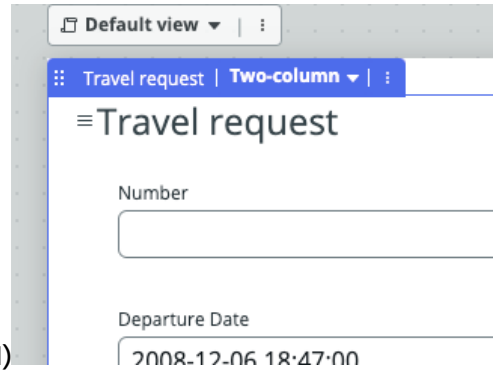
   - `Approval`
   - `Opened by`

   b. Select the field in the **Add form elements** panel, then drag the field into the **Default view** panel.

8. **Optional:** Change the layout of the form.

   a. Select your table in the **Default view** panel.
   When selected, your table appears with a blue border.

(Optional)



b. In the **Section** customization panel, select **One column**, then select **Two columns** to arrange the form fields evenly into a two-column layout.

> **Tip:**
> For more information about the customization options available in the **Section** panel, see Customize your form layout in Table Builder.

9. **Optional:** Arrange the table fields into the order that you want them to appear by moving the fields.
   In our tutorial, we arrange the fields into the following order:
   a. Number
   b. Opened by
   c. Departure Date
   d. Return Date
   e. Reason for Travel
   f. Estimated Airfare
   g. Approval
   h. Status
10. Select **Save**.
11. **Optional:** Select **Preview** to review how your form appears.

Result
Your table is configured to capture the necessary data for employee travel requests.

What to do next
To complete the data model for the employee travel request application, we must connect the travel request table to a separate table that stores airport data. Proceed to the next step: Share data between tables.

Share data between tables

Share data between tables to avoid data duplication.

Before you begin
Role required: admin, sn_app_eng_studio.user, or delegated developer

Select the following link to download the material needed for this step in the app creation tutorial.

App creation tutorial airport spreadsheet

About this task

The final phase in building the data model for the employee travel request application is to link the travel request table to a separate table that stores airport data. Doing so enables employees to choose which airports they want to use when they complete employee travel requests.

Phase 1	✓	Create a data table
Phase 2	✓	Configure a data table
Phase 3	○	Share data between tables

Storing data in multiple tables enables you to keep your data organized and modular. When you want to share data between tables you can create reference fields, which pull records from one table into another without duplicating the data.

Download the airport spreadsheet and follow along with the tutorial to create references fields between the employee travel request and airport tables.

https://player.vimeo.com/video/967025312?badge=0&autopause=0&player_id=0&app_id=58479

Video sections

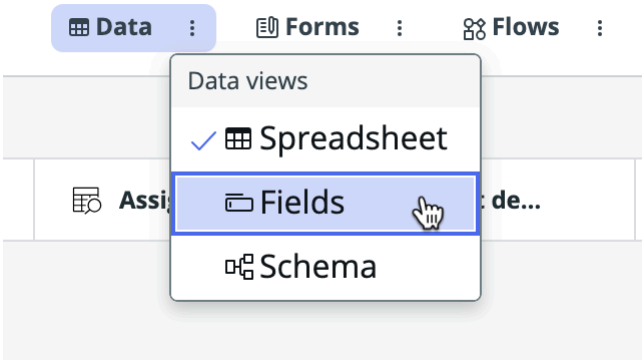
Timestamp	Section
0:03	Create a table to store the data that you want to reference.
0:26	Configure the table.
1:05	Open your existing table.
1:13	Add new fields to the existing table.
1:19	Set the field type to **Reference** and select the table that you want to pull data from.
1:36	Save your changes.
1:38	Add the new reference fields to your table in **Form** view.
1:59	Customize the form layout.
2:10	Save your changes.

Procedure

1. Create a new table to store airport information.
   In our tutorial, we create a new table from a spreadsheet that stores airport information. To follow along with the tutorial, download the airport spreadsheet. Then use the procedures in Import a spreadsheet and Create new table from spreadsheet import to create a new table from the airport spreadsheet.
2. Customize the table so that it displays the information that you want to reference.

a. Select the airport table from your application dashboard in App Engine Studio.

b. On the table landing page, select the More actions icon (⋮) next to **Data** in the top ribbon, then select **Fields**.



c. On the **Fields** page, in the **Name** field, toggle on the **Display** switch ( ) to enable other tables to reference airport names.

> **Important:**
> You can select only one field to be referenced by other tables. If you attempt to select multiple fields, Table Builder keeps only one of your selections when you save your changes.

d. Select **Save**.

3. Navigate to your application dashboard in App Engine Studio.
4. Select the employee travel request table, where you'll create the reference fields that pull data from the airport table.
5. On the table landing page, select the More actions icon (⋮) next to **Data**, then select **Fields**.
6. Create the reference fields.
   In our tutorial, we create two reference fields to collect airport choices for employee travel requests.

   a. On the **Fields** page, select **+ Add a field in the table**.

   b. In the **Column label** field, enter `Travel From`.
   The **Column name** field auto-populates based on the label that you entered.

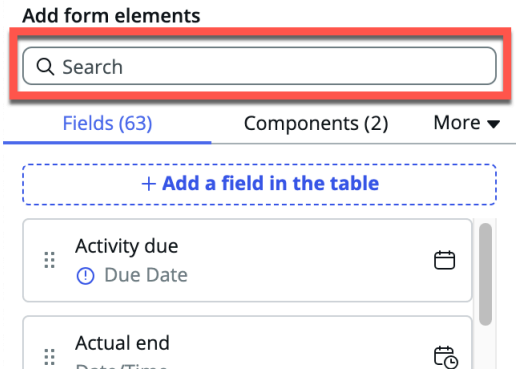
   c. In the **Type** column, select **Reference**, then select the airport table from the list.
   In our tutorial, we create another reference field to capture where the employee is traveling to. We label this field `Travel To`.

7. Select **Save**.
8. Add the reference fields to the form view of the table.

   a. Select **Forms** in the top ribbon.

   b. Enter the label of the reference field in the **Search** bar.

In our tutorial, the reference fields are labeled `Travel From` and `Travel To`.



c. Drag the reference fields from the **Add form elements** panel to the **Default view** panel.

9. **Optional:** Repeat the process in steps 6–8 to add as many reference fields as you need.
10. Select **Save**.

Result

The data model for the employee travel request application is complete.

What to do next

Continue building the employee travel request application by proceeding to the next step in the app creation tutorial: Creating user experiences.

Creating user experiences

Create the user experiences for your application. Learn about experiences in App Engine Studio and how we build the user experience for the employee travel request application.

We continue building our application by creating user experiences.

This is the fourth step in the app creation tutorial. In this step, you learn about user experiences and add an experience to the employee travel request application.

Step 1	✓	Planning your application
Step 2	✓	Create an app
Step 3	✓	Building a data model
Step 4	○	Creating user experiences
Step 5	○	Adding logic and automation
Step 6	○	Test your application

Overview of user experiences

User experiences, or interfaces, determine the options for users to access and engage with application content. There are several kinds of experiences that you can add to your application,

such as record producers and portals. For more information about experiences in App Engine Studio, see Add an application experience.

Tutorial user experience

In our tutorial, we add a record producer, which is one of the application experiences available in App Engine Studio. The record producer creates the form that employees will use to submit travel requests.

We build the experience for our application in two phases:

Phase 1	Add a record producer
Phase 2	Configure a record producer

Next steps

Start building the user experience for the employee travel request application: Add a record producer.

Add a record producer

Create a record producer to start building user experiences for the employee travel request application.

Before you begin
Role required: admin or catalog_admin

About this task
The first phase in building the employee travel request application's user experience is to select an experience. In our tutorial, we add a record producer, which enables us to create the form that employees will use to submit travel requests.

Phase 1		Add a record producer
Phase 2		Configure a record producer

This procedure covers the first part of the task demonstrated in the tutorial video. The rest of the procedure is outlined in the next topic Configure a record producer.

Follow along with the tutorial to add a record producer to the employee travel request application.

https://player.vimeo.com/video/953207342?badge=0&autopause=0&player_id=0&app_id=58479

Video sections

Timestamp	Section
0:06	Add an experience.
0:10	Select the record producer experience.

Video sections (continued)

Timestamp	Section
0:14	Enter a name and description for the record producer.
0:20	Create the record producer.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. Select the travel request application.
3. On the application dashboard, select **+ Add** next to **Experience**.
4. Select **Record producer**, then select **Begin**.
5. Define the properties of the record producer.
   a. In the **Name** field, enter `Raise a travel request`.
   b. **Optional:** In the **Short description** field, enter the following description of the record producer: `This request is for employees who are seeking approvals for travel requests`.
6. Select **Continue**.
7. Select **Edit record producer** to continue setting up your record producer.

Result

You have added a record producer to your application. The record producer is ready for configurations.

What to do next

Complete the setup of the record producer by proceeding to the next phase: Configure a record producer.

Configure a record producer

Configure the record producer so that it contains the necessary questions for employee travel requests.

Before you begin

Role required: admin or catalog_admin

About this task

The second phase in building the user experience for the employee travel request application is to configure the record producer. We configure the record producer so that it contains the necessary questions for employee travel requests, such as travel dates, location, and estimated airfare.

Phase 1		Add a record producer
Phase 2		Configure a record producer

This procedure covers the second part of the task demonstrated in the tutorial video. The first part of the procedure is outlined in the previous topic Add a record producer.

Follow along to configure the record producer for the employee travel request application.

https://player.vimeo.com/video/953207342?badge=0&autopause=0&player_id=0&app_id=58479

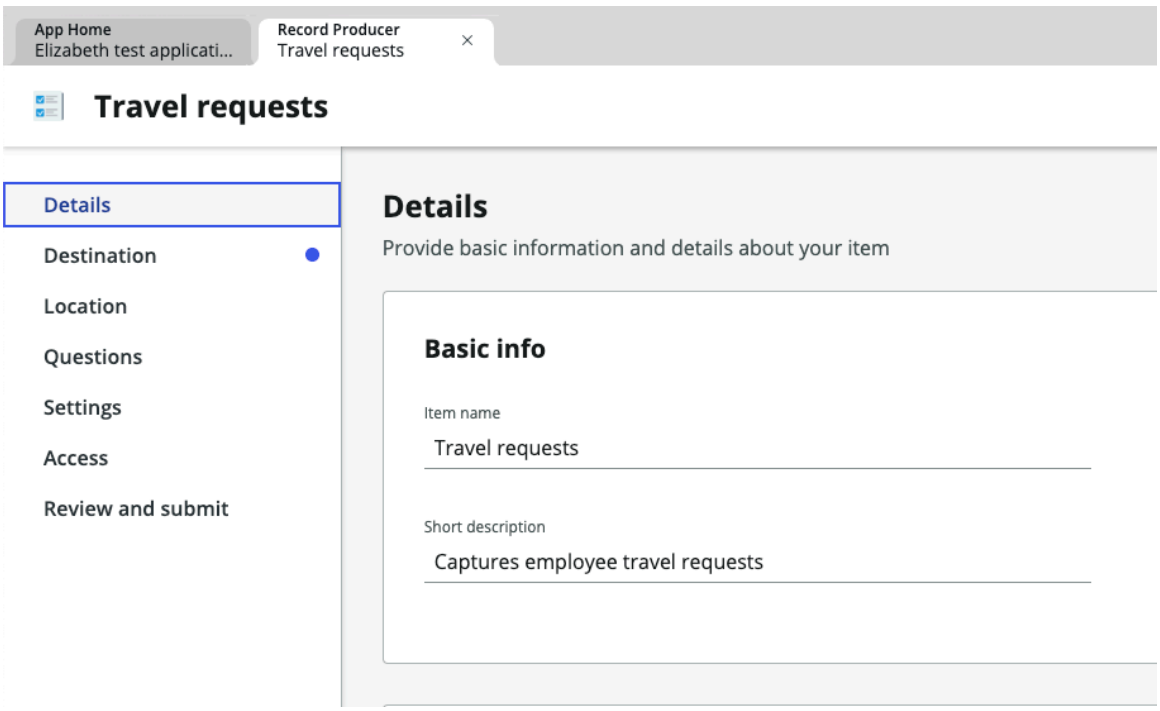
Video sections

Timestamp	Section
0:21	Specify a destination table.
0:32	Choose the location.
0:42	Create question containers.
1:01	Insert questions.
3:49	Preview the record producer.
3:58	Configure settings.
4:05	Select user access.
4:10	Review and submit the record producer.

Procedure

1. Ensure that the travel request record producer is open.
   - To open a record producer from your instance home page, navigate to **All** > *App Engine* > *App Engine Studio*. Then select your application and select the record producer that you want to configure.
   - To open a record producer that you have created, select **Edit record producer**.

   When your record producer is open, it appears in the canvas space.



2. **Optional:** Edit or add details about the record producer in the **Item name** or **Short description** fields.

3. Select **Continue to Destination** to specify the table in which the record producer creates records.
4. Enter `Travel request` in the **Record submission table** field, then select the employee travel request table from the list.
   By setting the travel request table as the destination table, travel requests submitted through the record producer become records in the employee travel request table.
5. Select **Continue to location** to specify the location of your record producer.

   Note:
   Location determines where users can find the record producer. You can locate your record producer in a catalog, such as the Service Catalog, which is a set of business and technical products, services, and offerings that users can order. You can also locate your record producer with a topic, such as a knowledge base article. For more information about locations for record producers, see Creating or editing catalog item template.

   In our tutorial, we locate our record producer in the Service Catalog, so that employees can access the employee travel request form easily.
6. In the **Catalogs** card, select **Browse**.
7. From the **Available options** list, select **Service Catalog** and use the move icon () to add it to the **Selected catalogs** list.
8. Select **Save selections**.
9. Select **Continue to questions** to start building the form questions.
10. Create containers, or sections, for the form questions.
    a. Select the arrow icon () in the **Insert new question** button to expand the menu of available question types.
    b. Select **Single column container** from the list.
    c. In the **Title** field, enter `General Information`.
    d. Select **Submit**.
    e. Repeat the procedure in steps a-d to create as many containers as needed.
    In our tutorial, we create another container for our form questions with the following specifications:

Container type	Title
Two column container	`Travel Details`

11. Add a question to the form.

    Note:
    You can build different types of questions for your record producer. To see the full list of available question types in Catalog Builder, see Create a question for a catalog item in Catalog Builder.

    In our tutorial, we create several questions to collect details about employees' travel requests.

    a. In the correct question container, hover over the plus icon (), then select **+ Insert**.
    In our tutorial, we insert this question in the General Information container.

b. Select **New question**.

c. Select and enter the following values for the new question.

Question type	Question subtype	Map to specific field on table	Table field	Question label	Name	Mandatory
Choice	**Dropdown (fixed values)**	Yes	**Reason for travel**	`What is the reason for travel?`	`reason_for_travel`	Yes

d. Select **Continue to Choices** to complete additional configurations for the question.

e. In the **Available choices** section, hover over the plus icon (), then select **+ Insert**.

f. In the **Display name** field, enter `Customer meeting`.

g. Repeat the process in steps e and f to add additional choices.
In our tutorial, we add two additional choices. The following list includes the names for each additional choice that we add:

- `Internal meeting`
- `Training`

h. Select **Insert question**.

12. Repeat the procedure outlined in step 11 to create as many questions as needed.
In our tutorial, we add the following additional questions to our form in the Travel Details container:

a. We add a question to determine the employee's departure date.

Question type	Question subtype	Map to specific field on table	Table field	Question label	Name	Mandatory	Additional configuratio
Date / Time	**Date**	Yes	**Departure date**	`When are you leaving?`	`departure_date`	Yes	None, select **Insert question**.

b. We add a question to determine the employee's return date.

Question type	Question subtype	Map to specific field on table	Table field	Question label	Name	Mandatory	Additional configuratio
Date / Time	**Date**	Yes	**Return date**	`When are you returning?`	`return_date`	Yes	None, select **Insert question**.

c. We add a question to determine where the employee is traveling from.

Question type	Question subtype	Map to specific field on table	Table field	Question label	Name	Mandatory	Additional configuratio
Choice	**Record reference**	Yes	**Travel from**	`Where are you traveling from?`	`travel_from`	Yes	Select **Source table** > **Airport**.

d. We add a question to determine where the employee is traveling to.

Question type	Question subtype	Map to specific field on table	Table field	Question label	Name	Mandatory	Additional configuratio
Choice	**Record reference**	Yes	**Travel to**	`Where are you traveling to?`	`travel_to`	Yes	Select **Source table** > **Airport**.

e. We add a question to determine the estimated cost of the travel.

Question type	Question subtype	Map to specific field on table	Table field	Question label	Name	Mandatory	Additional configuratio
Text	**Single line**	Yes	**Estimated airfare**	`What is your estimated airfare?`	`estimated_airfare`	Yes	Select **Text validation** > **Number**.

13. Optional: Preview your form by selecting **Preview**.

14. When you're ready to finalize your form, select either **Continue to settings** or the **Settings** tab in the side panel.
15. Select the check box next to any of the following portal settings.
    In our tutorial, we select the check box next to **Hide 'Add to wishlist' button** and **Hide attachment button**. You can select or deselect these settings in your record producer.
    - To prevent users from saving your record producer item to their wish list, select the check box next to **Hide 'Add to wishlist' button**.
    - To hide the component that enables users to provide attachments in the record producer form, select the check box next to **Hide attachment button**.
    - To require users to provide attachments, such as receipts or screenshots for service requests, select the check box next to **Make attachment mandatory**.
16. Select **Continue to access**.
17. **Optional:** Choose from the following options to define which users or groups have access to the form.

    Important:
    If you don't select any users or groups to grant or deny access, your form is available to everyone.

    In our tutorial, we don't grant or deny access to any users or groups.
    - To make the form available to specific users or groups, select **Browse** in the **Available for** card, then search for the users or groups that you want to grant access to. Move the users or groups from the **Available options** list to the **User criteria granted access** list using the move icon ( ).
    - To make the form unavailable for certain users or groups, select **Browse** in the **Unavailable for** card, then search for the users or groups that you want to deny access to. Move the users or groups from the **Available options** list to the **User criteria denied access** list using the move icon ( ).
18. Select **Continue to review and submit** to review and finalize your form.
19. Select **Submit**.

Result
Your record producer is configured and ready for testing.

What to do next
Continue building the employee travel request application by proceeding to the next step: Adding logic and automation.

Adding logic and automation

Add logic and automation to your application. Learn about logic and automation in App Engine Studio and how we automate the employee travel request application.

We continue building the employee travel request application by adding logic and automation.

This is the fifth step in the app creation tutorial. In this step, you learn about logic and automation in App Engine Studio. You build a decision table and create a flow for the employee travel request application.

Step 1	✓	Planning your application

Step 2		Create an app
Step 3		Building a data model
Step 4		Creating user experiences
Step 5		Adding logic and automation
Step 6		Test your application

Overview of logic and automation

Logic and automation enable you to define the actions that your application performs and the conditions that trigger those actions. Logic helps you define when certain actions should occur. For example, your application logic can determine whether support tickets are marked as "critical." Automation then defines the actions that the application performs. For example, if support tickets are marked as "critical", your application automation can move those tickets to the top of the queue.

There are several ways to implement logic and automation in App Engine Studio. Our tutorial focuses on decision tables and flows. To learn about the full range of logic and automation capabilities in App Engine Studio, see Add logic and automation.

Tutorial logic and automation

In our tutorial, we create a decision table and a flow to store the logic and automation for the employee travel request application. Decision tables enable you to set and manage business logic in your application separate from your code. The decision table in our tutorial determines which regional heads receive travel requests based on employees' geographic location.

Flows are automated processes that use a trigger, actions, and logic to define the behavior of an application. The flow in our tutorial defines the sequence of actions that the employee travel request application completes once a travel request is created.

We add logic and automation to our application in two phases:

Phase 1	Build a decision table
Phase 2	Create a flow

Next steps

Start adding logic and automation to the employee travel request application: Build a decision table.

Build a decision table

Build a decision table for the employee travel request application that determines which regional head to route travel requests to.

Before you begin
Role required: admin, decision_table_admin, or delegated developer permissions

About this task

The first phase in adding logic and automation to the employee travel request application is to build a decision table. Our decision table evaluates where an employee is located and uses that information to determine which regional head to route their travel request to.

Phase 1		Build a decision table
Phase 2		Create a flow

For more information about using decision tables, see Create decision tables in Workflow Studio.

Follow along with the tutorial to build a decision table for the employee travel request application.

https://player.vimeo.com/video/953653842?badge=0&autopause=0&player_id=0&app_id=58479

Video sections

Timestamp	Section
0:05	Create a decision table.
0:12	Create a new decision table.
0:13	Enter a unique name and choose the scope for the decision table.
0:28	Add an input.
0:36	Add a condition column.
0:52	Add conditions.
0:59	Add a result column.
1:09	Add results.
1:16	Add more conditions.
1:34	Save your changes.
1:36	Verify that the decision table has been added to your application.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. Select the travel request application.
3. On the application dashboard, select **+ Add** next to **Logic and automation**.
4. Select **Decision**, then select **Begin**.
5. Select **Create a new decision table**.
6. Define the properties of the decision table.

a. Enter `Regional head approvals` in the **Name** field.

b. In the **Accessible from** field, select **This application scope only** to have the logic in the decision table apply to only the selected application.
If you want the logic in your decision table to apply to all applications, select **All application scopes**.

c. Select **Continue**.

7. Select **Edit decision table** to continue setting up your decision table.
8. Add an input to the decision table.

Note:
Inputs define the data that is evaluated in the decision table.

In our tutorial, we set the input as the travel request table so that the decision table can evaluate employee information associate with each travel request.

a. Select **+ Add an input**.

b. In the **Type** field, select **Reference**, then select the travel request table from the list.

c. In the **Label** field, enter `Employee travel requests`.

d. **Optional:** Repeat this procedure to create as many inputs as you need for your decision table.
In our tutorial, we don't create additional inputs.

9. Add a condition column to the decision table.

Note:
Condition columns act as filters that refine the input data by specifying which values should be evaluated by the decision table.

In our tutorial, the condition column refines the input data to evaluate only the employees' country codes. Employees' country codes determine which regional head their travel requests should route to.

a. Select **+ Add condition column**.

b. In the **Condition column label**, enter `Employee regions`.

c. In the **Input** field, select the travel request table input.

d. For **Data to evaluate**, select **Field**.

e. In the **Field** field, select **Opened by** > **Country code**.

f. In the **Default operator** field, select **is one of**.

g. Select **Done**.

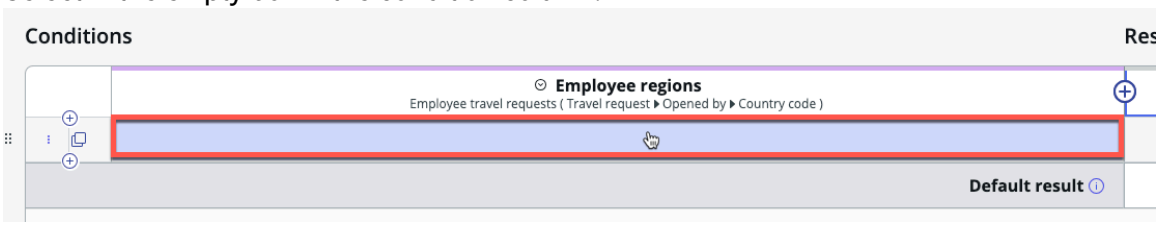
h. **Optional:** Repeat this procedure to create as many condition columns as you need for your decision table.
In our tutorial, we don't create additional condition columns.

10. Define individual conditions for the condition column.

> **Note:**
> Conditions represent the individual values that the decision table evaluates to return results.

In our tutorial, the conditions that we define represent each country that corresponds to a different regional head. We define individual conditions for the countries that make up the Americas (AMS) region, the Asia Pacific (APAC) region, and the Europe, Middle East, and Africa (EMEA) region.

a. Select in the empty box in the condition column.



b. Select **is**, then select **is one of** from the list.

c. In the empty space beneath **is one of**, select **Brazil** and **United States**.

d. Select **OK**.

e. Select **+ Add a new decision row** to add additional conditions to the condition column.

f. **Optional:** Repeat the process in steps a-e to define additional conditions.
In our tutorial, we define two additional conditions for the countries that make up the APAC and EMEA regions. The following table outlines the condition column values that we set:

Operator	Value
is one of	▪ **China** ▪ **Japan**
is one of	▪ **France** ▪ **Germany** ▪ **Italy** ▪ **Spain** ▪ **United Kingdom**

11. Add a result column to the decision table.

Note:
Result columns determine the type of data to return after evaluating the input and condition values.

In our tutorial, the result column determines which regional head to route travel requests to. As the regional heads are individual users in the system, the result column references the User [sys_user] table.

a. Select **+ Add result column**.

b. In the **Result column label** field, enter `Regional heads`.

c. Optional: In the **Description** field, enter a description for the result column.

d. In the **Type** field, enter `Reference`, then select **Reference** from the list.

e. In the **Reference table** field, enter `User`, then select **User [sys_user]** from the list.

f. Select **Done**.

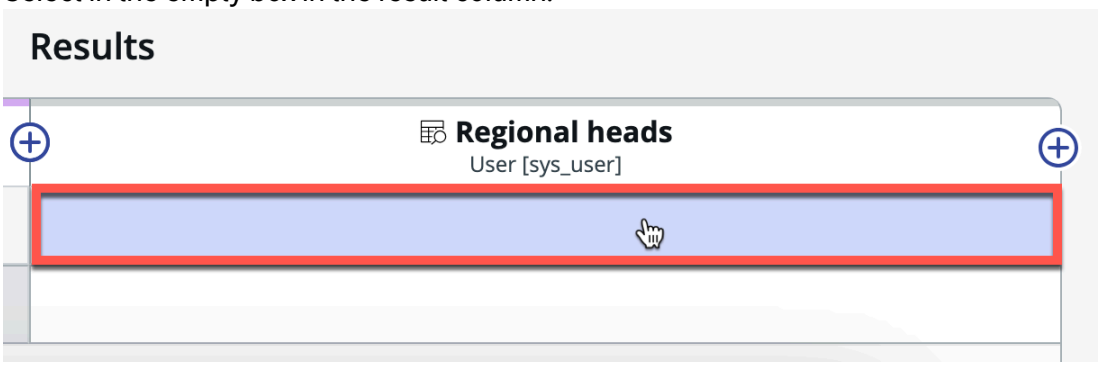
g. Optional: If you want to define additional results for your decision table, repeat this procedure to create as many result columns as needed.
In our tutorial, we don't create additional result columns.

12. Define the results for the result column.

Note:
Results are the individual values, or decisions, that are generated based on inputs, conditions, and results defined in the decision table.

In our tutorial, the results represent the regional heads for each region.

a. Select in the empty box in the result column.



b. In the empty field, enter the name of the regional head.
For the Americas (AMS) region, enter `Lucius Bagnoli`.

c. Select the regional head from the list, then select the Enter key.

d. Optional: Repeat the process in steps a-c to create as many results as needed for the decision table.

In our tutorial, we create two additional results for the APAC and EMEA regional heads. The following table outlines the regional head user information for each region:

Region	User
Asia Pacific (APAC)	`Rob Phil`
Europe, Middle East, and Africa (EMEA)	`Abel Tuter`

13. Select **Save**.
14. **Optional:** Verify that your decision table has been added to your application.
    a. Navigate to your application home page.
    b. Confirm that your decision table appears in the **Logic and automation** section.

Result
You have built a decision table for your application.

What to do next
Proceed to the next phase in adding logic and automation to the employee travel request application: Create a flow.

Create a flow

Automate the workflow for the employee travel request application by creating a flow.

Before you begin
Role required: admin or flow_designer

About this task
The second phase in adding logic and automation to the employee travel request application is to create a flow. The flow that we create automates the workflow for the application after an employee travel request is created.

Phase 1	✓	Build a decision table
Phase 2	○	Create a flow

For more information about flows, see Building flows.

Use the following tutorial to create a flow for the employee travel request application.

https://player.vimeo.com/video/953653961?badge=0&autopause=0&player_id=0&app_id=58479

Video sections

Timestamp	Section
0:09	Add a flow to your application.
0:14	Build the flow from scratch.

Video sections (continued)

Timestamp	Section
0:17	Enter a unique name and description for the flow.
0:22	Continue setting up your flow.
0:25	Create a trigger.
0:41	Add an Ask for Approval action.
1:09	Add If flow logic.
1:25	Integrate decision tables.
1:48	Duplicate repeating actions.
2:17	Add an Update Record action.
2:38	Add Else flow logic.
2:50	Add a Send Email action.
4:14	Add End Flow flow logic.
4:19	View your flow as a diagram.
4:22	Save your changes.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. Open the employee travel request application.
3. On the application dashboard, select **+ Add** next to **Logic and automation**.
4. Select **Flow**, then select **Begin**.
5. Select **Build your flow from scratch**.
   You can also choose to build your flow with Now Assist. For more information, see Create a flow with Now Assist.
6. Define the properties of the flow.
   a. In the **Name** field, enter `Approvals workflow`.
   b. In the **Description** field, enter `Approval workflow for managers and regional heads`.
   c. Select **Continue**.
7. Select **Edit this flow** to continue setting up your flow.
8. Add triggers to the flow.

> **Note:**
> A trigger specifies when to run the flow. When the trigger conditions are met, the system runs the flow using the data provided by the trigger.

In our tutorial, we create a trigger that runs the flow whenever an employee submits a travel request.

a. In the **Trigger** section, select **+ Add a trigger**.

b. In the **Trigger** field, select **Record** > **Created**.

For more information about trigger types, see Workflow Studio flow trigger types.

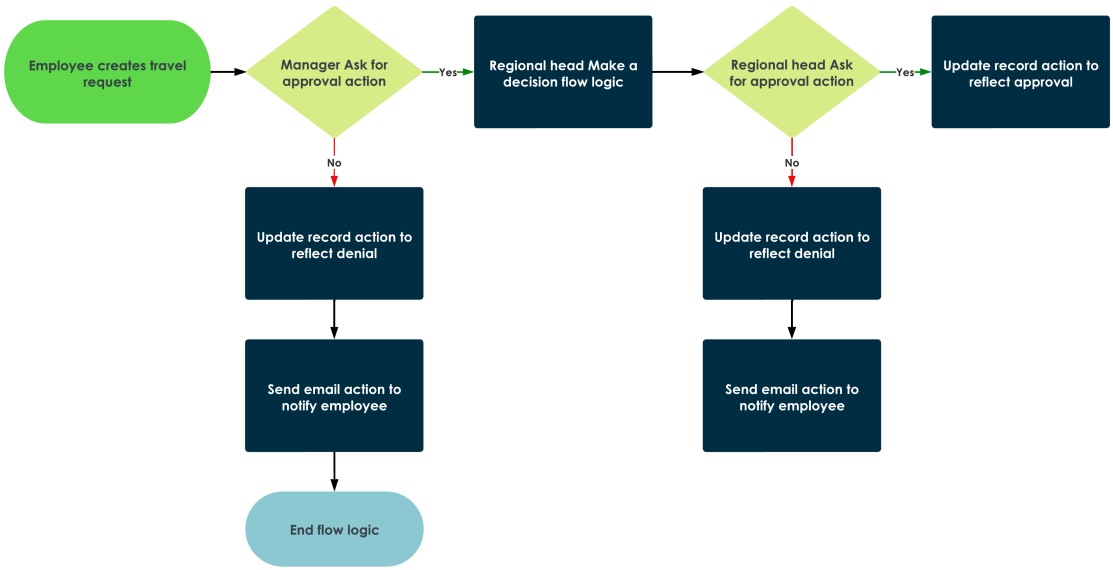
c. In the **Table** field, enter the name of the travel request table and select it from the list.

d. Select **Done**.

9. Add actions, flow logic, and sublows to the flow.

> **Note:**
> You can add actions, flow logic, and subflows to enable your flow to perform desired actions. For example, you can create an action that enables your application to send emails automatically.

In our tutorial, we add several actions and branches of flow logic to automate the employee travel request process. The following diagram demonstrates the flow that we create in our tutorial.



Instructions for adding the actions and flow logic demonstrated in the tutorial are outlined in the following topics.

10. **Optional:** See how your flow appears as a diagram by toggling the switch next to **View**.
11. Select **Save** to save your changes.

Result

You have created a flow that will automate the end-to-end workflow for the employee travel request application.

What to do next

Continue building the flow for the employee travel request application. Proceed to the next step: Add an Ask for Approval action.

Add an Ask for Approval action

Request approvals for any record by adding the Ask for Approval action to your flow.

Before you begin

Role required: admin or flow_designer

About this task

The Ask for Approval action is a ServiceNow Core action template that enables you to request approvals easily. You can specify which records require approval and assign users to approve or reject the record.

In our tutorial, we use the Ask for Approval action to request approvals from both managers and regional head for employee travel requests. This procedure outlines the Ask for Approval action that routes to the manager. The procedure for creating the Ask for Approval action that routes to the regional head is outlined in Duplicate repeating actions.

For more information about the Ask for Approval action, see Ask for Approval action.

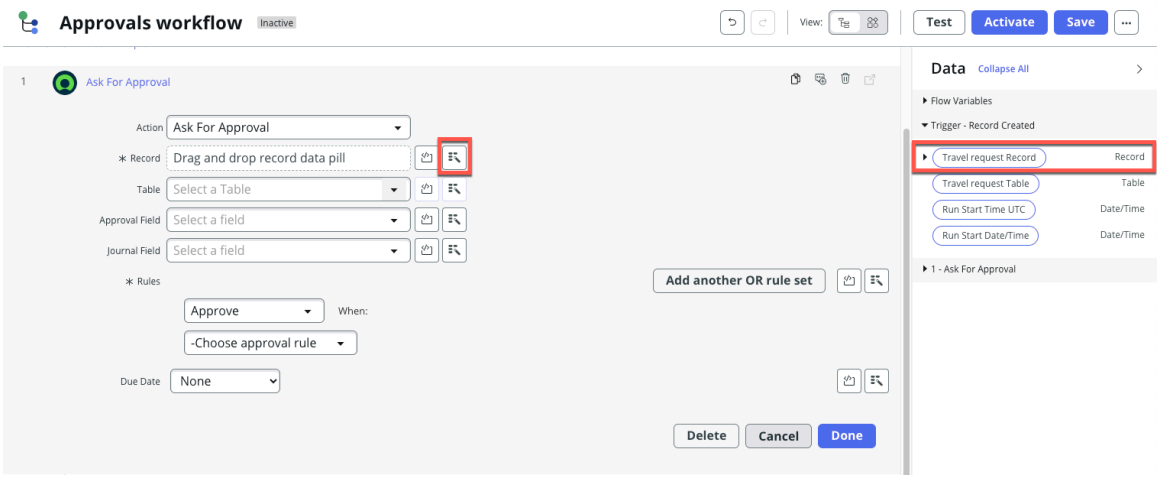
Procedure

1. At the correct location in your flow, select **+ Add an Action, Flow Logic, or Subflow**.
   In our tutorial, the Ask for Approval action that routes to the manager occurs just after the trigger. To see where the Ask for Approval action occurs in the tutorial flow, see the diagram in Create a flow.
2. Select **Action**.
3. From the **ServiceNow Core** options, select **Ask for Approval**.
4. Choose from one of the following options to connect the action to the appropriate trigger.

   Note:
   Some flows have multiple triggers, so you must specify which trigger corresponds to the action.

   In our tutorial, we add the travel request record trigger to the **Record** field, so that the action runs whenever an employee submits a travel request.

   - To add your trigger within the Ask for Approval dialog, select the **Data Pill Picker** (), then select the trigger from the list.
   - To add your trigger from the **Data** panel, drag the data pill that contains the trigger into the **Record** field.



5. Set the rules for the action.

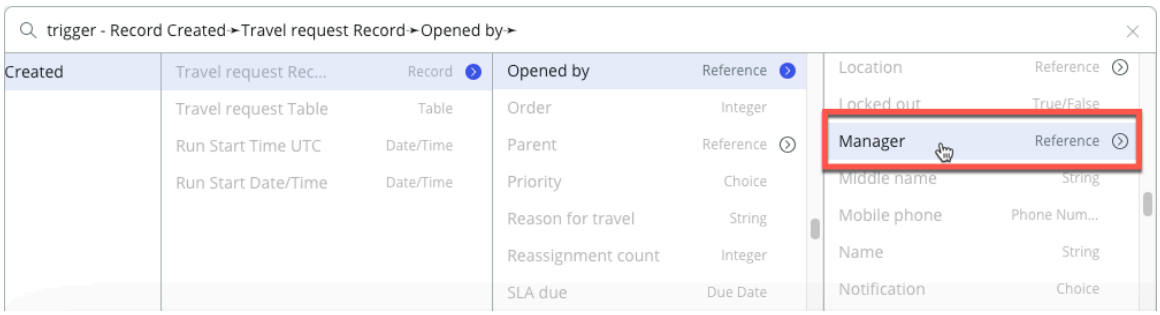
   Note:
   Rules determine which users can approve or reject requests, and what happens after approval or rejection. For more information about the rules available for the Ask for Approval action, see Ask for Approval action.

In our tutorial, we configure the rules for the Ask for Approval action to send travel requests to the manager of the user who submitted the request. The manager can then approve or deny the request.

a. Select the **Approve** field, then select **Approve or Reject** from the list.

b. Select the **-Choose approval rule** field, then select **All users approve or reject**.

c. Choose which users or groups can complete the approval actions using the **Data Pill Picker** ( ), the add user icon ( ), add group icon ( ), the add manual approvers icon ( ), or by dragging data pills from the **Data** panel into the field.
In our tutorial, we want the Ask for Approval action to route to the manager of the user who submitted the travel request. So we select **Trigger - Record Created** > **Travel request Record** > **Opened by** > **Manager**.



The second Ask for Approval action, which you create in Duplicate repeating actions, routes the approval to the regional head.

6. Select **Done**.

7. Select **Save**.

What to do next
Proceed to the next step: Add If flow logic.

Add If flow logic

Use If flow logic to direct your flow to perform actions based on specific conditions.

Before you begin
Role required: admin or flow_designer

About this task
Add If flow logic to your flow to have your application perform actions only when certain criteria are met. If flow logic creates a specific path, or branch, within a flow that runs only when the conditions are met.

In our tutorial, we use If flow logic to define what the application does if a travel request has been approved. For example, if a travel request has been approved by the regional head, the **State** of the travel request record should be changed to **Closed complete**.

There are two instances of If flow logic in the flow in the app creation tutorial: One that represents manager approval and another that represents regional head approval. This procedure covers creating the branch that represents manager approval. You can use this procedure to create the branch that represents the regional head approval and adjust the **Column label** and **Condition** field values accordingly.

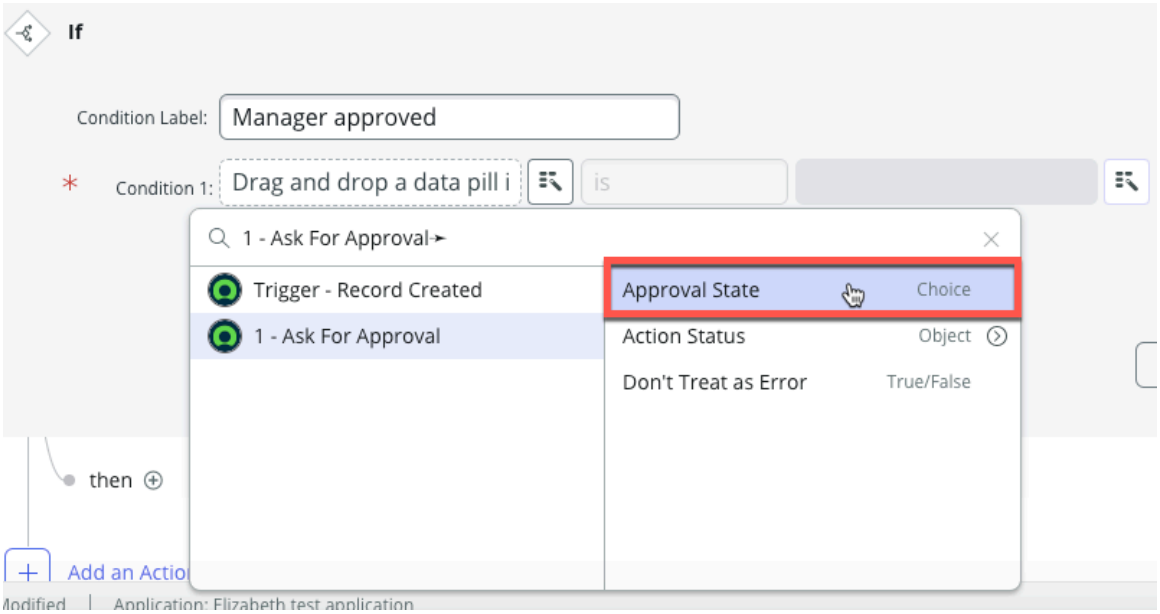
For more information about using If flow logic, see If flow logic.

Procedure

1. At the correct location in your flow, select **+ Add an Action, Flow Logic, or Subflow**.
   The If flow logic that represents manager approval occurs just after the first Ask for Approval action. To see where If flow logic occurs in the tutorial flow, see the diagram in Create a flow.
2. Select **Flow Logic**.
3. Select **If**.
4. **Optional:** In the **Condition label** field, enter a description to describe the conditions that the branch represents.
   In our tutorial, we enter `Manager Approved`, as this branch represents that a manager has approved the travel request.
5. Select the condition under which the branch runs using the **Data Pill Picker** ( ) or by dragging the data pill from the **Data** panel into the **Condition 1** field.

   Note:
   The condition is the data container that the flow evaluates when determining whether to run the branch. You can define one or multiple conditions in If flow logic.

   In our tutorial, we want this branch of the flow to represent what happens if a manager has approved a travel request, so we set the condition to **Approval State**.



6. Define the condition state that enables the branch to run by selecting the fields beside **Condition 1**, then choosing the appropriate values.

   Note:
   The condition state is the actual value of the condition that defines when the branch should run.

   In our case, this branch should run when a travel request has been approved by a manager. So we set the condition state to **is** and **Approved**.
7. Select **Done**.
8. Select **Save**.

Result
By default, If flow logic has no output. It simply evaluates whether a condition is met or unmet. To have your flow complete actions when the conditions in the If flow logic are met, you must add branching actions or flow logic.

What to do next
Proceed to the next step: Integrate decision tables.

Integrate decision tables

Integrate decision tables into your flow using Make a decision flow logic.

Before you begin
Role required: admin or flow_designer

About this task
Make a decision flow logic enables you to integrate decision tables within flows easily. Make a decision flow logic runs the decision table and returns results, which can be displayed as branches in the flow or data pills in the **Data** panel.

In our tutorial, employee travel requests are sent to the regional heads after receiving manager approval. We use Make a decision flow logic to connect the flow to the regional head decision table and retrieve the correct regional information.

For more information about Make a decision flow logic, see Make a decision flow logic.

Procedure

1. At the correct location in your flow, select **+ Add an Action, Flow Logic, or Subflow**.
   We add Make a decision flow logic beneath the branch of If flow logic that represents manager approval. To see where we add Make a decision flow logic in the tutorial flow, see the diagram in Create a flow.
2. Select **Flow logic**.
3. Select **Make a decision**.
4. Select the **Decision table** field, then select the correct decision table from the list.
   In our tutorial, we select the regional head approvals decision table.
5. Choose to select or deselect the check box for **Use Branches**.

   Note:
   If you select the check box for **Use Branches**, the flow displays each possible decision table result as a separate branch.

   In our tutorial, the approval process is the same for each of the regional heads, so we deselect **Use Branches**. If the employee travel request process was different for employees of a certain region, we could select **Use Branches** to represent the different processes based on region.
6. Add the correct trigger to the **Decision table inputs** field using either the **Data Pill Picker**( ) or by dragging the data pill from the **Data** panel into the field.

   Tip:
   When you integrate a decision table into a flow, you must specify the data values for the decision table to evaluate within the context of the flow.

   In our tutorial, we need the decision table to evaluate the user information that's associated with the travel request trigger. So we add our trigger to the **Decision table inputs** field.
7. Select **Done**.

Result
The Make a decision flow logic generates results from the decision table, which you can use in your flow.

What to do next
Proceed to the next step: Duplicate repeating actions.

Duplicate repeating actions

For actions that repeat within your flow, save time by duplicating the actions and adjusting their values as needed.

Before you begin
Role required: admin or flow_designer

About this task
Duplicating actions enables you to build flows more quickly and efficiently.

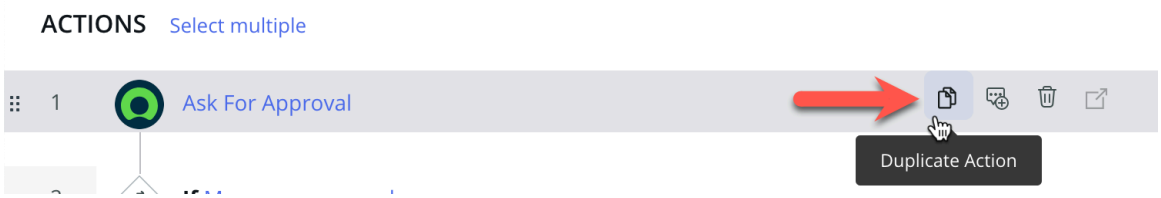
In our tutorial, there are several actions that repeat within the employee travel request flow.

- The Ask for Approval action repeats to request both the manager and regional head approvals for employee travel requests.
- The Update Record action updates the travel request record at several places in the flow, such as when the request is rejected by a manager.
- The Send Email action occurs in two places to notify employees that their travel requests have been rejected by either the manager or the regional head.

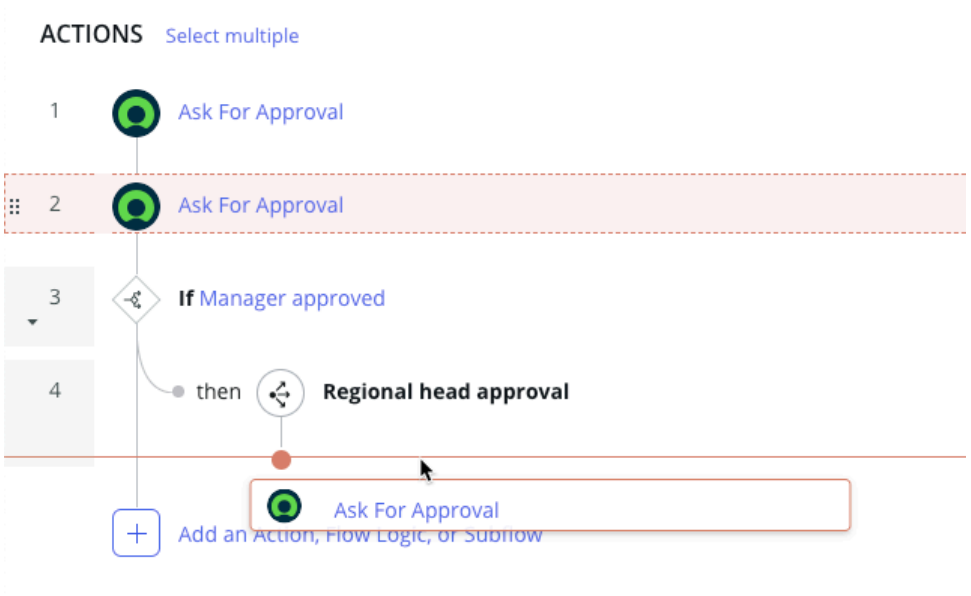
This procedure outlines duplicating the Ask for Approval action to request regional head approval. You can use the steps outlined here to duplicate the other actions that repeat and adjust the action location and field values accordingly.

Procedure

1. Hover over the action that you want to duplicate and select the Duplicate action icon ( ).
   In our tutorial, we duplicate the Ask for Approval action.



2. Move the duplicated action into the correct place in the flow by hovering over the action, selecting the drag icon ( ), and dragging the action into the correct place.
   We move the duplicated Ask for Approval action beneath the Make a decision flow logic that returns the regional head information.



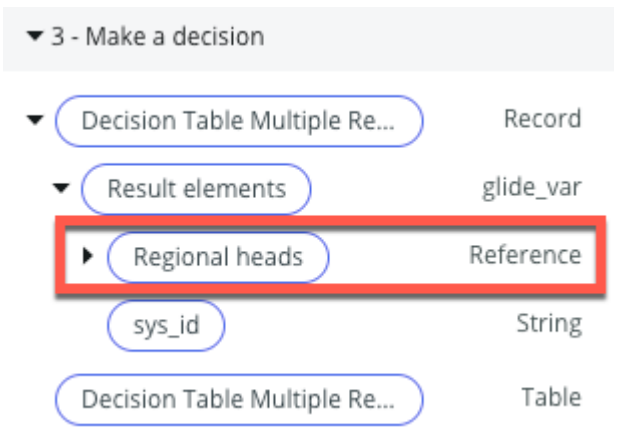
3. Adjust values in the action as needed.

   a. Select the duplicated action to open the action dialog.

   b. Select the remove icon ( ) to remove any field values that you must change.
   In our tutorial, we must change the user that the Ask for Approval routes to. So we select the remove icon ( ) in the data pill that contains the manager user information.

   c. Provide the correct field values by selecting the **Data Pill Picker** ( ) or by dragging data pills from the **Data** panel into the fields.
   To route the Ask for Approval action to the correct regional head, we must add the data pill that contains the regional head information.

   - Using the **Data Pill Picker** ( ), we select **Make a decision** > **Decision Table Multiple Result Record** > **Result elements** > **Regional heads**.
   - Using the **Data** panel, we select and drag the regional heads data pill into the field.



4. Select **Save**.

5. **Optional:** Repeat this procedure to duplicate as many actions as needed in your flow.
   In our tutorial, we also duplicate the Update Record and Send Email actions.

What to do next
Proceed to the next step: Add an Update Record action.

Add an Update Record action

Automate record updates in a flow using the Update Record action.

Before you begin
Role required: admin or flow_designer

About this task
The Update Record action is a ServiceNow Core action template that you can add to your flow to update existing records.

In our tutorial, we use the Update Record action to update the travel request record after it has been approved or rejected. This procedure outlines creating the Update Record action if a travel request has been approved by the manager and regional head. You can use this procedure to create the other Update Record actions and change the fields and field values as needed.

For more information about the Update Record action, see Update Record action.

Procedure

1. At the correct location in your flow, select **+ Add an Action, Flow Logic, or Subflow**.
   We add the Update Record action that represents manager and regional head approvals beneath the If flow logic branch for regional head approval. To see where we add the Update Record action in the tutorial flow, see the diagram in Create a flow.
2. Select **Action**.
3. From the **ServiceNow Core** options, select **Update Record**.
4. Select the record that you want to update by selecting the **Data Pill Picker** ( ) or by dragging the data pill from the **Data** panel into the **Record** field.
   In our tutorial, we want to update the travel request record, so we add the travel request trigger to the **Record** field.
5. Choose the field or fields that you want to update in the record by selecting **Add a field value**, then selecting the field that you want to update from the list.
   In our tutorial, we must update several fields in our travel request record after the request has been approved by the manager and regional head. We select the following fields:
   - **Approval**
   - **Assignment group**
   - **State**
6. Set the desired value of each field that you added by selecting anywhere in the **Select** field, then selecting the correct value from the list.
   In our tutorial, we set the following values for the fields that we added:

Field	Value
Approval	Approved
Assignment group	Travel desk
State	Closed complete

7. Select **Done**.
8. Select **Save**.

What to do next
Proceed to the next step: Add Else flow logic.

Add Else flow logic

In flows with If flow logic, add Else flow logic to create alternate paths when conditions aren't met.

Before you begin
Role required: admin or flow_designer

About this task
Add Else flow logic to define the actions that your flow performs when If flow logic conditions aren't met. Else flow logic creates a path in the flow that runs only when the If flow logic conditions aren't met.

In our tutorial, we add Else flow logic to specify what happens when a travel request is rejected by either a manager or regional head.

Procedure
1. At the correct location in your flow, select **+ Add an Action, Flow Logic, or Subflow**.
   We add Else flow logic at two places in the flow: One beneath the branch of the flow that represents manager approval and another beneath the branch that represents regional head approval. To see where we add Else flow logic in the tutorial flow, see the diagram in Create a flow.
2. Select **Flow logic**.
3. In the **Search flow logics** list, select **Else**.
4. Select **Save**.

Result
By default, Else flow logic has no output. It just creates a branch for the flow to run when the If flow logic conditions aren't met. To have your flow complete actions in the Else flow logic block, you must add branching actions or flow logic.

What to do next
Proceed to the next step: Add a Send Email action.

Add a Send Email action

Automate sending email notifications using the Send Email action.

Before you begin
Role required: admin

About this task
The Send Email action is a ServiceNow Core action template that you can add to your flow to automate sending emails to specified users or groups.

In our tutorial, we add Send Email actions to notify employees that their travel requests have been rejected. This procedure covers the Send Email action that notifies employees that their travel request has been rejected by the regional head. You can use this procedure to create the other Send Email action for the manager rejection and adjust the field values accordingly.

For more information about the Send Email action, see Send Email action.

Procedure

1. At the correct location in your flow, select **+ Add an Action, Flow Logic, or Subflow**.
   We add the Send Email action beneath the Else flow logic that represents regional head rejection. To see where we add Send Email actions in the tutorial flow, see the diagram in Create a flow.
2. Select **Action**.
3. From the **ServiceNow Core** options, select **Send Email**.
4. Add the record that the email is associated with to the **Target Record** field using the Data pill picker ( ), or by dragging the data pill from the **Data** panel.
   In our tutorial, we want the email to be associated with the travel request record in our trigger.
5. Add recipients for the email in the **To** field using the Data pill picker ( ), or by dragging the data pill from the **Data** panel.
   In our tutorial, we want the user who created the travel request to receive the email. The user information is stored under **Trigger - Record Created** > **Travel request Record** > **Opened by**.
6. **Optional:** Add additional recipients to the email in the **CC** and **BCC** fields.
   We don't add additional recipients to the Send Email action in our tutorial.
7. Enter a subject for the email in the **Subject** field.
   In our tutorial, we enter the following subject for the email: `Travel request rejected`.
8. Enter the content for the email message in the **Body** field.

   Tip:
   You can add dynamically created content, or content that is generated within the flow, to the Send Email action. To add dynamic content, drag the data pills from the **Data** panel into the **Body** of the email.

   In our tutorial, the body of our email notifies the employee that their travel request has been rejected and to contact their manager for additional information.
9. Select **Done**.
10. Select **Save**.

What to do next

Proceed to the next step: Add End Flow flow logic.

Add End Flow flow logic

Add End Flow flow logic to stop running the current flow.

Before you begin

Role required: admin

About this task

If you want your flow to end when certain conditions are met, you can add End Flow flow logic. End Flow flow logic can be contained within a conditional flow logic block, such as an If, Else If, or Else flow logic. End Flow flow logic stops running the current flow.

In our tutorial, we add End Flow flow logic to end the flow if a travel request has been rejected.

For more information about End Flow flow logic, see End Flow flow logic .

Procedure

1. At the correct location in your flow, select **+ Add an Action, Flow Logic, or Subflow**.
   We add End Flow flow logic in the branch that represents manager rejection of a travel request.
   To see where we add End Flow logic in the tutorial flow, see the diagram in Create a flow.
2. Select **Flow Logic**.
3. In the **Search flow logics** list, select **End Flow**.
4. Select **Save**.

What to do next

The logic and automation for the employee travel request application are complete. Proceed to the final step in the app creation tutorial: Test your application.

Test your application

Verify that your application works as intended before publishing by testing the application experience and flow.

Before you begin

Role required: admin or flow_designer

About this task

The final step in building an application is testing. There are several ways to test an application, including simulating the user experience and running flow executions to verify that everything works as expected.

This is the last step in the app creation tutorial. In this step, we create a test record in the record producer to verify that it triggers the flow to run. We also verify that approvals route to the correct users and that the flow performs the actions that we defined, such as updating records.

Step 1	✓	Planning your application
Step 2	✓	Create an app
Step 3	✓	Building a data model
Step 4	✓	Creating user experiences
Step 5	✓	Adding logic and automation
Step 6	○	Test your application

For more information about testing your application, see Testing and debugging applications.

Follow along with the tutorial to test the employee travel request application.

https://player.vimeo.com/video/953653889?badge=0&autopause=0&player_id=0&app_id=58479

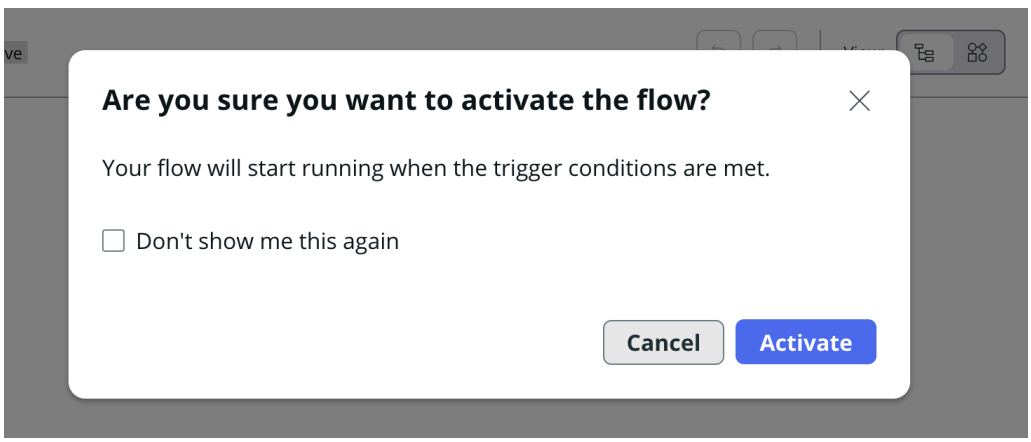
Video sections

Timestamp	Section
0:07	Activate your flow.
0:10	Navigate to your instance home page.
0:15	Impersonate a user to test your user experience.
0:20	Find and open your record producer.
0:26	Create a test record.
0:42	End the impersonation.
0:45	Navigate back to your flow.
0:48	Test your flow using the test record that you created.
0:56	Review the flow execution details.
1:00	Perform additional tests to verify that branching actions and flow logic run correctly.

Procedure

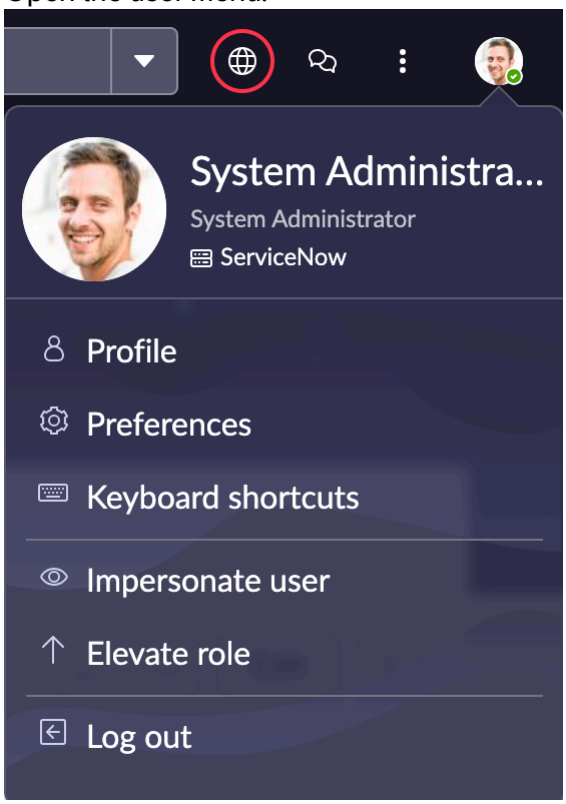
1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. Open your application's flow.
   - If your application isn't already open, navigate to **All** > **App Engine** > *App Engine Studio*. Then open your application and select the flow under the **Logic and automation** heading.
   - If your flow is already open, verify that your changes are saved.
3. Select **Activate**, then select **Activate** again to make your flow available to run.

> **Note:**
> You can also test your flow without activating it by creating a test record within Workflow Studio. For more information about testing before activating your flow, see Test a flow.



4. Navigate to your ServiceNow AI Platform instance home page.
5. Impersonate a user to test that your record producer functions as intended.

a. Open the user menu.



b. Select **Impersonate user**.

c. Select a user from the **Recent Impersonations** list or enter a different user's name in the user selection field.
When testing your application, you should impersonate users who have the permissions required to access the features that you're testing.
In our tutorial, we select a user with regular user permissions, as the record producer that we're testing is accessible to all users.

d. Select **Impersonate user**.
The system updates the user menu and dashboard to reflect the correct information for the user that you're impersonating.

6. On the home page, navigate to **All** > **Self Service** > **Service Catalog**.
7. Select **Services**.
8. Select your record producer from the list.
In our tutorial, we select our record producer called `Raise a travel request`.
9. Complete the record producer fields to generate a test record.
10. Select **Submit**.
11. End the impersonation.
    a. Open the user menu.
    b. Select **End impersonation**.
12. Reopen your application's flow.

a. Navigate to **All** > **App Engine** > *App Engine Studio*.

b. Open your application.

c. Select your flow under the **Logic and automation** heading.

13. Select **Test**.

14. In the **Test Flow** dialog, select the record field, then select the record that you created during the impersonation.

15. Select **Run Test**.
The system runs the flow based on the test record that you selected.

16. Select **Your test has finished running. View the flow execution details**.

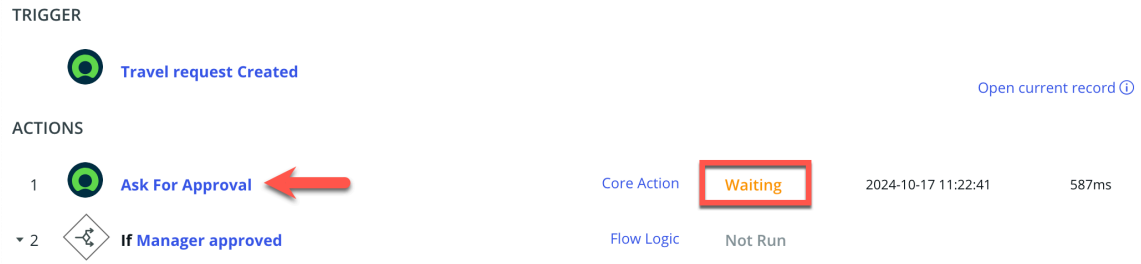
17. Review the flow execution details to verify that your flow runs as intended.
The flow execution details page enables you to view detailed information about an action or flow, such as the run-time, current state, items run, and values produced. For more information about flow execution details, see Flow execution details.

18. **Optional:** Perform additional tests to verify that the flow completes all desired branches of actions and flow logic.

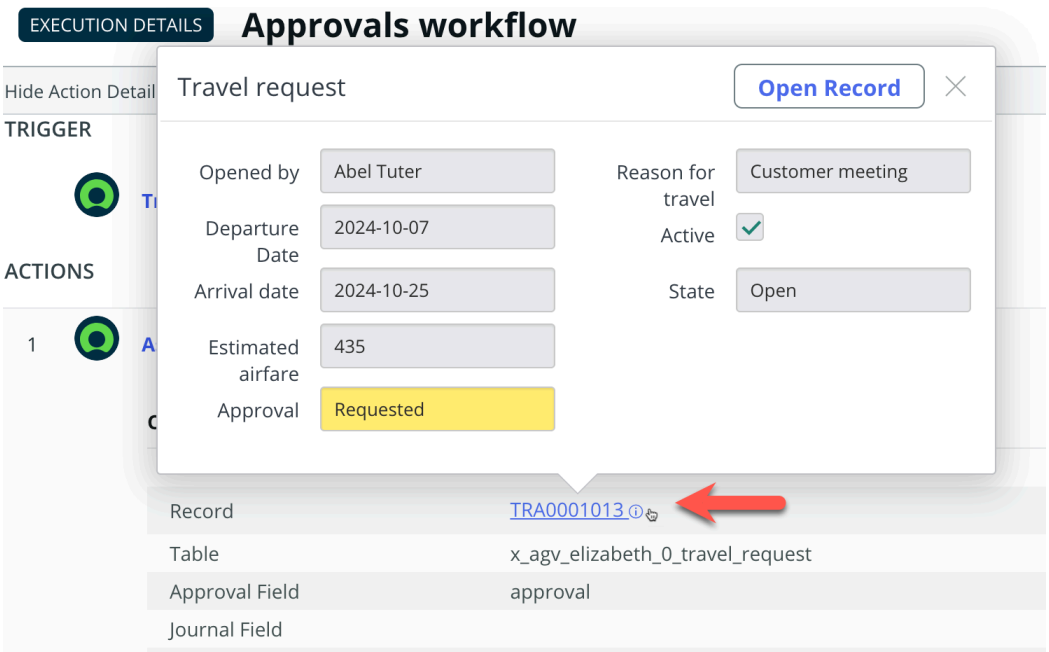
(Optional) For example, if your flow performs an action only after certain conditions are met, you can create those conditions to verify that the branching actions and logic run correctly.

In our tutorial, we simulate the manager's approval to test the branching actions and flow logic.

a. Select the action that is in the **Waiting** state to view the action details.



b. In the action details, select the test record.



c. Select **Open Record**.

d. Open the approval record by selecting the list item in the **Approvers** list.

> **Tip:**
> If your test record page doesn't display the **Approvers** list, you can adjust the page configurations to display any lists that you want to appear. Complete the following steps to configure the lists that appear on your record page.
>
> i. On the record page, select the Additional actions icon ( ).
>
> ii. Select **Configure** > **Related lists**.
>
> iii. Select the **Approvers** list item or any other lists that you want to appear on the record page and move them from the **Available** list to the **Selected** list.
>
> iv. Select **Save**.

e. On the approval record page, select **Approve** to simulate the manager's approval.

f. Navigate back to your flow.

g. Select the refresh icon ( ) to update your flow.

h. Verify that your flow has run branching actions or flow logic based on the additional test that you performed.

19. **Optional:** Complete this procedure to perform as many additional tests as needed to verify that all branches of your flow run correctly.

Result

Your have tested the employee travel request application and verified that it functions as expected.

What to do next

Congratulations! You have completed the app creation tutorial by planning, building, and testing an application.You are ready to start building your own applications in *App Engine Studio*.

To see what tasks you could perform after building an application, such as publishing or managing app deployments, see Publish your app.

Plan your app development

The application development process in App Engine Studio (AES) begins with your idea for the next effective app. Careful planning is the key to creating a successful app that is beneficial to your business.

Fit for the ServiceNow AI Platform

Consider the characteristics of your application to help determine whether it is suited for the ServiceNow AI Platform.

Good fit	Poor fit
• Simple forms • Task management • Request management • Spreadsheet-driven processes • Repeatable processes • Third-party integrations • Orchestration of multiple systems • Single experience from functions in multiple systems • Web and mobile access to the same apps and data simultaneously	• Unstructured data • Unrepeatable processes • Content that needs graphics processing • Streaming audio or video • Highly customized user interface

Plan before you build

In order to build your application, you need access to a ServiceNow instance and an admin or delegated developer role in that instance. If you have delegated developer permissions, you can develop applications but have fewer privileges than an admin.

Essentially, an application is a digital program that supports user tasks. As you plan your app, consider the questions in the following table.

Questions	Answers and considerations
What are the goals, objectives, and outputs of your application? What business problem are you trying to solve?	Without a clear business objective, you might have difficulty measuring the success of your application or justifying its continued use within the organization.
Are you turning a spreadsheet into a ServiceNow application or does the application exist somewhere else?	The answer to this question helps determine the tools you would use within the ServiceNow AI Platform to support your efforts.
Who will use your application?	Identifying your target audience has a direct impact on the features you include in your application, the data you choose to capture, and the interface you provide for the application.
Do you want all users to have the same ability to see and edit parts of your application or should some people have more or less access than others?	Identifying who has access to what information during the planning stage is a critical step in application development.
What is the main purpose of the application? Is the application used to provide information, collect information, route information, look up information, request something, or collaborate on information?	Identifying the application's purpose helps to establish the features and functions you need to build into your application.

Questions	Answers and considerations
Will your application require entering information or does the data in your application exist in your ServiceNow instance (that is, user data)? Will data be imported from an external source?	Use available data sources as much as possible to avoid duplication of data and to ensure your application has the data it needs to meet business objectives.
How will users interact with your application? Will users access your application using their computer or mobile device?	Understanding how users access your application affects how you build your application's functionality.
How will you report on your application to stakeholders?	If your application is meeting a business purpose, you might need to provide reports showing usage, adoption, and key business objectives related to your application.
How will you maintain this application?	Planning for the maintenance of your application at the start can prevent roadblocks further into the development process.

The answers to these questions can help you decide whether you want to base your application on a predefined template or create your app from scratch.

Irreversible considerations

Some actions you take when building an application might be irreversible. Be aware of these actions and plan for them in advance.

Action	Considerations
Creating a scoped or global application	When you create an application, you can choose to create it in a private scope (scoped application) or in a global scope (global application). Scoped applications have extra functionality for managing development, application deployment, and data security. By default, all applications are created in a private scope. Citizen developers should generally work with scoped applications.
Using different instances	Proof of concept (PoC) applications can be built in a personal developer instance (PDI) obtained from the ServiceNow Developer site. • PDI names are similar to dev12345.service-now.com. • PoC applications can be rebuilt in your PDI. Don't import the PoC app into your PDI. Production applications that your organization uses should be created in a development instance so they can be subject to your organization's testing and deployment process. Ask your ServiceNow administrator which instance to use for developing

Action	Considerations
	applications that will eventually be deployed to your organization's production instance.
Selecting an application name	Based on your application's display name, auto-complete displays suggestions for an internal name also known as the application scope. Application scopes are written in the form x_[company code]_[app_name], for example, x_acme_legal_request. Every property created in your application inherits the application scope name so be sure to choose it carefully before starting to develop your application. **Note:** You can always change the application's display name but the application scope name can't be changed.
Selecting table and field names	After your application is created, begin creating tables and fields. Tables and fields have internal database names that should be edited only at creation time.

Application Intake process

Any member of your organization can submit ideas for app development through a process called Application Intake. After the idea has been submitted and approved, developers can begin building the app with a guided, intuitive app development environment in App Engine Studio.

The Application Intake request process benefits your organization as follows:

- Simplifies the process to request, approve, track, and store app ideas.
- Improves planning by providing visibility into all app ideas.
- Provides an efficient process to filter out repetitive requests.

For more information, see Submit your idea for app development.

- The intake request form is available through the standard Service Catalog. For information about how you can modify this form, see Service catalog items.
- The intake request process uses Flows in Workflow Studio to determine the approval flow. To adjust the approval flow, see Flows.
- Admins review intake application requests in App Engine Management Center . For more information, see Managing app development using the App Engine Management Center.

Application templates

An application template provides predefined content to support a certain purpose. For example, the Travel Request template provides application content for submitting and approving employee travel requests. Choose the template that most closely fits your application goals.

If the available templates don't fit your application goals, you can create your app from scratch and control all aspects of the development process.

Additional resources for planning your app development

Learn more about planning app development	ServiceNow resources
ServiceNow provides additional resources on planning your app development	Launching an effective Citizen Development program

Create your app

Use a template in App Engine Studio (AES) to build data, experience, logic and automation, and security into your application automatically. Or, create your app from scratch and customize it as needed.

Note:
Before creating an app, Plan your app development.

To build an application in App Engine Studio, add the following content:

Data

Information that is stored in your application. For example, employee phone numbers or office locations. You configure application data using tables.

Experience

Graphical interface that your users interact with. For example, you can create a portal where users find information, submit requests, or complete business tasks.

Logic and automation

Automate all the work in your application by adding logic and automation. For example, you can build a flow that sends a notification to the admin when someone makes a request.

Security

Roles and access controls to limit who can use your application.

Note:
To create apps in AES, you must be an admin or in the App Engine Studio Users group. If you are in the App Engine Studio User Limited group, you can only edit existing apps, not create new ones.

If you use an application template, the template automatically adds one or more of these items to your application. You can then edit them to tailor to your specific business needs. You can also add more data, experience, logic and automation, or security to an application that you created using a template.

To build an application from scratch, add data, experience, logic and automation, and security to your application and then edit each.

Now Assist for app generation in AES

Note:
If you using a Xanadu Store Release 2 instance, Now Assist for app generation works with ServiceNow Studio (not App Engine Studio). For detailed information, see Now Assist for app generation in ServiceNow Studio.

Get started

Important:

- Not all model providers are available for customers with in-country SKUs, and some Now Assist products/features are currently unavailable for in-country customers. For more information, see the KB1584492 article in the Now Support Knowledge Base. Be sure to check for model provider availability updates in future releases.
- Some Now Assist products/features are currently unavailable for customers in the FedRAMP, NSC DOD IL5, or Australia IRAP-Protected data centers, self-hosted customers, or in other restricted environments. For more information, see the KB0743854 article in the Now Support Knowledge Base . Be sure to check for availability updates in future releases.
- Some Now Assist products/features are currently available only for customers in some regions. Be sure to check for availability updates in future releases.
- Some AI products and skills are not available in Regulated Markets. For more information, see KB2593939: Regulated Markets AI Products/Skills Not Available. Be sure to check for availability updates in future releases.

Troubleshoot and get help

AI limitations

This application uses artificial intelligence (AI) and machine learning, which are rapidly evolving fields of study that generate predictions based on patterns in data. As a result, this application may not always produce accurate, complete, or appropriate information. Further, there is no guarantee that this application has been fully trained or tested for your use case. To mitigate these issues, it is your responsibility to test and evaluate your use of this application for accuracy, harm, and appropriateness for your use case, employ human oversight of output, and refrain from relying solely on AI-generated outputs for decision-making purposes. This is especially important if you choose to deploy this application in areas with consequential impacts such as healthcare, finance, legal, employment, security, or infrastructure. You agree to abide by ServiceNow's AI Acceptable Use Policy, which may be updated by ServiceNow.

Data processing

This application requires data to be transferred from ServiceNow customers' individual instances to a centralized ServiceNow environment, which may be located in a different data center region from the one where your instance is, and potentially to a third-party cloud provider, such as Microsoft Azure. This data is handled per ServiceNow's internal policies and procedures, including our policies available through our CORE Compliance Portal.

Data collection

ServiceNow collects and uses the inputs, outputs, and edits to outputs of this application to develop and improve ServiceNow technologies including ServiceNow models and AI products. In addition, this application will collect information about applications (and associated application files) in which App generation was utilized. Customers can opt out of future data collection at any time, as described in the Now Assist Opt-Out page.

Exploring app generation in AES

Note:
If you using a Xanadu Store Release 2 instance, Now Assist for app generation works with ServiceNow Studio (not App Engine Studio). For detailed information, see Now Assist for app generation in ServiceNow Studio.

App generation overview

For more information about using app generation, see Generate apps with Now Assist for Creator for use with AES.

App generation benefits

Benefit	Feature	Users
Quickly reach a starting point and establish a base for further development.	Generate apps with Now Assist for Creator for use with AES	Developer

General guidelines for using app generation in AES

Learn about general guidelines for using the app generation skill.

Note:
If you using a Xanadu Store Release 2 instance, Now Assist for app generation works with ServiceNow Studio (not App Engine Studio). For detailed information, see Now Assist for app generation in ServiceNow Studio.

Configuring app generation in AES

Note:
If you using a Xanadu Store Release 2 instance, Now Assist for app generation works with ServiceNow Studio (not App Engine Studio). For detailed information, see Now Assist for app generation in ServiceNow Studio.

Install Now Assist for app generation to use with AES

Before you begin

Review the Now Assist for Creator application listing in the ServiceNow Store to learn about dependencies, licensing, and subscription requirements, and release compatibility. Now Assist for Creator installs the Now Assist for app generation application.

Note:
If you using a Xanadu Store Release 2 instance, Now Assist for app generation works with ServiceNow Studio (not App Engine Studio). For detailed information, see Now Assist for app generation in ServiceNow Studio.

Role required: admin

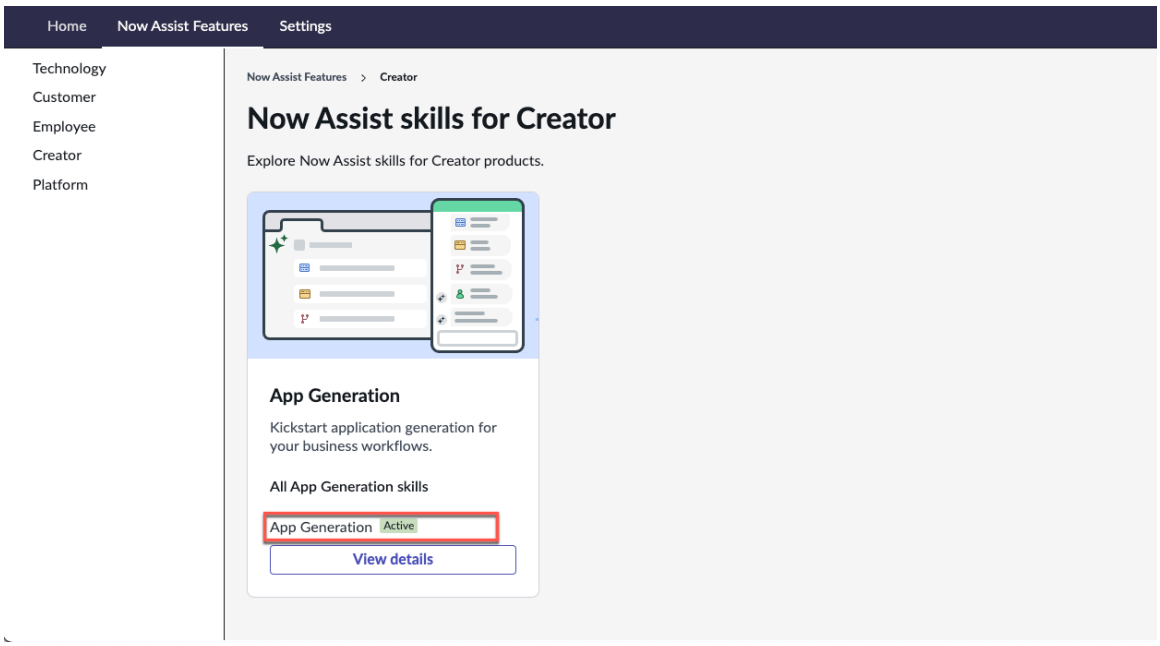
Procedure

1. Navigate to the Now Assist for Creator application on the ServiceNow Store .
2. On the Now Assist for Creator application page, select **Request App**.
3. After your request is approved, navigate to **All** > **System Applications** > **All Available Applications** > **All**.
4. Find the Now Assist for Creator application (sn_now_creator) by using the filter criteria and search bar.
5. Select **Install**.
6. Verify that Now Assist for Creator is installed.

a. Navigate to **All** > *Now Assist Admin* > **Features**.

b. In the workflow list, select **Creator**.

c. On the App Generation card, verify that the app generation skill is active.



For more information about using the Now Assist Admin console to access information about setting up, configuring, and monitoring Now Assist applications, see Now Assist Admin console.

What to do next

Grant the admin and now.assist.creator roles to each user that you want to create and edit applications using app generation.

To begin generating applications, see Generate apps with Now Assist for Creator for use with AES.

Related topics

Install Now Assist for Creator

Generate apps with Now Assist for Creator for use with AES

Have a conversation with the Now Assist for Creator application to start building applications.

Note:
If you using a Xanadu Store Release 2 instance, Now Assist for app generation works with ServiceNow Studio (not App Engine Studio). For detailed information, see Now Assist for app generation in ServiceNow Studio.

This video shows you how to perform the following procedure in App Engine Studio.

https://player.vimeo.com/video/996001913?h=35af70a157&badge=0&autopause=0&player_id=0&app_id=58479

Before you begin

To use app generation, you must activate the skill in Now Assist for Creator. For more information, see Install Now Assist for app generation to use with AES.

Role required: admin and now.assist.creator

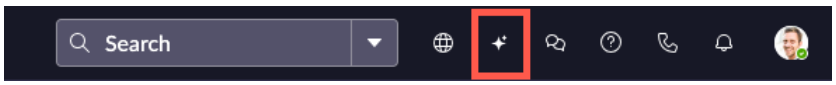
Note:
As of Xanadu Store Release 2, if you have users that only need to edit (not create) apps, they can be assigned the delegated_developer, now_assist_panel_user, and now.assist.creator roles.

About this task

When app generation is enabled on an instance, the Now Assist icon ( ) appears on the home page banner.

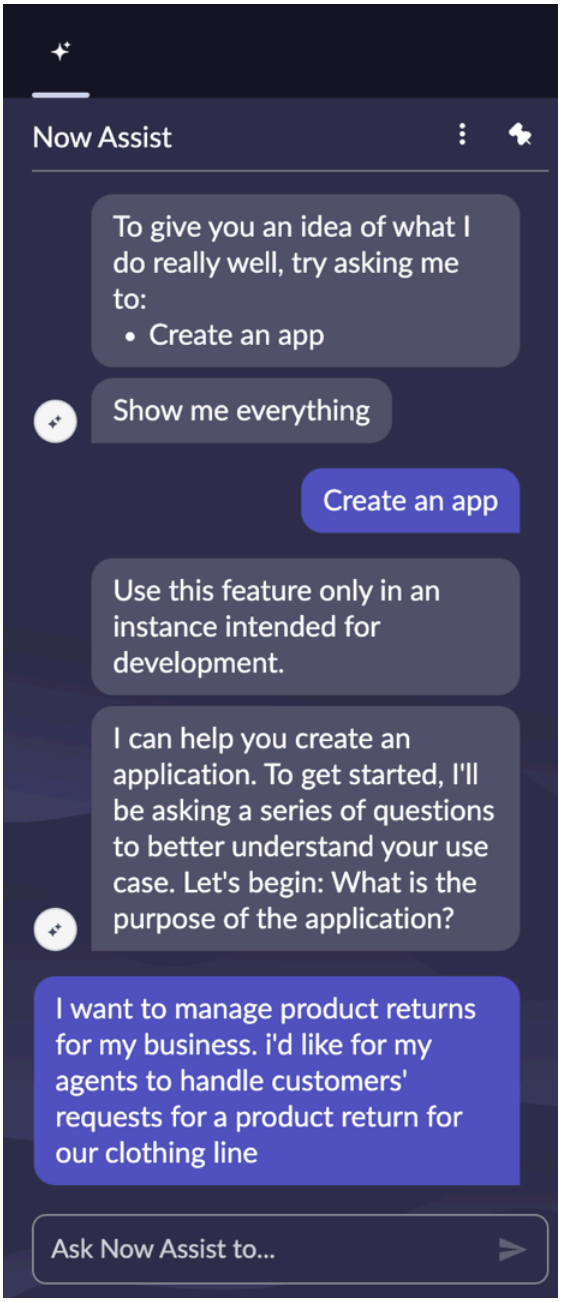
Procedure

1. Open the Now Assist panel by selecting the Now Assist icon.



2. In the Now Assist panel, select **Create an app**.
   Now Assist asks you to describe your application.
3. Summarize your current business process.

   Describe your application's use case so Now Assist understands the purpose of your application. You can be highly detailed if you have a clear idea of what you want. If you don't, start with a broad description. Now Assist narrows down your app's requirements.



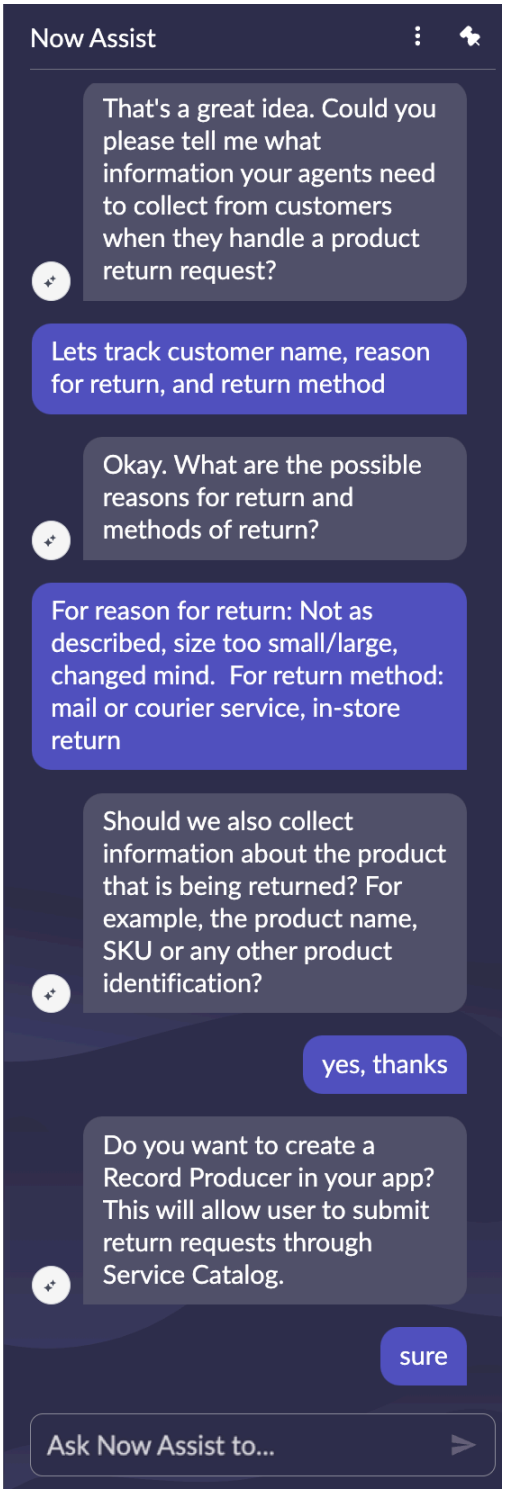
4. Continue the conversation with Now Assist by providing details about how you want the app to work.

   Example

   Now Assist asks you questions to understand the data to be collected, the users involved and their permissions, and the desired interface. Your answers help Now Assist create the correct tables, roles, access control lists (ACLs), forms, and record producers for your application.

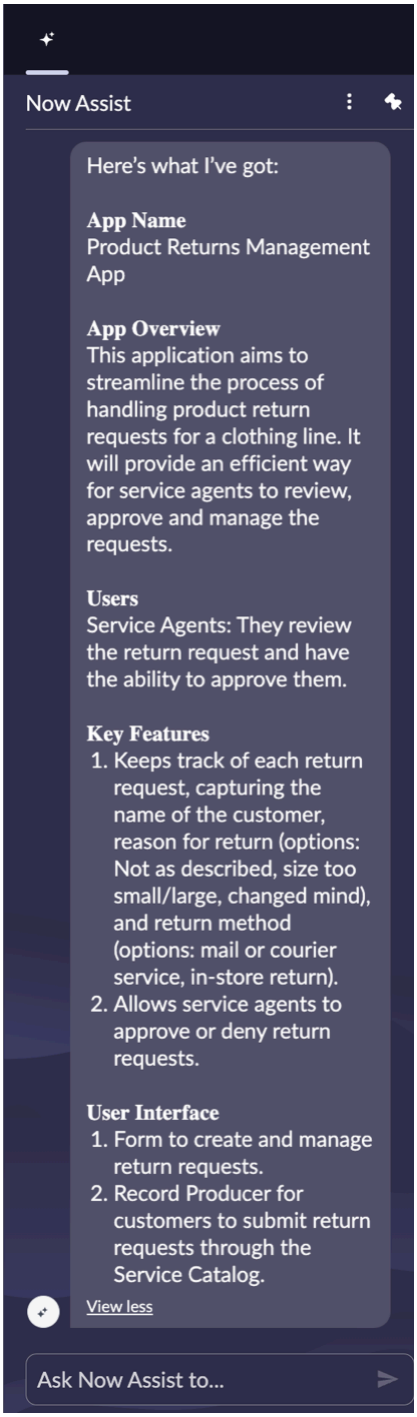
   If you know exactly how you want your app to work, be specific about its functionality. If you don't, interact with Now Assist to determine the correct application requirements. For more information, see General guidelines for using app generation in AES.

   When Now Assist collects enough information, it provides a detailed summary of the application requirements.



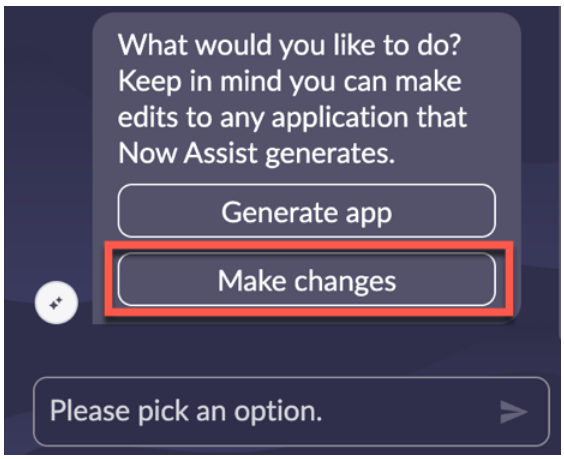
5. Review the summary of your application requirements.

Note:
Because the information is generated by AI, review the text to make sure it's accurate.



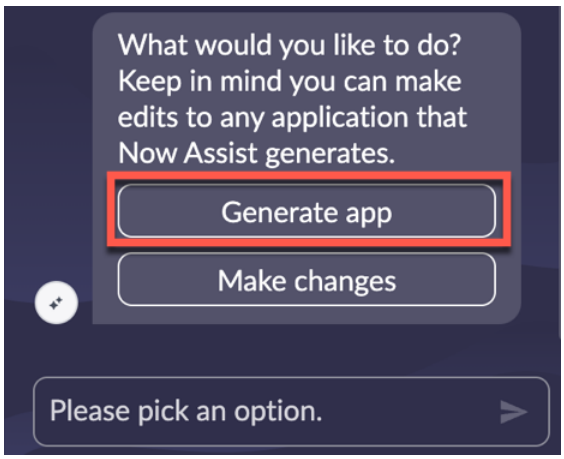
6. Finalize and generate the app.

a. If necessary, select **Make changes** to keep the Now Assist panel open so that you can keep editing.

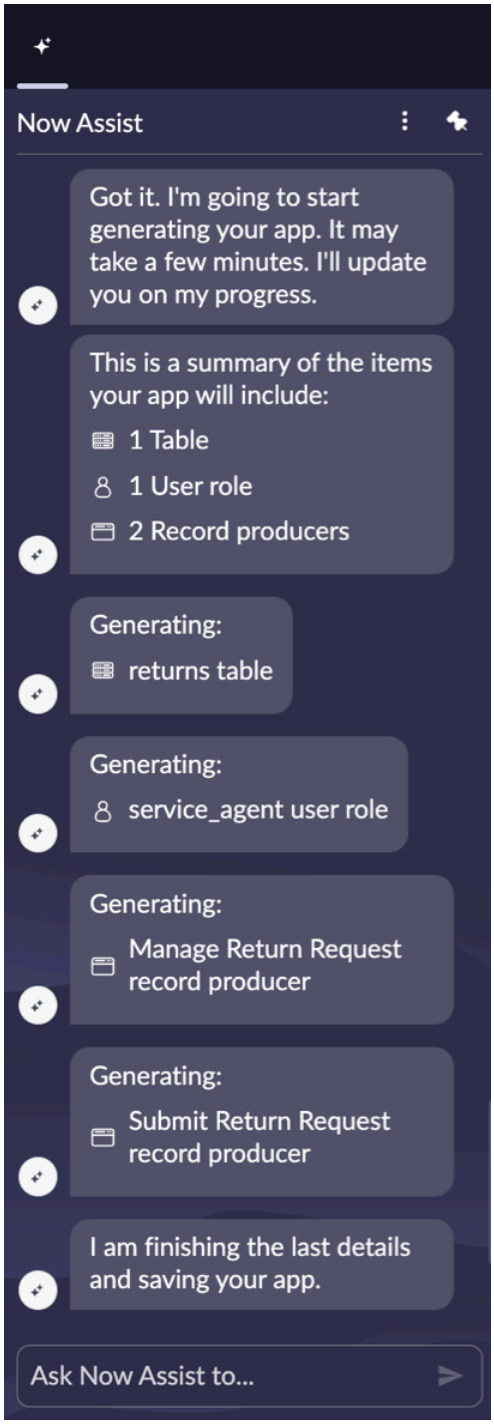


Continue to interact with Now Assist until the summary it produces matches your app's requirements.

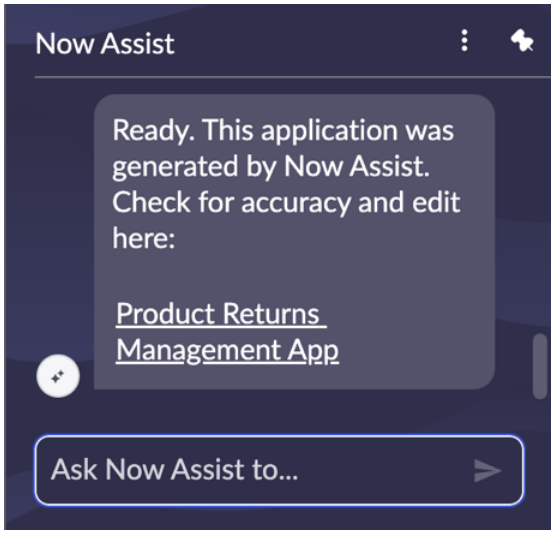
b. After you're satisfied with the application requirements, select **Generate app**.



Now Assist tells you what it's generating.



Now Assist provides a link to open the app and its supporting components in App Engine Studio:



For more information about App Engine Studio, see Build apps using App Engine Studio.

Result
Now that your app is created, review its contents and verify for accuracy. Then, use the tools in App Engine Studio to add more features and enhance your app further.

Review the apps generated by Now Assist for Creator in App Engine Studio

In Xanadu Store Release 1, use the App Engine Studio development environment to verify and modify the application that you created with Now Assist for Creator.

> **Note:**
> If you using a Xanadu Store Release 2 instance, Now Assist for app generation works with ServiceNow Studio (not App Engine Studio). For detailed information, see Now Assist for app generation in ServiceNow Studio.

This video shows you how to perform the following procedure in App Engine Studio.

https://player.vimeo.com/video/995459091?badge=0&autopause=0&player_id=0&app_id=58479

Before you begin
Check that you have an application created using Now Assist for Creator.

Role required: admin and now.assist.creator (as of Xanadu Store Release 2, if you have users that only need to edit, not create, apps, they can be assigned the delegated_developer, now_assist_panel_user, and now.assist.creator roles)

About this task
The application generated by Now Assist for Creator provides a starting point for further development. Examine the contents of the application and confirm that they align with your business process. Enhance the application by adding functionality as needed in App Engine Studio.

In Xanadu Store Release 1, apps generated with Now Assist automatically open in App Engine Studio.

Procedure

1. If the application is not already open, navigate to App Engine > App Engine Studio and select the application tile.

   Notice the banner prompt to review and that the line items generated by Now Assist have the following:

   - AI indicator AI
   - **Review** button

   In contrast, observe that in the **Experience** section, the **Product Returns Mobile** experience was created without Now Assist and does not include these elements.

   To learn more about the AES home page, see AES user interface.

2. Review the generated tables.

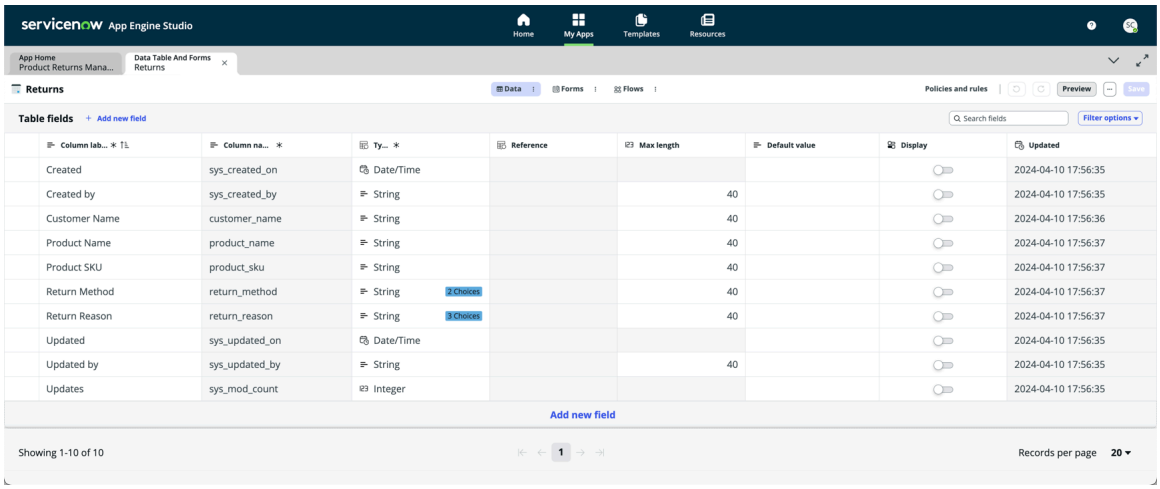
   a. Under the **Data** heading, select the Additional actions icon (•••) for an existing table in your application, and then select **Edit**.
   When you select a data table or select **Edit** to edit data for your application, Table Builder launches. Table Builder is a tool for editing the data tables that you added to your application.

   b. Check the table data for accuracy and completeness.

   On the **Data** tab:

   - Manage table fields.
   - Edit the table and field column properties.
   - Verify that the generated choices are implemented correctly.

Now Assist created tables based on your instructions. Confirm that the tables capture the desired data to be collected. For example, the following table includes the fields discussed during the conversation.



For more information on editing tables in Table Builder, see Modify application data tables.

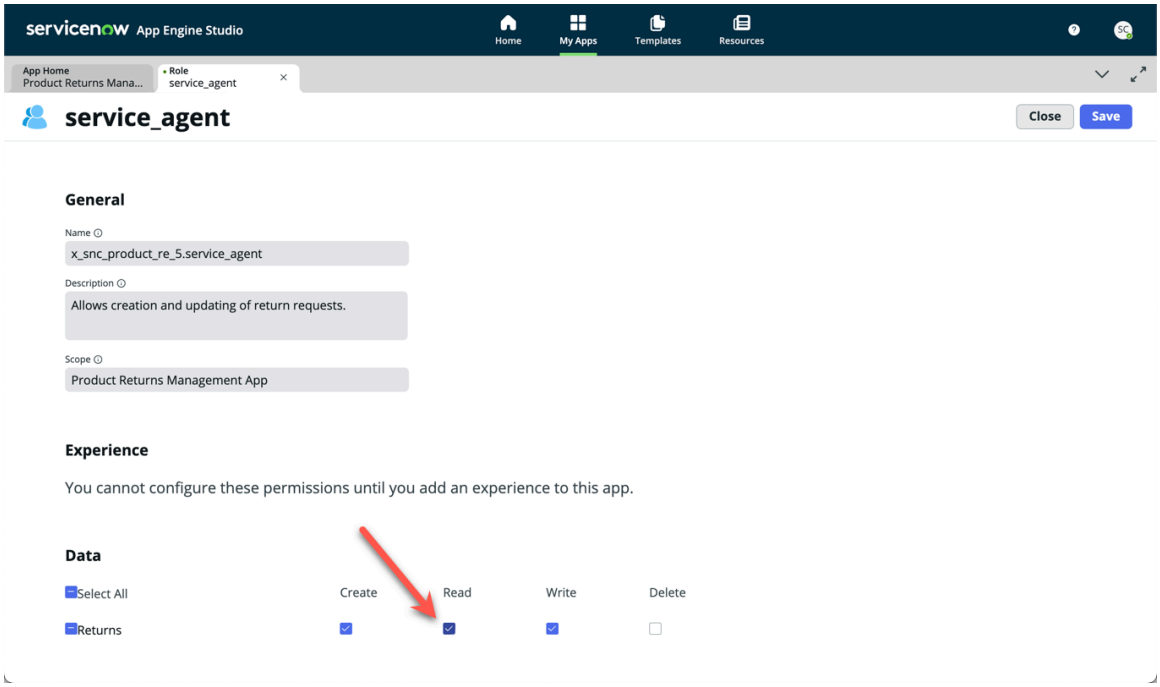
3. Select the **App Home** tab to review the generated roles and access control lists (ACLs).

   a. Under the **Security** heading, select the Additional actions icon (•••) next to a role, and then select **Edit**.

      You can also select the bar that lists the role you want to view.

   b. Verify that the created roles and their assigned permissions accurately represent the users of your application.

      You can configure the roles and their permissions to align with your workflow. For example, the role in the following example was granted permissions to create and update return requests. You want this role to read the requests, so you would configure that access on the Role page.



For more information on configuring roles and access, see Working with roles.

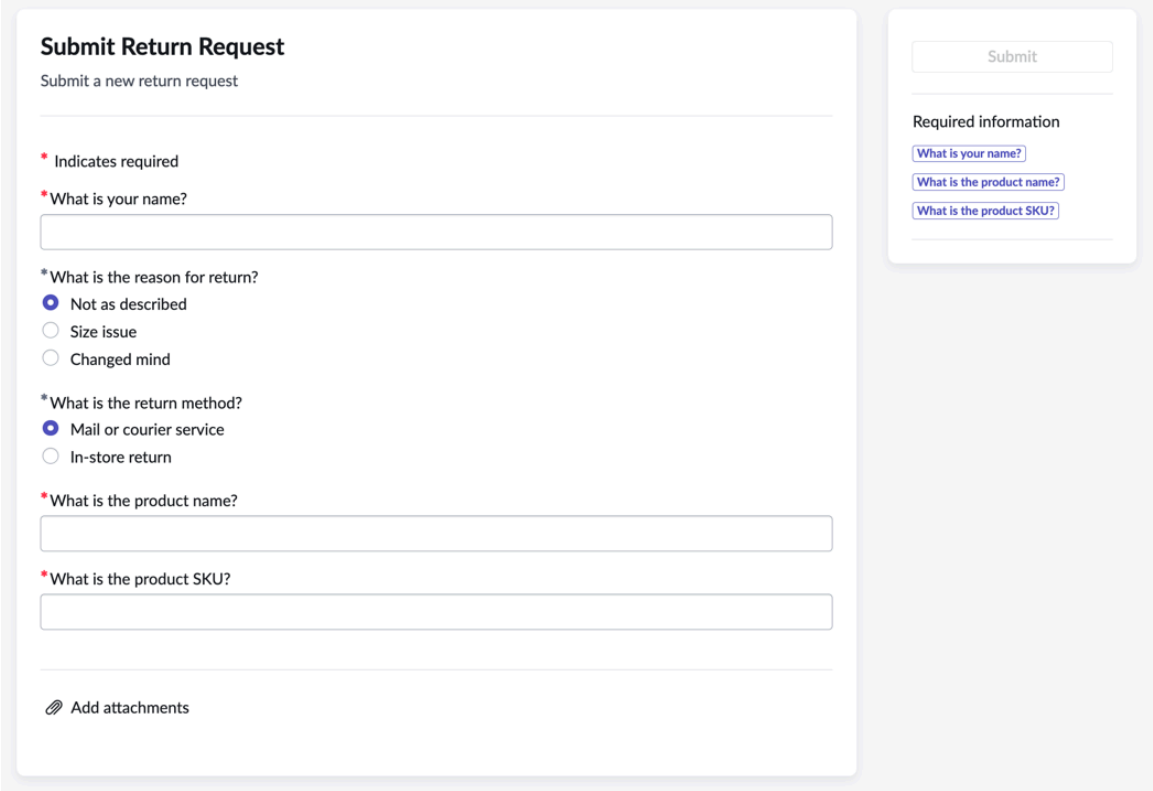
4. Select the **App Home** tab to review the generated forms and record producers.

   a. Under the **Experience** heading, select the Additional actions icon (•••) for a form or record producer in your application, and then select **Edit**.

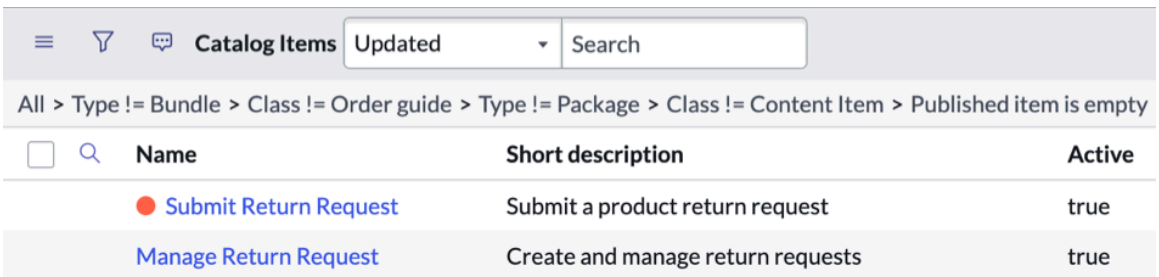
      You can also select the bar that lists the experience you want to view.

   b. Modify the item if necessary.

      You can preview the item. Confirm that the question field types match their intended purpose.



Verify that the catalog item for your record producer appears in the Service Catalog. To learn more, see Service Catalog.



If you want to make changes, you can fine-tune the experience by using App Engine Studio. For more information, see Add a record producer.

What to do next

Set up the application to perform tasks according to predefined rules or logic. You can add flows, create decision tables, build playbooks, write script includes and business rules, or configure an email notification. For more information, see Add logic and automation.

App generation in AES reference

Reference topics provide additional information about configuration properties, roles, and more.

Note:
If you using a Xanadu Store Release 2 instance, Now Assist for app generation works with ServiceNow Studio (not App Engine Studio). For detailed information, see Now Assist for app generation in ServiceNow Studio.

App generation roles for AES

The following roles are installed for use with the Now Assist for Creator app generation skill.

Note:
If you using a Xanadu Store Release 2 instance, Now Assist for app generation works with ServiceNow Studio (not App Engine Studio). For detailed information, see Now Assist for app generation in ServiceNow Studio.

Administrator [admin] role for Now Assist with AES

Access all system features, functions, and data, regardless of security constraints.

Now Assist Creator [now.assist.creator] role for Now Assist with AES

Create applications through a conversation with generative AI.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

None.

Create your app using an application template

Build an application in App Engine Studio (AES) that uses predefined data, experience, logic and automation, and security. Add to the template contents to customize the app for your organization.

Before you begin

Note:
To create apps in AES, you must be an admin or in the App Engine Studio Users group. If you are in the App Engine Studio User Limited group, you can only edit existing apps, not create new ones.

Role required: admin, sn_app_eng_studio.user

About this task

Using templates in App Engine Studio helps you save time and effort creating applications. You can download several templates from the ServiceNow Store, or you can create templates from your existing applications. To install a template on your PDI, see Activating a plugin from your PDI.

This video shows you how to perform the following procedure.

Short video of creating an app from a template

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the **Templates** tab, browse the available templates.
3. Hover over the template you want to use and select **Use template**.
4. Enter a **Name** and **Description** for your application.

5. **Optional:** Add a logo by dragging an image into the AES page or browsing your computer for the file.
6. Select **Continue**.
7. On the summary screen, select **Go to app home**.
8. From the app home, review the data, experience, logic and automation, and security that was created with the template.
   To tailor the application to your business needs, you can edit these predefined items or add your own. For more information, see Enhance your app.

What to do next

After you've finished building your application, submit the application for approval to get it reviewed and deployed by an administrator. For more information, see Submit your app for approval and publishing.

Available templates

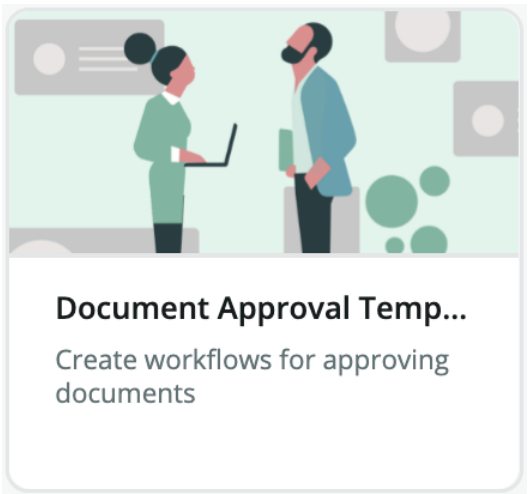
Use an application template to create an application in App Engine Studio (AES) with preconfigured data, experience, logic and automation, and security.

Templates are a good starting place for many applications you might want to build. You can also begin your application using a template and then customize the application. Use any of the templates below to build a fully-fledged application, or use them as a starting point to create an app customized to your needs.

Document Approval template

Build an application in App Engine Studio (AES) using the Document Approval template to manage the approval of documents in your organization.

To use the Document Approval template, install this application from the ServiceNow Store.



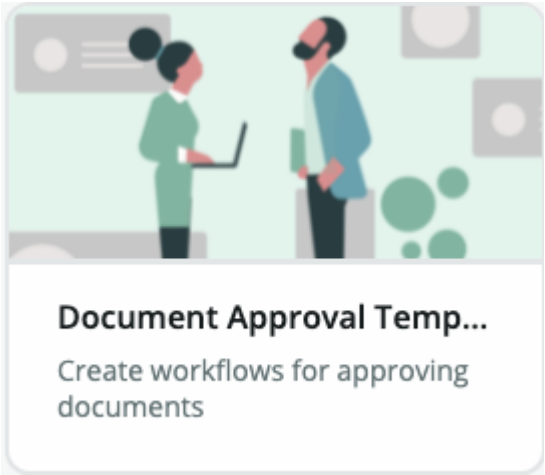
A document approval app enables your users to quickly create and use document approval workflows. Document owners and submitters can upload documents needing approvals and check the progress on those approvals. Designated approvers can approve, reject, or return documents with comments.

Admins can use the document approval application to create different workflows for different document types.

This app template is an ideal way to quickly and efficiently make your internal workflows for processing documents. Document owners and submitters can upload a document needing

approval to a portal using simple upload functionality that automatically sends submissions through a unique workflow. Once a document has been received, submitters follow the progress of their documents while designated users approve, reject, or return their document for edits. Both submitters and approvers use comments to add notes and feedback to the submission, which is stored in the system for future reference. To give this app even more variety, admins can create unlimited workflows that are customized for each document type and user that allows for multiple stages and approvers depending on what the document category requires.

Document Approval template



For more information on creating an application using a template, see Create your app using an application template.

Document Approval template contents

The following tables, experiences, automated workflows, and roles are included in the Document Approval template for App Engine Studio (AES).

Tables in the Document Approval app template

Table label [name]	Description
Document Approver Table [x_ <company-code>_ <document_approver>]	Tracks document approvers, their comments, and state of a document.
Document Approval Category Table [x_ <company-code>_ <document_approval_category>]	Tracks the category of document approval requests.
Document Approval Table [x_ <company-code>_ <document_approval>]	Tracks the document approval requests.

Experiences in the Document Approval app template

Experience	Experience type	Description
Document Approval | Default view	Form	Form for creating a document approval request.

Experience	Experience type	Description
Document Approval | Portal	Form	Simplified form for creating a document approval request.
Document Approval Category | Default view	Form	Form to attach a flow to a document approval record.
Document Approval Category | Workspace	Form	Form to attach a flow to a document approval record.
App name Workspace	Workspace	Main document approval app workspace, where users can upload documents, check the status of an approval, edit documents, and view their submissions in the workspace. Approvers can view assigned approvals, view previous submissions, and approve or reject submissions.
Document Approver | Workspace	Form	Form for assigning document approvers to records.
Document Approval | Workspace	Form	Form for creating a document approval request.
Document Approver | Default view	Form	Approvers can view assigned approvals and approve or reject submissions.
App name Portal	Portal	Main portal for people to submit documents for approvals and manage previous submissions.
Document Approval Mobile Experience	Mobile experience	Mobile app that employees and managers can use to check the status of an approval, approve or reject documents, and view submissions using your organization's iOS or Android app.

Automated workflows in the Document Approval app template

Workflow name	Workflow type	Description
Document Approval - Master Flow	Flow - record	Executed when a new document approval record is submitted. It then retrieves the flow to be executed from the document category and executes it.
Document Approval Notification	Email	Notifies users of changes to their document approvals.

Workflow name	Workflow type	Description
Single Stage Approval	Flow	Allows for the user's manager to be the approver, with basic email notifications being generated on approval, return, or rejection.

Roles in the Document Approval app template

Role title [name]	Description	Contains roles
Approvers [x_<company-name>_<document_approval_app>.approver]	Approvers can create, read, delete all documents, and read document approval category data.	Create, Read (all), Edit (all)
Admins [x_<company-name>_<document_approval_app>.admin]	Admins can create, read, write, and delete in the Document Approval [x_ <company-code>_<document_approval>] and Document Approval Category [x_ <company-code>_<document_approval_category>] tables.	Create, Read (all), Edit (all), Delete (all)
Submitters [x_<company-name>_<document_approval_app>.submitter]	Submitters can create documents, read their own documents, edit their own documents when status is not submitted and delete their own documents. They can also read data from document approval category.	Create, Read (own), Edit (own when status is not submitted), Delete (own)

Emergency Alert template

Build an application in App Engine Studio (AES) using the Emergency Alert template to manage communications and track essential resources during an emergency.

To use the Emergency Alert template, install this application from the ServiceNow Store.

An emergency alert app allows your organization to keep employees informed and connected during natural disasters and infectious diseases, such as COVID-19.

You can use the Emergency Alert template to create command center dashboards and a mobile app to monitor and notify employees about the latest news. Employees can self-report their status, request work-from-home or time off, and receive instructions during an emergency. Managers can assess the impact on their respective teams, approve or reject requests, request for status, and automatically receive instruction on actions to take during any emergency.

For more information on creating an application using a template, see Create your app using an application template.

Emergency Alert template contents

The following tables, experiences, automated workflows, and roles are included in the Emergency Alert template for App Engine Studio (AES).

Tables in the Emergency Alert app template

Table label [name]	Description
Status Report Request Table [x_<company>_<my emergency_alert_app>_status_report_requests]	Track the severity of an emergency reported by employees. For example, the status, the color associated with danger levels, and conditions.
Self Report Table [x_<company>_<my emergency_alert_app>_status_report]	Track reported emergencies created by employees or managers. For example, the emergency details, status, duration, and affected individuals.
Emergency Alert Table [x_<company>_<my emergency_alert_app>_emergency_alert]	Track emergency alerts for your company. For example, the emergency type, who created the alert, and who has read the alerts.
Work Status Request Task Table [x_<company>_<my emergency_alert_app>_work_status_request_task]	Track the work status request of an emergency. For example, the requester, the assignee, and the state of the work status.

Experiences in the Emergency Alert app template

Experience	Experience type	Description
Emergency alert | SendEmergency AlertWS	Form	Form to create a new emergency alert record.
Self Report | Employee View	Form	Form for employees to report an emergency.
Self Report | Default View	Form	Form for employees to report an emergency.
Emergency Alert - Portal	Portal	Portal where employees can view reported emergencies, the status of their team, and submit a self report.
Emergency Alert | Default View	Form	Form to create a new emergency alert and connect knowledge resources to it.
Self Report | Update Report	Form	Form for employees to self report their health status.
Self Report | Activity View	Form	Form to add comments about a self report.
Self Report | RequestReportWS	Form	Form to self report an emergency within a specific time frame.
Status Report Request | Default View	Form	Form to send an update about an emergency with time and location details.
Self Report | Update status report	Form	Form to add an update about an emergency.
App name Workspace	Workspace	Workspace where admins can set up and send notifications, view dashboards, and configure lists and forms.
Work Status Request Task | Default view	Form	Form to update an employee about a work status request.

Automated workflows in the Emergency Alert app template

Workflow name	Workflow type	Description
Emergency report/update state for managers	Email	Notifies managers to update an emergency report if the source is empty.
Emergency Alert App - Please report or update status	Flow - record	Requests a status update on work.

Workflow name	Workflow type	Description
Emergency Alert App - Status request for employees from manager	Flow - record	Notifies employees that a status request is made by their manager.
Self report submitted without manager	Email	Notifies that an employee submitted an expense request without listing their manager.
Emergency Alert App - Create Work Status Task When Self Report is created	Flow - record	Starts the work status task when a self report emergency is submitted.
Emergency Alert App - Create Status Report Requests for Affected	Flow	Creates or updates status report requests.
Emergency alert app - Create App Self Reports	Flow - record	Sends a notification when a report request is created or updated.
Emergency Alert App - Request for WFH/Time off submitted	Flow - record	Starts the work from home or time off request approval flow.
Emergency instructions for employees	Email	Notifies users if a status update is requested.
Emergency Alert App - Employee emergency report changes to submitted	Flow - record	Sends a notification when an employee self report has been submitted.
Emergency Alert App - Request for WFH/Time off approved/denied	Flow - record	Sends a notification to an employee when a WFH or Time off request is approved or denied.
Emergency Alert App - Employee emergency report request response submitted	Flow - record	Sends a notification when an employee emergency report has been submitted.
Request for WFH approved	Email	Notifies an employee that their request to work from home was approved.
Emergency alert app - Emergency instructions for employees	Flow - record	Sends employees instructions to follow during an emergency.
Please report/update status of employee	Email	Requests information about the status of an employee.
Self-report submitted for manager	Email	Notifies a manager that an emergency alert has been created and needs review.
Emergency Instructions for managers	Email	Notifies managers that their request was created and that their team will receive information about it.

Workflow name	Workflow type	Description
Please report/update status	Email	Sends a notification when a status change has been committed.
Request for WFH/Time off submitted	Email	Notifies an employee that their work from home or time off request was successfully submitted.
Employee Emergency report submitted	Email	Notifies an employee that their emergency report was successfully submitted.
Emergency Alert App - Manager emergency request submitted	Flow - record	Sends a notification when a manager emergency report has been submitted.
Emergency Alert App - Employee emergency report submitted	Flow - record	Sends a notification when an employee submits changes to an emergency report.
Create KB article	Flow - record	Creates a knowledge base article when a new emergency alert is created.
Employee emergency report request submit	Email	Notifies an employee that their request for status was submitted and that their manager will be notified.
Emergency Alert App - Cancel work status task if self report closed	Flow - record	Cancels a work status request if the self report is closed.
Manager emergency request submitted	Email	Notifies managers that the emergency report was sent.
Please report/update status of employee	Email	Notifies employees of action needed on their self report.
Request for WFH denied	Email	Notifies the employee that their work from home request was denied.
Emergency Alert App - Emergency report/update state for managers	Flow - record	Sends a notification based on changes in an emergency alert report.

Roles in the Emergency Alert app template

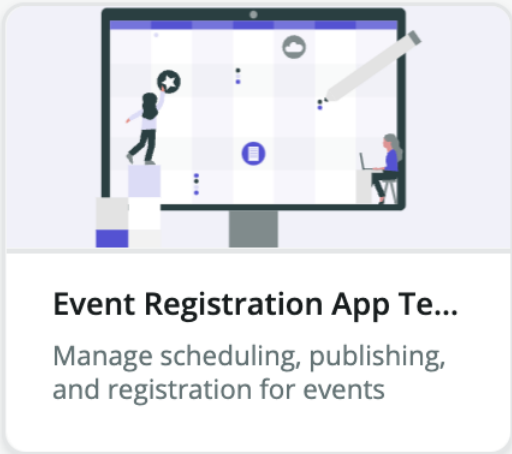
Role title [name]	Description	Contains roles
Emergency alert admin [x_<company-code>_ <my emergency_alert_app>.emergency_alert_admin]	Admins manage the app and configure the dashboard	Create, Read (all), Edit (all), Delete
Emergency alert manager	Managers can approve or reject requests, access	Create, Read (all), Edit (all)

Role title [name]	Description	Contains roles
[x_<company-code>_ <my emergency_alert_app>.manager]	dashboards, and send notifications	
Emergency alert employee [x_<company-name>_ <my emergency_alert_app>.emergency_alert_employee]	Self-report emergency alerts	Create, Read (own), Edit (own)
Admin	The System Administrator role. This role has access to all system features, functions, and data regardless of security constraints.	Create, Read (all), Edit (all), Delete
Public	No login is required to access features or functions with the public role.	No access by default.

Event Registration template

Build an application in App Engine Studio (AES) using the Event Registration template to manage scheduling, booking, and registration for company events.

To use the Event Registration template, install this application from the ServiceNow Store.



An internal event registration app allows your event organizers to publish a list of events to employees and collect attendees in a centralized database. The app helps streamline the event discovery and registration process.

Event organizers can manage events and wait-lists, publish new events, and view registered users' details. Employees and attendees can view a list of events, view event info, and register to attend in a portal. Organizers can set the size of the event, and requesters will automatically be added to a wait-list.

For more information on creating an application using a template, see Use an application template.

Event Registration template contents

The following tables, experiences, automated workflows, and roles are included in the Event Registration template for App Engine Studio (AES).

Tables in the Event Registration app template

Table label [name]	Description
Attendee Table [x_<company-code>_<attendee>]	Track event attendee information such as name, status, and date of submission.
Event Table [x_<company-code>_<event>]	Track event information such as event name, date of the event, and capacity.
Event Location Table [x_<company-code>_<event_location>]	Track event location details such as capacity and location.

Experiences in the Event Registration app template

Experience	Experience type	Description
Event Location | Workspace	Form	Workspace where organizers and admins can configure events, create event applications, and view lists.
App name Portal	Portal	Main portal for organizers to create and view details about the event.
Attendee | Default view	Form	Form that attendees can use to view the event name, change their status, and take notes about the event.
Event | Default view	Form	Form that organizers can use to create events.
App name Workspace	Workspace	Workspace where users can register for an event and where admins/organizers can manage registration information.
Event Location | Default view	Form	Form for organizers to add event location name, location address, status, and capacity.
Event | Workspace	Form	Form for organizers to add event name, location details, timelines, and comments.
Attendee | Workspace	Form	Form for attendees to register for events and add notes about the event.
Mobile app for organizers	Mobile experience	Organizers can view or edit events and view attendees using your organization's iOS or Android app.

Automated workflows in the Event Registration app template

Workflow name	Workflow type	Description
Event Details Have Changed	Email	Notifies users/attendees of changes to the event.
Event Reminder - Confirmed attendees	Email	Sends a reminder about the event to confirmed attendees.
Attendee registered confirmed	Email	Notifies attendees of confirmed registration.
Send Event Reminder Email	Flow	Sends a reminder email to event attendees.
Send Event Details Changed Email	Flow - record	Sends an email to all confirmed and waitlisted attendees when details of an event have changed or the event was cancelled.
Send Waitlist Confirmation Email	Flow - record	Sends an email to attendees when they are added to the waitlist of an event.
Event Registration cancelled events	Flow - record	Updates attendee records when an event is cancelled.
Update Event Registration attendee records	Flow	Updates attendee records when an event is cancelled or is past the end date.
Attendee waitlisted confirmed	Email	Confirms attendees on event waitlist.
Event Registration expired events	Flow	Sets the **Event state** field to Expired and the **Attendees** field to Event ended after the event ends.
Send On Hold Confirmation	Flow - record	Allows for organizers to send an email to attendees when they are on-hold to attend an event.
Event Registration Confirmation Email	Flow - record	Sends an email to attendees when they are confirmed to attend an event.
Attendee registration on hold	Email	Informs attendees that their registration is on hold.
Event Has Been Cancelled	Email	Informs users of event cancellation.
Event Registration Process Flow	Flow	Processes all pending requests.

Roles in the Event Registration app template

Role title [name]	Description	Contains roles
Organizer [x_<company-name>_<my events app>.organizer]	Organizers create and manage events.	Create, Read (all), Update (all).
Attendee [x_<company-name>_<my events app>.attendee]	Attendees can search, sign up, and RSVP to events.	Create, Read (all), Update (own).
Admin [x_<company-name>_<my events app>.admin]	Admins configure event locations and applications.	Create, Read (all), Update (all), Delete.
Public [x_<company-name>_<my events app>.public]	No login is required to access features or functions with the public role.	No access by default.

Expense Pre-Approval template

Build an application in App Engine Studio (AES) using the Expense Pre-Approval template to create, track, and manage planned expenses in your organization.

To use the Expense Pre-Approval template, install this application from the ServiceNow Store.

Expense Pre-Approval Te...

Create, track, and manage planned expenses in your organization

Employees can easily submit their planned expenses for multiple levels of approval using the Expense Pre-Approval application. Managers can then review every submitted request. Approved requests are assigned to the budget review group, which can approve or reject the request. The employee receives a notification with the final status of the request.

To ensure compliance and improved financial planning, admins can customize the existing flow and levels of approval using decision tables. For more information, see Exploring decision tables.

For more information on creating an application using a template, see Create your app using an application template.

Expense Pre-Approval template contents

The following tables, experiences, automated workflows, and roles are included in the Expense Pre-Approval template for App Engine Studio (AES).

Tables in the Expense Pre-Approval app template

Table label [name]	Description
Budget definition [x_<company-code>_<expense_approval_app>_budget_definition]	The description of all budgets.
Expense request [x_<company-code>_<expense_approval_app>expense_request]	The expense requests submitted by employees.
Expense line item [x_<company-code>_<expense_approval_app>_expense_line_item]	Each expense line item in an expense request.

Experiences in the Expense Pre-Approval app template

Experience	Experience type	Description
Expense request | Default view	Form	Form to create a new expense request.
Budget definition | Default view	Form	Form to define budgets for a specified time frame.
Budget Reviewer	Mobile experience	Way to define what the mobile experience for budget reviewers looks like.
Expense request | Workspace	Form	Form to create a new expense request.
Expense request | Cost Approval	Form	Form to create a new expense request from an admin.
Manager	Mobile experience	Way to define what the mobile experience for managers looks like.
Budget definition | Workspace	Form	Form in the workspace view to define budgets for a specified time frame.
App name - Budget workspace	Workspace	Way to configure a high-level view of all budget requests.
Expense request	Record producer	Way for employees to submit an expense request.
Expense line item | Default view	Form	Form to add an expense line item to an expense request.

Experience	Experience type	Description
Expense Request SLA | Default view	Form	Form to create an expense request based on a breach of service level agreement (SLA).
Budget definition | Cost Approval	Form	Form in the cost approval view to define budgets for a specified time frame.
App name - Manager workspace	Workspace	Workspace where managers can approve or reject the expense requests assigned to them.
Cost Approval Mobile App	Mobile experience	iOS or Android app used for the following actions: • Approving or rejecting expense requests. • Viewing dashboards that display historical data to compare budget and expense requests. • Creating or modifying budgets by budget reviewers.
Cost Approval Workspace - Budget Reviewer	Workspace	Budget reviewers can use the workspace for the following actions: • Approving or rejecting expense requests. • Creating or modifying budgets. • Viewing the data on the budget funds allocated, spent, available, and allocated for the future. • Viewing dashboards that display historical data to compare the budget and expense requests.

Automated workflows in the Expense Pre-Approval app template

Workflow name	Workflow type	Description
Expense request approved - reviewer	Email	Notifies users that an expense request has been approved.
Expense Request Assigned	Email	Notifies users that an expense request has been assigned.

Workflow name	Workflow type	Description
Expense request - SLA breached	Email	Notifies users that a service level agreement (SLA) has been breached.
Budget Creation	Flow - record	Executed when a budget reviewer creates a budget. It checks the start date of an expense request and associates the request to a budget with corresponding time frame.
Expense request - SLA- close to due	Email	Notifies users that a service level agreement (SLA) is close to due.
Expense Request Reassigned	Email	Notifies users that their request was reassigned.
Expense request comment added - Assigned	Email	Notifies users about a comment that has been added to their request.
New Expense Request or manager approval	Email	Notifies users about a new expense request.
Expense request reject	Email	Notifies users that their request was rejected.
Budget state update	Flow	Updates each budget record by priority.
Expense Request Inserted - Requestor	Email	Notifies users that their request was successfully created.
Expense Request Approved	Email	Notifies users that their request was approved.
Expense request work note added	Email	Notifies users a work note was added to their request.
Notify Team - Work note added	Email	Notifies a team that a work note was added to a request.
Expense request comment added - Employee	Email	Notifies users a comment was added to a request.
Expense Request Rejected	Email	Notifies users that their request was rejected.
Budget Updation	Flow - record	Executed when a budget reviewer modifies the budget. After a budget is modified, this flow updates the **Budget** field in the corresponding expense requests.
Notify Requestor - Comments added	Email	Notifies users that a comment was added to a request.

Workflow name	Workflow type	Description
SLA Notification - Expense Request - warning	Flow - record	Warns admins about a potential service level agreement (SLA) issue.
Budget Approval Process	Flow - record	Executed to obtain expense approvals in the following scenarios: • When an employee submits an expense request for the manager's approval. • Upon the manager's approval, the expense request is sent to the budget reviewer for the final level of approval.
Budget Calculations	Flow	Recalculates the budget spent and the available budget when a budget reviewer performs any of the following actions: • Creates a budget • Modifies an existing budget • Approves an expense request

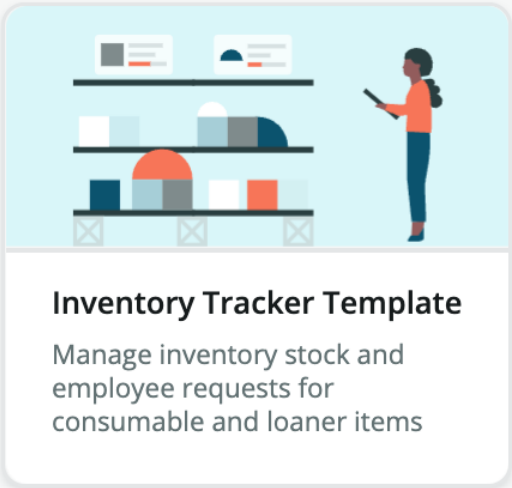
Roles in the Expense Pre-Approval app template

Role label [name]	Description
Budget Reviewer [x_<company-code>_<expense_approval_app>.Budget reviewer]	Budget reviewers can create or modify budgets and provide the final level of approval on expense requests.
Manager [x_<company-code>_<expense_approval_app>.Manager]	Managers can submit, view, and approve or reject expense requests at the first level.
Employee [x_<company-code>_<expense_approval_app>.Employee]	Employees can submit and track expense requests.
Admin	The System Administrator role. This role has access to all system features, functions, and data, regardless of security constraints.

Inventory Tracker template

Build an application in App Engine Studio (AES) using the Inventory Tracker template to track the status of inventory and assets.

To use the Inventory Tracker template, install this application from the ServiceNow Store.



An inventory tracker app enables your business and teams to easily track what they have, where it is, and who has it. Anytime, anywhere, and on any device. If your company needs to track the stock of items, this app can be used as a stock management tool or inventory tracker at home or in a warehouse.

This app covers three inventory use cases: consumables, loaners, and discontinued. Employees can request items via mobile app or web portal from any warehouse. Inventory managers can set reorder levels and will be automatically notified if an item is low on stock. Discontinued items with outstanding stock can still be requested but will not prompt inventory managers for reorder. Inventory managers can create items manually or by uploading a spreadsheet.

For more information on creating an application using a template, see Create your app using an application template.

Inventory Tracker template contents

The following tables, experiences, automated workflows, and roles are included in the Inventory Tracker template for App Engine Studio (AES).

Tables in the Inventory Tracker app template

Table label [name]	Description
Inventory Control Table [inventory_ x_<company-code>_<my_inventory_tracker_app>_inventory_control]	Track the stock of items used by your business. For example, item name, manufacturer, image, category, and location.
Inventory Request Table [x_<company-code>_<my_inventory_tracker_app>_inventory_request]	Track inventory requests submitted by employees. For example, the name and department of the requester, stock location, count, requested date, and return date.
Stock Location Table	Track the location of stocked items. For example, name, address, and inventory manager.

Table label [name]	Description
[x_<company-code>_<my_inventory_tracker_app>_stock_location]	

Experiences in the Inventory Tracker app template

Experience	Experience type	Description
Inventory Control | Portal	Form	Form for admins and managers to add inventory items, view stock quantity, and add stock locations.
Inventory request | Workspace	Form	Form for employees to submit and manage inventory requests.
Inventory Control | Default view	Form	Form for admins and managers to manage inventory items, view stock quantity, and manage stock locations.
App name | Portal	Portal	Portal where all users can manage inventory requests and tracking.
Inventory request | Default view	Form	Form for admins and managers to inventory items, view stock quantity, stock locations, and add notes.
Inventory request | Portal	Form	Form for admins and managers to request inventory items.
App name | Workspace	Workspace	Workspace to manage all Inventory tracker app configuration.
Stock Location | Workspace	Form	Form for inventory managers to add stock names, addresses, and descriptions.
Stock Location | Default view	Form	Form for inventory managers to add stock name, address, description, and department.
Inventory Control | Workspace	Form	Form for admins and managers to manage inventory items, view stock quantity, and stock locations.
Inventory Tracker App	Form	Form for employees to view inventory list, see stock quantities, request items, and check the status of their requests using their

Experience	Experience type	Description
		organization's iOS or Android app.

Automated workflows in the Inventory Tracker app template

Workflow name	Workflow type	Description
Inventory Tracker Request Completed - Admin/Manager	Flow - record	Sends a notification when an inventory request has been completed.
Request Update as Submitted - Manager	Email	Notifies a manager that they have a new update on a requested item.
Item Out of Stock- Admin	Email	Informs an admin of items that are out of stock.
Return Date Updated - Manager	Email	Notifies manager of an updated return date.
Inventory Tracker Request Submitted - Manager	Flow - record	Notifies managers when an inventory request is submitted.
Inventory Tracker Inventory track Created - Admin	Flow - record	Notifies admins when an inventory track is created.
Stock Location Updated - Admin	Email	Informs an admin of updated stock location.
Inventory Tracker Checked Out - Employee	Flow - record	Notifies an employee when an item is checked out.
Request Overdue - Manager	Email	Informs a manager of an overdue request.
Item Returned - Manager	Email	Informs a manager of returned items.
Request Completed - Manager	Email	Informs a manager of a completed request.
Inventory Tracker Request Approved - Employee/Admin/ Manager	Flow - record	Notifies employees, admins, and managers when an inventory request is approved.
Inventory Tracker Request Submitted - Employee	Flow - record	Notifies employees when their inventory request is submitted.
Checked Out - Employee	Email	Notifies employees of items that are checked out.
Inventory Tracker Out of Stock - employee	Flow - record	Notifies employees if an inventory item is out of stock.
Return Date Updated - Admin	Email	Informs an admin of an updated return date.

Workflow name	Workflow type	Description
Request Canceled - Manager	Email	Notifies a manager when a request is cancelled.
Inventory Tracker Stock Location Updated - Admin	Flow - record	Notifies admins when a stock location is updated.
Item Out of Stock - Manager	Email	Notifies a manager when an item is out of stock.
Inventory Tracker Item Returned - Employee/ Manager	Flow - record	Notifies an employee or manager when an item is returned.
Inventory Tracker Inventory track updated- Admin	Flow - record	Notifies an admin when an inventory track is updated.
Item returned - Employee	Email	Notifies employees of returned items.
Request Denied - Admin	Email	Informs admins of denied requests.
Inventory Tracker Stock Location Created - Admin	Flow - record	Notifies an admin when a stock location is created.
Inventory Item Discontinued - Admin	Email	Notifies admins of discontinued items.
Request Approved - Manager	Email	Notifies managers of an approved request.
Inventory Item Updated - Admin	Email	Notifies admin of updated inventory item.
Inventory Tracker Inventory track Created - Admin	Flow - record	Notifies an admin when an inventory track is created.
Out of stock - Employee	Email	Notifies employees of items that are out of stock.
Inventory Tracker Request Denied - Admin	Flow - record	Notifies admins when an inventory request is denied.
Request Approved - Employee	Email	Notifies employees of approved requests.
Inventory Tracker Item Out of stock - Admin/Manager	Flow - record	Notifies admins and managers when an inventory item is out of stock.
Request Approved - Admin	Email	Notifies admins of an approved request.
Request submitted - Manager	Email	Notifies admins of a submitted request.
Request Overdue - Admin	Email	Notifies admins of an overdue request.
Request Denied - Manager	Email	Notifies managers of a denied request.

Workflow name	Workflow type	Description
Stock Location Created - Admin	Email	Notifies admin when a stock location is created.
Overdue - Employee	Email	Notifies employee of overdue items.
Inventory Tracker Request Updated - Manager	Flow - record	Notifies managers when an inventory request is updated.
Request Denied - Employee	Email	Notifies employee of a denied request.
Inventory Tracker Inventory Discontinued - Admin	Flow - record	Sends a notification when an inventory item is discontinued.
Inventory tracker Return Date Changes - Admin/ Manager	Flow - record	Sends a notification to admin and manager when a return date changes.
Comments Added - Manager	Email	Notifies a manager about added comments.
Comments Added - Admin	Email	Notifies admins about added comments.
Inventory tracker Request Denied - Employee	Flow - record	Sends a notification to employees when their inventory request is denied.
Request Submitted - Employee	Email	Notifies employees when they submit a request.
Request created - Admin	Email	Notifies admins when a request is created.
Inventory Tracker Comments Added - Admin/Manager	Flow - record	Sends a notification to admins and managers when comments are added to inventory requests.
Request Canceled - Admin	Email	Notifies admins of a canceled request.
Inventory Tracker Request Overdue - Employee/ Manager/Admin	Flow	Sends a notification to employees, managers, and admins if a request is overdue.
Inventory Item created - admin	Email	Notifies an admin when an inventory item is created.
Request Completed - Admin	Email	Notifies an admin when a request is completed.
Inventory tracker Request Cancelled - Admin/Manager	Flow - record	Sends a notification to admins and managers when an employee cancels an inventory request.
Inventory tracker Request Created - Admin	Flow - record	Sends a notification to admins when an inventory request is created.

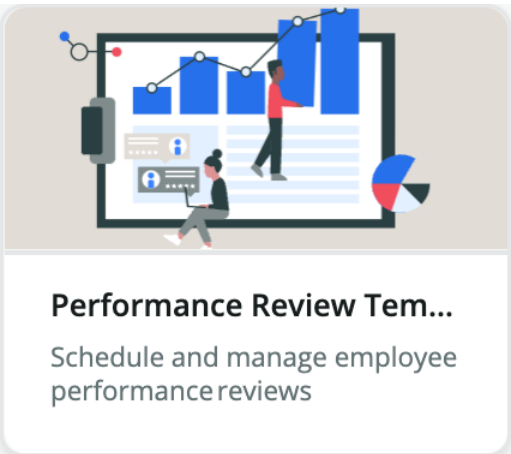
Roles in the Inventory Tracker app template

Role title [name]	Description	Contains roles
Employee [x_<company-name>_<my_inventory_tracker_app>.employee]	Employees can view inventory lists, check stock, request items, and check the status of their requests.	Create, Read (own), Update (own)
Admin [x_<company-name>_<my_inventory_tracker_app>.admin]	Admins can set up multiple inventory managers and stock locations.	Create, Read (all), Update (all), Delete
Inventory Manager [x_<company-name>_<my_inventory_tracker_app>.inventory_manager]	Inventory managers can create inventory items, define the type of item, monitor inventory levels, and update vendor information.	Create, Read (all), Update (all)
Public [x_<company-name>_<my_inventory_tracker_app>.public]	Public users require no login to access features or functions with the public role.	Contains no roles.

Performance Review template

Build an application in App Engine Studio (AES) using the Performance Review template to automate scheduling, notifications, and feedback for performance reviews.

To use the Performance Review template, install this application from the ServiceNow Store.



A performance review app automates the process of scheduling annual or quarterly reviews, reviewing employee performance, and providing manager feedback. The app displays report information by default and lets managers view, update, and request employee performance reviews.

Employees can complete their self-evaluation, monitor the status, and confirm evaluations via a web portal. The app will automatically notify employees and managers to submit their evaluations.

Managers can request an update to the self-evaluations, submit manager-evaluations, confirm evaluations, and monitor the status of their team's submissions via a portal.

The HR/admin role can select an annual, bi-annual, or quarterly review process schedule and edit both the self-evaluation and manager-evaluation templates. HR/admins can monitor the status of all evaluations by department, organization, or manager.

You can improve this template by incorporating the following features:

- Add continuous option as a review process
- Use Playbook to manage review schedules
- Include HR review/escalation process for both self-reviews and manager reviews
- Add peer reviews process
- Add goal setting or objectives and key results (OKRs)
- Add integration with HR software
- Add skill set assessment metrics
- Add performance improvement plan (PIP) process/individual development plans
- Include compensation info/annual performance review (APR)

For more information on creating an application using a template, see Create your app using an application template.

Performance Review template contents

The following tables, experiences, automated workflows, and roles are included in the Performance Review template for App Engine Studio (AES).

Tables in the Performance Review app template

Table label [name]	Description
Performance Review Table [x_<company-code>_<my performance_review_app>_performance_review]	Track the performance evaluations created by employees and managers. For example, the employee name, state of the review, manager feedback, and state of the review.

Experiences in the Performance Review app template

Experience	Experience type	Description
Performance Review | Edit Settings	Form	Form where managers can configure performance review settings and add notifications.
App name | Workspace	Workspace	Workspace where admins and managers can configure review schedules, update evaluation templates, and monitor the status of all evaluations.
Performance Review Test | Emp Mgr feedback	Form	Form for managers to create employee evaluation questions, monitor the status, and leave feedback.

Experience	Experience type	Description
Performance Review | Manager Review	Form	Form managers can use to include questions, review employees responses, and leave feedback.
Performance Review | Self Review WS	Form	Form for employees to complete self review questions.
Performance Review | Workspace	Form	Form for mangers to monitor the status of their team's submissions.
App name | Portal	Portal	Portal where employees can submit, update, review, and confirm evaluations.
Performance Review | Default View	Form	Form that managers and employees can use to view performance reviews.
Performance Review | Self Review	Form	Form employees and managers can use to submit a self-assessment of their performance.
Mobile app	Mobile experience	Employees can access their performance reviews using your organization's iOS or Android app.

Automated workflows in the Performance Review app template

Workflow name	Workflow type	Description
Perf Review - Send PR Employee Update Self-Eval email	Flow - record	Triggers the PR Employee Update Self-Eval email.
PR Employee Manager - Eval submitted	Email	Notifies managers that an evaluation has been submitted.
Perf Review - Send PR Employee Complete Evaluation email	Flow - record	Triggers the PR Employee Complete Evaluation email.
PR Employee Manager - Eval submitted DJ	Email	Notifies managers when self-evaluations are submitted.
PR Admin Eval Deadline Passed	Email	Notifies admins when an evaluation deadline has passed.
PR Reminder: Manager need to submit eval	Email	Reminds managers to submit their evaluations.

Workflow name	Workflow type	Description
PR Manager Self Evaluation Submitted	Email	Notifies admins that managers have submitted self-evaluations.
Perf Review - Send PR Employee Manager - Eval submitted	Flow - record	Triggers the PR Employee Manager - Eval submitted email.
PR Reminder - Employee Self Evaluation	Email	Notifies employees to submit self-evaluation.
Perf Review - Send deadline email	Flow	Triggers a deadline reminder email on the date indicated in the system properties.
PR Employee Complete Evaluation	Email	Notifies employees their evaluation is complete.
PR Employee Update Self Evaluation	Email	Notifies employees they need to update their self-evaluation.
Perf Review - Main Flow	Flow	Controls when reviews are triggered, email reminders, and end of review period is reached. This is the main flow that triggers daily.
Perf Review - Send reminder emails	Flow	Triggers reminder emails on the date indicated by sys_properties.
Perf Review - Create records	Flow	Triggers review records on the date indicated by sys_properties.
Perf Review - Set review inactive	Flow	Inactivates reviews on the end date of the review period, specified in sys_properites.
PR Admin Self - Eval Submitted w/o Manager	Email	Notifies admins if a self-evaluation is submitted without a manager or title.
PR Reminder Employee Update Self Eval	Email	Notifies employees to update self-evaluation.
Perf Review - Send Manager/ Admin Self-Evaluation Submitted email	Flow - record	Triggers the PR Admin Self-Evaluation Submitted without manager or the PR Manager Self Evaluation Submitted email.

Roles in the Performance Review app template

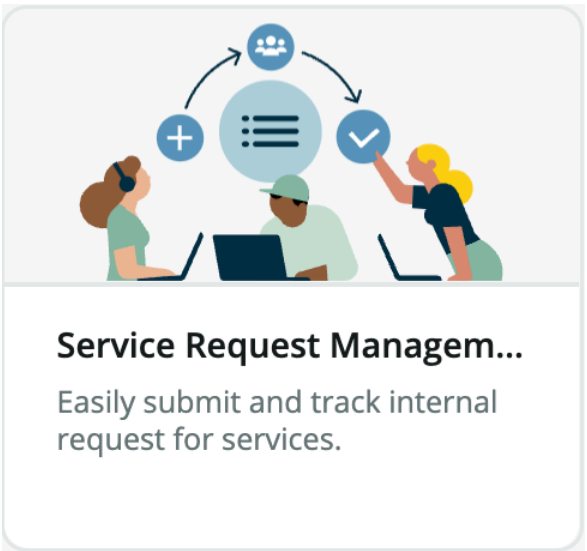
Role title [name]	Description	Contains roles
Employee	Employees can complete/ update self-evaluations and confirm evaluations.	Read (own) and Update (own)

Role title [name]	Description	Contains roles
[x_<company-name>_ <my performance_review_app>.employee		
HR/Admin [x_<company-name>_ <my performance_review_app>.admin	HR/Admins can schedule reviews (annual, bi-annual, custom, or manual), edit self and manager evaluation templates, and monitor the status of all reviews.	Create, Read (own), Update (own), Delete (all)
Manager [x_<company-name>_ <my performance_review_app>.manager	Managers can request updates to a self-evaluation, submit manager-evaluations, and monitor issues related to evaluation submissions.	Read (my team) and Update (my team)

Service Request Management template

Build an application in App Engine Studio (AES) using the Service Request Management template to create, track, and manage service requests in your organization.

To use the Service Request Management template, install the application from the ServiceNow Store.



Personas in the Service Request Management template

This template contains several important roles that correspond to individuals or groups who may use the app in some way. The following information describes how each persona may interact with the application you build. For more information on the permissions each role contains, see the Security section.

Requester

You are a person who has a request.

Problem: You need a service or a physical item to complete your responsibilities. You want to know that your request is in progress and reassurance that it is making progress. If you have questions or your request has changed, you want the ability to communicate that to those working on the request.

App objective: Empower employees by guiding them through the process, including what information is required. Make the approval process transparent, and keep them updated on the status and outcome of their request.

Fulfiller

You are a person or team who must complete a task in a timely manner.

Problem: You only want to be assigned a task when it is ready to be fulfilled, meaning after required approvals or dependent tasks (if relevant) are closed. You need to ensure that requests are closed in a timely fashion, especially in adherence with SLAs.

App objective: Direct the fulfiller's attention to the tasks assigned to them and their team. Empower them by providing the information they need such as request information and SLA.

Fulfiller's manager

You are the manager of the fulfillment team, and you can fulfill tasks.

Problem: You need to ensure tasks are being efficiently closed by your team. You want to spot bottlenecks such as popular service requests creating a backlog of tasks, a fulfiller who is under-performing, or late approvals blocking fulfillers from completing their tasks on time.

App objective: Direct the fullfiller's manager to tasks that need immediate attention so SLAs are met. Clearly show what their team is working on so they can re-prioritize work as needed.

Service owner

You are the owner of the services within the app.

Problem: You need to analyze how services are performing and identify which services need attention. You need information that will help you recommend improvements to the process, if necessary.

App objective: Provide aggregate information that indicates each service's performance, measured by resolution and response time.

Approver

You are the gatekeeper and can respond to or reject requests, saving time for fulfillers.

Problem: You must review requests before they are assigned to a fulfillment team to ensure the ticket is appropriate.

App objective: Direct the approver's attention to the requests that require their approval. Empower them by providing the information they need such as request and SLA information.

Related concepts

For information about how to set up a service for your Service Request Management application, see Service catalog setup.

Service Request Management template contents

The following tables, experiences, automated workflows, and roles are included in the Service Request Management template for App Engine Studio (AES).

Tables in the Service Request Management app template

Table label [name]	Description
Primary [x_ <company-code>_<primary>]	Table that extends the Task table and stores the details of requests raised for the Service Request Management: Primary catalog item. To create a new service and table, extend this Primary table.
Example Request [x_ <company-code>_<example_request>]	Example Request table created by extending the Primary table that stores the details submitted from the Travel Request catalog item.
Fulfiller Task [x_ <company-code>_<fulfiller_task>]	Stores fulfiller tasks and helps admins keep service requests organized.

Experiences in the Service Request Management app template

Experience	Experience type	Description
Travel Request | Fulfiller view	Form	Form for fulfillers to create a travel request record.
Primary | Fulfiller view	Form	Form for fulfillers to create a service request record.
Fulfiller task | Default view	Form	Form for users to create a fulfiller task.
Fulfiller Workspace	Workspace	Workspace for fulfillers to see requests that need their attention, create requests, view request assignments, and see data and analytics related to their requests.
Approver Workspace	Workspace	Workspace for approvers to see requests pending their approval, approve or deny requests, and see data and analytics related to their requests.
Fulfiller Task | Fulfiller task view	Form	Form for users to create a fulfiller task.
Service Request Management: Primary	Record producer	Contains questions to add information and attach documents relevant to a service request.
Travel Request	Record producer	Contains questions to add information and attach documents relevant to a travel request.

Experience	Experience type	Description
Primary | Default view	Form	Form for users to create a service request record.
Fulfiller's Manager	Workspace	Workspace for the fulfiller's manager to see requests pending their approval, create requests, approve or deny requests, and see data and analytics related to their and their team's requests.
Travel Request | Default view	Form	Form for users to create a travel request record.

Automated workflows in the Service Request Management app template

Workflow name	Workflow type	Description
Fulfiller task work notes added	Email	Notifies users in the Assigned to field, Work notes list, and Watch list when work notes are added to a fulfiller task.
Fulfillment Process Trigger	Email	Notifies a service owner when a fulfiller task has been created but has no default Fulfiller or Fulfillment Assignment Group.
On Insert empty Assigned to	Email	Notifies an assignment group when a request record has been created and has no assignee.
On Insert/Change Assigned to	Email	Notifies a user that a request record has been assigned to them.
Assignment Process	Flow - record	Creates and updates a new record as it moves through the assignment, approval, and fulfillment processes.
Fulfiller Decision	Decision table	Defines the default fulfiller user and fulfiller assignment group for each service.
Approval Process	Flow	Moves a record through the approval process.
Approver Decision	Decision table	Defines the default approver and approver assignment group for each service.
Fulfillment Process	Flow	Moves a record through the fulfillment process.
Child worknotes added	Email	Notifies users named in the **Assigned to** field, Work notes

Workflow name	Workflow type	Description
		list, and Watch list when work notes are added to a travel request task.
Primary worknotes added	Email	Notifies users in the **Assigned to** field, Work notes list, and Watch list when work notes are added to a request record on the Primary table.

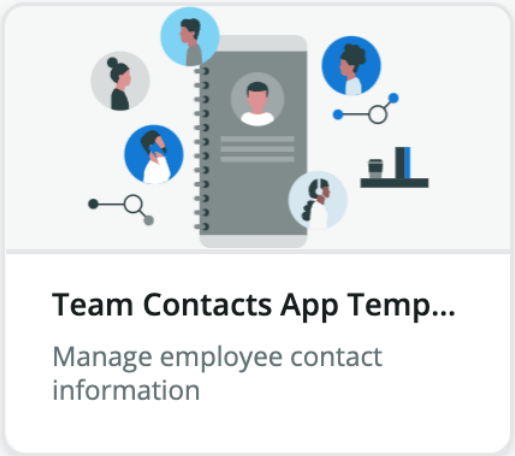
Roles in the Service Request Management app template

Role title [name]	Description
Approver [x_<company-name>_ <app_name>.approver]	Provides access to approver workspace and provides read and write access to the Primary [x_ <company-code>_<primary>] and Travel Request [x_ <company-code>_<travel_request>] tables.
App admin [x_<company-name>_ <app_name>.app_admin]	Provides complete access to the Service Request Management data and workspaces.
Fulfiller's manager [x_<company-name>_ <app_name>.fulfillers_manager]	Provides access to fulfiller's Manager workspace and provides read and write access to the Primary [x_ <company-code>_<primary>], Travel Request [x_ <company-code>_<travel_request>], and Fulfiller Task [x_ <company-code>_<fulfiller_task>] tables.
Requestor [x_<company-name>_ <app_name>.requestor]	Provides access to submit a request for default record producers from a service portal and provides read and write access to the Primary [x_ <company-code>_<primary>] and Travel Request [x_ <company-code>_<travel_request>] tables.
Fulfiller [x_<company-name>_ <app_name>.fulfiller]	Provides access to the fulfiller workspace and provides read and write access to the Primary [x_ <company-code>_<primary>], Travel Request [x_ <company-code>_<travel_request>], and Fulfiller Task [x_ <company-code>_<fulfiller_task>] tables.
admin [x_<company-name>_ <app_name>.admin]	The System Administrator role. This role has access to all system features, functions, and data, regardless of security constraints.

Team Contacts template

Build an application in App Engine Studio (AES) using the Team Contacts template to manage contact information for the people in your organization.

To use the Team Contacts template, install this application from the ServiceNow Store.



A team contacts app uses a mobile experience to view employee contact information, tag favorites, and add privacy notes. The app displays report information by default and lets an employee search for employees, view employee profiles, and create a list of favorite employee contacts.

For more information on creating an application using a template, see Create your app using an application template.

Team Contacts template contents

The following tables, experiences, automated workflows, and roles are included in the Team Contacts template for App Engine Studio (AES).

Tables in the Team Contacts app template

Table label [name]	Description
Relationship Contact Table [x_<company-code>_<team_contact>_relationship_contact]	Tracks employee contact information. For example, contact names, date created, favorites, and updates.
Reminder Table [x_<company-code>_<team_contact>_relationship_contact_reminders]	Tracks reminders created by your team. For example, when to send a reminder and the subject of a reminder.
Relationship Notes Table [x_<company-code>_<team_contact>_relationship_notes]	Tracks the notes that employees create for each other. For example, the employee name, reason for contact, HTML notes, and option to mark the contact as a favorite.

Experiences in the Team Contacts app template

Experience	Experience type	Description
Employees Mobile experience	Mobile experience	Provides employees access to an employee directory and relationship notes using your organization's iOS or Android app.

Experience	Experience type	Description
Team contact	Portal	Portal where employees and managers can view employee profiles, mark favorite contacts, and add relationship notes using a website. The team contacts portal includes a sign-in page, a home page, and a page to add relationship notes.
Note | Default view	Form	Form to add notes to contact information.
Relationship contact	Form	Form to view contact information.
Reminder | Portal	Form	Form for employees and managers to set reminders.
Reminder | Default view	Form	Form for employees and managers to set reminders.
Note | Portal	Form	Form for managers and employees to add notes to contacts.

Automated workflows in the Team Contacts app template

Workflow name	Workflow type	Description
Team Contact Reminder Push	Email	Sends a reminder push to employees.
Notify Contact Reminder	Flow - record	Sends a notification about a reminder that an employee sets up in a relationship note. The notification contains details from the relationship note.
Team Contact Reminder Notification	Email	Sends a reminder to employees.
Team Contact Reminder Ackn Notification	Email	Sends employees a reminder to acknowledge a notification.

Roles in the Team Contacts app template

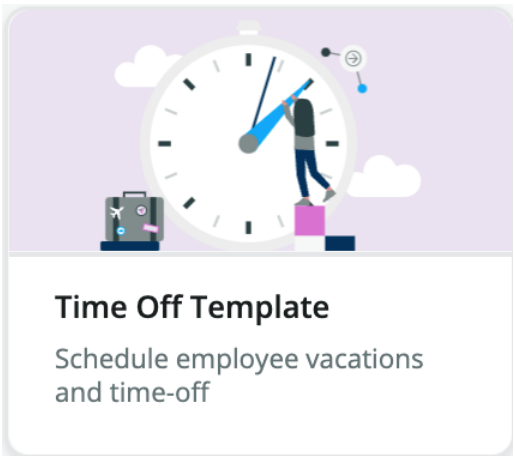
Role title [name]	Description	Contains roles
Manager [x_<company-name>_ <app-name>.manager]	Managers can view profile info, add relationship notes, and see their direct reports.	Create, Read (own), Update (own), Delete (own)

Role title [name]	Description	Contains roles
Admin [x_<company-name>_ <app-name>.admin]	Managers can configure the team contacts app and grant access to the app.	Read (all), Update (all), Delete
Employee [x_<company-name>_ <app-name>.employee]	Employees can view information on their team, search for employees, view employee profiles, and mark favorite contacts.	Create, Read (own), Update (own), Delete (own)
Canvas user	User role for Canvas Core application	

Time Off template

Build an application in App Engine Studio (AES) using the Time Off Requests template to schedule employee vacations and time-off.

To use the Time Off template, install this application from the ServiceNow Store.



Create a time off application to streamline the process for employees to request time off through a single mobile or web-based form. Managers are notified via email when a request is submitted. They can use a mobile app or a web-based portal to view historical and pending requests by month or year for an employee or their entire team. This allows the manager to make informed decisions, improve planning for upcoming work, or identify where shifts must be covered. Employees are automatically notified when their requests are approved or rejected and why. If plans change and updates to an approved request are required, the employee can edit and resubmit their requests for approval through the portal.

For more information on creating an application using a template, see Create your app using an application template.

Time Off template contents

The following tables, experiences, automated workflows, and roles are included in the Time Off template for App Engine Studio (AES).

Tables in the Time Off app template

Table label [name]	Description
Time Off Request Table [x_<company-code>_<my_time_off_request_app>_request]	Track time off requests that employees create using the Time Off Request app. For example, the employee name, creation date, manager, requested days off, and state of the time off request.

Experiences in the Time Off app template

Experience	Experience type	Description
Time Off Request | Default view	Form	Form for managers and admins to use as a template for time off requests.
Time Off Request | Workspace	Form	Workspace where managers can view, submit, and approve or reject time off requests. The workspace also contains historical records which can be viewed by team, employee, and time.
App name | Portal	Portal	Portal for managers and admins to view, submit, and approve or reject time off requests and for employees to view, edit, review, or cancel their time off requests.
App name | Workspace	Workspace	Workspace where managers and admins can use view, submit, and approve or reject time off requests.
Time Off Request | Record	Form	Form that managers can use to view, submit, and approve or reject time off requests.
Time Off Request | New	Form	Users can create new (save, submit, or cancel), update (save, submit, delete, or cancel), and review (approve or reject) time off requests.
Mobile app	Mobile experience	Employees can request time off and access their requests. Managers can submit, view, update, approve or reject time off requests using your organization's iOS or Android app.
Dashboard	Mobile experience	Managers and admins can view time off requests using

Experience	Experience type	Description
		your organization's iOS or Android app.

Automated workflows in the Time Off app template

Workflow name	Workflow type	Description
Time off request - Send comments	Flow - record	Sends a notification to an employee or manager when a comment has been added to a time off request.
Daily Time Off inactivating records	Flow	Updates the remaining time off on Time off request records until the remaining days is set to 0.
Time Off Req Approved	Email	Notifies an employee of an approved time off request.
Time Off Req Updated/ resubmitted	Email	Notifies managers of updated/ resubmitted time off requests.
Time Off Comments	Email	Notifies an employee or manager of a comment added to a time off request.
Time Off requests - Send notifications	Flow - record	Sends a notification to an employee or manager when a time off request state changes. The notification contains details from the time off request.
Time Off Request Cancelled	Email	Notifies an employee or manager of a cancelled time off request.
Time Off Request Rejected	Email	Notifies an employee of a rejected time off request.
Time Off Request - updated/ resubmitted	Flow - record	Sends a notification to an employee or manager that a time off request is updated/ resubmitted.
Time Off Req Submitted	Email	Notifies a manager when a time off request is submitted.
Time Off Request	Email	Employees can draft, request, approve, reject, and cancel time off requests.

Roles in the Time Off app template

Role title [name]	Description	Contains roles
Manager [x_<company-name>_ <my time_off_request_app>.manager]	Managers can submit, view, approve, and reject time off requests	Create, Read (all), Edit (all)
Employee [x_<company-name>_ <my time_off_request_app>.employee]	Employees can submit, view, edit, and cancel time off requests	Create, Read (own), Edit (own), Delete (own)
Admin [x_<company-name>_ <my time_off_request_app>.admin]	Admins can manage the time off app and view all records	Create, Read (all), Edit (all), Delete (all)
Public	Public users require no login to access features or functions within the application.	Role contains no access by default.

Build a custom template

App Engine Studio (AES) provides various predefined application templates. However, creating custom templates can speed up time to production if you have types of applications that you want to create more than once.

You can create a custom template from scratch or use existing content as a starting point. If one of the predefined AES templates is close to what you need, consider extending that template and then customizing it for your needs. Complete your template by adding and customizing data, experiences, logic and automation, and security roles for access.

Build a custom template from an existing application

Use an existing application as a starting point to build a custom template in App Engine Studio (AES). Existing data, experience, logic and automation, and security roles from the application are automatically added to the custom template.

Before you begin

Role required: admin, app_template_author

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the Template page, select **Create new template**.
3. Select **Existing app**, and then select **Continue**.
4. On the app selection screen, select an existing application for the custom template creation, and then select **Continue**.
   The following outcomes are possible.

- All items are supported: The custom template is created. All the objects are available in the custom template and in apps created from the custom template.
- Some items aren't supported: You can continue to create the template but a few items are not available in the custom template. There's no impact on the custom template or the apps created from the template.
- Some items are denied: You encounter an error message and cannot continue further until the errors are fixed. The author must change the app, if it was created from an existing app or the template, if it was created from scratch.

Note:
For more information, see Supported features and metadata in custom templates.

5. Enter a name and description for the custom template.
6. Accept or change the application's logo.
   - If the existing application has a logo in SVG format, the same logo is applied to the custom template.
   - If there's no logo or the logo is in a format other than SVG, upload an SVG logo for the custom template by either dragging the image to the **Browse or drag an SVG image** field or selecting the field, selecting the image from your file directory, and selecting **Open**.
7. Select **Continue**.
8. Specify which users or groups should have access to this template.

Option	Description
Share with specific users and groups	**a.** From the **Shared with** list, select **Specific users and groups**. **b.** Add users individually or in groups. **c.** Select **Give access**. **d.** Select **Continue**.
Share with all users and groups	**a.** From the **Shared with** list, select **All users and groups**. **b.** Select **Continue**.

For more information about template sharing and permissions, see App template sharing.

9. Access the custom template in one of the following ways.

Result
Your custom template is created and ready for your use. The custom template is activated and is available to App Engine Studio users who have access to it.

Build a custom template from scratch

Build your custom template from scratch if none of the predefined App Engine Studio (AES) templates fit your business needs or you don't have an existing application as a starting point.

Before you begin
Role required: admin, app_template_author

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the Template page, select **Create new template**.
3. Select **Start from scratch**, and then select **Continue**.
4. Enter a name and description for the custom template.
5. **Optional:** Add a logo to the custom template by either dragging the image to the **Browse or drag an SVG image** field or selecting the field, selecting the image from your file directory, and selecting **Open**.
6. Select **Continue**.
   A progress message indicates when the empty custom template has been created.
7. Specify which users or groups should have access to this template.

Option	Description
Share with specific users and groups	**a.** From the **Shared with** list, select **Specific users and groups**. **b.** Add users individually or in groups. **c.** Select **Give access**. **d.** Select **Continue**.
Share with all users and groups	**a.** From the **Shared with** list, select **All users and groups**. **b.** Select **Continue**.

   For more information about template sharing and permissions, see App template sharing.
8. On the template details screen, select **Go to template dashboard**.
9. Add data, experience, logic and automation, and security measures to the custom template. For more information, see the following topics:
   - Create a data model for your application
   - Add an application experience
   - Add logic and automation
   - Add application security
10. Select **Save**.

What to do next

Provide an overview of the custom template and activate the template to make it available to App Engine Studio users through the template library. For more information, see Update custom template contents and properties.

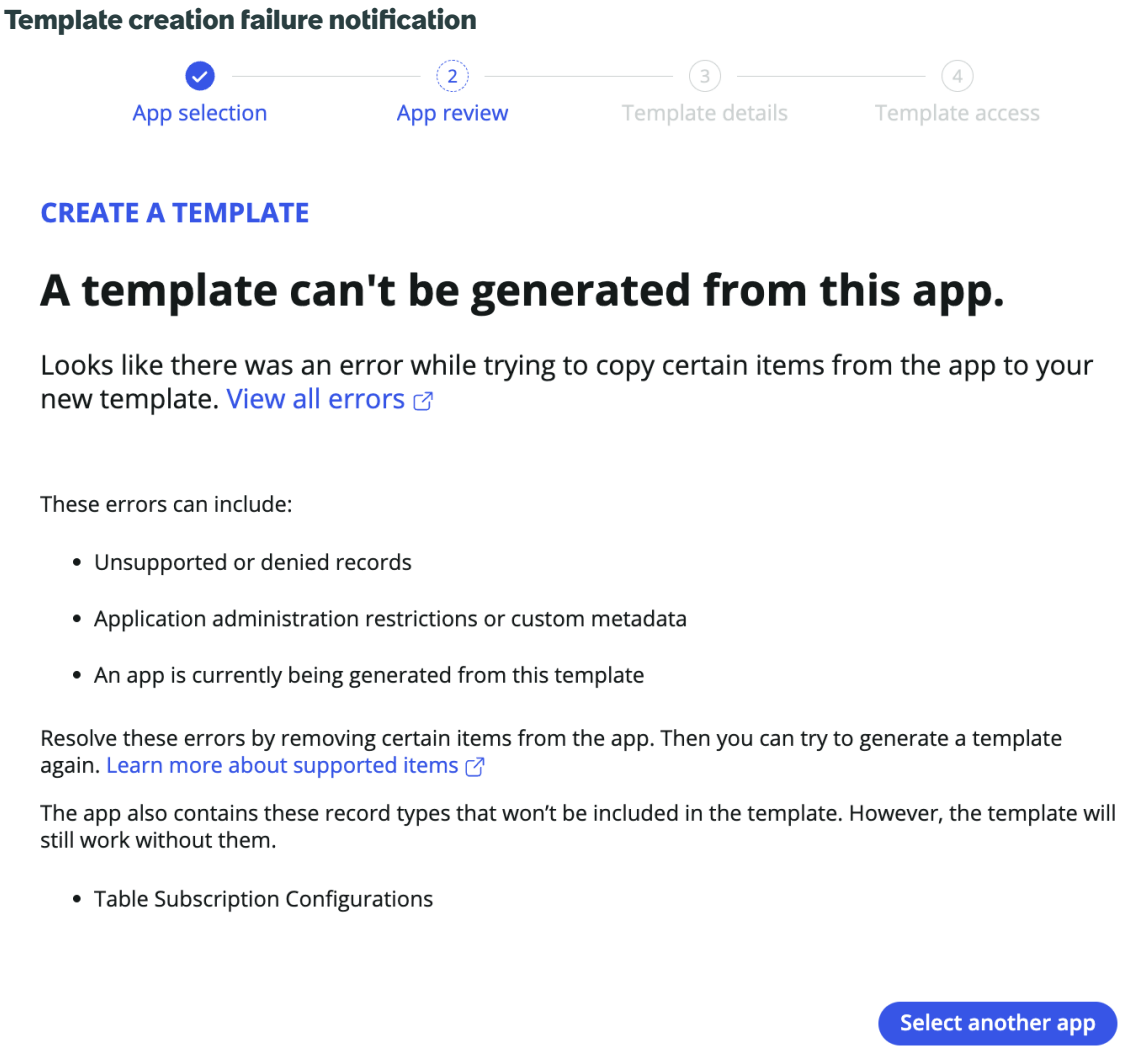
Identifying and fixing app template creation errors

Learn how to identify and fix your app when unsupported features or metadata stop the template creation process in App Engine Studio (AES).

Unsupported features

Sometimes items in a source application from which you created a custom template aren't supported in the template. You must remove unsupported items before you can create a template from the application.

When an error happens during the template creation process, an error message is displayed.



You can identify which elements of your application are causing it to fail the template creation process by selecting **View all errors**, which displays the Scan Failure [sys_app_scan_failure] table. For more information about the errors in the table and their cause, see Template creation errors in the Scan Failure table.

Template creation errors in the Scan Failure table

Errors that occurred during the creation of a custom template that are displayed in the Scan Failure [sys_app_scan_failure] table and their cause.

Error messages

For more information about what types of records are allowed and skipped, see Supported features and metadata in custom templates.

Error message	Definition	More details
Unsupported_table	Record class for which there is no allow rule, and there's an unknown level of support.	One or more unsupported records are unrecognized by App Engine Studio and must

Error message	Definition	More details
		be removed for the template creation process to continue.
Denied_table	Record class for which there is a deny rule, and template creation isn't supported.	The record class is explicitly denied and must be removed for the template creation process to continue.
Scripted_record	Scripted rule that runs on each record in the app.	Current scripted deny rules include, but aren't limited to: • Custom metadata: The app has tables that extend the sys_metadata table. • Scoped administration: The app has scoped administration turned on. • Template execution in progress: The template associated with the source app is currently being executed.
Scripted_app	Scripted rule that runs once for the app.	

Assign permissions to publish custom templates

Assign permissions for developers to publish a custom template to the application repository or the ServiceNow Store. You can grant permissions to publish either a specific custom template or publish all existing custom templates in App Engine Studio (AES).

Assign permissions to publish an individual custom template

Assign permissions to developers so they can publish an individual App Engine Studio (AES) custom template to the application repository or ServiceNow Store.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **App Engine** > **Templates** > **App Templates**.
2. Select the personalize List icon (⚙).
3. Add the Package column by moving the **Package** value from the **Available** list to the **Selected** list and select **OK**.
4. From the Package column, select the package link for your custom template.
5. Under the **Related links** heading, select **Manage Collaborators**.
6. Assign permissions to new or existing collaborators.

Result
The specified user or group now has permission to publish an individual custom template.

Assign permissions to publish custom templates and apps

Assign permissions for developers to publish custom App Engine Studio (AES) templates and applications to the app repository or ServiceNow Store.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **App Engine** > **Collaboration** > **Descriptors**.
2. In the **Name** field of the All Collaboration Descriptors page, search for and select **Owner**.
3. From the **Development Permission Sets** tab, select **Edit**.
4. Move the **Publish To App Repo** and **Publish To App Store** values from the **Collection** list to the **Development Permission sets** list.
5. Select **Save**.

Result

Developers who own applications now have permissions at a platform level to publish all custom templates to their application repository or ServiceNow Store.

Publish a custom template

You can publish a custom template that is built from scratch or from an existing application using App Engine Studio (AES).

Before you begin

You must have permissions to publish a custom template. For details, see Assign permissions to publish custom templates.

Role required: admin, app_template_author

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio** > **Templates**.
2. Point to the custom template, select the More actions icon (•••), and select **Properties**.
3. On the **General** tab, select the **Activate this template** check box.
4. Select **Publish template**.
5. **Optional:** For a custom template built from scratch, select **Publish anyway**.

   (Optional) App Engine Studio displays the publish template fields.
6. Fill in the fields.

Provide a version number and release notes

Field	Description
Version	Provide a new version number for the custom template.
Release notes	Provide a brief description of the changes made to the custom template.
Publish options	Select where you want the custom template published. ○ To publish the template to your application repository, select **My application repository (Make the app available to my instances)**. ○ To publish the template to the ServiceNow Store, select **ServiceNow Store (Submit this app to the ServiceNow Store for review)**.

7. Select **Continue**.
8. On the confirmation screen, select **Close**.

Result
The custom template is published and available to users the app template admin shares it with.

Update custom template contents and properties

Improve the effectiveness of your custom template by updating its contents or properties in App Engine Studio (AES).

Before you begin
Role required: admin, app_template_author

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. Select the **Template** tab.
3. Modify different aspects of the template to make them more useful to your needs.

Manage template activation

Manage template activation and deactivation to ensure that users creating apps in App Engine Studio (AES) have access to the best application templates for their needs.

Before you begin
Role required: app_template_admin

About this task
App template admins manage the templates that are active in non-production instances and determine which users can see and use those templates. Admins may want to deactivate custom templates that deviate from company standards or don't suit the needs of their users.

Procedure

1. Navigate to **All** > **App Engine** > **Templates** > **App Templates**.
2. Select the template that you want to activate or deactivate.
3. To edit the template, select **here** in the message that appears.
4. Activate or deactivate the template.
   - To activate the template, select the **Active** check box.
   - To deactivate the template, clear the **Active** check box.
5. Select **Update**.

App template sharing

Specify which users and groups have access to predefined and custom templates in App Engine Studio (AES).

Implicit sharing

Templates are implicitly shared with some users in your organization, meaning that no sharing record exists that determines sharing. The three rules governing implicit sharing are:

- Instance administrators can see and use all templates.
- App template admins (users with the app_template_admin role) can also see and use all templates.
- App template authors (users with the app_template_author role) can see templates that are not shared with them if they have permission to edit the scope in which the template resides.

These sharing rules apply regardless of whether a template is active.

Explicit sharing

You can share app templates with anyone in your organization by creating a sharing record for that user or group. However, regardless of sharing permissions, the user or group must have the sn_app_eng_studio.user role to see and use the template. The three ways to share templates are:

- Share globally with every user in your organization
- Share with a specified user group
- Share with a specified single user

Note:
If you stop sharing a template with an individual user but that user is a part of any group the template is shared with, that user is still able to see and use the template.

Manage template sharing permissions

Share App Engine Studio (AES) templates globally, with groups, or with individual users to ensure users have access to the right templates.

Before you begin
Role required: app_template_admin

Procedure

1. Navigate to **All** > **App Engine** > **Templates** > **App Templates**.
2. Select the template you want to modify sharing permissions for.
3. In the Template Sharing Permissions related list, select **New**.
4. Select a sharing option.
5. Select **Submit**.

Create your application from scratch

If the available application templates in App Engine Studio (AES) don't fit your application goal, create an empty application to which you can add data, experience, logic and automation, and security.

Before you begin

Note:
To create apps in AES, you must be an admin or in the App Engine Studio Users group. If you are in the App Engine Studio User Limited group, you can only edit existing apps, not create new ones.

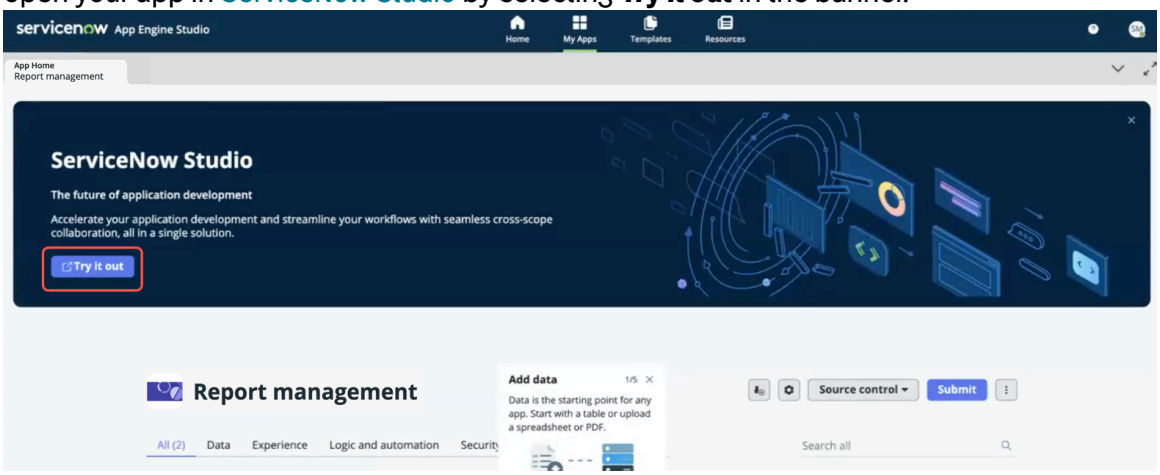
Role required: admin, sn_app_eng_studio.user

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. Select **Create app**.
3. Enter a **Name** and **Description** for your application.
4. **Optional:** Add a logo by either dragging the image to the **Drag app logo or browse to upload** field or selecting the field, selecting the image from your file directory, and selecting **Open**.
5. Select **Continue**.
6. Control who has access to create, read, write, and delete content in your application by adding or customizing roles.
   To add security roles to your app, select **Add a role**, and enter a name and description for the role.

   Note:
   At least one role must have **Read** access to be able to update application security.

7. Select **Continue**.
8. On the summary screen, select **Go to app dashboard**.
9. **Optional:** If you want a more advanced app development environment to work in, you can open your app in ServiceNow Studio by selecting **Try it out** in the banner.



10. **Optional:** Review the guiding information for each section of your application by enabling the **Guidance** toggle ( ) in the bottom left corner of the window.
11. Continue building your application by adding data, experiences, logic and automation, and security to your app.
    For more information, see the following topics:
    - Create a data model for your application
    - Add an application experience
    - Add logic and automation
    - Add application security

What to do next

After you've finished building your application, submit the application for approval to get it reviewed and deployed by an administrator. For more information, see Submit your app for approval and publishing.

Prepare your app for approval

Prepare your app for the approval process by making any needed changes, such as renaming your app, editing the app description, or replacing the app image. You can also delete the app from App Engine Studio (AES) if it has taken a wrong turn.

Before you begin

Role required: admin, sn_app_eng_studio.user

About this task

You can change certain features of your application, based on your permissions. To request delete permissions, contact your administrator.

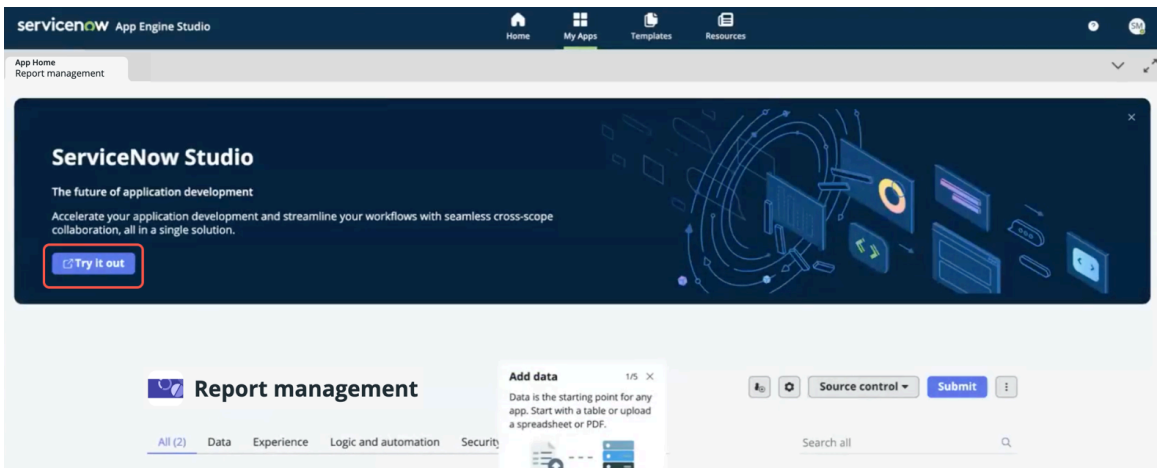
Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. From the app home, select the Edit application properties icon ( ).
4. Update the application properties.
   - To rename the application, update the **Name** field.
   - To rewrite the application description, update the **Description** field.
   - To replace an image, select **Remove image** and then add a new image.
   - To delete your application, select **Delete application**, type `Delete` to confirm your choice, and select **Delete**.
5. Select **Save**.

Enhance your app

Whether you use a template or create your app from scratch in App Engine Studio (AES), you must enhance it by creating a data model, user experiences, logic and automation, and security.

If you're creating apps in App Engine Studio (AES) and want a more advanced app development environment to work in, you can open your app in ServiceNow Studio. When you open your app in AES, a banner appears with information about ServiceNow Studio. Select **Try it out** to open your app in ServiceNow Studio.



Use the following topics as guides as you build out your application.

Resources for enhancing your app

As you add data, experience, logic and automation, and security to your application, you might interact with several different parts of the ServiceNow AI Platform. The links in the following table point you to resources for adding content in App Engine Studio and also Table Builder, UI Builder, Decision Builder, App Engine Management Center, and the ServiceNow AI Platform.

Resources for adding content to your application

Add data	Add an experience	Add logic and automation	Add security
Add data to your application in App Engine Studio. • Create a data model for your application • Create a blank table • Use a spreadsheet to add data • Use a PDF to create data tables • Create a data integration • Modify application data tables	Work in App Engine Studio to add experiences to your application. • Add an application experience • Add a record producer • Add a standard catalog item • Add a workspace • Add a portal • Add a mobile experience • Editing an experience in App Engine Studio	Build logic and automation into your application in App Engine Studio. • Add logic and automation • Add a pre-built flow using a template • Add a flow from scratch • Add a decision • Add an email notification • Edit a process	Configure roles to manage your application's security in App Engine Studio. • Add application security • Build a new role for your application • Use an existing role for your application • Collaborate with other developers • Change access settings for a role • Delete a role
Seamlessly transition to using Table Builder to enhance your application's data. • Exploring Table Builder • Data in Table Builder • Forms in Table Builder • Policies and rules in Table Builder • Flows in Table Builder	Use Workspace Builder and UI Builder to further enhance experiences in your application. • Add a workspace • Configure a workspace in Workspace Builder • UI Builder and configurable workspaces • Configure how users interact with your applications in UI Builder • Customize UI Builder pages using components	Use Decision Builder to easily manage business logic for your application. • Create decision tables in Workflow Studio • Manage decision tables in Excel • Modify decision table structure in Workflow Studio • Modify decision table rules in Workflow Studio	Configure and manage roles for your organization and application using the ServiceNow AI Platform and App Engine Management Center. • Configure AES personas and roles • Configure users and groups • Add users to the App Engine Admin group • Delegate developers using AES

Resources for adding content to your application (continued)

Add data	Add an experience	Add logic and automation	Add security
			• Managing developers using AEMC • Manage collaboration requests

Create a data model for your application

Create a data model in App Engine Studio (AES) for your application by creating the tables that will house your application data. Create data tables that will be used in your application by creating the table from scratch, uploading a spreadsheet or PDF, or by using an existing table as a template. You can also create and schedule data imports by mapping a spreadsheet to an existing table in your application.

Creating a data model and populating data into user interfaces are crucial starting points for any new application. Users may provide data, such as their name and phone number, when they fill in a form, and other users may refer to data as they fulfill a request.

In App Engine Studio, application data is stored in table format. When users update application data, they create a row or change an existing row in the table (each row is also known as a data record). You can create tables from existing ServiceNow AI Platform tables, from a spreadsheet or PDF, or customize a completely new table for your application to store records in.

The data records stored in your application may come from several sources. One table might store data records entered by users who are using your application, another might be populated via the import and mapping of data from a spreadsheet or through a script that updates data records with data from another ServiceNow AI Platform table.

Application templates and data

Application templates automatically add data to your application. If you use a template to create your application, you can edit the tables that were added or add different tables.

Forms

When you add data to your app, any associated form views display in the **Experience** section of your app. To edit the form, select it in the **Experience** section. Form views can be edited in the **Forms** tab of Table Builder. For more information, see Forms in Table Builder.

Table extension

There are several tables that your organization may already be using in other applications. For example, your organization may be using the Configuration item [cmdb_ci] table for an application that houses configuration data. You can create a table for your application by extending any of these existing tables.

Table extension allows a table to share fields and records with a parent table. You might extend a table if you expect users to fill in similar fields across different form views in an application. For example, to create a ticketing type of table, you might extend the Task [task] table. The Task table includes fields that are standard for most work tickets, such as **Number** and **Assigned to**.

Many organizations create extensible standardized tables for their citizen developers to use when designing their apps. This enables the developers to standardize the way data is utilized across multiple applications within the organization.

To make a table in your application extensible, select **Make extensible** during table creation. After extending an existing table, you can further customize the new table by adding more columns.

The following table provides a list of commonly extended tables in the ServiceNow AI Platform. For more information on commonly extended tables and models for extension, see Table extension and classes.

Commonly extended tables

Table	Short Description	Description
task	Task	Stores fields for the core applications such as Incident, Problem, and Change Management. It provides a series of standard fields used on each of the tables that extend it. Any table which extends the task table can take advantage of task-specific functionality for driving tasks.
cmdb_ci	Configuration Item	Stores configuration items. This table can be extended for configuration items such as hardware, services, etc.
sn_customerservice_case	Customer Service Case	Stores customer service case records.
sm_order	Service Order	Stores data that defines and manages work that needs to be performed.
sm_task	Service Task	Stores units of work performed by one person in one session (one location, one time).
planned_task	Planned Task	Stores additional fields for tasks pertaining to time and effort as part of a planned, multi-stage process.
cmn_location	Location	Stores location information.
cmdb_serviceorder_product_model	Service Order Model	Stores service order templates.
cmdb_servicetask	Service Task Model	Stores service task templates.

Commonly extended tables (continued)

Table	Short Description	Description
_product_mode		
cmdb_qb_result _base	Query Results	Stores query results created by the CMDB Query Builder.
alm_asset	Asset	Stores general, financial, and contractual information about assets.
cmdb_ci_service	Business Service	Stores IT Services data that directly supports a business process.
sys_user	User	Stores user data. The User table provides a list of all system users and their related department.
sys_user_group	User Group	Stores and groups a set of users who share a common purpose. Groups may perform tasks such as approving change requests, resolving incidents, receiving email notifications, or performing work order tasks.
core_company	Company	Stores company information.
cmn_schedule	Schedule	Stores records that specify a time zone and a type of schedule and use one or more schedule entries.
cmn_department	Department	Stores a list of all departments and their related business unit.
cmn_cost_center	Cost Center	Stores cost center records. This is a reference between financial systems and IT. Cost center records represent business entities, and have a related list of CI Cost Center Relationships that measure the cost center's consumption of business services.
cmdb_model	Product Model	Specific versions or various configurations of an asset. Models are used for managing and tracking assets through various ServiceNow platform asset applications, including Product Catalog,

Commonly extended tables (continued)

Table	Short Description	Description
		Asset Management, and Procurement.
life_cycle_stage	Life Cycle Stage	Stores standard fields and values for tracking life cycle stages for CIs. Using these standard values consistently across applications helps to effectively track assets through their life cycle transitions.
life_cycle_stage _status	Life Cycle Status	Stores standard fields and values for tracking life cycle stage status for CIs. Using these standard values consistently across applications helps to effectively track assets through their life cycle transitions.
incident	Incident	Stores deviations from an expected standard of operation.
sysapproval	Approval	Stores data that allows you to require authorization on tasks before the work is done. You can define approvals for all tasks and associate users or groups to a task to approve or reject them.

Use the methods listed below to create a data model and add data to your application.

Create a blank table

Add a data table to your application from an existing table that you or someone else previously created or from scratch.

Before you begin

Role required: admin, sn_app_eng_studio.user, or delegated_developer

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to the Data heading, select the Add icon (⊕).
4. Select **Create a blank table**, and then select **Continue**.
5. Choose from the following choices.

Option	Description
Create new table	Select this option to create a blank table from scratch. **a.** Choose **Create new table**. **b.** Click **Continue**.
Create from an extensible table	Select this option to create a new blank table from an existing extensible table in the Servi ceNow AI Platform. **a.** Choose **Create from an extensible table**. **b.** Search for and select an existing table. **Note:** Tables already in the app display first in the list and recommended Service Now AI Platform tables display next, along with a short description of the type of information the table stores. **c.** Select **Continue**.

6. On the form, fill in the properties of your new table.

Field	Description
Table label	Unique label to identify the table.
Table name	Database name for the table. A table name is created automatically after you enter a table label. You can edit the name if needed.
Make extensible	Option to allow other tables to share data from this table. For more information on table extension, see Table extension.
Auto number	Option to track table records with a unique number. If you select this option, define the **Prefix**, **Starting number**, and **Number of digits**.
Prefix	Abbreviated name of the table to append to the beginning of the record number. For example, if you are creating a "Laptop" table, then your prefix may be "LPTP" or "LT."
Starting number	Number to identify the first record created for your table.
Number of digits	Maximum number of digits to allow in the record number. This value determines the highest possible record number. For example, if you enter 7, then the highest possible number is 9999999.

7. Select **Continue**.
8. Control who has access to create, read, write, and delete content from this table by adding new roles and/or defining the desired Create, Read, Write, Delete permissions for existing roles.

Roles that you create in the table persist throughout the application and can be further defined in other tables you add. See Add application security for more information on how security permissions work.

Note:
At least one role must have read access for you to be able to preview the table.

9. Select **Continue** to add the new table.
10. Return to your application home page or continue editing your table.
    - Select **Done** to return to your application home page.
    - Select **Edit table** to review the columns that were added to your table and continue editing it in Table Builder.
11. If you continue editing, in the new tab that opens, review the table columns.

    Each table column appears as a row in Table Builder.

    A lock icon ( ) appears next to columns from the extended table. You can't modify these columns.
12. Customize your table by adding table columns.

    a. In Table Builder, select **+ Add new field**.

    b. On the empty row, fill in the fields.

Table column properties

Field	Description
Column label	Unique label for the column.
Column name	Database name for the column.
Type	Type of information that the column contains. For example, to contain plain text in the column, select **String**. Depending on the type that you select, fill in the additional fields to further define the table column. For example, if you select **String**, define the character limit of the string input. Or, if you select **Choice**, define the choices that users can choose from. See Field types.
Reference	Table that is associated with the column. This field applies only if the column type is **Reference**.
Max length	Maximum number of characters that users can enter in the field.
Default value	Value that populates the field automatically after a new record is created.
Display	Option to set the column as the display value for the table. A reference field shows the display value of the table to which it is referring. For example, the **Opened by** column of the task table refers to the user table. Because the display value of the user table

Field	Description
	is the user name, the **Opened by** field shows something like **Beth Anglin** or **Joe Employee**. When you select a display value, choose the table column that would act as an appropriate title for individual records. Only one column can act as the display value for a table.

13. Select **Save**.

What to do next
For more information on Table Builder, see Table Builder.

Use a spreadsheet to add data

Add data tables and records to your application by uploading a Microsoft Excel spreadsheet.

Use the following procedures to upload a spreadsheet and use it to create data tables and import data records. Use the Import a spreadsheet procedure first to upload your spreadsheet, and then create data tables from your spreadsheet import as needed.

Import a spreadsheet

Upload a Microsoft Excel spreadsheet and use it to create your application data model.

Before you begin
Check that the spreadsheet meets the following requirements:

- Formatted with horizontal columns and a header label for each
- Saved as an XLSX file type

Note:
The Excel spreadsheet you upload can have multiple worksheet tabs, each of which you might use to create a data table. If multiple worksheets are present, you will be prompted to select which worksheet tab to create the table from after you upload the file.

Role required: admin, sn_app_eng_studio.user or delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to the Data heading, select the Add icon ( ).
4. Select **Import a spreadsheet**, and then select **Continue**.
5. Upload your spreadsheet and then select **Continue**.

   You can drag the spreadsheet file onto App Engine Studio or browse your computer.
6. You will be presented with one of the following paths:
   - If your spreadsheet only has a single worksheet tab, proceed to the next step.
   - If the spreadsheet has multiple worksheet tabs, you will have a list of sheets to choose from. From this list of sheets, you can select which worksheet tab to add as a table to your application first.

a. In the **Enter a row number for the table header** field, enter the row number in which the sheet column headers are located.
For example, if the headers are in the second row, enter 2.

b. **Optional:** To upload the information below the column headers in the sheet (e.g., the data in your spreadsheet), select the **Import spreadsheet data** option.
To upload only the column headers, leave the check box cleared. You may want to upload only the headers if you intend to use this table as a template and don't want any of the other data added to your AES table.

7. Make one of the following selections.
   - If you have uploaded an Excel file with multiple worksheet tabs, select **Convert to table** to proceed with converting the selected worksheet tab to a table, and then proceed to next step.
   - If you have uploaded an Excel file with a single worksheet tab, select **Continue**.

   Options display for where to import your file into.
8. Based on what you would like to do with your spreadsheet data, navigate to one of the following procedures to continue.

Option	Description
Create a new table directly from the spread sheet import	Refer to Create new table from spreadsheet import for next steps.
Create a new table by extending an existing table, and then using the spreadsheet im port to update it	Refer to Create new table from extensible ta ble and spreadsheet import for next steps.
Use spreadsheet import to update an exist ing application table	Refer to Modify existing table using spread sheet import for next steps.

Create new table from spreadsheet import

Create new tables directly from a Microsoft Excel spreadsheet import.

Before you begin

- Import a spreadsheet into App Engine Studio. See Import a spreadsheet.

Role required: admin, sn_app_eng_studio.user or delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. After you have uploaded your spreadsheet as described in Import a spreadsheet, choose what you want to do with the imported data in the displayed wizard.

Create new table from spreadsheet

   a. Select **A new table**.

   b. Choose **Create new table**.

2. Select **Continue**.

3. Review the properties for each column header, using the **Expand options** drop-down to display more properties.

Column header property	Description
Field Label	Unique label for the column.
Field name	Database name for the column.
Type	Type of information that the column contains. For example, to contain plain text in the column, select **String**. Depending on the type that you select, fill in the additional fields to further define the table column. For example, if you select **String**, define the character limit of the string input. Or, if you select **Choice**, define the choices that users can choose from. See Field types.

Column header property	Description
Character limit	Max length of the strings that can be stored.
Display	Option to set the column as the display value for the table. A reference field shows the display value of the table to which it is referring. For example, the **Opened by** column of the task table refers to the user table. Because the display value of the user table is the user name, the **Opened by** field shows something like **Beth Anglin** or **Joe Employee**. When you select a display value, choose the table column that would act as an appropriate title for individual records. Only one column can act as the display value for a table.
Mandatory	Option to require that the column must contain a value before a new record can be saved.

To add another column to your table, select **Add new field**.

To delete a column, select the trash icon (🗑).

4. Select **Continue** to define table properties.
5. On the form, fill in the fields.

Field	Description
Table label	Unique label to identify the table.
Table name	Database name for the table. A table name is created automatically after you enter a table label. You can edit the name if needed.
Make extensible	Option to allow other tables to share data from this table. For more information on table extension, see Table extension.
Auto number	Option to track table records with a unique number. If you select this option, define the **Prefix**, **Starting number**, and **Number of digits**.
Prefix	Abbreviated name of the table to append to the beginning of the record number. For example, if you are creating a "Laptop" table, then your prefix may be "LPTP" or "LT."
Starting number	Number to identify the first record created for your table.
Number of digits	Maximum number of digits to allow in the record number. This value determines the highest possible record number. For example, if you enter 7, then the highest possible number is 9999999.

6. Select **Continue**.
7. Control who has access to create, read, write, and delete content from this table by adding new roles and/or defining the desired Create, Read, Write, Delete permissions for existing roles.

Roles that you create in the table persist throughout the application and can be further defined in other tables you add. See Add application security for more information on how security permissions work.

Note:
At least one role must have read access for you to be able to preview the table.

8. Select **Continue** to add the new table created from your spreadsheet to your app.
9. **Optional:** Convert any remaining worksheets if your file contained multiple worksheet tabs.
   - **Note:**
     For each sheet that you want to convert, you will need to select **Convert to table**, and then repeat steps in this procedure or choose a different pathway for the additional worksheet (see Create new table from extensible table and spreadsheet import or Modify existing table using spreadsheet import for steps).
   - If you do not have multiple worksheets, proceed to the next step.
10. Select **Done** on the summary screen.
    Alternatively, to view your table in Table Builder, you can select **Edit table(s)** on the summary screen.

What to do next

For more information on editing your data tables in Table Builder, see Table Builder.

Create new table from extensible table and spreadsheet import

Create a new table by extending an existing table, and then using a Microsoft Excel spreadsheet import to update or customize it.

Before you begin

- Import a spreadsheet into App Engine Studio. See Import a spreadsheet.

Role required: admin, sn_app_eng_studio.user, delegated developer permissions for "Integration" must be present to view data import and mapping options. For more information, see Delegate developers using AES.

Procedure

1. After you have uploaded your spreadsheet as described in Import a spreadsheet, choose where to import your file in the displayed wizard.

Import into a new data table

   a. Select **A new table**.

   b. Choose **Create from an extensible table**.

2. Select **Continue**.
3. Search for an select an existing **Table** to add that table's data to your app and create an extension with branching logic.

> **Note:**
> Tables already in the app display first in the list and recommended ServiceNow AI Platform tables display next, along with a short description of the type of information the table stores.

4. Select **Continue**.
5. On the form, fill in the fields.

Field	Description
Table label	Unique label to identify the table.
Table name	Database name for the table. A table name is created automatically after you enter a table label. You can edit the name if needed.
Make extensible	Option to allow other tables to share data from this table. For more information on table extension, see Table extension.

Field	Description
Auto number	Option to track table records with a unique number. If you select this option, define the **Prefix**, **Starting number**, and **Number of digits**.
Prefix	Abbreviated name of the table to append to the beginning of the record number. For example, if you are creating a "Laptop" table, then your prefix may be "LPTP" or "LT."
Starting number	Number to identify the first record created for your table.
Number of digits	Maximum number of digits to allow in the record number. This value determines the highest possible record number. For example, if you enter 7, then the highest possible number is 9999999.

6. Select **Continue**.
7. Control who has access to create, read, write, and delete content from this table by adding new roles and/or defining the desired Create, Read, Write, Delete permissions for existing roles.

   Roles that you create in the table persist throughout the application and can be further defined in other tables you add. See Add application security for more information on how security permissions work.

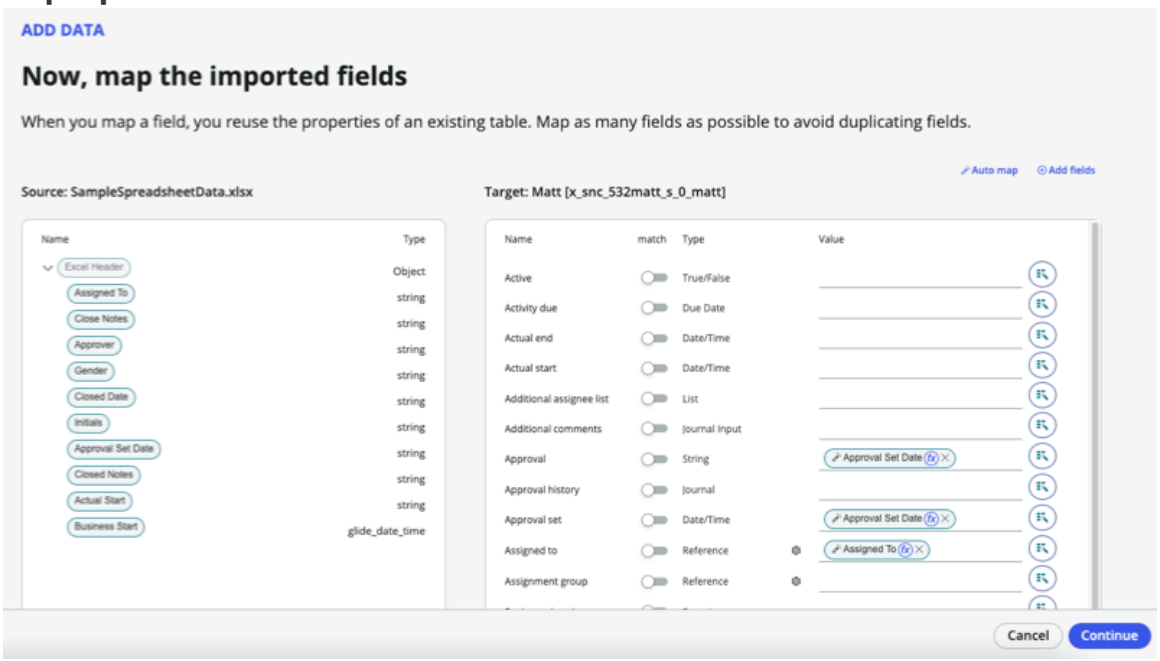
   Note:
   At least one role must have read access for you to be able to preview the table.

8. Select **Continue**.

   Note:
   Now your table is ready for data. In the next step, fields from your import are matched with fields on your newly extended table. You will have an opportunity to adjust mapping or create new fields from your import in it.

9. Select **Continue** to proceed to mapping fields.
   A screen displays where you can map field columns from your source spreadsheet on the left to field columns in your newly extended target table that you just created on the right.

Map imported fields



10. You have the following choices available to you during this step.

Option	Description
Batch map fields using Automap	Select **Automap** to automatically map your spreadsheet fields to displayed fields in the selected target table. Automap maps source entities to similarly named target entities. For a target entity that has already been mapped, selecting **Automap** doesn't change its value. An automapped field has a wand icon on its data pill.
Map fields by dragging and dropping	Map fields from your import to your target table by dragging data pills representing columns in the imported spreadsheet to the **Value** column in the target table. You can also map fields by using the pill picker to the right of each target table field.
Map fields using the data picker	Map data by using the pill picker ( ) on the right side of the target table. You can enter more than one value in the **Value** column, you can also enter text.
Add transform options	Add transform options for each of the individ ual mapped spreadsheet fields by clicking the FX icon ( ) on the right side pane. For example, you can use the Uppercase trans form function to change an input string to all uppercase characters. See Transform func or information on how to use these

Option	Description
	to trim data for your imported spreadsheet fields. **Note:** Not all the transform functions available in Flow Designer are available.
Activate data record matching	Specify fields where the system should check for matching data and, if found, update existing records instead of creating new ones by enabling the **Match** toggle in your target table. For example, if a target table has an **Order number** field and a record with an order number of 743, there are two options for handling potential matches. ○ If the **Match** toggle switch for the **Order number** field is on, the system checks for matching data. If the source data has a record with the same order number, the system updates the existing record in the target table. ○ If the **Match** toggle switch for the **Order number** field is off, the system doesn't check for matching data. If the source data has a record with the same order number, the system creates a new record in the target table. In this case, the target table will have two records, both with an order number of 743.
Configure reference and choice field behavior	Configure behavior for **Choice** and **Reference** field types. **a.** Click the gear icon (⚙). **b.** In **Field**, select the field column to match the incoming record value against in the target table. **c.** In **If no matching record exists then do the following**, specify what to do if that record isn't found in the target table. ▪ **Create a new choice/record:** Creates the choice or record in the target table's matching field column from the data imported for the field. ▪ **Ignore this field:** Ignores the field in the target table and leaves it null. ▪ **Skip this record:** Skips adding the entire record (row) in the target table. **d.** Click **Done**.
Add new field columns to target table	Add unmapped field columns from your import to your target table or create new fields in your target table.

Option	Description
	a. Select **Add fields** above the target table on the right. **b.** Choose which fields to add to your target ta ble by selecting the checkbox on the left or select **All** to choose all of them. **c.** You can also perform the following func tions: ▪ Edit the **Field Label** for the imported field. ▪ Edit field properties for the imported field by selecting the **Edit icon** ( ). ▪ Create a new field by clicking **Create a new field** in the top right corner of the window. **d.** Select **Add fields** to add the selected fields to your target table.

11. Select **Continue** to create the data import mapping and update your target table.
12. **Optional:** Convert any remaining worksheets if your file contained multiple worksheet tabs.
    - **Note:**
      For each sheet that you want to convert, you will need to select **Convert to table**, and then repeat steps in this procedure or choose a different pathway for the additional worksheet (see Create new table from spreadsheet import or Modify existing table using spreadsheet import for steps).
    - If you do not have multiple worksheets, proceed to the next step.
13. Select **Done** on the summary screen.
    Alternatively, to view your table in Table Builder, you can select **Edit table(s)** on the summary screen.

What to do next

For more information on editing your data tables in Table Builder, see Table Builder.

Modify existing table using spreadsheet import

Use a Microsoft Excel spreadsheet import to update an existing application table.

Before you begin

- Import a spreadsheet into App Engine Studio. See Import a spreadsheet.

Role required: admin, sn_app_eng_studio.user or delegated developer permissions. For more information, see Delegate developers using AES.

Procedure

1. After you have uploaded your spreadsheet as described in Import a spreadsheet, choose where to import your file in the displayed wizard.

Import into an existing application table

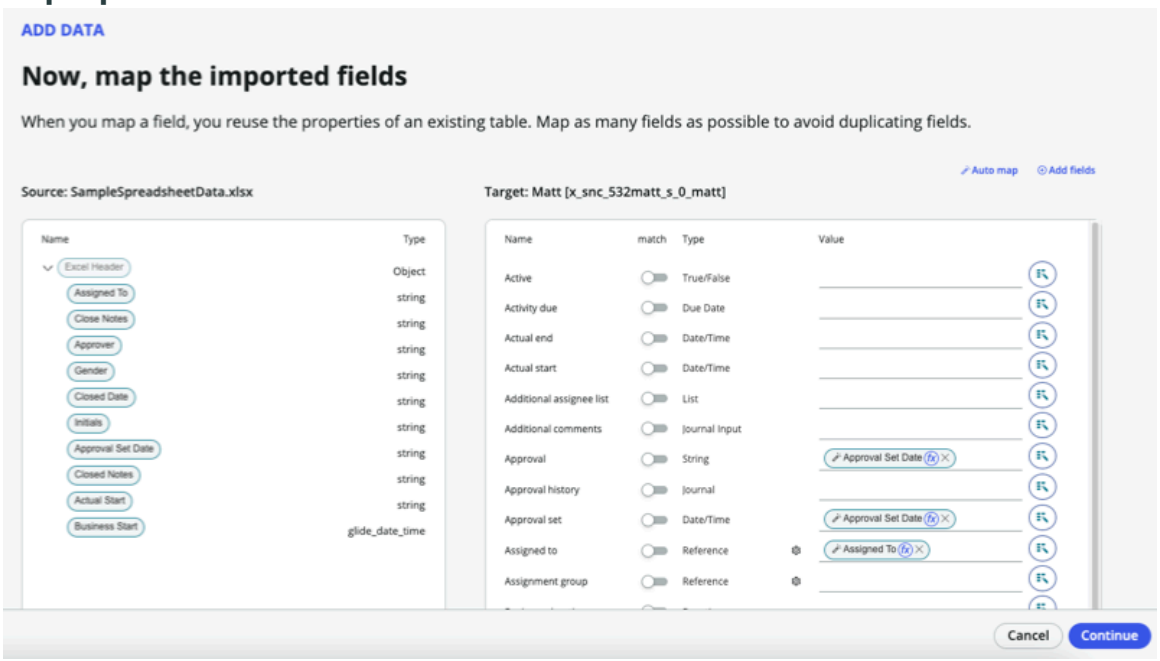
   a. Select **An existing table**.

   b. Select an existing application table from the list that displays.

2. Select **Continue**.
   A screen displays where you can map field columns from your source spreadsheet on the left to field columns in your existing target application table on the right.

> **Note:**
> You will have the opportunity to adjust mapping or create new fields from your import in it.

Map imported fields



3. You have the following actions available to you during this step.

Option	Description
Batch map fields using Automap	Select **Automap** to automatically map your spreadsheet fields to displayed fields in the selected target table. Automap maps source entities to similarly named target entities. For a target entity that has already been mapped, selecting **Automap** doesn't change its value. An automapped field has a wand icon on its data pill.
Map fields by dragging and dropping	Map fields from your import to your target table by dragging data pills representing columns in the imported spreadsheet to the **Value** column in the target table. You can also map fields by using the pill picker to the right of each target table field.
Map fields using the data picker	Map data by using the pill picker ( ) on the right side of the target table. You can enter more than one value in the **Value** column, you can also enter text.
Add transform options	Add transform options for each of the individ ual mapped spreadsheet fields by clicking the FX icon ( ) on the right side pane. For example, you can use the Uppercase trans form function to change an input string to all uppercase characters. See Transform func or information on how to use these

Option	Description
	to trim data for your imported spreadsheet fields. **Note:** Not all the transform functions available in Flow Designer are available.
Activate data record matching	Specify fields where the system should check for matching data and, if found, update existing records instead of creating new ones by enabling the **Match** toggle in your target table. For example, if a target table has an **Order number** field and a record with an order number of 743, there are two options for handling potential matches. ○ If the **Match** toggle switch for the **Order number** field is on, the system checks for matching data. If the source data has a record with the same order number, the system updates the existing record in the target table. ○ If the **Match** toggle switch for the **Order number** field is off, the system doesn't check for matching data. If the source data has a record with the same order number, the system creates a new record in the target table. In this case, the target table will have two records, both with an order number of 743.
Configure reference and choice field behavior	Configure behavior for **Choice** and **Reference** field types. **a.** Click the gear icon (⚙). **b.** In **Field**, select the field column to match the incoming record value against in the target table. **c.** In **If no matching record exists then do the following**, specify what to do if that record isn't found in the target table. ▪ **Create a new choice/record:** Creates the choice or record in the target table's matching field column from the data imported for the field. ▪ **Ignore this field:** Ignores the field in the target table and leaves it null. ▪ **Skip this record:** Skips adding the entire record (row) in the target table. **d.** Click **Done**.
Add new field columns to target table	Add unmapped field columns from your import to your target table or create new fields in your target table.

Option	Description
	a. Select **Add fields** above the target table on the right. **b.** Choose which fields to add to your target ta ble by selecting the checkbox on the left or select **All** to choose all of them. **c.** You can also perform the following func tions: ▪ Edit the **Field Label** for the imported field. ▪ Edit field properties for the imported field by selecting the **Edit icon** ( ). ▪ Create a new field by clicking **Create a new field** in the top right corner of the window. **d.** Select **Add fields** to add the selected fields to your target table.

4. Select **Continue** to create the data import mapping and update your target table.

   Note:
   You will be prompted if there are any unmapped fields remaining in your spreadsheet. You can map those fields or continue without mapping them.

5. **Optional:** Convert any remaining worksheets if your file contained multiple worksheet tabs.

   - **Note:**
     For each sheet that you want to convert, you will need to select **Convert to table**, and then repeat steps in this procedure or choose a different pathway for the additional worksheet (see Create new table from spreadsheet import or Create new table from extensible table and spreadsheet import for steps).
   - If you do not have multiple worksheets, proceed to the next step.

6. Select **Done** on the summary screen.
   Alternatively, to view your table in Table Builder, you can select **Edit table(s)** on the summary screen.

What to do next

For more information on editing your data tables in Table Builder, see Table Builder.

Use a PDF to create data tables

Create tables from a PDF form using the PDF extractor tool in App Engine Studio.

Note:
This feature is only available if your licensing entitles you to "exclusive low code capability" and you have Table Builder for App Engine installed. Contact your Solutions consultant for more information.

Overview

The PDF extractor in App Engine Studio allows you to upload a PDF and then extract table fields for use in a custom app. This streamlines the process of building application data tables from pre-existing PDF forms because you no longer need to manually type in field labels.

Note:
Ensure that you are mindful about recreating any tables that may already exist on the ServiceNow AI Platform. For example, with a PDF containing user demographic data, determine whether you want to reference existing user data tables rather than creating new tables from the PDF.

General navigation

The following table contains a list of some of the other basic navigational elements within the PDF extractor tool.

Navigational elements in PDF extractor

Navigational element	Description
Collapse / expand icons ()	Select these icons to toggle between collapsing or expanding the PDF and table panes.
Page controls ()	Use the arrows at the bottom of the PDF to page through the document one page at a time or navigate directly to the beginning or end of the document.
Zoom controls ()	Use the zoom controls to zoom in or out in the PDF.
Add new field icon ()	Add a field column to your table manually by selecting **+Add new field**, and then enter details directly. This is similar to how you add fields on the **Data** tab of Table Builder.
Add reference table icon ()	Select **Add reference table** in the right side panel to add a reference field in your table that points to a new table.
Open data table and form icon ()	Select **Open data table and form** to open the selected table within Table Builder.
Table additional actions list ()	Use the table additional actions menu to edit basic properties for your table, or if you have added a reference table, select **Delete** to delete the table.

Navigational elements in PDF extractor (continued)

Navigational element	Description
Trash icon (🗑)	Select the **Trash icon** (🗑) to delete fields from a table.

PDF parsing limitations

The following limitations currently exist when uploading a PDF using this tool:

- PDF cannot be converted from an image.
- PDF cannot be longer than 25 pages.
- PDF file size cannot exceed 5 MB.
- Languages other than English and French are not currently supported.

Create a table from a PDF form

Add data tables to your application by uploading a PDF in App Engine Studio.

Before you begin

Note:
This feature is only available if your licensing entitles you to "exclusive low code capability" and you have Table Builder for App Engine installed. Contact your Solutions consultant for more information.

Verify that the PDF meets the following requirements:

- PDF cannot be converted from an image.
- PDF cannot be longer than 25 pages.
- PDF file size cannot exceed 5 MB.
- Languages other than English and French are not currently supported.

Role required: admin, sn_app_eng_studio.user, or delegated_developer

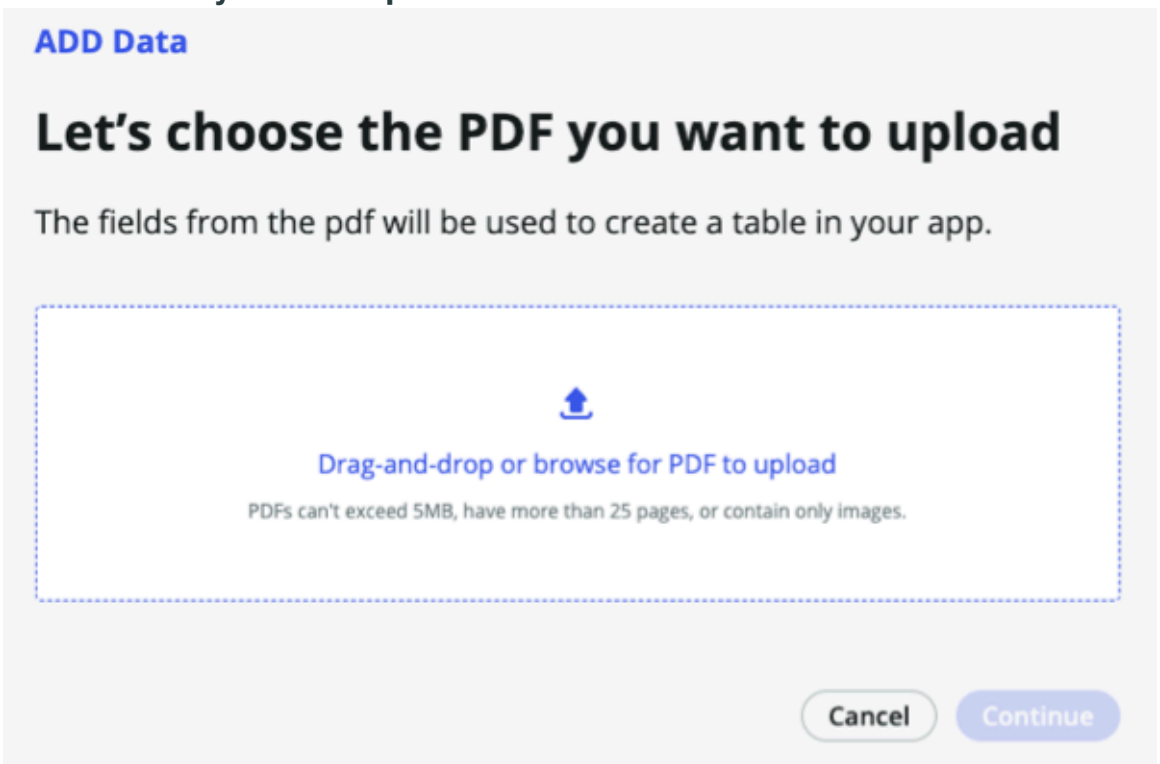
Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to the Data heading, select the Add icon (⊕).
4. Select **Create a blank table**, and then select **Continue**.
5. Select **Upload a PDF** and then select **Continue**.
6. Select and upload the PDF.

   You can drag the PDF file onto App Engine Studio or browse your computer.

   Note:
   It may take a moment for the PDF to load. Select the trash icon (🗑) to clear the PDF selection.

Choose the PDF you want to upload



7. Select **Continue**.

> **Note:**
> It may take up to a minute for the PDF to be parsed.

8. Define the properties for your new table.

Property	Description
Table label	Unique label to identify the table.
Table name	Database name for the table. A table name is created automatically after you enter a table label. Once this is created, this field is read only.
Make extensible	Option to allow other tables to share data from this table. For more information on table extension, see Table extension.
Auto number	Option to track table records with a unique number. If you select this option, define the **Prefix**, **Starting number**, and **Number of digits**.
Prefix	Abbreviated name of the table to append to the beginning of the record number. For example, if you are creating a "Laptop" table, then your prefix may be "LPTP" or "LT."

9. Select **Continue**.
   You may now configure permissions for your new data table.
10. Control who has access to create, read, write, and delete content from this table by adding new roles and/or defining the desired Create, Read, Write, Delete permissions for existing roles.

    Roles that you create in the table persist throughout the application and can be further defined in other tables you add. See Add application security for more information on how security permissions work.

    Note:
    At least one role must have read access for you to be able to preview the table.

11. Select **Continue** after you have configured table permissions.
12. Select **Go to PDF extractor** to open up the PDF in the PDF extractor.

What to do next

Next, you will add fields from the uploaded PDF. Follow the steps in Add new fields from a PDF form to populate your new data table with field columns.

Add new fields from a PDF form

Add field columns to your data table using the PDF extractor in App Engine Studio.

Before you begin

Note:
This feature is only available if your licensing entitles you to "exclusive low code capability" and you have Table Builder for App Engine installed. Contact your Solutions consultant for more information.

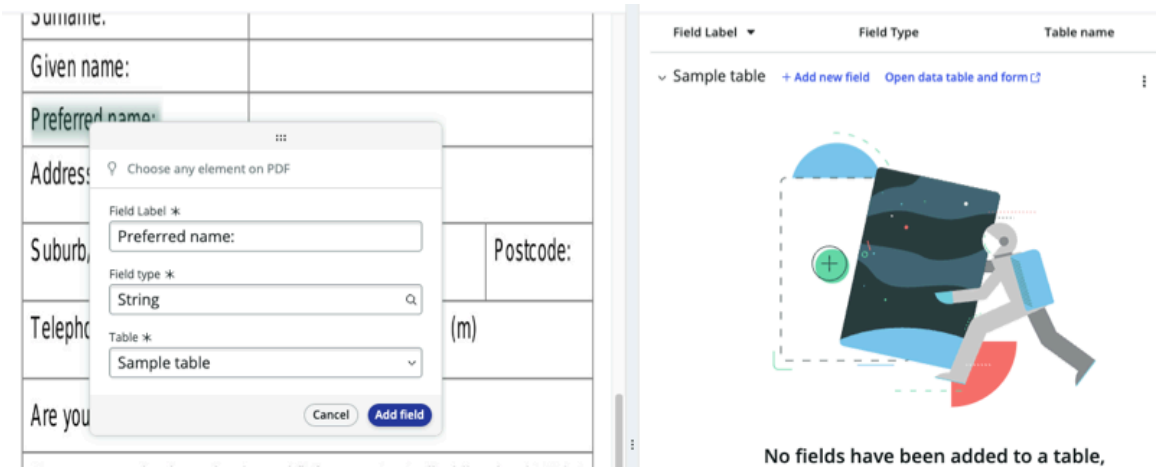
Role required: admin, sn_app_eng_studio.user, or delegated_developer

Procedure

1. Choose one of the following options:
   - Follow the steps outlined in the previous procedure to upload a PDF (see Create a table from a PDF form).
   - If you have already uploaded the PDF, select the **Open pdf extractor** element on the **Forms** or **Table** tab in Table Builder to launch the PDF extractor tool.

   The PDF form displays.
2. Review the PDF.
   Use any of the navigational controls in the PDF pane to navigate to where you'd like to begin adding fields. See General navigation.
3. Click **Select** to enter text selection mode.
4. In the PDF, click on a field or text phrase to highlight it to use it as the basis for a new field.

Add fields from PDF



5. Edit the extracted text in the **Field Label** as needed for the new field you are going to add.
6. Choose a **Field type**.

   Field type refers to the type of data that the new column will store. For example, to store plain text in the column, select **String**. To understand the basic field properties, see Add and customize a field in a table.

   Depending on the type that you select, you may need to fill in additional fields to further define the table column. For example, with Reference field types, search for and select the appropriate data table to reference.

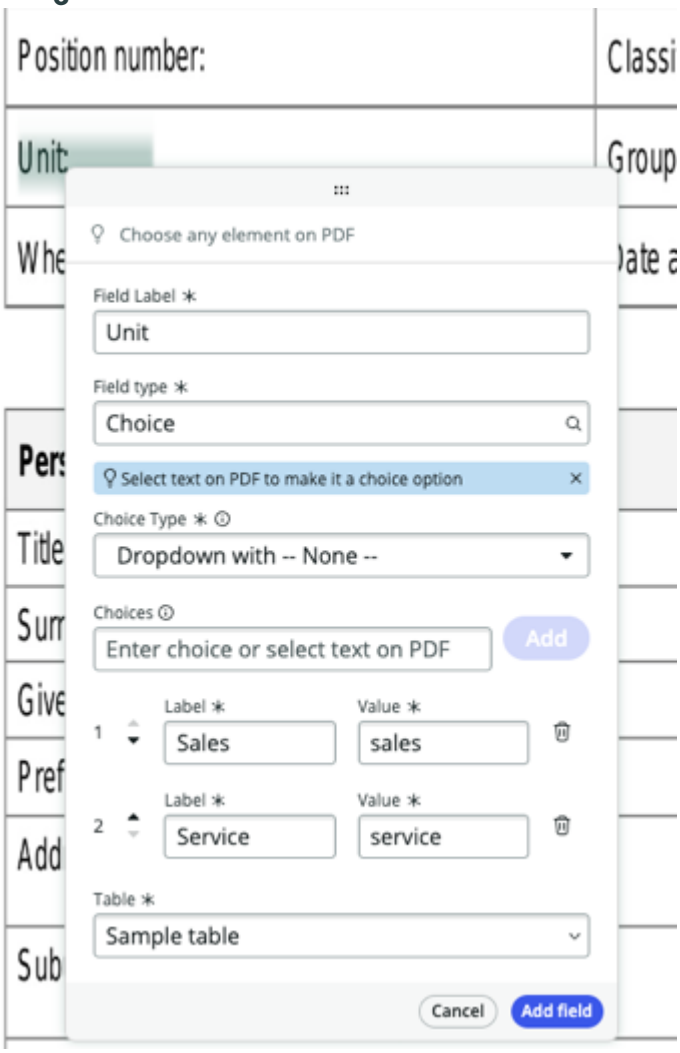
   a. **Optional:** If you have chosen to create a choice field, perform the following actions to populate options for the choice field.

      i. Choose a **Choice Type** from the menu. This controls whether or not the list will have None as an option.

      ii. Click in the **Choices** field, and then enter text manually or select text on the PDF to automatically extract it.

      iii. Click **Add** to add your choice to the list.

Adding a choice field



b. Optional: Repeat the previous steps until all choices have been added for your choice field.

7. Select the **Table** where you want to add the new field.
   Multiple options may appear if you have added reference tables. The original table is selected by default.
8. Select **Add field** to add the field to the list of fields in the table on the right.

> **Note:**
> Any fields you add to the table on the right remain highlighted in green in the PDF to remind you that you have created a related field from them. If you delete a field from the tables on the right, the extracted text will no longer be highlighted.

9. Repeat the steps above until you have added all the fields you want to add from the PDF.

> **Note:**
> You can also add fields manually by clicking **+Add new field** in the table on the right and entering details directly similar to how you add fields on the **Table** tab of Table Builder.

10. Review the fields in your table and edit as necessary.

Table pane actions

Action	Description
Move fields between tables	To move a field between tables within the PDF extractor, change the selected **Table Name** to the desired table location.
Delete reference table	Delete any additional reference tables that you add by selecting **Delete** from the Additional actions list in the top right corner of the table (⋮)
Add a new field	Add a field column to your table manually by selecting **+Add new field**, and then enter details directly. This is similar to how you add fields on the **Data** tab of Table Builder.
Edit a field	To edit field properties (e.g., Field type), click on the field property to select it, and then make your edits.
Delete a field	Select the **Trash icon** (🗑) to delete fields from a table.
Open table within Table Builder	Select **Open data table and form** to open the selected table within Table Builder.

11. Select **Save**.

What to do next

To open your data table in Table Builder, select **Open data table and form** above the displayed tables. For more information on editing your data tables in Table Builder, see Table Builder.

To add a reference table, see Add a reference table from a PDF form.

Add a reference table from a PDF form

Move fields into a new referenced data table using the PDF extractor in App Engine Studio.

Before you begin

Note:
This feature is only available if your licensing entitles you to "exclusive low code capability" and you have Table Builder for App Engine installed. Contact your Solutions consultant for more information.

Role required: admin, sn_app_eng_studio.user, or delegated_developer

About this task

You may decide that you want to add some of the form information into separate tables that are referenced from the original table and can be referenced by other tables. For example, if you work for an insurance company, you may want to create separate data tables for bills, claims, and policies that can be referenced as separate data tables even though the information is extracted from a single PDF form.

You can add a reference field, and then create the corresponding reference data table directly from the PDF extractor in App Engine Studio.

Note:
Before you create any new reference tables for your app, it's a good practice to verify that you are not accidentally recreating any tables that already exist on the ServiceNow AI Platform.

Procedure

1. Choose one of the following options:
   - Follow the steps outlined in the previous procedure to upload a PDF (see Create a table from a PDF form).
   - If you have already uploaded the PDF, select the **Open pdf extractor** element on the **Forms** or **Table** tab in Table Builder to launch the PDF extractor tool.

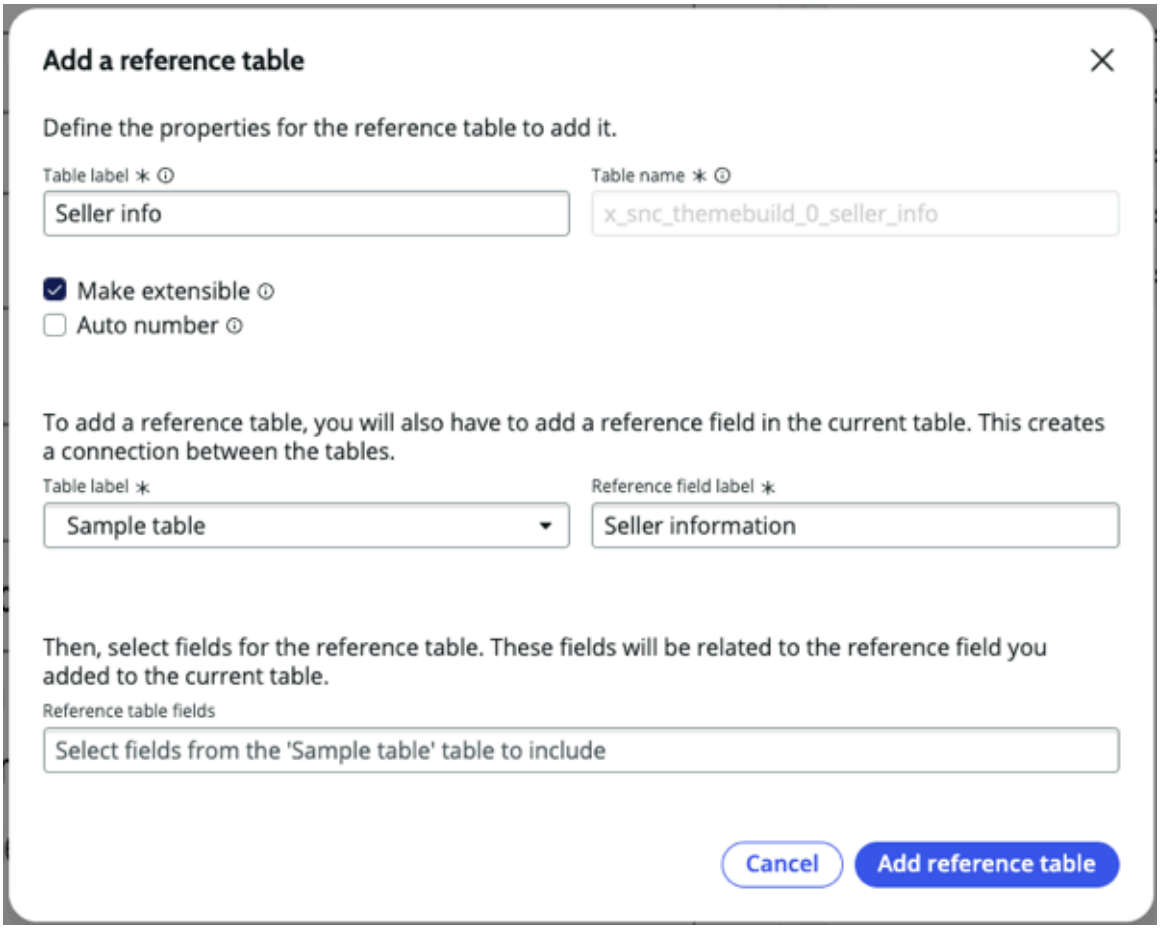
   The PDF form displays.
2. Select **Add reference table** in the right side panel to add a reference table to your table.
3. Enter the following properties for your reference table.

Column header property	Description
Table label	Unique label for the reference table.
Table name	Database name for the reference table.
Make extensible	Option to allow other tables to share data from this table. For more information on table extension, see Table extension.
Auto number	Option to track table records with a unique number. If you select this option, define the **Prefix**, **Starting number**, and **Number of digits**.

Next, you will add a reference field to the original table you are editing. This creates the connection between the tables (e.g., "Seller info").

4. Select the **Table label** of the table where you want to add your reference field in (the original table is selected by default).
   The original table should be selected by default in the **Table label** field.
5. Enter a **Reference field label** for this new reference field (e.g., "Seller information").
6. Select fields from your original table to add them to your new reference table.
   These fields are related to the reference field you added to the current table.

Add a reference table



7. Select **Add reference table**.
   The reference table appears below and contains the fields that you selected that were in the original table.
8. Review and edit the fields and table properties as necessary.

Table pane actions

Action	Description
Move fields between tables	To move a field between tables within the PDF extractor, change the selected **Table Name** to the desired table location.
Delete reference table	Delete any additional reference tables that you add by selecting **Delete** from the Additional actions list in the top right corner of the table (⋮)
Add a new field	Add a field column to your table manually by selecting **+Add new field**, and then enter details directly. This is similar to how you add fields on the **Data** tab of Table Builder.

Action	Description
Edit a field	To edit field properties (e.g., Field type), click on the field property to select it, and then make your edits.
Delete a field	Select the **Trash icon** ( ) to delete fields from a table.
Open table within Table Builder	Select **Open data table and form** to open the selected table within Table Builder.

See General navigation for more information on additional navigational controls in the table pane.

9. Select **Save**.

What to do next

To open your data table in Table Builder, select **Open data table and form** above the displayed tables. For more information on editing your data tables in Table Builder, see Table Builder.

Create a data integration

Add new or updated information to your current data sets by importing it into existing tables in your application through the power of Integration Hub. Schedule future imports to add data at specific times.

This video shows you how to perform the following procedure.

https://player.vimeo.com/video/982217306?badge=0&autopause=0&player_id=0&app_id=58479

Before you begin

- You must have an existing table in your application. For more information, see Create a blank table.

  Note:
  Currently, Excel files are the only accepted data format users can upload.

- Role required: admin, sn_app_eng_studio.user, or delegated_developer. For more information, see Delegate developers using AES.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to the Data heading, select the Add icon ( ).
4. Select **Create a data integration**.

Configure your data import source

5. Configure your data import source by performing the following steps.

   a. Fill in the fields for the data integration.

Field	Description
Name	Name of your integration.
Short description	Description of your integration.
Application	Name of the application scope for your integration.

   b. Select **Save & Continue**.

   c. Use the **Source type** menu to select a data source type.

   - To choose an Excel or CSV file, select **AD-HOC** > > **File**, then either **Excel** or **CSV**. In the File upload section, upload an XLSX, XLS, CSV, or ZIP file.
   - To choose a Data Stream action, select **Spokes**. Active Data Streams are organized by spoke and listed alphabetically. In the Connection section, select the connection alias. For Data Stream actions that use a connection alias, you can override the default connection alias with any of its children's aliases. For more information, see Create a Connection and Credential alias.

   d. Configure the data source.

   - To configure an Excel spreadsheet, specify which sheet to use and which row number to use for the header. Only one sheet and one header can be specified.
   - To configure a CSV file, select the delimiter.
   - To configure a data stream action, enter any required inputs. This section only appears if the Data Stream action has inputs to enter. Data Stream actions with inputs have unique inputs, so the fields in this section depend on which Data Stream action is selected and its configuration. Any default values already configured by the spoke inputs are pre-filled. You can view the details of the Data Stream action by clicking the information icon ( ) next to it. Clicking the icon opens the Data Stream action's configuration.

6. Select the **Save** button.

Choose your target table and configure import options

7. Select the **Map to target** tab.
8. Select the target table and options for the data integration you're creating.
   Mapping the source data to the target table allows you to control how the system treats the data you uploaded.

   a. On the Source to target table data mapping page, select **Add a table**.

   b. In the Mapping Properties window, fill in the fields.

Field	Description
Target table	Name of the table to transform your data to.

Field	Description
Run table's business rules when importing	Option to run the target table's business rules when you import the data.
Run the import synchronously	Option to run the import synchronously. When data is transformed in parallel, and there are multiple source records with a specific coalesce value, checking this option ensures that only one record with that coalesce value is inserted at a time. For more information, see the Synchronized inserts section on the Concurrent imports page.

c. Select **Save**.

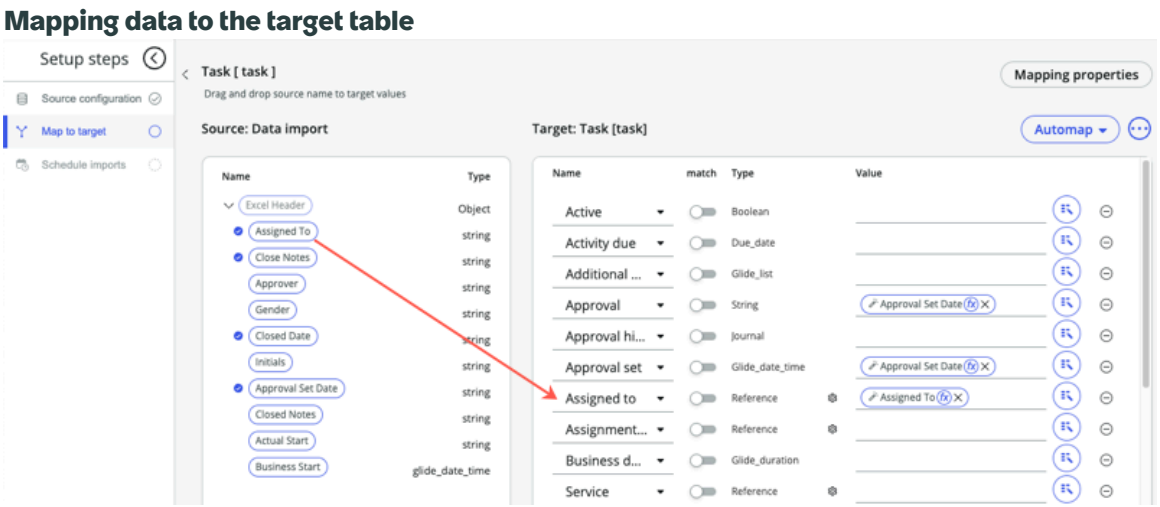
You can add multiple target tables to your integration. Repeat steps 4a through 4c for each target table you want to add.

Tables are listed in the order they're added. You can change the order by using the drag icon ⠿ to the left of each table card to drag the card to a different position. The order of the table cards determines the order in which data is transformed into the target tables at runtime.

Note:
You can't select the same table more than once, and you can't select an extended table or parent table of a table already in the integration.

Map import fields to your target table

9. Map the fields in your import to the target table by performing the following actions.



a. On the Source to target table data mapping page, select the button with the target table you want to map to.
This opens the data-mapping section for the table. The left side of the page shows the source data. The right side is for the target table.

b. Use the **Add a field**, **Add all fields**, or **Automap** button to configure the target side and begin mapping data.

- To add all the fields in the target table, select **Add all fields**. Fields are added alphabetically.
- To add fields individually, select **Add a field** and choose the field name from the list. A field can only be added once.
- To add fields and map them automatically, select **Automap**. Automap maps source entities to similarly named target entities. The **Automap** button has two options.
  - **All matching fields in the target table** adds all the fields and maps the ones that match.
  - **All unmapped fields in the target selection** maps only the fields that you've already added but haven't mapped yet. If you haven't added any fields yet, this option is not available.

- For a target entity that has already been mapped, selecting **Automap** doesn't change its value. An automapped field has a wand icon on its data pill.

  By default, Automap maps a maximum of one source entity to a target entity. You can change this by setting the *`glide.ih.automap.extractone`* property to false.

  Automap matches source to target entities by looking for column names that are at least an 80% match. You can modify this with the *`glide.ih.automap.minimum.score`* property. For example, to make matches based on a 60% similarity, you can set *`glide.ih.automap.minimum.score`* to 60.

c. Map data by dragging data pills from the source to the **Value** column on the target table.

You can also map data by using the pill picker () on the right side of the target table. You can enter more than one value in the Value column, you can also enter text.

After you map a source field to a target field, a small check mark icon () appears next to the source field name. If you move your cursor to the check mark, the tooltip lists the target fields that source field has been mapped to, up to five fields.

d. Optional: Use the **Match** toggle switch to specify fields where the system should check for matching data and, if found, update existing records instead of creating new ones.

(Optional) For example, if a target table has an **Order number** field and a record with an order number of 743, there are two options for handling potential matches.

- If the **Match** toggle switch for the **Order number** field is on, the system checks for matching data. If the source data has a record with the same order number, the system updates the existing record in the target table.
- If the **Match** toggle switch for the **Order number** field is off, the system doesn't check for matching data. If the source data has a record with the same order number, the system creates a new record in the target table. In this case, the target table will have two records, both with an order number of 743.

e. Optional: For choice and reference fields, specify the column to map data to.

i. Select the gear icon (⚙).

ii. In **Field**, select the column to map to.

iii. In **If no matching record exists then do the following**, specify what to do if that column isn't available.

- **Create a new choice/record**: Creates the choice or record in the target table.
- **Ignore this field**: Ignores only the field in the target table.
- **Skip this record**: Skips the entire record in the target table.

iv. Select **Done**.

f. **Optional:** Change or modify your data by applying transform functions.
For example, you can use the Uppercase transform function to change an input string to all uppercase characters. For more information, see Transform functions.

Note:
Not all the transform functions available while creating flows and subflows are available in Integration Hub - Import.

i. Select the transform function icon ( ).

ii. Select a transform function from the menu, then select **OK**.

iii. To apply additional transform functions, select **Add a new transform**. Transform functions are applied in the order they're selected.

iv. After you've added all your transform functions, select **Done**.

10. When you're done with your mapping, click **Save**.

Import the file or schedule the data import

11. Choose what to do with your data import you just created and mapped.
    - To import the data set you uploaded now, select **Run Import**.
    - To set up a future import of the data, select **Schedule an import**.

    See Run or schedule a data import.
12. **Optional:** If you ran the import, preview the table and ensure it appears with the additional content by returning to the target table, refreshing your browser screen, and clicking **Preview**.
13. **Optional:** If you added new columns during the import and want them to display on the target table, select **Personalize list** to edit the columns that display.

Modify application data tables

Use Table Builder to modify data tables used in your application.

Role required: admin, sn_app_eng_studio.user, or delegated_developer

To modify data tables associated with your application:

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the **My Apps** page, open your application.
3. Under the Data heading, select the Additional actions icon (•••) for an existing table in your application, and then select **Edit**.

When you click on a data table or select **Edit** in the Additional actions menu (•••) to edit data for your application, Table Builder is launched. Table Builder is a tool for editing data tables that you've added to your application.

You can perform the following actions in Table Builder:

- Manage your application data tables on the **Data** tab.
  - Manage table fields.
  - Edit table and field column properties.
  - View schema relationships between your data tables.

    Note:
    This feature is only available if your licensing entitles you to "exclusive low code capability" and you have Table Builder for App Engine installed. Contact your Solutions consultant for more information.

- Create and manage form views and display logic that is associated with the table on the **Forms** tab.
- Create and manage flows triggered when the table is updated or created on the **Flows** tab.

Note:
This feature is only available if your licensing entitles you to "exclusive low code capability" and you have Table Builder for App Engine installed. Contact your Solutions consultant for more information.

See Data in Table Builder for more information on editing tables in Table Builder.

Note:

To delete a table from your application, select the Additional actions icon (•••) for an existing table in your application, and then select **Delete** and follow the instructions.

Add an application experience

Use App Engine Studio (AES) to add an experience to your app. Experiences are the interface, or wrapper, for how users interact with your app.

Application templates automatically add experiences to your application.

Types of experiences

Experience	Definition	Example	Reference
Standard catalog item	A standard catalog item displays a form that users can fill in to create requests, such as a form to request an item or service. Standard catalog items make use of the Request table and produce a request record. In addition, generated request items are linked with a workflow, a catalog task, and any related approvals. Using standard catalog items, users can add multiple items to a	Create a catalog item form, such as a form to request time-off. After submitting the form, a request is created for a manager to approve or reject.	• Add a standard catalog item • Sample standard catalog item

Types of experiences (continued)

Experience	Definition	Example	Reference
	cart and generate a request for each requested item. Use a catalog item when you want the service catalog form to generate a request, complete with a workflow, approvals, tasks, etc.		
Record producer	A record producer is a simplified type of catalog item that displays a form for users to fill out. The completed and submitted form inserts a new data record in a selected custom target table that you set up. This type of catalog item enables users to create task-based records, such as an incident record (without any of the more complex functionality that comes with using a standard catalog item (e.g., creating requests). Use a record producer when you want the service catalog form to create a simplified type of record that isn't a request (e.g., a task record such as an incident, change, or enhancement, etc.).	Create a service catalog form that generates a task record, such as an incident, instead of a request.	• Add a record producer • Sample record producer
Workspace	A workspace is a suite of tools that provides agents, case managers, help desk professionals, and managers with tools to help answer customer questions and resolve customer problems.	Create an equipment fulfillment dashboard where employees can request laptops and other items. Workspaces are similar to portals but smaller in scope.	• Add a workspace • Building workspaces in AES • Configure a workspace in Workspace Builder • Configure workspace settings

Types of experiences (continued)

Experience	Definition	Example	Reference
			in Workspace Builder • Configure a workspace home page in Workspace Builder • Configure a record page for a workspace in Workspace Builder • Configure lists for a workspace in Workspace Builder • Configure analytics for a workspace in Workspace Builder • Sample workspaces you can build
Portal	A portal is a site where users inside of your organization can find information, submit requests, and complete business tasks.	Create a self-service portal, or entry point for employees to make requests and browse a knowledgebase, which you can then populate with additional workspaces and catalogs.	• Add a portal • Sample portals you can build
Mobile	A mobile experience enables users to access your application from a ServiceNow native mobile app. You must then populate the app with data.	Create a time-off request application for mobile for managers to approve or reject requests in the Now Mobile app on their mobile device.	• Add a mobile experience • Sample mobile experience

Choose between record producers and catalog items

Both the record producer and standard catalog item in App Engine Studio (AES) create experiences where users can submit requests through a service portal. However, record producers are more extensible, and enable users to create a record in any table.

Consider the level of customization

Record producers allow for more customization, making the most of the App Engine tools to build experiences from scratch.

Catalog items represent services or items a user can request. The catalog of all items is called the Service Catalog, and is part of Service Catalog Management.

Comparison of record producers and standard catalog items

Functional area	Record producer	Catalog item
Purpose	Create custom fulfillment experiences using App Engine automation tools.	Support simple request management applications for which a predefined approval and qualification process exists, such as requesting IT hardware and software.
Extensibility	Customizable.	Pre-defined.
Example	Password reset form that creates a password reset request.	Form to request a parking permit.
Development model	Process is as follows: **1.** Set up a business-focused data model. **2.** Define the kind of experience your users will leverage. **3.** Define the automation or business logic. **4.** Define the user roles that will use the app.	Catalog items heavily rely on the request fulfillment process for fulfilling items defined in Service Catalog, a central, accurate, and consistent source of data.
Reporting	Easier to create dashboards with a purpose-built data model.	Requires creating database views and scripting to gather variables into other tables to configure specific reports.
Scalability	Business-focused app makes it easier to find resources and make app changes in a low-code environment.	Typically part of a Service Catalog Management operation with a dedicated team managing each catalog.
Security	Scoped apps allow flexibility to manage permissions without being an administrator.	Catalog items are typically built in a specific scope, and less flexible.

Help topics on record producers and standard catalog items

For more information, see the following topics:

- Record producers:
  - Add a record producer
  - Sample record producer
- Standard catalog items:

- Add a standard catalog item
- Sample standard catalog item

Add a record producer

A record producer enables users to create task-based records, such as an incident record, in apps you create in App Engine Studio (AES) without creating a request. It enables a better end-user experience by standardizing requests using a simplified form.

Before you begin

Create a data table that the record producer will add a new record to when a user fills out the form. For more information, Create a data model for your application.

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

About this task

A record producer is a simplified type of catalog item that displays a form for users to fill out. The completed and submitted form inserts a new data record in a selected custom target table that you set up. This type of catalog item enables users to create task-based records, such as an incident record (without any of the more complex functionality that comes with using a standard catalog item (e.g., creating requests). Use a record producer when you want the service catalog form to create a simplified type of record that isn't a request (e.g., a task record such as an incident, change, or enhancement, etc.). When you add a record producer, you create a basic version of the record producer. You must then continue editing it in Catalog Builder before it's ready to deploy.

Note:
If you created an application using a template, a record producer may already be added to your application.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, next to Experience, select **Add**.
4. Select **Record Producer** and select **Begin**.
5. On the form, fill in the fields.

Record Producer form

Field	Description
Name	Name for the record producer.
Short description	Brief overview of the record producer.

6. Select **Edit record producer**.
7. In Catalog Builder, specify the required information.
   After completing each step, select **Save**.

Catalog Builder steps

Step	Description
Details	○ Basic info: Record producer name and short description. ○ Item details: Description of the record producer. **Note:** You can attach files such as graphics, images, videos, or a link to an external source of information.
Destination	Table in which the record producer creates records.
Location	○ Catalogs: Name of the catalog the record producer belongs to. ○ Categories: Available categories that can be linked with the record producer. ○ Topics: Available topics that can be connected to the standard catalog item. Find out more about topics in Associate a catalog item with a taxonomy topic in Employee Center.
Questions	Questions for the record producer. From the **Insert new question** list, you can include additional question sets, questions, deactivated questions, single-column container, two-column container, and line break. For information on creating a question and supported question types, see Create a question for a catalog item in Catalog Builder. You can also add dynamic form behavior for a question. For information on adding dynamic form behavior, see Edit a question in Catalog Builder.

Step	Description
	Note: ○ The questions within a question set can't be edited. The question sets can be reordered by dragging and dropping them. ○ Question sets specified in the template can't be removed, while the ones added by the user can be removed. ○ Removal of question sets simply removes the association with the item and doesn't delete the question set. ○ A single-column question set can be added to a single-column or a two-column container. A two-column question set can't be added to a container.
Settings	Options to customize the record producer behavior. ○ Hide 'Add to wishlist' button: Option to hide the **Add to wishlist** button for the record producer. ○ Hide attachment button: Option to hide the **Attachment** button for the record producer ○ Make attachment mandatory: Option to make the **Attachment** field required for the record producer.
Access	Group or individual users for whom the record producer is available or not available.
Review and Submit	Review and submit the record producer.

8. To preview a catalog item in Portal or Now Mobile, select **Preview**.

   Note:
   When you preview an item, you can interact with it but not submit it.

   a. To preview the item in the portal, select **Portal** for the **View within** field.

      Note:
      Portal preview is based on the portal URL configured for the Catalog Builder.

   b. To view an item representation in Now Mobile, select **Now Mobile** for the **View within** field.

c. To open the preview in a new tab, select **Open preview in a new tab**.

> **Note:**
> When you change the item and save it, the preview is dynamically refreshed in the opened tab.

9. Select **Submit**.

What to do next

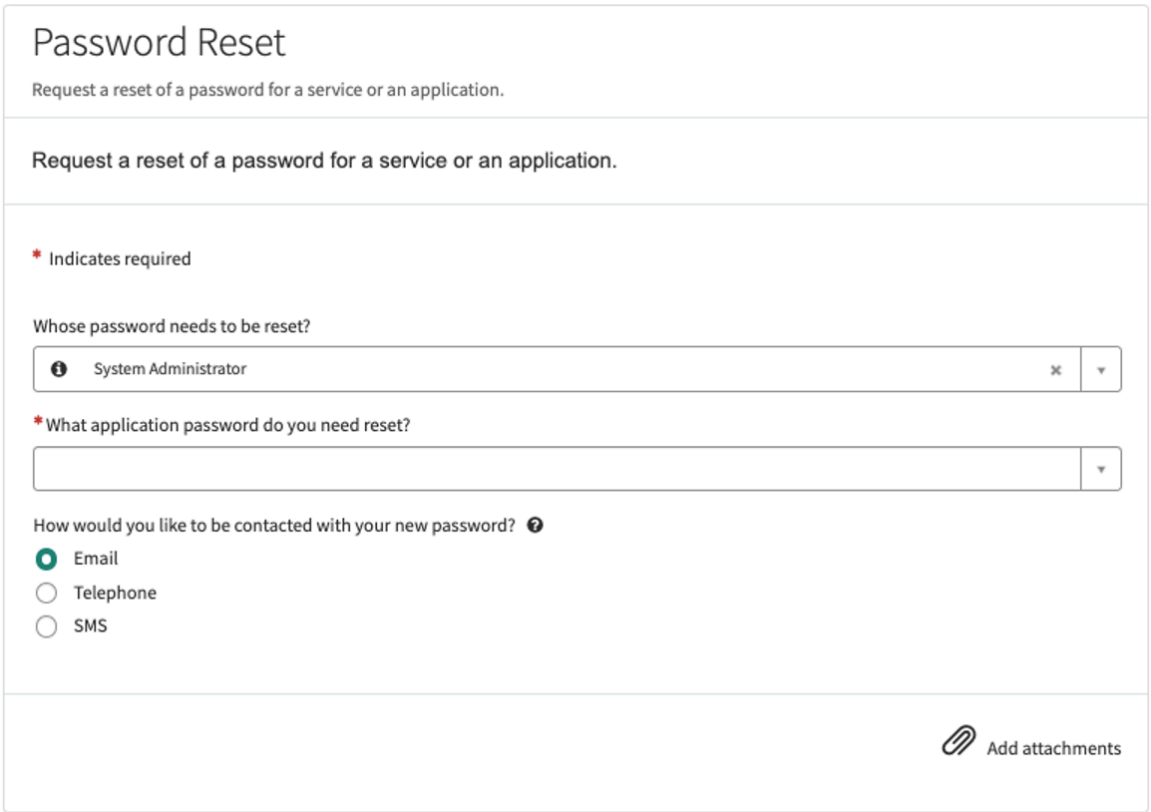
For the record producer you want to edit, select the menu icon (•••) and select **Edit**.

Sample record producer

A record producer experience that you create in App Engine Studio (AES) is a service catalog form that generates a task record, such as an incident, instead of a request.

Example record producer

The following provides an example of a record producer that creates a password reset request.



Add a standard catalog item

Add a standard catalog item to your application in App Engine Studio (AES) so users can submit requests for services and offerings.

Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

About this task

A standard catalog item displays a form that users can fill in to create requests, such as a form to request an item or service. Standard catalog items make use of the Request table and produce a request record. In addition, generated request items are linked with a workflow, a catalog task, and any related approvals. Using standard catalog items, users can add multiple items to a cart and generate a request for each requested item. Use a catalog item when you want the service catalog form to generate a request, complete with a workflow, approvals, tasks, etc. When you add a standard catalog item, you're creating a standard version of the catalog item, which you must then continue editing in Catalog Builder before it's ready to deploy.

Note:
If you created an application using a template, a standard catalog item may already be added to your application.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, next to Experience, select **Add**.
4. Select **Standard catalog item** and select **Begin**.
5. On the form, fill in the fields.

ADD EXPERIENCE form

Field	Description
Name	Name for the standard catalog item.
Short description	Brief overview of the standard catalog item.

6. Select **Edit catalog item**.
7. Specify the required information.

   After completing each step, select **Save**.

Catalog Builder steps

Step	Description
Details	○ Basic info: Standard catalog item name and short description. ○ Item details: Description of the standard catalog item. **Note:** You can attach files such as graphics, images, videos, or a link to an external source of information.
Location	○ Catalogs: Name of the catalog the standard catalog item belongs in. ○ Categories: Available categories that can be linked with the standard catalog item.
Questions	Questions for the standard catalog item.

Step	Description
	From the **Insert new question** list, you can include additional question sets, questions, deactivated questions, single-column container, two-column container, and line break. For information on creating a question and supported question types, see Create a question for a catalog item in Catalog Builder. You can also add dynamic form behavior for a question. For information on adding dynamic form behavior, see Edit a question in Catalog Builder. **Note:** ○ The questions within a question set can't be edited. The question sets can be reordered by dragging and dropping them. ○ Question sets specified in the template can't be removed, while the ones added by the user can be removed. ○ Removal of question sets simply removes the association with the item and doesn't delete the question set. ○ A single-column question set can be added to a single-column or a two-column container. A two-column question set can't be added to a container.
Settings	Configure the standard catalog item based on the request method. Request method: ○ Order: Use this method in scenarios, such as a corporate laptop request. ○ Request: Use this method in scenarios, such as a code access request. ○ Submit: Use this method in scenarios, such as a reset password request. Other options: ○ Hide 'Add to cart' button: Option to hide the **Add to Cart** button for the standard catalog item. This option is automatically selected if the **Request method** is **Request** or **Submit**. ○ Hide 'Add to wishlist' button: Option to hide the **Add to wishlist** button on standard catalog items.

Step	Description
	○ Hide quantity selector: Option to hide the **Quantity** list on standard catalog items. ○ Hide delivery time: Option to hide the **Delivery time** field on the standard catalog items. This option is automatically selected if you set the **Request method** to **Submit**. ○ Hide attachment button: Option to hide the **Attachments** button on standard catalog items. ○ Make attachment mandatory: Option to make the **Attachment** field mandatory on standard catalog items.
Access	Specify the group or individual users for whom the standard catalog item is available or not available.
Fulfillment	Flow with which you can associate the standard catalog item. The flow defines the fulfillment process for the standard catalog item. For more information on flows, see Flows.
Review and Submit	Review and submit the standard catalog item.

8. To preview a catalog item in Portal or Now Mobile, select **Preview**.

   Note:
   When you preview an item, you can interact with it but not submit it.

   a. To preview the item in the portal, select **Portal** for the **View within** field.

      Note:
      Portal preview is based on the portal URL configured for the Catalog Builder.

   b. To view an item representation in Now Mobile, select **Now Mobile** for the **View within** field.

   c. To open the preview in a new tab, select **Open preview in a new tab**.

      Note:
      When you change the item and save it, the preview is dynamically refreshed in the opened tab.

9. Select **Submit**.

What to do next

For the standard catalog item you want to edit, select the menu icon (•••) and select **Edit**.

Sample standard catalog item

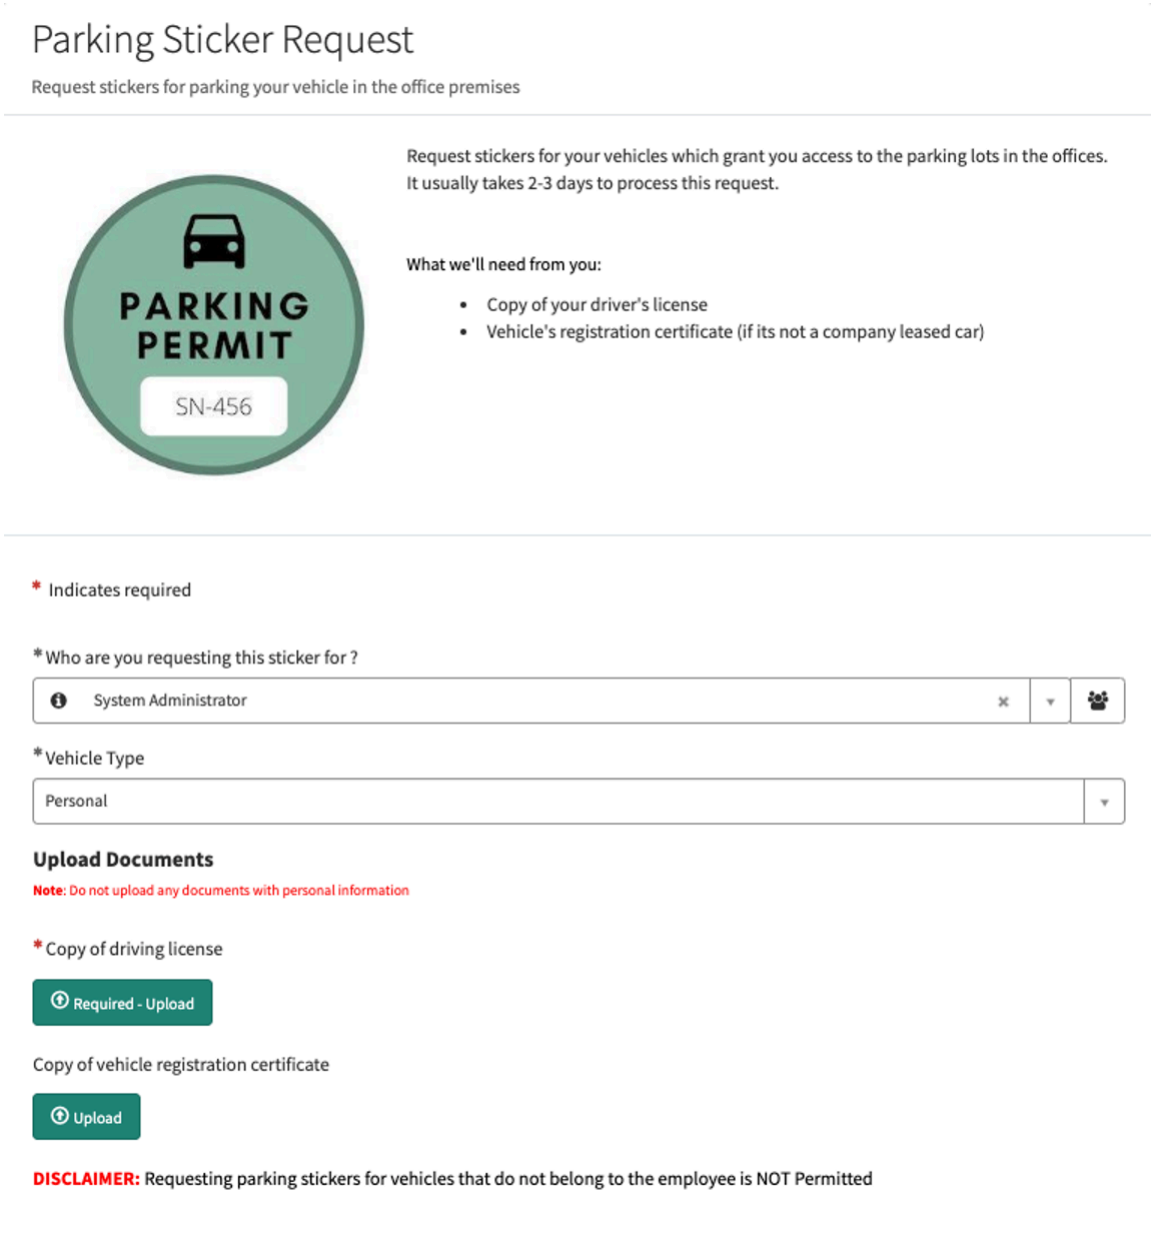
A standard catalog item displays a form that users can fill in to create requests, such as a form to request an item or service. Standard catalog items make use of the Request table and produce a request record. In addition, generated request items are linked with a workflow, a catalog task, and any related approvals. Using standard catalog items, users can add multiple items to a cart

and generate a request for each requested item. Use a catalog item when you want the service catalog form to generate a request, complete with a workflow, approvals, tasks, etc.

For example, an employee can fill in a catalog item form to request time-off for a holiday. After submitting the form, a request is created for a manager to approve or reject.

Example standard catalog item

The following provides an example of a standard catalog item to request a parking permit.



Add a workspace

Create a workspace in App Engine Studio (AES) to build a space that provides agents, case managers, help desk professionals, and managers with tools to help answer customer questions and resolve customer problems. Workspaces are primarily used for request and fulfillment processes, such as a service desk to manage tickets.

This video shows you how to perform the following procedure.

This video shows you how to add a workspace.

Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

About this task

When you add a workspace you're creating a basic version of it, which you must then continue editing in Workspace Builder before it's ready to deploy. For more complex customizations, edit the workspace in UI Builder.

If you create a workspace from an App Engine Studio workspace experience template, you can edit the home page, lists, and record pages in Workspace Builder. However, if you create the workspace using an application template, you must edit some of its pages and objects in UI Builder.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, next to Experience, select **Add**.
4. Select **Workspace**, and then select **Begin**.
5. On the form, fill in the fields.

Field	Description
Name	Name of the workspace that appears to users. By default, the workspace shares the same name as your application. **Tip:** Use a name that uniquely identifies the workspace from other experiences. For example, `Office art requests workspace`.
Description	Description of the workspace.
URL	Unique web address of the workspace. By default, the workspace URL is based on the application name, but you can edit it.
Roles	User roles to limit who can access the workspace. ○ You must specify at least one role to grant access to the workspace. ○ To use a custom role for your workspace, you must create one in **Security** first. For more information, see Add application security.

6. Select **Continue** to define data for your workspace.
7. On the form, fill in the fields.

Field	Description
Primary Table	Data table that workspace users view or update.

Field	Description
Secondary Tables	Additional data tables that workspace users view and update.

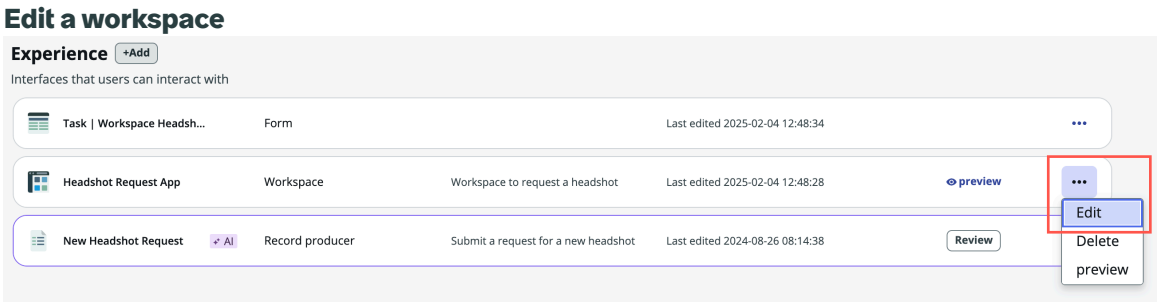
Note:
You can select only tables with default views. You can select from two sections: Tables that are already available in your app, and all tables outside the app scope.

Workspace Builder automatically generates a record page for the table you select.

8. Select **Continue**, and then select *Done*.
   After you create the workspace in AES, you must edit it in Workspace Builder by adding or configuring components on each page.

9. Next to the workspace you created, select the additional actions icon (•••) and then select **Edit**.

   You can also select the bar that lists the workspace in the Experience section of your app.



10. **Optional:** Edit your workspace home page in the In-line editor by selecting **Preview**.

    a. On your workspace home page, select **Edit**.
    If you don't see **Edit**, you may not have the permissions needed to edit the workspace home page.

    b. If the workspace is missing an Access Control List (ACL), enter the roles that should have access in the Add user roles to continue modal and select the **Add roles** button.
    For more information, see Configure workspace settings in Workspace Builder and Access Control List Rules.

    c. Adjust the home page elements and widgets by resizing, reorganizing, or reconfiguring them.

    Editing your workspace home page works similarly to editing a dashboard on your workspace. For more information, see Edit Platform Analytics dashboards.

    Note:
    If the workspace was created before Tokyo, you must edit it in UI Builder. See UI Builder for more information.

    If you created the workspace that contains a technical dashboard, Workspace Builder prompts you to **Open in UI Builder** when you try to edit the workspace.

    d. Select **Add new element** to add items to your workspace home page.

    e. Select **Exit Editing Mode** to stop editing in the In-line editor.

11. Edit the workspace in Workspace Builder. For more information, see Configure a workspace in Workspace Builder.

    You can also add more record pages to the workspace, if needed.

    Note:
    The default workspace record pages are read-only and can't be edited. To change the content of each record page, create a page variant and edit the variant.

Sample workspaces you can build

App Engine Studio (AES) provides a basic workspace that includes a home page, record pages, lists, an Analytics Center, and other functions.

The workspace that you create in App Engine Studio includes several default pages. You can use these pages as-is or edit them to suit your business needs.

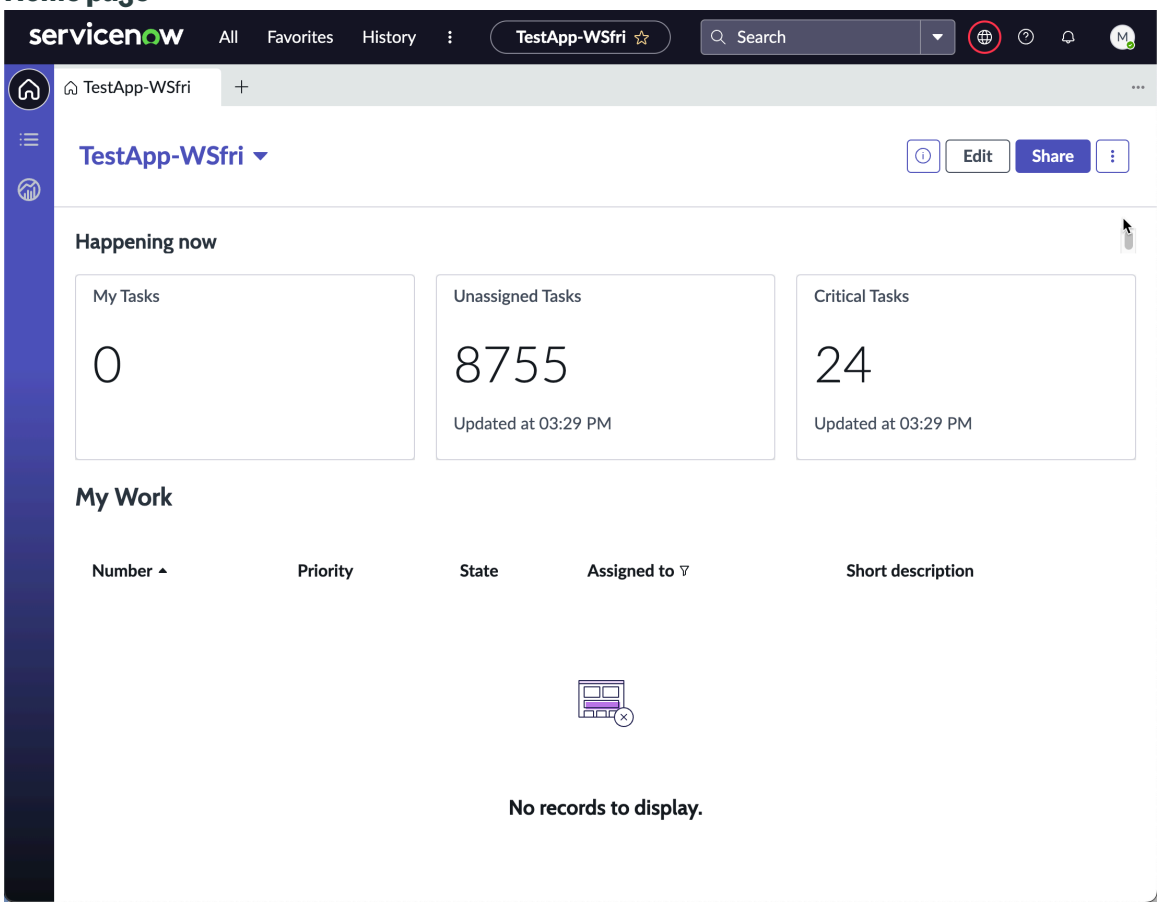
The following are some examples of the page customizations you can apply to the workspace after you add it:

- Home page
- List page
- Record page
- Search page
- Analytics Center

Workspace home page

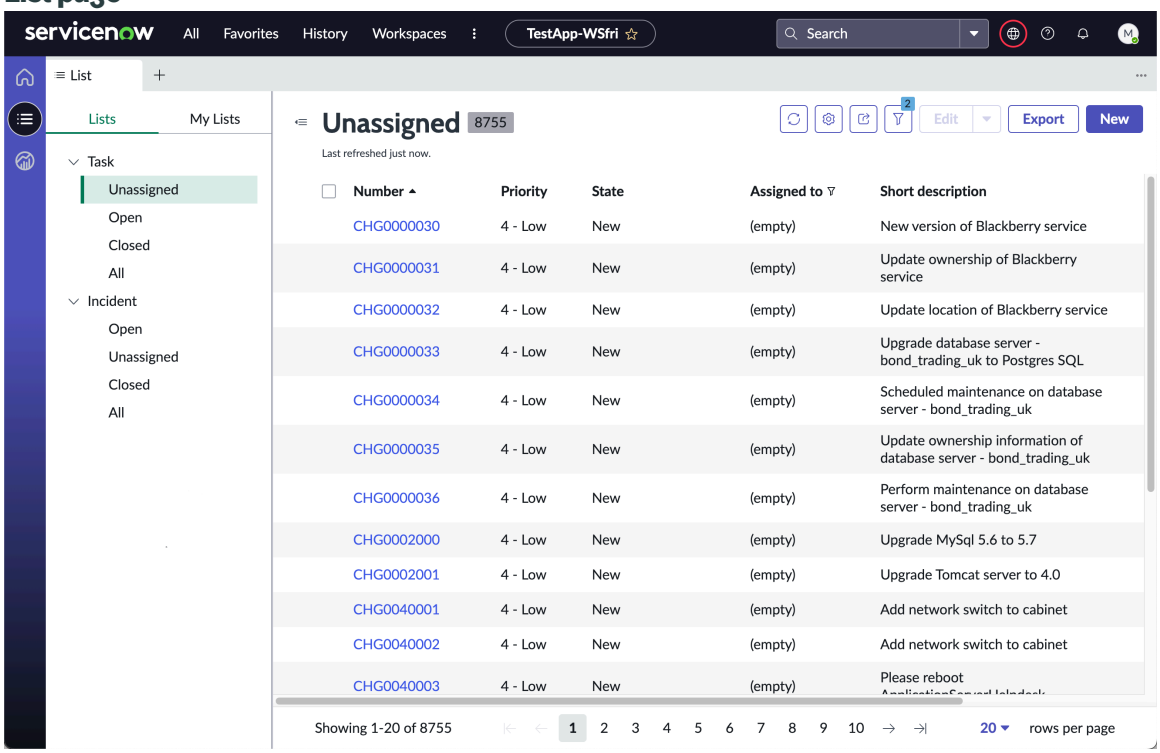
Note:
You can make changes to the home page, but editing all other pages requires creating a variant or copy of the page. If you edit the pages directly, then they won't get the latest code in a system upgrade.

Home page



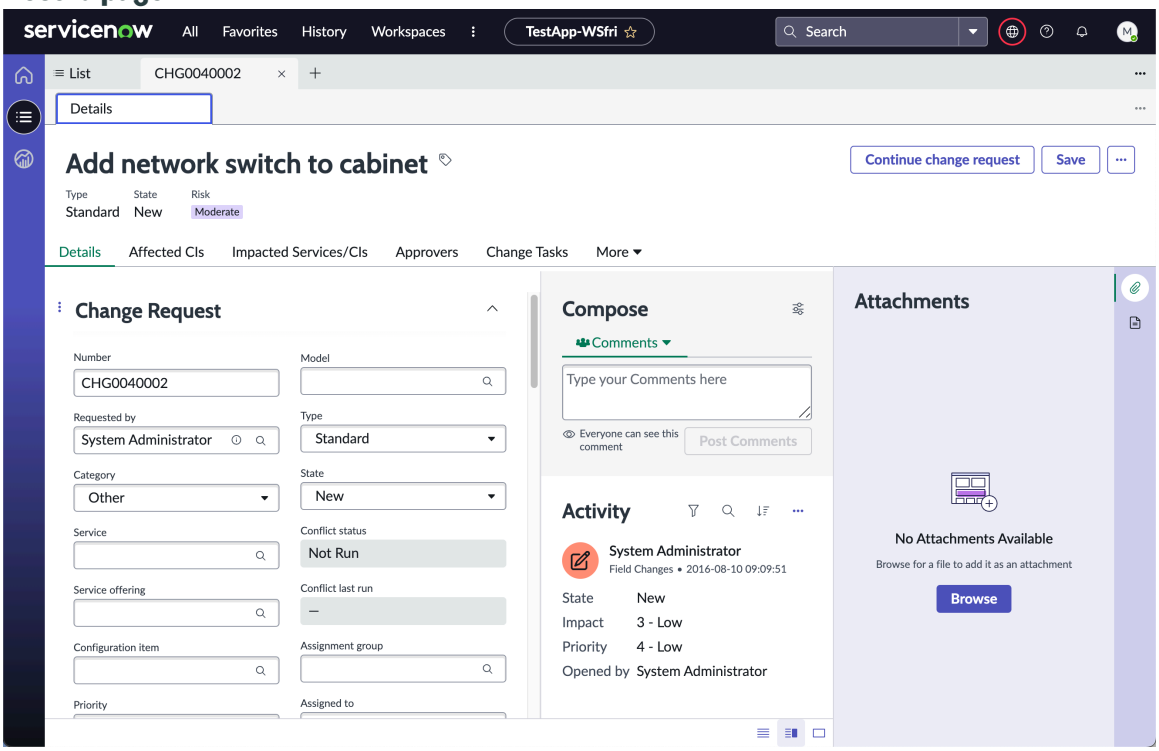
Workspace list page

List page



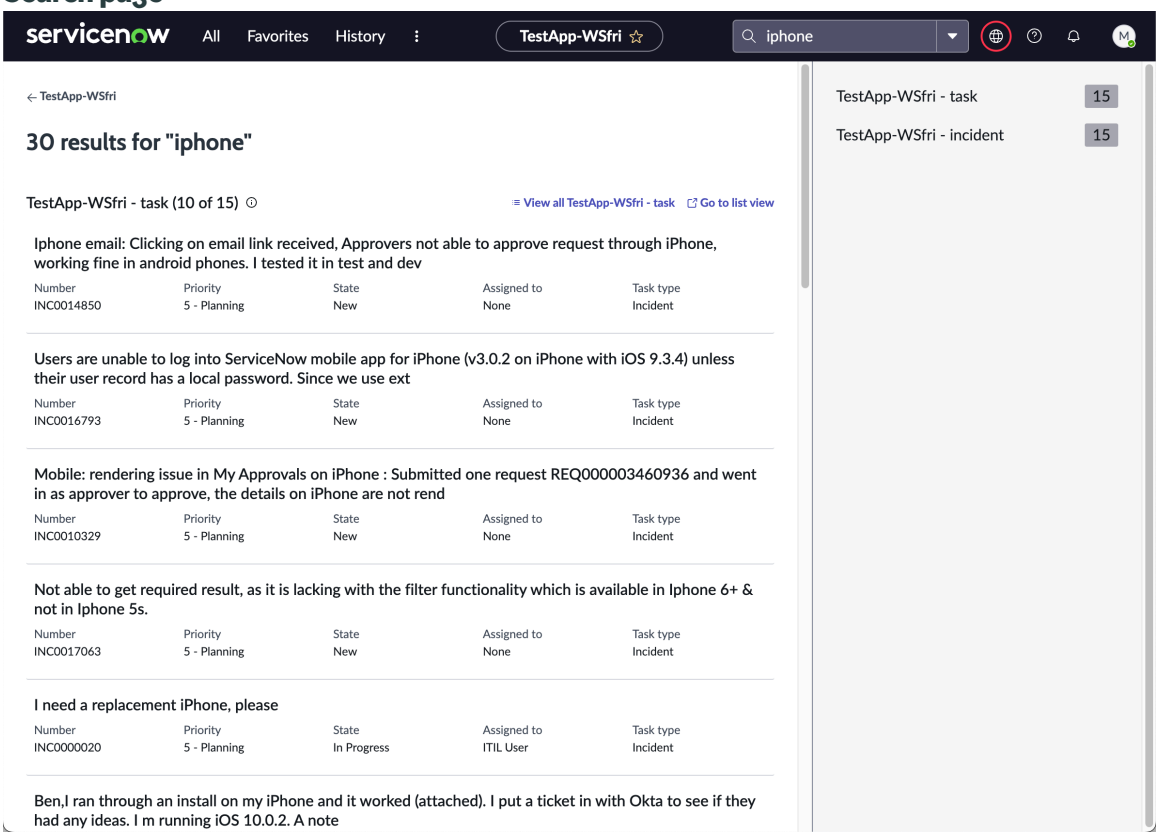
Workspace record page

Record page



Workspace search page

Search page



Workspace Analytics Center

The Analytics Center includes the following components:

Analytics Q&A

A field where you can ask natural language questions about the trends and health of your processes. (The Natural Language Query feature is required.)

Indicator Scorecard

A list of the Performance Analytics indicators that you are allowed to access based on your roles. Depending on the configuration, selecting an indicator can open it in KPI Details.

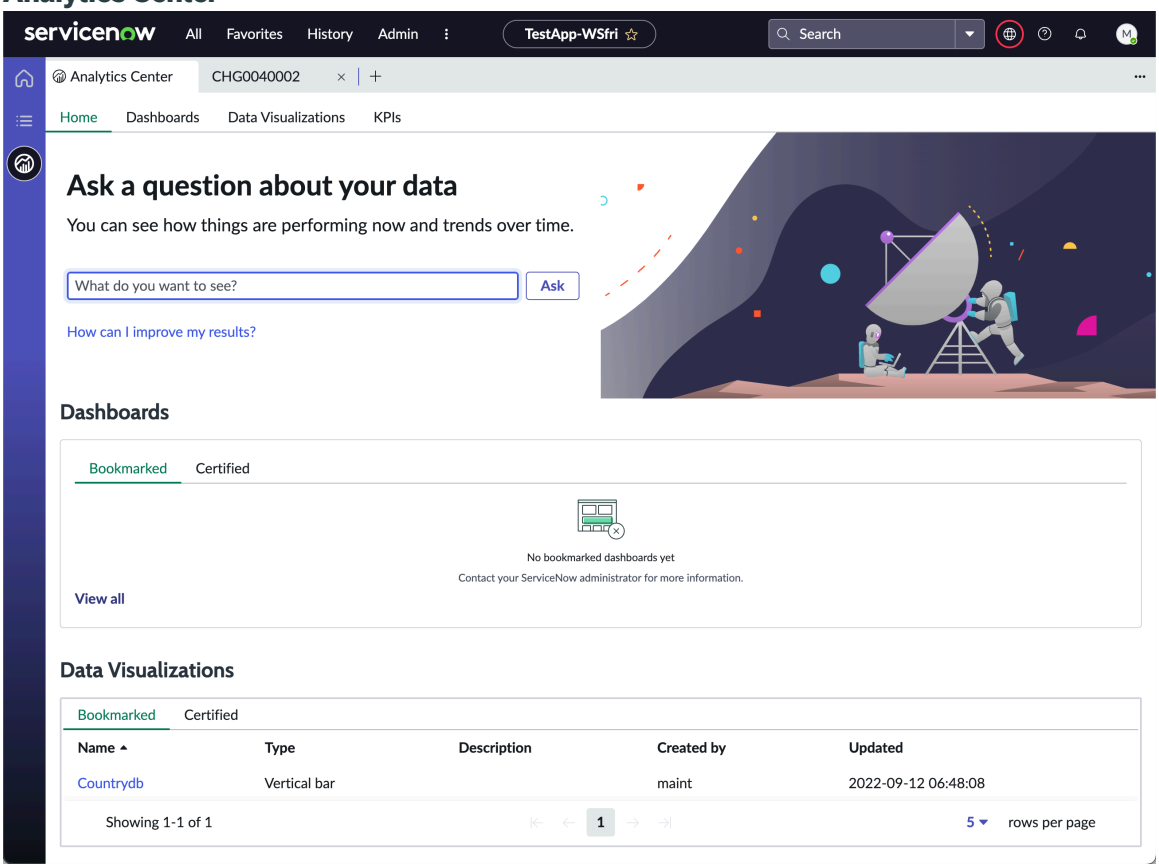
Dashboards Overview

A set of tiles for each dashboard on the instance that you are allowed to access. Selecting a tile opens that dashboard.

> **Note:**
> You can create and edit dashboards in-line. For more information, see Configure Platform Analytics dashboard details.

For more information on Analytics Center, see Analytics Center.

Analytics Center



Building workspaces in AES

Workspace Builder for App Engine is a streamlined, no-code environment that enables you to create a custom workspace from within App Engine Studio (AES) quickly and efficiently.

You can use Workspace Builder to quickly create workspaces for workspaces built starting with Xanadu. Workspace Builder enables you to edit the workspace home page, list pages, and record page contextual side panel directly in the Workspace Builder preview canvas.

For workspaces created before Xanadu, or if you need more robust functionalities and configurations, edit the workspace in UI Builder from a tab within AES.

Parts of a workspace

Build your workspace by including the following pages and elements.

Workspace pages and elements

Component	Definition
Home	Landing page for the workspace, which contains a dashboard and appears to users when first accessing the workspace. **Note:** The home page is an essential part of the workspace, and thus can't be hidden or removed. For more information on configuring the home page, see Configure a workspace home page in Workspace Builder. For information on configuring the basic settings for a workspace, see Configure workspace settings in Workspace Builder.
List	List pages for records from the specified tables, which help users to find individual records in a workspace. **Note:** If you remove the list page/route, you must use UI Builder to edit the workspace, not Workspace Builder. You can create a list category and then add filtered lists for each list category. Filtered lists apply unique conditions, ensuring that only the filtered subset of records appears. For more information on adding and editing lists in Workspace Builder, see Configure lists for a workspace in Workspace Builder.
Analytics	The customizable Analytics Center enables users to track and analyze records and usage with dashboards, data visualizations, and insights on your instance. **Note:** If Analytics Center page/route doesn't exist for a workspace, Workspace Builder is still available, but the Analytics Center tab doesn't appear in the workspace.

Workspace pages and elements (continued)

Component	Definition
	For more information on enabling the Analytics Center for a workspace, see Configure analytics for a workspace in Workspace Builder.
Record pages	Pages in a table that give users useful information to work on a task, issue, or incident. Useful information can include priority, state, activity, and so on. Create and customize record pages by using containers and components in different sections of the layout. You can also add a Playbook Experience to a record page. For more information, see Configure a record page for a workspace in Workspace Builder.

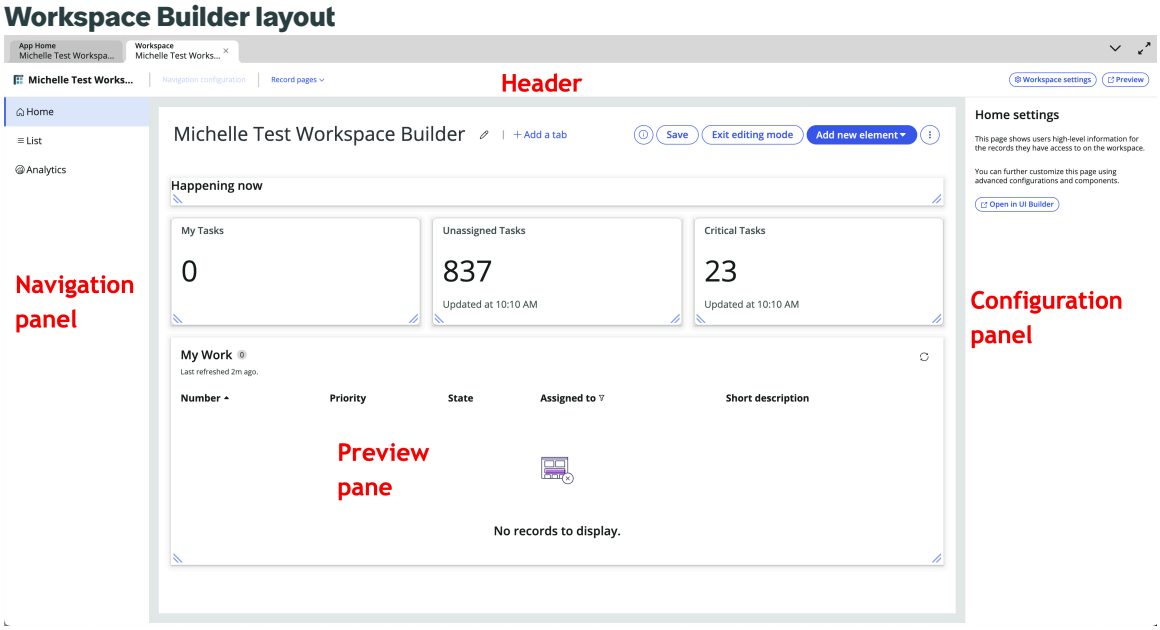
Note:
Your workspace must have a home page and lists for you to edit it in Workspace Builder. If they aren't present, you must edit the workspace in UI Builder.

Layout for Workspace Builder

The first time you access Workspace Builder, an onboarding modal displays a brief tour of what you can do in Workspace Builder.

Workspace Builder consists of the following sections:

- A left navigation panel to configure the pages that users can navigate to within the workspace.
- A preview of the workspace in the middle canvas.
- A right configuration panel for configuring the selected workspace component.
- An option to preview the workspace in a new browser tab.



The Workspace Builder header has the following navigation options just below the tab, where you can work with the following:

- Navigation configuration
- Record pages

Workspace Builder plugin

To use Workspace Builder, you must enable the com.devsnc_sn_workspace_builder plugin in the sn_ws_builder scope. It is a dependency of com.snc.aes.starter_workspace_template.

Configure a workspace in Workspace Builder

Edit a workspace in Workspace Builder to make customizations in App Engine Studio (AES).

This video shows you how to perform the following procedure.

Configure a workspace in Workspace Builder

Before you begin

Before you can configure a workspace in Workspace Builder, you must first create the workspace. See Add a workspace.

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

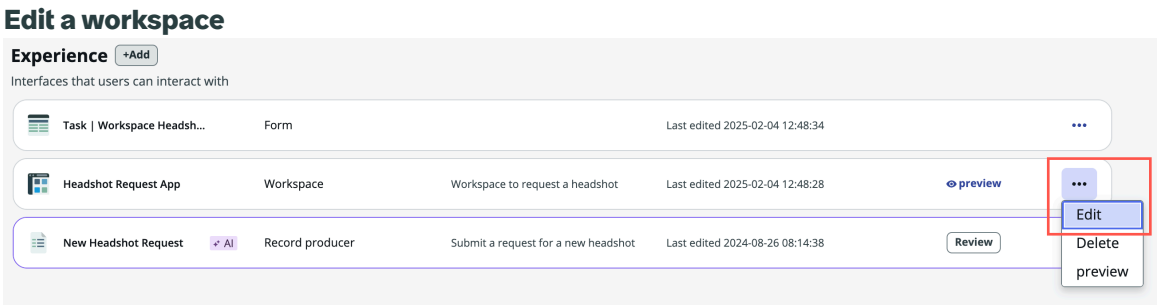
About this task

You can customize essential elements and components in Workspace Builder. For more complex configurations, or if you don't have the full entitlement for AES, you must edit the workspace in UI Builder.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to the workspace you created, select the additional actions icon (•••) and then select **Edit**.

You can also select the bar that lists the workspace in the Experience section of your app.

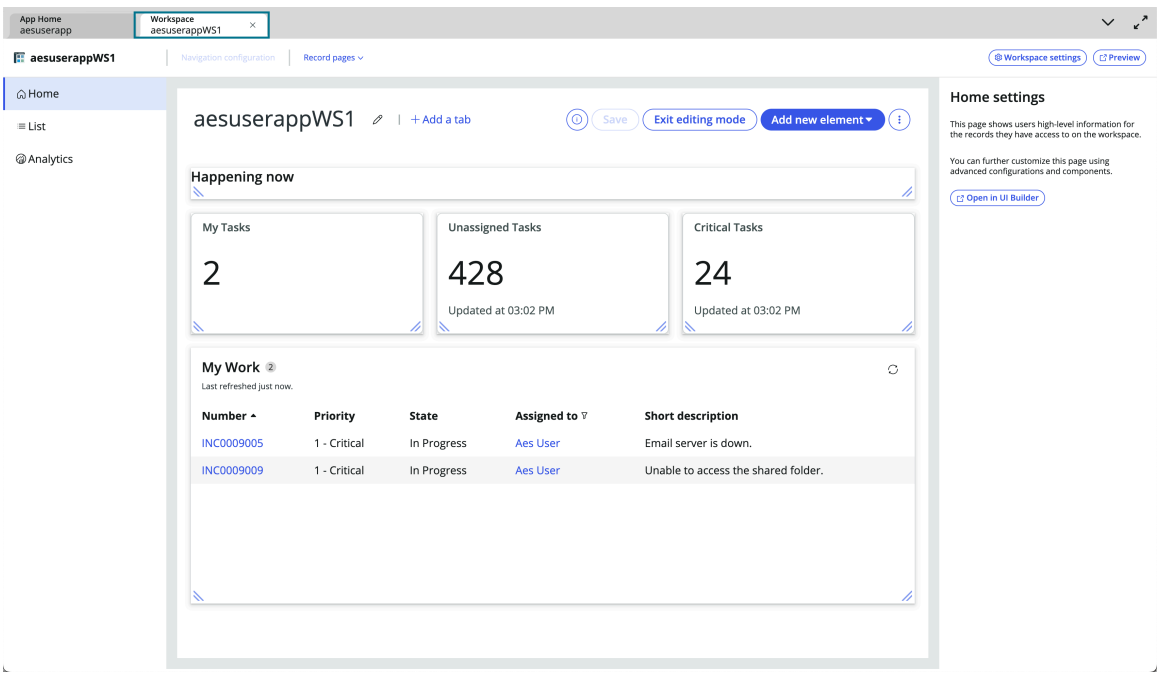


The Workspace Builder tab displays your workspace within AES:

- The left navigation panel is a list of pages or components, or building blocks of a page, that you can include in your workspace.

  Note:
  The home page is an essential part of the workspace, and thus can't be hidden or removed.

- The middle canvas is an in-line editing space for the home page for workspaces created in AES after Tokyo. For lists and other pages, the middle canvas is a preview of what you configure in the right configuration panel. You can preview workspace home pages built before Tokyo in Workspace Builder, but you must edit them in UI Builder.
- The right configuration panel is the configuration panel for working with selected components.



If you created the workspace that contains a technical dashboard, Workspace Builder prompts you to **Open in UI Builder** when you try to edit the workspace.

4. Edit the basic settings for the workspace by selecting **Workspace settings**.
   For more information, see Configure workspace settings in Workspace Builder.
5. Adjust the home page elements and widgets by resizing, reorganizing, or reconfiguring them.

For more information on editing a clickable home page, see Configure a workspace home page in Workspace Builder.

Note:
If the workspace was created before Tokyo, you must edit it in UI Builder. See UI Builder for more information.

6. Add or edit a list category and any subsequent filtered lists.
   For more information, see Configure lists for a workspace in Workspace Builder.
7. **Optional:** Enable an Analytics Center for the workspace.
   For more information, see Configure analytics for a workspace in Workspace Builder.
8. Add and edit a record page to configure the settings, tables, and related links that the workspace should support.

   When you create a record page, you're creating the metadata view, or shell, using a record page template for a type of record. You then edit the record page in Table Builder. Within Workspace Builder, you can only change the contextual side panel and the related items.

   For more information, see Configure a record page for a workspace in Workspace Builder.
9. Preview the workspace in a new browser tab by clicking **Preview**.

Result

If you made additional, more complex configurations to the workspace in UI Builder, such as custom additions to the contextual side panel or custom components, those changes may not appear in Workspace Builder.

Note:
Your workspace must have a home page and lists for you to edit it in Workspace Builder. If they aren't present, you must edit the workspace in UI Builder.

Configure workspace settings in Workspace Builder

Define workspace settings in App Engine Studio (AES) to control the basic functionality of the workspace, such as name and record page navigation.

This video shows you how to perform the following procedure.

This video shows you how to configure workspace settings in Workspace Builder.

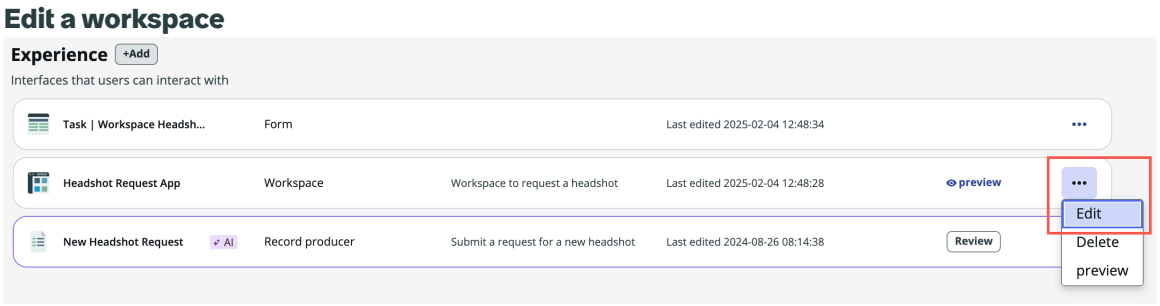
Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

Procedure

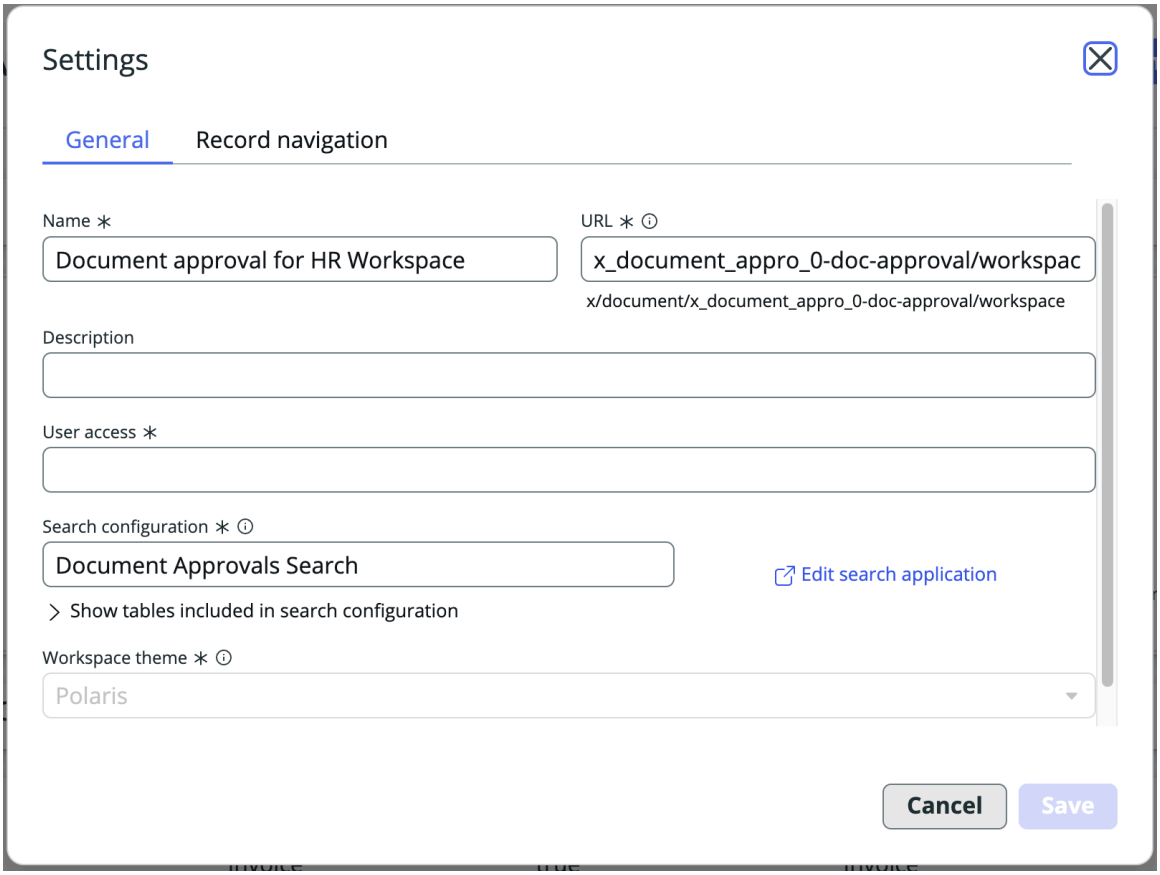
1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to the workspace you created, select the additional actions icon (•••) and then select **Edit**.

   You can also select the bar that lists the workspace in the Experience section of your app.



The workspace appears in Workspace Builder.

4. Display the Settings form by selecting **Workspace settings** in the Workspace Builder header.



5. On the **General** tab of the form, specify or change the basic settings for the workspace by filling in the editable fields.

Note:
Some settings are specified when adding a workspace, and can't be changed.

General workspace settings

Field	Description
Name	Name for the workspace, which is visible to users.
URL	Relative URL for the workspace. The path is automatically created based on the name of your workspace, and is preceded by your

Field	Description
	instance URL. However, you can customize the path in this field.
Description	Brief description of the purpose of the workspace.
User access	People and groups that can access the workspace. To give unrestricted access to the workspace, leave this field empty.
Search configuration	Source of information when users perform a search in the workspace. You can reuse an existing search configuration by selecting the profile from the menu. Select the **Edit search application** link to make additional, advanced configuration changes. If you select an AI Search profile, the following features are available: ○ Selection of multiple facet values simultaneously, which you can apply using the condition builder. ○ Ability to view parent documents with linked attachments, which you can download. ○ Dark mode. **Note:** AI Search must be enabled for your instance to select an AI Search profile. For more information, see AI Search.
Show tables included in search configuration	Option that displays one or more tables that the workspace searches as sources.
Workspace theme	Theme to define the visual style of the workspace, which you can select only if Polaris isn't enabled for the instance. Themes are retrieved from the UX Themes [**sys_ux_theme**] table..

Trouble?
Add only one **User access** role at a time. For more information, see this Knowledge article.

6. Select **Save**.
7. Specify what type of records users can create by selecting the **Record navigation** tab of the form and then filling in the fields.

Record navigation workspace settings

Field	Definition
Navigation type	How users interact with or navigate the workspace.

Field	Definition
	Tabbed navigation creates separate tabs for each page, enabling users to work on multiple records at a time. Choose tabs if you anticipate that users must change between records quickly. Tabs also enable users to create records directly from the navigation. **Note:** The default navigation type for workspaces built in AES is tabbed, and can't be changed after the workspace is created. You must create the workspace in UI Builder to specify breadcrumb navigation. You can't change the navigation type after the workspace is created.
Table	Data table that is added to when a user creates a record. The table you select automatically has associated lists. **Note:** The tables specified when the workspace was created appear automatically. Select **Add a table** to incorporate additional tables into the workspace. You can add each table only once. To remove a table, select its delete icon ( ). No confirmation message appears, but you can select **Cancel** to revert the deletion.
Label	Brief label for the option that appears when users select the new record menu. Specify a label that tells users what the record is used for.

8. Select **Save**.

Configure a workspace home page in Workspace Builder

Edit the home page for a workspace in App Engine Studio (AES). Adjust what users see when first accessing the workspace, which is a dashboard.

This video shows you how to perform the following procedure.

This video shows you how to configure a workspace home page in Workspace Builder.

Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

About this task

You can edit workspace home pages in Workspace Builder only for workspaces created in Tokyo and going forward. You can edit older workspaces in UI Builder.

Note:
The home page is an essential part of the workspace, and thus can't be hidden or removed.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to the workspace you created, select the additional actions icon (•••) and then select **Edit**.

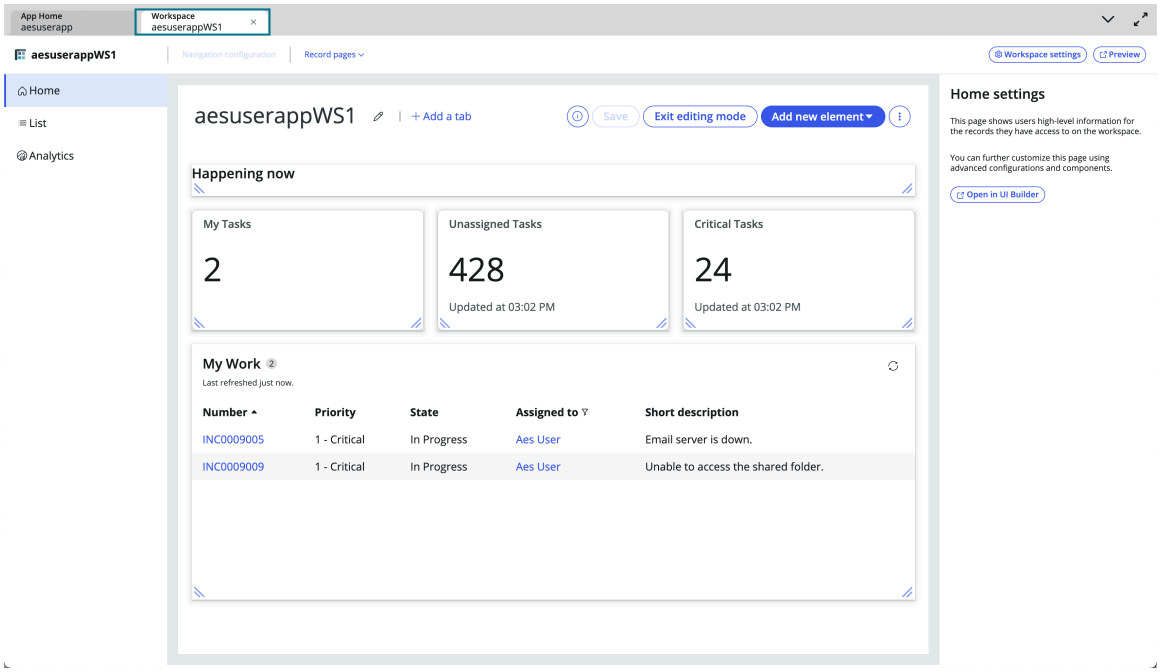
   You can also select the bar that lists the workspace in the Experience section of your app.

   The home page for the workspace appears in Workspace Builder, where you can drag elements and components to design the page.

   If you created the workspace that contains a technical dashboard, Workspace Builder prompts you to **Open in UI Builder** when you try to edit the workspace.

4. Add an element to the page.
   You must be in the **Navigation configuration** tab. If you're already in the **Navigation configuration** tab, you can't select it.

a. In the navigation panel, select **Home**.



b. In the home page canvas, select **Add new element**.

c. From the list, select the element or component that you want to add.

For example, to add a graphic of data from the specified table, select **Data visualization** and choose a **New data visualization** or a **Saved data visualization**.

You can add the following elements to the home page in Workspace Builder.

Home page elements

Element	Description	More information
Data visualization	Graphic, visual representation of current instance data. You can create a new data visualization or repurpose an existing data visualization by choosing it in the Select visualization from library modal and selecting **Add to dashboard**. In addition to data visualizations, you can select the **Library** element to add an already-saved data visualization to the home page.	▪ Data visualizations in Platform Analytics ▪ Create a single score data visualization in the Visualization Designer or on a dashboard ▪ Developer site data visualization component listing

Element	Description	More information
Filter	Refine the visualizations on a dashboard based on specified criteria. The filters can apply to both tables and indicators.	▪ Filters in Platform Analytics ▪ Developer site filter component listing
Heading	Title or text for the top of the home page or section.	Developer site heading component listing
Image	Static or animated images or pictures for the workspace.	Developer site image component listing
List - Simple	Table data that you can customize for the dashboard audience.	▪ Simple List widget or List - Simple Usage - Developer site ▪ Developer site List - simple component listing

The Workspace Builder components for home pages has details on home page elements. For more information, see Platform Analytics dashboard overview.

If you want to include additional elements that aren't available in the **Add new element** menu, you must edit the workspace in UI Builder. For a complete list of elements you can add in UI Builder, see the components documentation on the ServiceNow Developer Site.

The element appears on the dashboard, where you can make edits.

d. Drag the element to move or resize it.

e. In the canvas header, select **Save**.

5. **Optional:** If needed, complete any additional changes to an element.

Option	Description
Edit an element	**a.** Select the element that you want to edit, such as a data visualization. (Optional) A header appears with the name of the element type.

Option	Description
	 **b.** Select the settings icon ( ) in the element header to open the configuration panel within the canvas. **Note:** You can also select the context menu icon ( ) and select **Configure** to edit the element. **c.** Edit the configuration of the element in the configuration panel as needed. (Optional) For example, if you're editing a data visualization, you must specify the source table. For more information on edit ing components, see Add and configure components. **d.** In the canvas header, select **Save**.
Copy an element to reuse on the home page	Select the context menu icon ( ) and select **Duplicate** to copy the element. You can then make additional changes to the copied ele ment.
Add an element to the library for reuse	Select the context menu icon ( ) and select **Add to library** to include the element in your library to reuse on other dashboards.
Delete an element from the workspace dash board	**a.** Select the element that you want to delete. (Optional) A header appears with the name of the element type.

Option	Description
	b. In the header, select the context menu icon ( ) and select **Delete**.  **Note:** There's no confirmation message. The element disappears from the dash board.

6. **Optional:** If needed, complete any additional configuration changes to the dashboard.

Option	Description
Configure the dashboard layout	Select and drag an entire element to move it around the dashboard layout. (Optional) Resize an element by selecting and dragging the handlebars ( ) in the low er corners of the element.
Duplicate the dashboard	To make a copy of the dashboard: ○ Select the more options icon for the dash board ( ). ○ Select **Duplicate**. ○ Enter the **New name** and **Description** for the copied dashboard on the modal. ○ Select **Duplicate**. Access the duplicated dashboard by exiting out of editing mode and selecting the new dashboard from the dashboard name drop-down menu. 
Option	Description
Add tabs to the workspace and edit them as needed	**a.** Add a tab to the home page by selecting **Add a tab**. When you add your first tab to a home page dashboard, a new part of the layout ap pears below the title. Elements you add to the tab are visible no matter which tab the user is on. A tab labeled **untitled** is added next to any existing tabs. **b.** Rename a tab by selecting the tab name, selecting the edit icon ( ), typing the new name, and pressing **Enter**. **c.** Reorder a tab by selecting the tab and drag ging it to the new position. **d.** Delete a tab by selecting its delete icon ( ) then selecting **Delete**. **Note:** No confirmation message appears. The tab disappears from the dash board.
Preview a workspace and make in-line edits	Make basic edits to a workspace when pre viewing it using the In-line editor. **a.** In the Workspace Builder header, select **Preview**. **b.** In the preview that appears in a new brows er tab, select **Edit**. **c.** Adjust the home page elements and wid gets by resizing, reorganizing, or reconfigur ing them. For more information, see Edit Platform Ana **d.** Select **Add new element** to add items to your workspace home page. **e.** Select **Exit Editing Mode** to stop editing in the In-line editor.
Open a printer-friendly version of the dash board	Select the more options icon for the dash board ( ) and select **Printer friendly** to dis play the workspace home page in a format suitable for printing.
Add a bookmark to Analytics Center	Select the more options icon for the dash board ( ) and select **Add to bookmarks** to include a bookmark for the workspace in the Analytics Center Bookmarks section.

Option	Description
Make additional or more advanced configurations to the home page	In the configuration panel, select **Open in UI Builder**.
Delete the dashboard	Select the more options icon for the dashboard ( ) and select **Delete**. You must select **Delete** again to conform. **Note:** Workspaces should have at least one dashboard home page.

7. Share the dashboard.

   a. Select the more options icon for the dashboard ( ) and select **Share**.

   b. On the modal, fill in the fields.

   Share dashboard options

Option	Description
Grant access to	Users and groups that can access the dashboard.
Allow recipients to add, edit, or delete sharing permissions associated with this dashboard	Option that enables the users and groups you share the dashboard with to add, edit, and delete the sharing rights for any user, group, or role.
Add as viewer / Add as editor	Option to specify read-only or write access for the dashboard.
Manage access	Roles that can access the dashboard. Search for and select a role in the search box. For each role with access, select the access level: ▪ **Can edit** ▪ **Can view** ▪ **Can share**
Copy link with filter	Button that copies the dashboard URL for the specified users and roles with the currently applied filters.
Copy link	Button that copies the dashboard URL for the specified users and roles without any filters.

   c. Select **Confirm**.

8. In the Workspace Builder header, select **Save**.

Workspace Builder components for home pages

Several UI Builder components are available as elements to build home pages and contextual side panels in Workspace Builder. Workspace Builder helps you quickly create workspaces in App Engine Studio (AES).

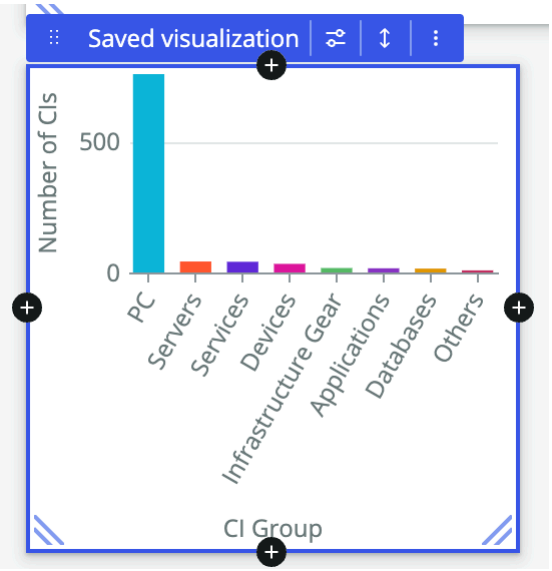
For complete details on all elements and components, see the ServiceNow® Developer site.

Data visualization components

The data visualization component is a container for available chart types for use in Workspace Builder home pages. Select the chart type to display data in different ways depending on your application. You can create a new data visualization or repurpose an existing data visualization by choosing it in the Select visualization from library modal and selecting **Add to dashboard**.

For more information on data visualization components, see the following topics and sources:

- Data visualizations in Platform Analytics
- Create a single score data visualization in the Visualization Designer or on a dashboard
- Data visualization component listing on the Developer site



Filter components

Filters enable you to filter data visualizations without modifying the visualizations. Add a filter element when working with the home page in the canvas. Then select a table, field, and other properties to configure the filter. When a user selects one or more values of the field, the filter applies to those data visualizations that are based on the same data source.

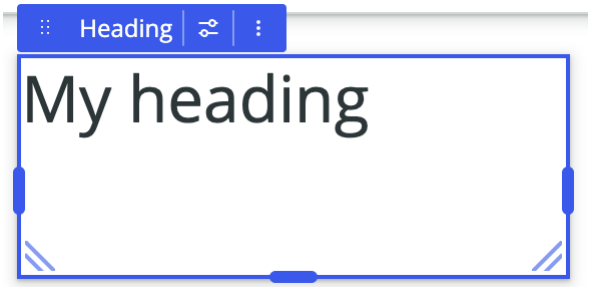
For more information on using filters components to build a workspace, see the following topics and sources:

- Next Experience filters
- Developer site filter component listing

Heading components

Heading components are available in the home pages for workspaces. Add a title to your landing page using a heading component.

The following image shows a "My Heading" heading.

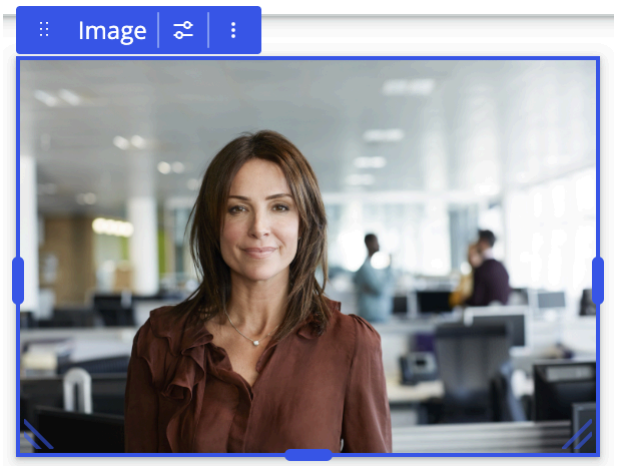


For more information on heading components, see Heading component listing on the Developer site.

Image components

Add images to your landing page with an image component.

When you drag the image component icon (Image) into the preview pane, a stock image appears that you can change and resize. You can change the stock image by supplying your image's URL.

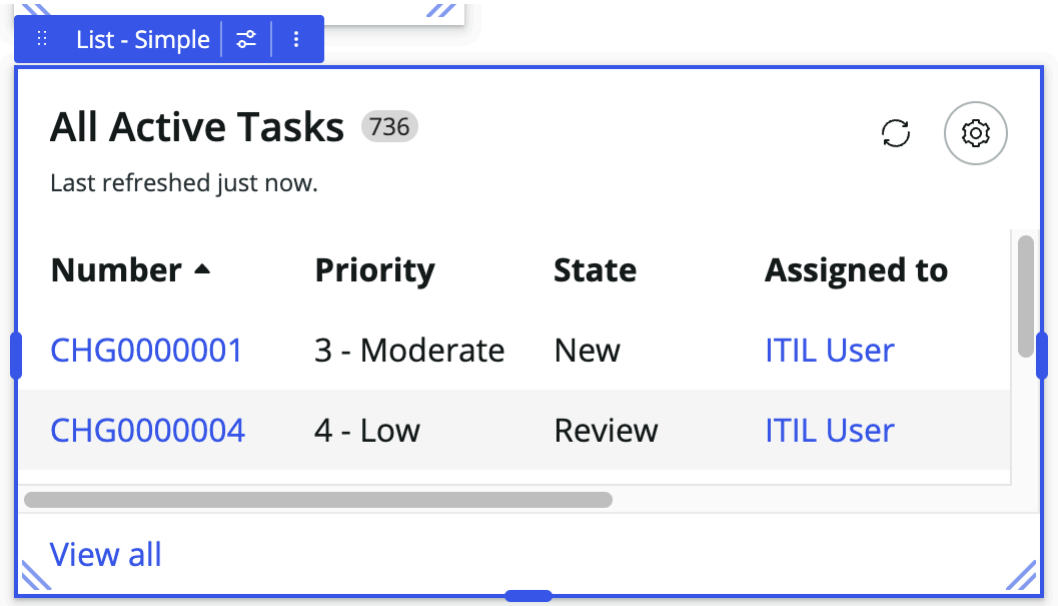


For more information on image components, see the Image component listing on the Developer site.

List components

Use a list component to add lists to your landing page.

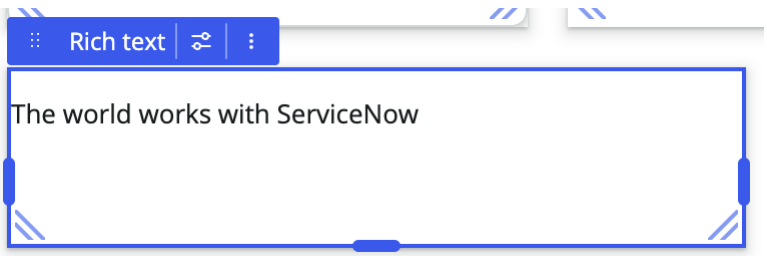
When you drag the list component icon (List) into the preview pane, a sample list appears.



For more information on list components, see the List component listing on the Developer site.

Rich text components

Add text to your landing page with a rich text component to explain parts of your landing page, for example, "Tackle these priority 1 incidents first."



For more information on rich text components, see the Rich text component listing on the Developer site.

Configure a record page for a workspace in Workspace Builder

Configure a record page for a workspace in App Engine Studio (AES). Use containers and components to guide a user through an experience. Each record page is linked to only one data table.

Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

About this task

Components are the building blocks of your page. Add components to your page to build or customize your workspace experience. For example, add a button component to your page that lets users submit requests.

A container is a type of component that can contain other components. Containers have layout properties applied to them. Change the page layout and visual styling to make the record page a unique experience.

Note:
Starting with workspaces built after the AES Workspace UI Template v22.0.3 release, you can work with record pages in Workspace Builder. For older workspaces, you must edit the record pages in UI Builder.

If you don't see the record page for a table you configured for the workspace, see this Knowledge article for more information.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to the workspace you created, select the additional actions icon (•••) and then select **Edit**.

   You can also select the bar that lists the workspace in the Experience section of your app.

   The workspace appears in Workspace Builder.

4. Create a record page.
   AES automatically generates record pages for the tables that you selected when you created the workspace.

   a. In the Workspace Builder header, from the **Record pages** menu, select **+ Create new**.

   b. On the form, fill in the fields.

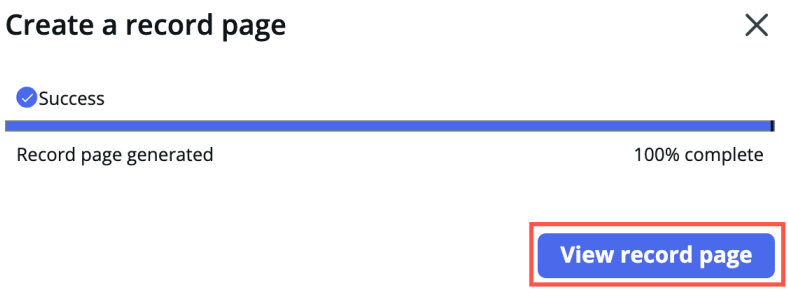
Record page settings

Field	Description
Name	Brief name that identifies the purpose of the record page.
Table	Table that the record page is linked to and updates. The following rules apply:

Field	Description
	▪ If you're using a table that you or someone at your organization created, the table must contain at least one new field or column. Otherwise, the form view and the record for the table can't be created. ▪ You can link each table to only one record page. You can select from two sections: Tables that are already available in your app, and all tables outside the app scope.

c. Select **Create**.

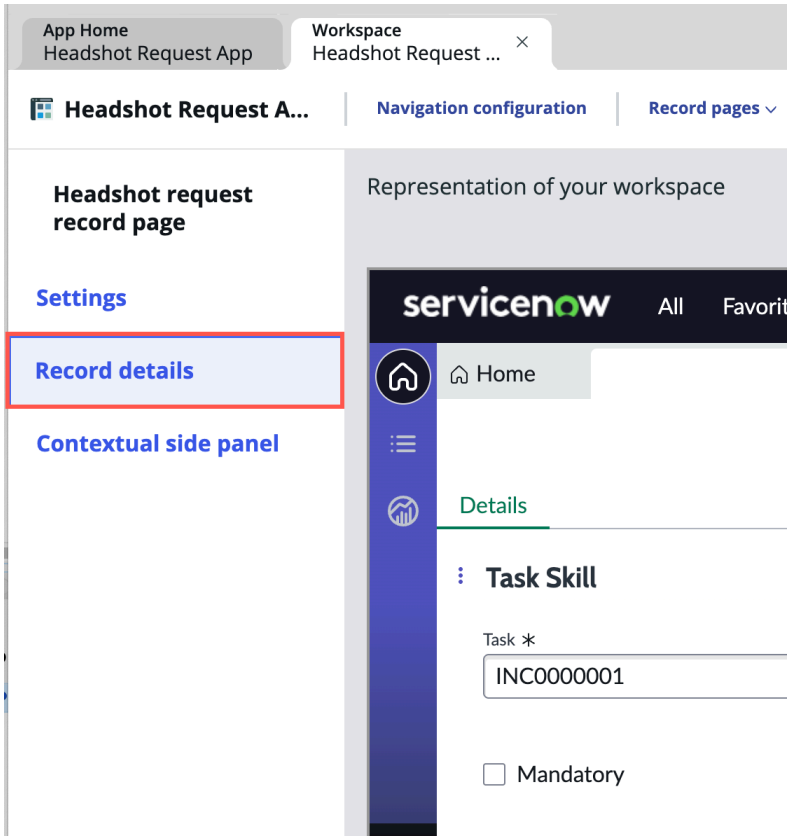
d. Select **View record page**.



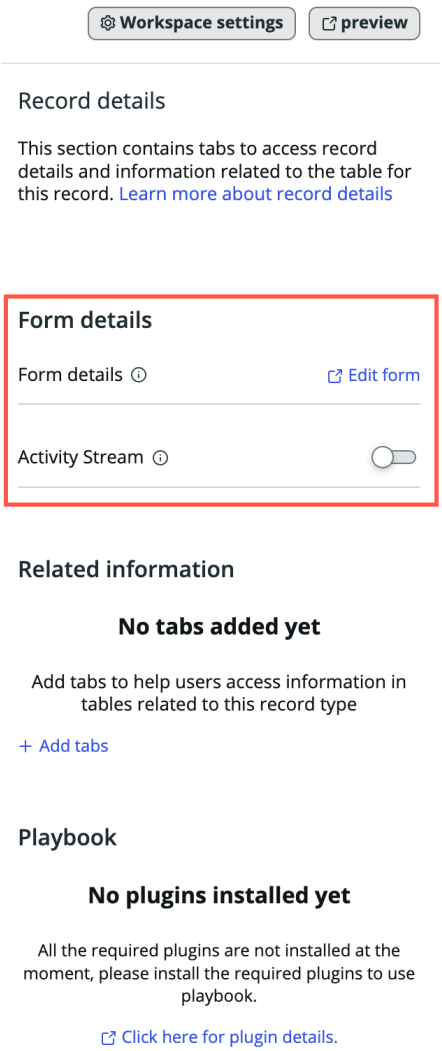
The page appears in the preview panel. You can select the page from the **Record pages** menu.

5. Edit the record details for the record page.

a. In the navigation panel, select **Record details**.



b. In the **Form details** section of the configuration panel, select **Edit form** and fill in the fields.



Form details for record page

Field	Description
Form details	Select the **Edit form** link to edit the form in a Table Builder tab inside AES. **Note:** After you leave the record page in the Table Builder tab, a dialog prompts you to **Reload this page**. For more information on editing forms for a record page, see Forms in Table Builder.
Activity stream	Option to enable the Activity stream for the record page. The Activity stream enables your workspace users to communicate with requesters and

Field	Description
	make internal notes about the work done on a record. For more information on the Activity stream, see Activity streams.

6. Configure the related information in the Related information section of the configuration panel for the record page.
   Related information includes tables that are related to the record, which appear as tabs, such as Child Incidents. For more information on configuring related information, see Related lists.

   Note:
   You can't create a table for the related information in a record page. The table must exist in ServiceNow AI Platform.

   a. If no related lists exist yet, add a new related list by selecting **+ Add tabs** in the **Releated information** section.

   If related lists exist for the record page, select the **Manage related information** link in the configuration panel.

b. In the form that appears in a new tab within AES, move the related list that you want to appear as a tab from the **Available** panel to the **Selected** panel.

c. Use the arrow buttons to move the selected lists into the order you want them to appear.

d. Select **Save** and return to the Workspace Builder tab within AES.

e. View the changes that you made by selecting **Reload this page** in the dialog box that appears.

Each related information component has an information icon (ⓘ) that, when selected, displays its related table.

7. Provide fulfillers with visibility into cross-business workflows and the actionable tasks used to complete these workflows by specifying the playbook.
For more information on playbooks, see About Playbook Experience.

> **Note:**
> You must have the Playbook Experience plugin installed. If you used a template to create the app, you can't add a playbook to the record page. For details on how to add a playbook for workspaces created from templates, see this knowledgebase article.

a. In the Playbook section of the configuration panel, select **Add a playbook**.

b. On the form, fill in the fields.

Playbook details

Field	Description
Tab name	Label for the record tab that contains the playbook.
Playbook experience	Existing playbook to add to the record. **Note:** You can choose only from the playbooks that are available for the table.

c. Select **Add**.

d. Update the playbook by selecting the settings icon (⚙), making the change, and then selecting **Update**.

> **Note:**
> If you want to make additional changes to the playbook, you must open and edit the playbook in Playbooks.

e. Delete a playbook from the workspace by selecting its delete icon (🗑) and selecting **Delete** on the confirmation dialog.

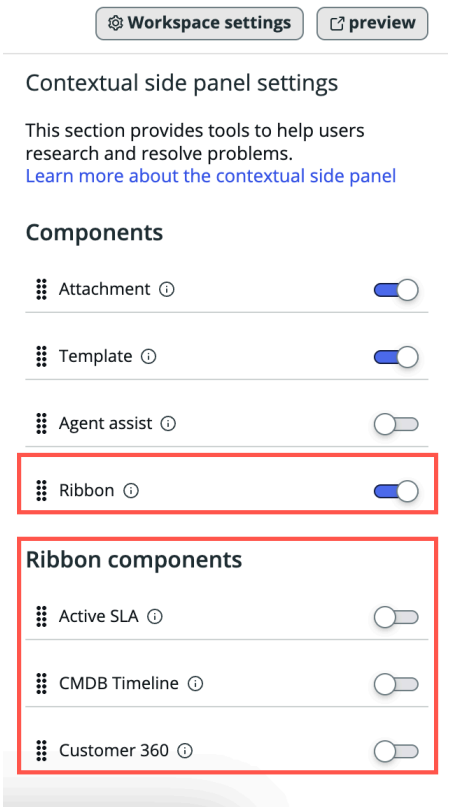
8. Configure the contextual side panel for the record page, which contains the icons for the tools that appear on the right side of the page.
   The contextual side panel contains icons that enable agents to research and resolve issues using various ServiceNow AI Platform tools. If your organization created any custom right tab components in UI Builder, you can add them as well. For more information, see Tabs sidebar.

   Note:
   If you used a template to create the app, you can't add a contextual side panel to the record page.

   a. In the navigation panel for the record page, select **Contextual side panel**.

   b. In the **Context side panel settings**, select the toggle switch for each component and ribbon component that you want to appear on the record page.
   For example, you can include Agent assist and attachments for the record. Attachments and templates are enabled by default, though you can disable them by deselecting their toggle options.

   To see the ribbon components, set the **Ribbon** component toggle to on.



To add pre-existing custom components, edit the workspace in UI Builder.

Contextual side panel components

Tool	Type	Description	More information
Active SLA	Ribbon component	Display active Service License Agreements (SLAs) for the case, including time remaining, the SLA state, and any breaches.	SLA ribbon
Agent assist	Component	Display automatic search results that show possible solutions for records that agents open.	Agent Assist
Attachment	Component	Add attachments to the record, such as images and PDFs.	Attachments
Configuration Management Database (CMDB) Timeline	Ribbon component	Display a chronological summary of case activities, including state changes and interactions between the agent and the	Timeline ribbon component

Tool	Type	Description	More information
		requester (usually the customer). The ribbon also displays how much time that the fulfiller and requester spent on the case.	
Customer 360	Ribbon component	Display customer information, such as the contact or consumer name, email address, and phone numbers.	Customer 360 ribbon component
Ribbon	Component	Display the contextual side panel ribbon, which contains tools to help agents resolve issues. Ribbon components can have additional components added to them.	Viewing ribbon information in the contextual side panel
Template	Component	Display templates that help reduce the time agents spend responding to requesters by automatically filling in record fields.	Form templates

The selected tools appear in the record page preview canvas.

c. In the configuration panel, drag the components to rearrange them.

d. Optional: Complete any additional configuration for components by selecting the settings icon (⚙).
For example, Customer 360 requires that you specify additional settings before the component works on the record page.

Workspace Builder automatically saves the changes to the contextual side panel.

9. Complete any additional changes and configurations.

Option	Description
Update the name of the record page	**Note:** You can't change the table that a record page is linked to after you create the page. To change the table for the record page, you should create a separate record page. **a.** From the Record pages menu, select the page that you want to edit. A preview of the record page appears. **b.** In the navigation panel, select **Settings**. **c.** In the Record page settings configuration panel that appears, enter the new page name. **d.** Select **Save**.
Preview the record page in a new browser tab	Select **Preview** in the Workspace Builder header. The record page appears in the workspace. If no data exists for the table, AES displays a page where you can add data to the table.
Delete a record page	**a.** From the Record pages list, select the page. **b.** In the navigation panel, select **Settings**. **c.** At the bottom of the configuration panel, se lect **Delete record page**. **d.** On the confirmation dialog, select **Delete**.

Configure lists for a workspace in Workspace Builder

Create list categories in App Engine Studio (AES) to add pages that list table records. You can add filter conditions and change columns to create variations on the list.

Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

About this task

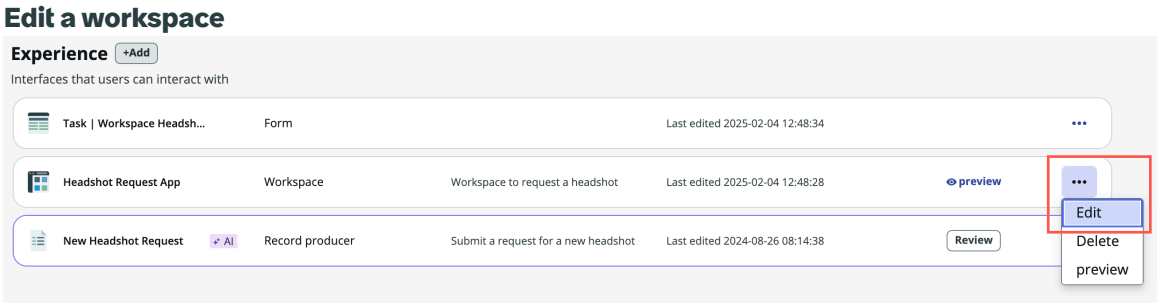
Note:

- You can launch and view workspaces in the Workspace Builder. However, you can only edit workspaces created through ServiceNow Studio and App Engine Studio within those specific tools.
- If you remove the list page/route, you must use UI Builder to edit the workspace, not Workspace Builder.

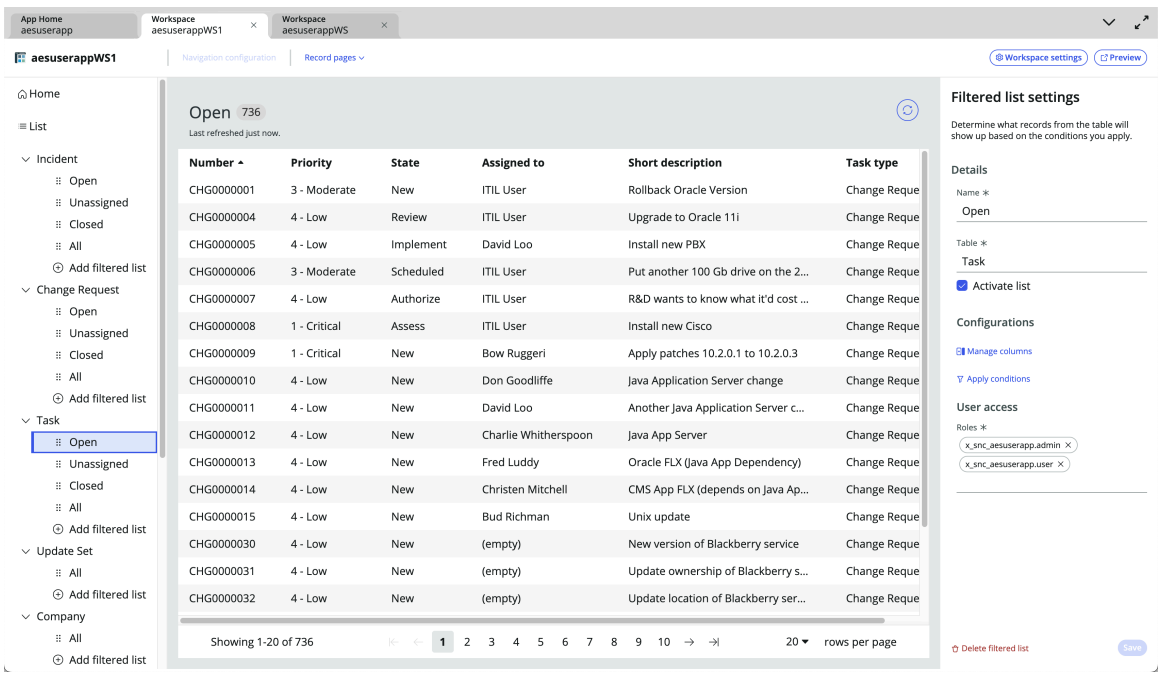
Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to the workspace you created, select the additional actions icon (•••) and then select **Edit**.

   You can also select the bar that lists the workspace in the Experience section of your app.



4. If they aren't already activated, activate lists to enable them for the workspace.
   You must be in the **Navigation configuration** tab. If you're already in the **Navigation configuration** tab, you can't select it.
   a. In the navigation panel, select **List**.
   b. In the list, select **Task** > **Open**.
   c. In the configuration panel, select the **Activate list** option.



5. Add a list category.
   a. In the navigation panel, select **Add list category**.
      If the table associated with the workspace isn't a core table, you must add new list categories.
   b. On the form, fill in the fields.

List category settings

Field	Definition
Name	Name to identify the list category.
Description	Brief description of the contents of the list category to help developers understand the purpose. **Note:** Workspace users don't see the description.

c. Select **Add**.

6. **Optional:** To rearrange the order in which list categories appear, drag them to a new position.
7. Add a filtered list to a list category.
   For example, in the list category for the Task table, you could create separate filtered lists for Opened, Unassigned, and Closed tasks.

   a. In the navigation panel, expand the list category you want to create a filtered list for.

   b. Select **Add filtered list**.

   c. On the form, fill in the fields.

   Filtered list settings

Field	Definition
Name	Name to identify the filtered list.
Table	Table that contains the subset of records that appear in the filtered list.You can select from two sections: Tables that are already available in your app, and all tables outside the app scope.

   d. Select **Add**.

   The preview canvas displays the contents of the filtered list.
8. Refine how the filtered list displays its content by adding filter conditions to narrow what it displays.
   You can make additional configurations to the filtered list.

   a. In the navigation panel, select the filtered list to edit.

   b. In the configuration panel, specify the additional settings.

More filtered list settings

Field	Definition
Activate list	Option to enable users to work with the filtered list.
Manage columns	Option to select and arrange the columns that appear. In the Manage columns dialog box, move columns from **Available columns** to **Selected columns**, drag to rearrange the columns, and select **Apply**. You can select a field on a related table by dot-walking to it. For more information, see Dot-walking to data in related tables.
Apply conditions	Option to add a filter condition to the list. In the dialog box that appears, you can do the following: ▪ To apply a predefined filter, select **Use existing filter** and search for the filter. ▪ To view existing conditions, expand the **Filter overview** section. ▪ To create a filter condition, use the condition builder. For more information on building conditions, see Condition builder. ▪ To change the sort order of the filtered results, expand the **Sort by** section and make changes. ▪ To save the filter condition that you created for reuse, select **Save filter**. When you're done creating the filter condition, select **Apply filter**. For more information on working with filters for lists, see Filters.

c. Select **Apply filter**.

d. In the configuration panel, select **Save**.

9. Complete any additional actions on the list.

Option	Description
Edit a list category	**a.** In the navigation panel, select the list category. **b.** In the configuration panel, specify its **List category settings**. **c.** Select **Save**.
Change how the filtered list appears by selecting the list in the navigation panel	**a.** In the configuration panel, select **Manage columns**. **b.** In the form that appears, move columns from **Available columns** to **Selected columns**, drag to rearrange the columns, and select **OK**. **c.** Refresh the canvas preview by selecting the refresh icon ( ) in the canvas header.
Delete a list category	**a.** In the navigation panel, select the list category. **b.** In the configuration panel, select **Delete list category**. **c.** In the confirmation dialog, select **Delete**.
Delete a filtered list	**a.** In the navigation panel, select the filtered list. **b.** In the configuration panel, select **Delete filtered list**. **c.** In the confirmation dialog, select **Delete**.

Configure analytics for a workspace in Workspace Builder

Enable the Analytics Center for a workspace in App Engine Studio (AES). The Analytics Center enables users to track and analyze records and usage with dashboards, data visualizations, and insights on the instance.

Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

About this task

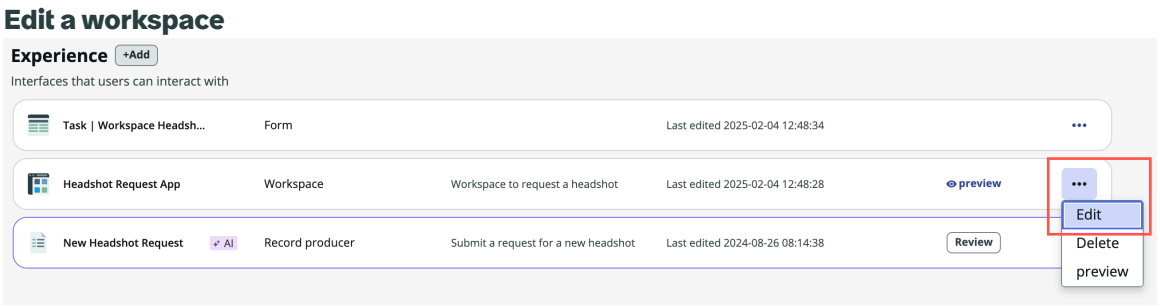
If Analytics Center page/route doesn't exist for a workspace, Workspace Builder is still available, but the Analytics Center tab doesn't appear in the workspace.

The Analytics Center always displays current, refreshed content.

Procedure

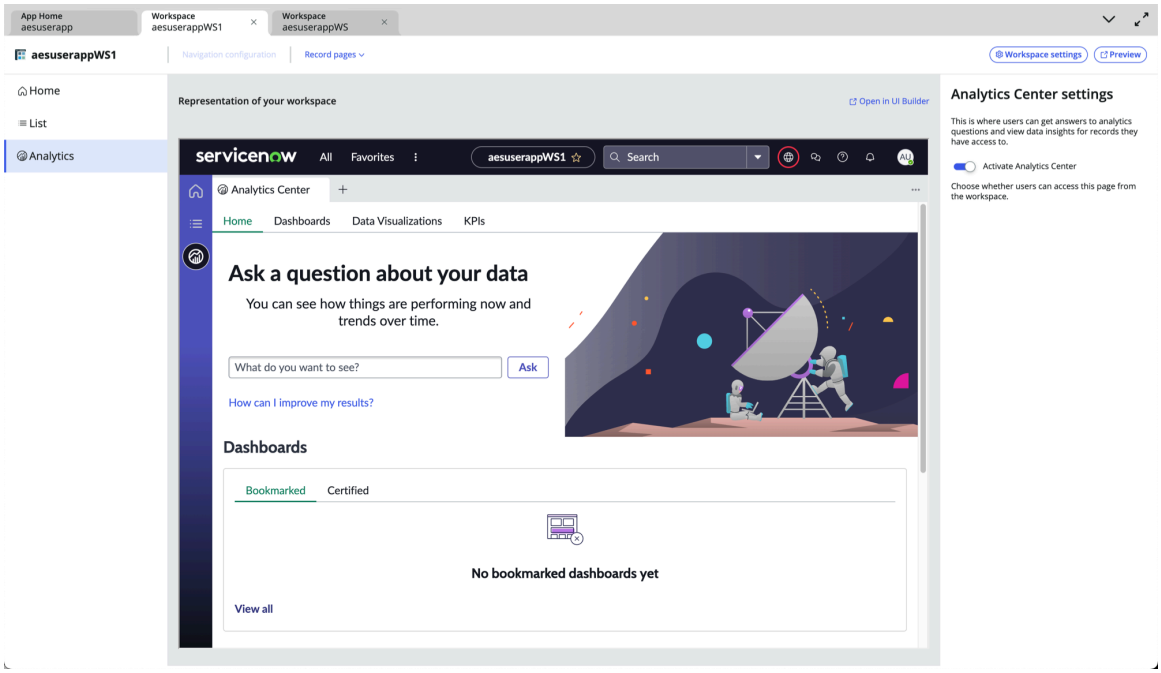
1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to the workspace you created, select the additional actions icon (•••) and then select **Edit**.

You can also select the bar that lists the workspace in the Experience section of your app.



The workspace appears in Workspace Builder.

4. In the navigation panel, select **Analytics**.
   You must be in the **Navigation configuration** tab. If you're already in the **Navigation configuration** tab, you can't select it.
   A mock-up of the Analytics Center appears in the preview panel.



5. In the configuration panel, select the **Activate Analytics Center** toggle option.
6. Make additional configuration updates to the Analytics Center by selecting the **Open in UI Builder** link in the canvas header.

Result

For more information on working with the Analytics Center, see Dashboards in Platform Analytics.

Add a portal

Create a portal in App Engine Studio (AES) to give your users a site where they can find information, create requests, and complete business tasks.

Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

About this task

When you add a portal you're creating a basic version of it, which you must then continue editing in UI Builder before it's ready to deploy.

Note:
If you created an application using a template, a portal may already be added to your application.

Most companies implement a maximum of three portals, which they then populate with catalogs.

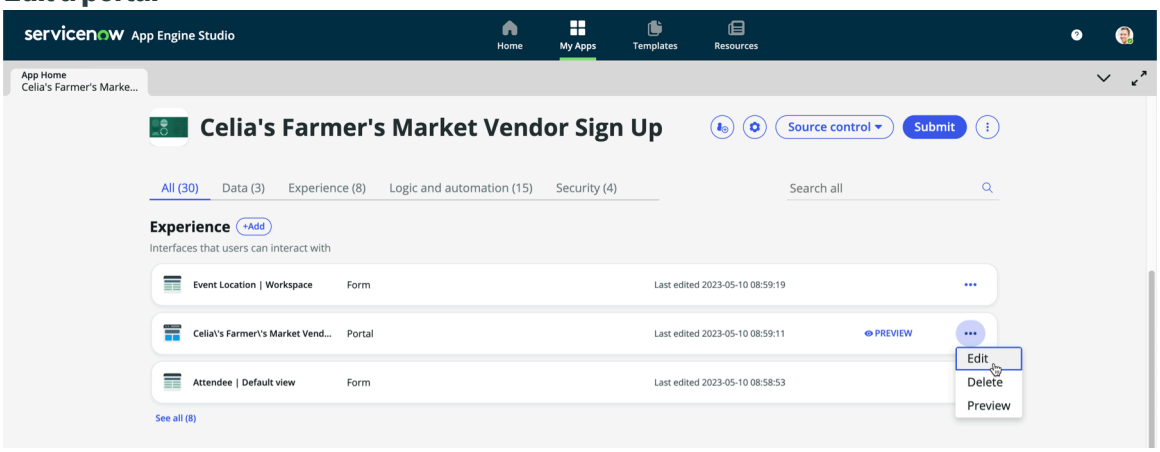
Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, next to Experience, select **Add**.
4. Select **Portal**, and then select **Begin**.
5. On the form, fill in the fields.

Field	Description
Name	Name of the portal. By default, the portal shares the same name as your application. **Tip:** Use a name that uniquely identifies the portal from other experiences. For example, `Office art portal`.
Description	Description of the portal.
URL	Web address of the portal. By default, the URL is based on the application name.
Roles	User roles to limit who can access the portal. To use a custom role for your portal, you must create one in **Security** first. For more information, see Add application security.

6. Select **Continue**, and then select **Done**.
   After you create the portal in AES, you must edit it in UI Builder by adding or configuring components on each page.
7. Next to the portal you created, select the menu icon (•••) and then select **Edit**.

Edit a portal



8. In UI Builder, edit the portal by adding or configuring components on each page. You can also add more pages to the portal, if needed.

> **Note:**
> The default portal pages are read-only and can't be edited. To change the content of each page, create a page variant and edit the variant.

What to do next

For more information on using UI Builder to edit portals, see UI Builder.

Sample portals you can build

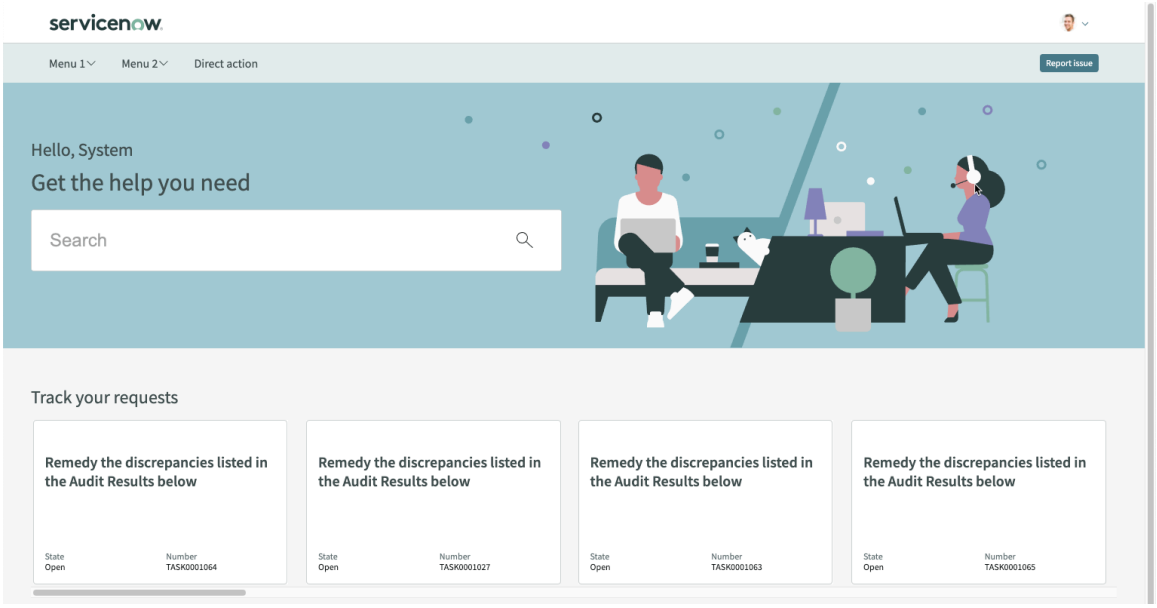
A portal is a site where users inside of your organization can find information, submit requests, and complete business tasks.

The portal that you create in App Engine Studio includes several default pages. You can use these pages as-is or edit them to suit your business needs.

- Article page
- Catalog item page
- Landing page
- Login
- Order success
- Record page(request)
- Record page(task)
- Search page
- Settings page
- Task approved
- Task rejected

> **Note:**
> Unlike Service Portal, the portal that you can create in App Engine Studio is built on the Next Experience UI Framework. You edit the portal by configuring pages and components in UI Builder.

Home page



Add a mobile experience

Add a mobile experience, or interface, to enable users to access your application from a ServiceNow native mobile app.

Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

About this task

When you add a mobile experience, you're creating a basic version of the mobile app, which you must then continue editing in Mobile App Builder before it's ready to deploy.

Use Mobile App Builder to build and manage screens and records that make up workflows within the mobile apps that you build with AES. For example, you can add a webpage or a list that appears as a tab on a phone app.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, next to Experience, select **Add**.
4. Select **Mobile experience**, and then select **Get started**.
5. Select the kind of mobile experience that you want to add and select **Continue.**
   - Mobile Agent
   - Now Mobile

   For more information about the mobile experience options and important considerations when choosing a mobile experience, see Design considerations for mobile apps.
6. On the form, fill in the fields.

Add experience form

Field	Description
Add an icon	Icon that best reflects the content of the screen.
Label for experience	Description for the screen.
Roles	Roles that have access to the screen. You can specify multiple roles, but you must select them one at a time from the list that appears when you start typing in the **Roles** field. **Note:** If you do not specify a role, all users will have access to the mobile experience.
Available offline	Option to make the experience available offline. **Note:** Offline experiences are available only in Mobile Agent apps.

7. Select **Continue**.
8. Select the type of screen to add and select **Continue**.

Type of screen options

Option	Description
List	Screen that lists information retrieved from an existing data table, which you choose in the next step. **Note:** Creating a List screen adds all of the data table's values to the mobile experience.
Webpage	Screen that displays an existing webpage, which you specify the URL for in the next step.

9. To add a list page to the mobile experience, do the following:

   a. Select the table that will appear as a list on the screen.
   After you select a data table, some of its contents appear on the page.

   b. To make the table conditional, select **Set conditions for this table** and define the conditions that must be met for the data to appear using the condition builder.

   For more information, see Condition builder.

c. Select **Continue**.

d. Specify attributes for the data extracted from the table and select **Continue**.

Identifiers for table data

Field	Description
Add an icon	Icon that reflects the data in the table.
Screen label	Brief label to describe the list screen.

10. To add a webpage to the mobile experience, do the following:

a. Specify the attributes for the table data and select **Continue**.

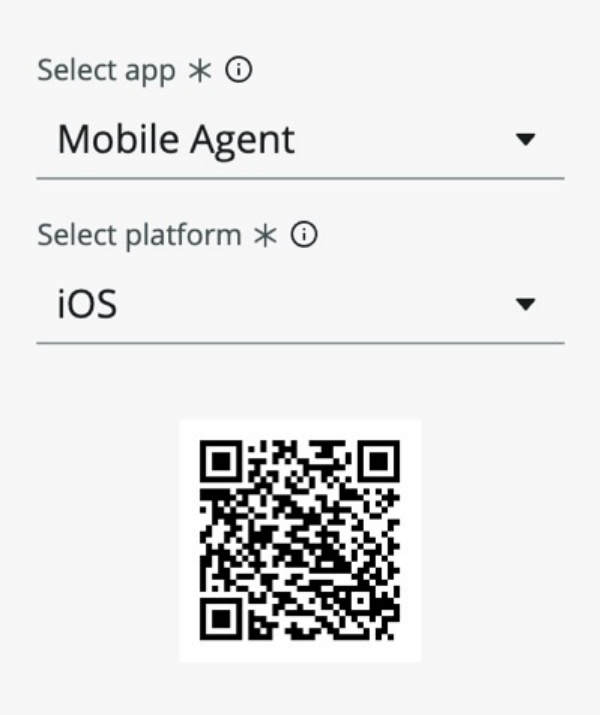
Identifiers for table data

Field	Description
Add an icon	Icon that reflects webpage.
Screen label	Brief label to describe the webpage.
URL	Absolute or relative URL for the webpage.

11. Depending on if you are done or not, do one of the following:
    - If you are done adding screens to the mobile experience, select **Done adding screens**.
    - To add more screens to the mobile experience, select **Add more screens**.
12. To finish creating the mobile experience, select **Done**.
    After you create the mobile experience in AES, you must edit it in Mobile App Builder.
13. Next to the mobile experience you created, select the menu icon (•••) and then select **Edit**.
14. Edit the mobile experience in Mobile App Builder.
    For more information, see Mobile App Builder.

What to do next

Scan or copy the QR code for your mobile experience using the **Select app** and **Select platform** fields.



For more information on modifying mobile experiences, see Mobile App Builder.

Sample mobile experience

A mobile experience enables users to access your application from a ServiceNow native mobile app.

Example mobile experience

The following example illustrates a sample mobile experience that you can build using the Mobile App Builder integration in App Engine Studio.

For more examples of mobile experiences that you can build, see Native Mobile Examples.

Editing an experience in App Engine Studio

Tailor your app's experience to suit your business needs by building interfaces in App Engine Studio (AES), such as for mobile apps or catalog items.

Editing workspaces in Workspace Builder

Workspace Builder is a streamlined no-code tool that enables you to configure custom workspaces built in AES quickly and easily. For more information on using Workspace Builder, see Building workspaces in AES. For more complex customizations, edit the workspace in UI Builder.

Editing forms created in Table Builder

When you add data to your app, any associated form views display in the **Experience** section of your app. To edit the form, select it in the **Experience** section. Form views can be edited in the **Forms** tab of Table Builder. For more information, see Forms in Table Builder.

Preview an experience

See what an application experience built in App Engine Studio (AES) looks like to your users by previewing it in a browser.

Before you begin

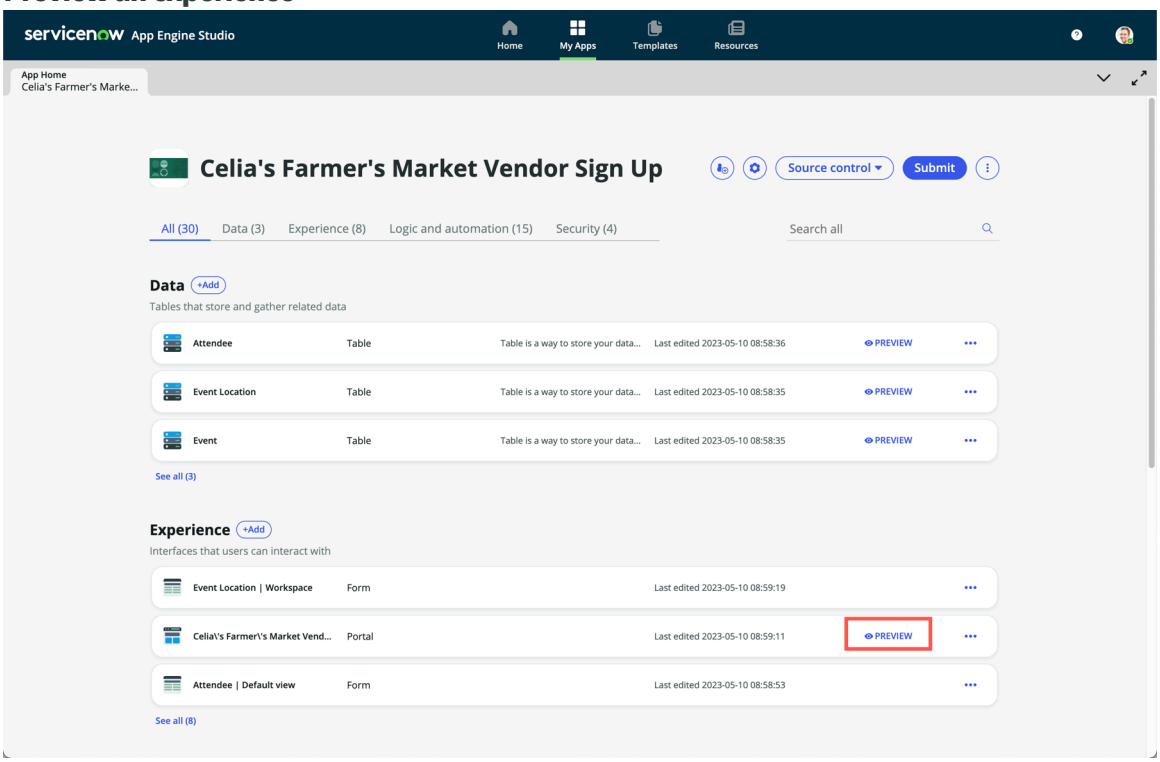
Add an experience to your application. For more information, see Add an application experience.

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to an experience, select **Preview**.

Preview an experience



4. On the browser tab that opens, review the experience.

What to do next

If the experience looks or behaves differently than expected, edit the experience.

Delete an experience

Delete an experience, such as a portal or record producer form, that you no longer need within App Engine Studio (AES).

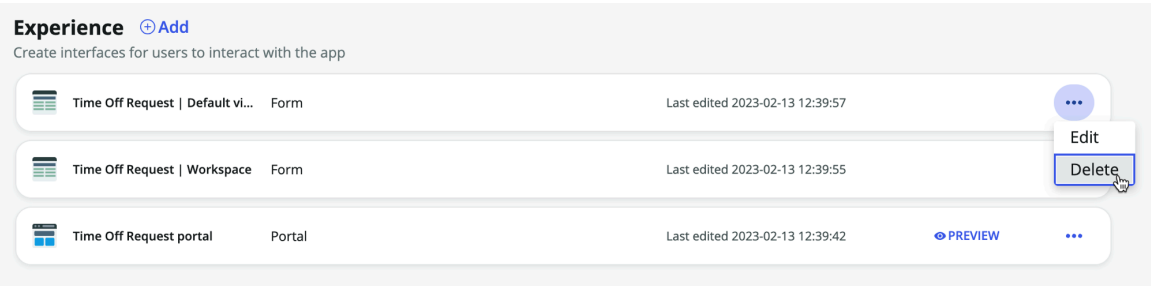
Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to an experience, select the menu icon (•••) and then select **Delete**.

Delete an experience



4. On the dialog box that appears, enter `delete` and then select **Delete**.

Add logic and automation

Replace manual work by adding logic and automation to your app in App Engine Studio (AES).

Application templates automatically add logic and automation to your application.

Types of automation

Automation	Definition	Example	Reference
Decision	Decisions decouple logic from code by creating decision rules, such as inputs that evaluate data from existing records, external data sources, or data provided at runtime.	Automatically apply cascading discounts to different products based on the increasing number of units ordered.	• Add a decision • Modify decision table structure in Workflow Studio
Email notification	Notifications are emails that are automatically sent when the specified conditions are met.	Automatically send an email when a new support record is created.	• Add an email notification • Modify an email notification
Flow	A flow is a sequence of reusable actions, initiated by a trigger event, and passing variables between actions.	Automatically generate a Twitter post when an incident is closed or send an email when a record in a specific table is	• Add a flow from scratch • Modify a flow

Types of automation (continued)

Automation	Definition	Example	Reference
		updated or created (record-based flow).	• Work with record-based flows in Table Builder **Note:** This feature is only available if your licensing entitles you to "exclusive low code capability" and you have Table Builder for App Engine installed. Contact your Solutions consultant for more information.
Process	Processes are cross-enterprise workflows that enable you to create a single, unified process. Processes can include multiple flows.	Standardize and automate how agents handle chat interactions with VIP users.	• Create a playbook • Edit a process

Note:
If you're using source control to collaborate with other developers, only changes that have been checked in are available to other developers. For example, if an admin creates a new flow for an app that's linked to Git, the new flow won't be available in the app for other AES users until the admin checks the flow into Git.

Add a pre-built flow using a template

Use a pre-built flow to quickly automate manual work in the app you're building in App Engine Studio (AES).

Before you begin

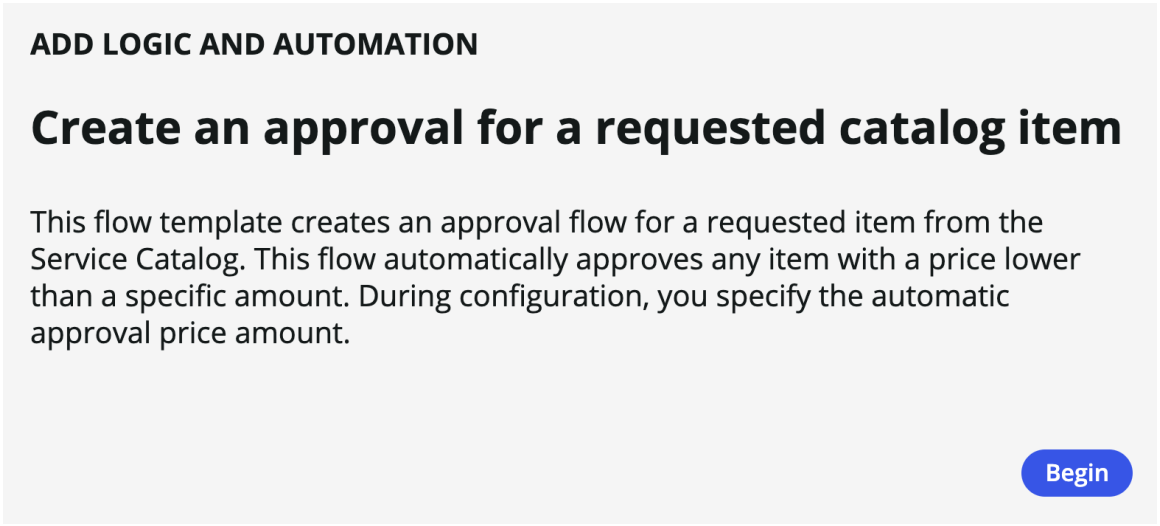
Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, in the Logic and Automation section, select **Add**.

4. Select the card for **Flow**.
5. From the gallery of automation templates, select a template and then select **Begin**.

Template automation



6. Complete the wizard for the template that you selected.
7. On the summary screen, select **Done**.

What to do next
You can edit the flow to tailor it to your business needs. For more information on working with automation, see Modify a flow.

Add a flow from scratch

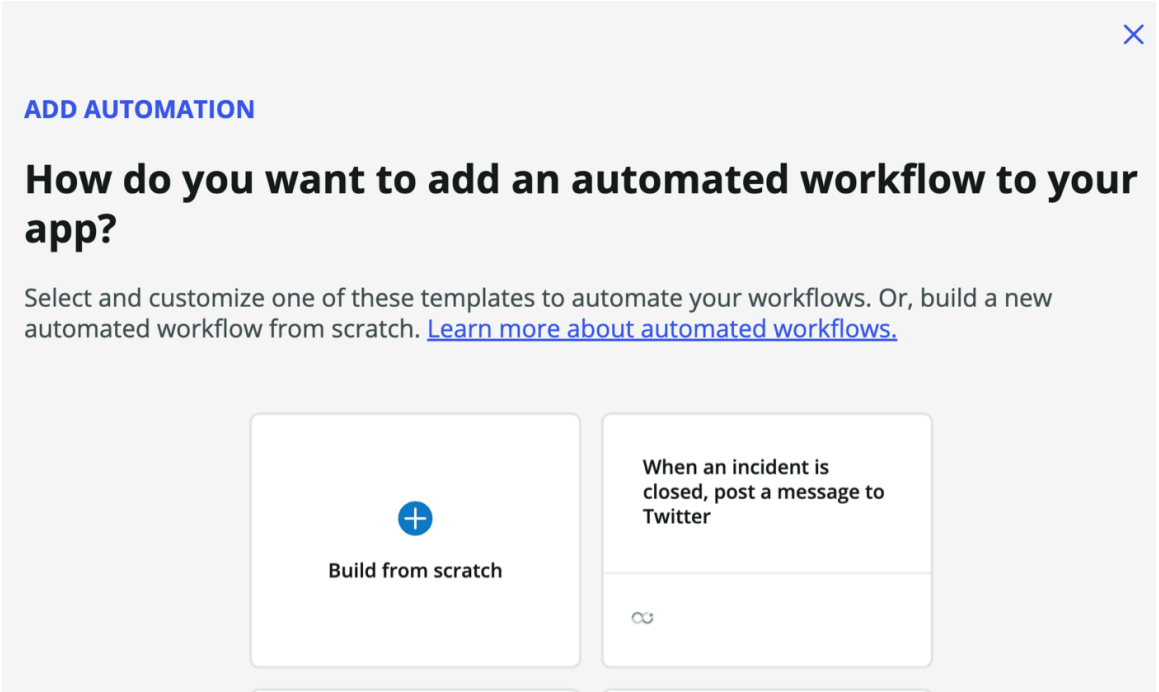
If an existing automation template doesn't fit your application goal, define custom automation in App Engine Studio (AES) by building a new flow.

Before you begin
Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

About this task
If a pre-built flow already exists, you can easily add its template to your app and then customize it. For more information, see Add a pre-built flow using a template.

Procedure
1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, in the Logic and Automation section, select **Add**.
4. Select the card for **Flow**.
5. Select **Build from scratch**.

Build from scratch

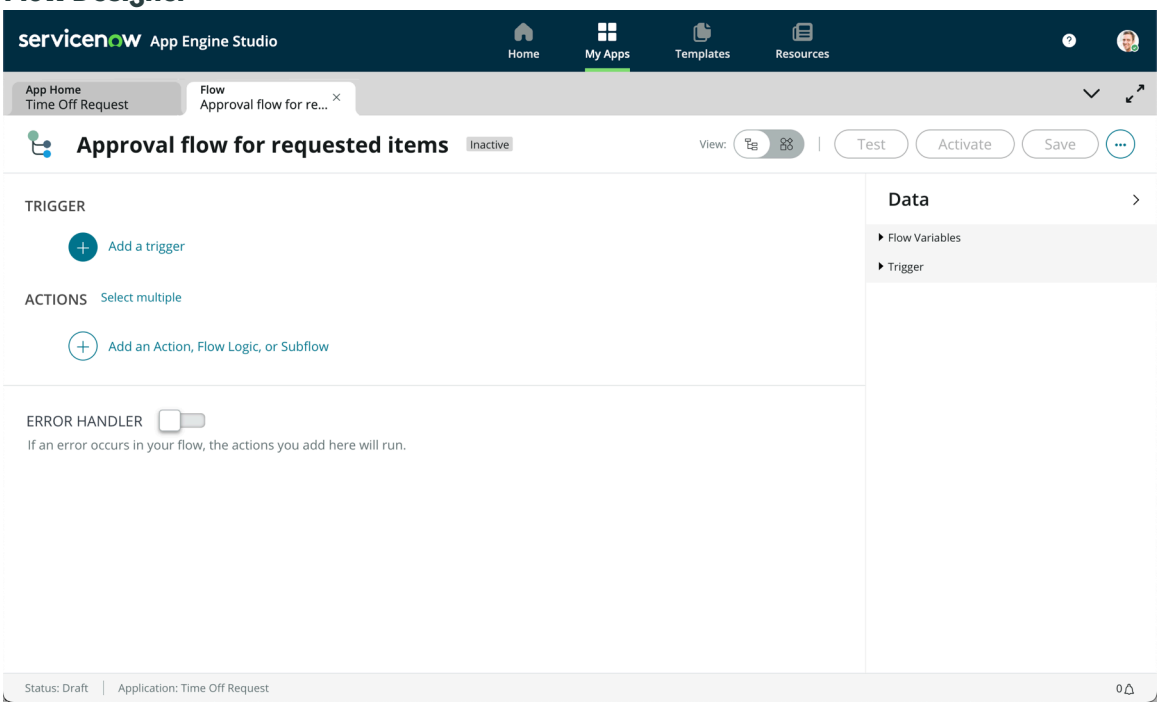


6. On the form, fill in the fields and then select **Continue**.

Field	Description
Name	Name to identify your flow.
Description	Description of your flow.
Protection	Access settings for the flow. You can select one of the following options: **-- None --** Option to enable other users to edit the flow. **Read-only** Option to enable other users to view the flow but not edit it.
Run as	Selection to specify if the flow runs as a system user or the user who initiates the session. If updates should come from the user who triggered the flow, select **User who initiates session**. For example, when you want incident record comments to come from the current user, or approval emails to originate from the approver.
Run with roles	Roles that the flow runs with. This option is available only when **Run as** is set to **User who initiates session**. To use a custom role for your flow, you must create one in **Security** first. For more information, see Add application security.

7. On the summary screen, select **Edit this flow** to open your flow.

Flow Designer



For an example of how to build a flow, see Build your first flow in Flow Designer.

8. Add a trigger to your flow.

   a. Under the TRIGGER section, select **Add a trigger**.

   b. From the Trigger list, select a trigger that will start running your flow.
   For more information on trigger types, see Workflow Studio flow trigger types.
   The system displays a set of fields depending on the type of trigger that you've selected.

   c. Set up your trigger by filling in the fields.
   For a record-based trigger, for example, select a table and set field conditions that, when met, will start running your flow.

   d. Click **Done**.

9. To add actions, flows, subflows, or flow logic, select **Add an Action, Flow Logic, or Subflow**.

   a. Select an option.

Option	Description
Action	Select the desired action. Workflow Studio includes Workflow Studio actions that are available to flows and subflows. Alternatively, a user with the action_designer role can create additional actions to add to flows. The Integration Hub and Spokes plugins install additional actions. To add draft actions from the More Actions menu, set **Show draft actions** to **true**.

Option	Description
	To view spokes that are available in the ServiceNow Store, set **Show store spokes** to **true** from the More Actions menu. **Note:** Under **Not Installed Spokes**, the system displays spokes that are available in the ServiceNow Store based on compatibility with the ServiceNow version and application dependency on Workflow Studio.
Flow Logic	Select an option to specify conditional or repeated operations.
Subflow	Select a published subflow and define the input values. In addition to adding a subflow as a flow action, you can enable the **Show triggered flows** option from the More Actions menu to select an activated flow and define the required inputs. Running a triggered flow ignores its trigger conditions and runs all actions.

To change the order of an action in a flow, drag the handle on the left side of the action to the desired location.

The system displays a set of fields depending on the option that you selected.

b. To configure the action, flow logic, or subflow, fill in the fields.

c. Select **Done**.

d. Repeat adding actions until complete.

10. To specify how the app will handle errors, enable the **ERROR HANDLER** switch and fill in the fields.
    For more information on configuring how errors are handled in flows, see Flow error handler.
11. Select **Save**.
    The ServiceNow AI Platform saves a draft of the flow, trigger, and actions.

What to do next

Test your flow until you're ready to activate it. For more information on testing and editing flows, see Activate a flow.

Note:
Your application can trigger only activated flows.

Modify a flow

To update or change an existing flow for an app you built in App Engine Studio (AES), edit it.

Before you begin

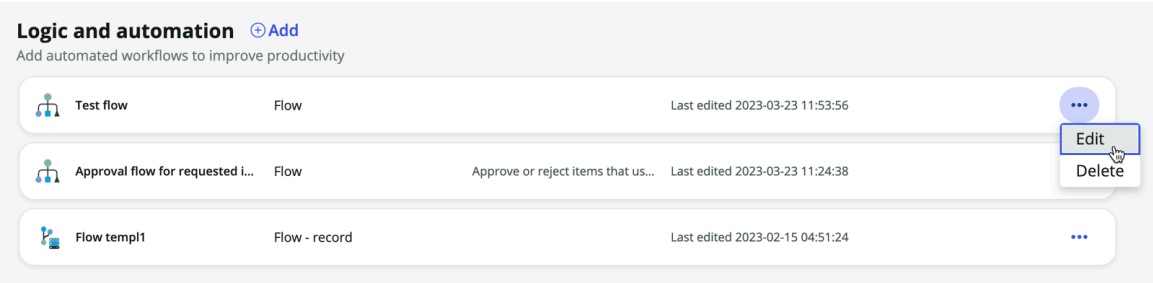
Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

Add logic and automation to your application. If you created an application using a template, logic and automation may already be added to your application. For more information on adding custom logic and automation, see Add logic and automation.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to a flow, select the menu icon (•••) and then select **Edit**.

Edit a flow



Note:
When a flow is triggered by a record being created or updated in a data table, it's referred to as a record-based flow. Record-based flows display in the list of logic and automation with a distinct icon ( ). These flows open up within the **Flows** tab in Table Builder if you are licensed for Table Builder for App Engine and have it installed. Contact your account team for details. For more information on flows functionality in Table Builder, see Flows in Table Builder.

4. Take the appropriate actions to edit the flow.

Option	Description
Change the flow name, description, or roles	In the main header, select **Properties**, enter the values you want into the appropriate fields, and then select **Update**.
To edit the trigger	In your flow, select the trigger description, fill in the fields as desired, and then select **Done**. **Note:** Modifying triggers can result in the deletion of referenced action configurations.
To edit an existing action	In your flow, select the action description, fill in the fields as desired, and then select **Done**.
To add a new action	In your flow, select the plus icon in the ACTION section, then proceed as you would for adding an action to a new flow.

For more information on editing flows, see Edit a flow.

5. To save your changes, select **Save**.

What to do next

Test a flow to make certain it works the way you expect. For more information on testing flows, see Test a flow.

Add a decision

Create automation for decisions in App Engine Studio (AES). The automation decouples decision logic from code by enabling you to create and manage decision rules.

Before you begin

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, in the Logic and Automation section, select **Add**.
4. On the Add logic and automation screen, select **Decision** and then **Get started**.
5. Specify the name and scope of the decision table.

Decision Table form

Field	Description
Name	Name for the decision table.
Accessible From	Scopes that can use the decision table. Available values are as follows: ○ **All application scopes** ○ **This application scope only**

6. Select **Done**.

What to do next

After you create the decision table, you must edit it to specify inputs and triggers. For more information on editing decision tables, see Modify decision table structure in Workflow Studio.

Learn more about decisions in AES	Additional ServiceNow resources
ServiceNow provides several additional resources on adding decisions in App Engine Studio.	 Getting started with Decision Builder YouTube video
	 Build my first App Engine Studio application

Learn more about decisions in AES	Additional ServiceNow resources
	ServiceNow University Introduction to App Engine Studio on-demand course

Edit a decision

To update or change an existing decision for an app built in App Engine Studio (AES), edit it in Workflow Studio.

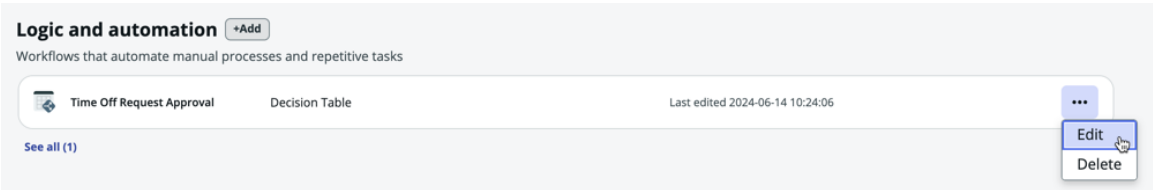
Before you begin

Add logic and automation to your application. If you created an application using a template, logic and automation may already be added to your application. For more information on adding custom logic and automation, see Add logic and automation.

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to a decision, select the menu icon (•••) and then select **Edit**.



4. Take the appropriate actions to edit the decision.
   For more information on editing decision tables, see Modify decision table structure in Workflow Studio.
5. To save your changes, select **Save**.

Add an email notification

Build notifications in App Engine Studio (AES) to create automated emails for events using templates or custom messages.

Before you begin

You can perform this task if you're either an administrator or a developer for the application. The required developer permission is **All File Types**. For more information on being a developer for an application, see Delegated development in App Engine Studio.

Role required: admin or delegated_developer

About this task

Email notifications enable you to send emails to the selected users about activities in the system, such as updates to incidents or change requests.

Note:
You can't currently create any other types of automatic notifications, such as SMS messages.

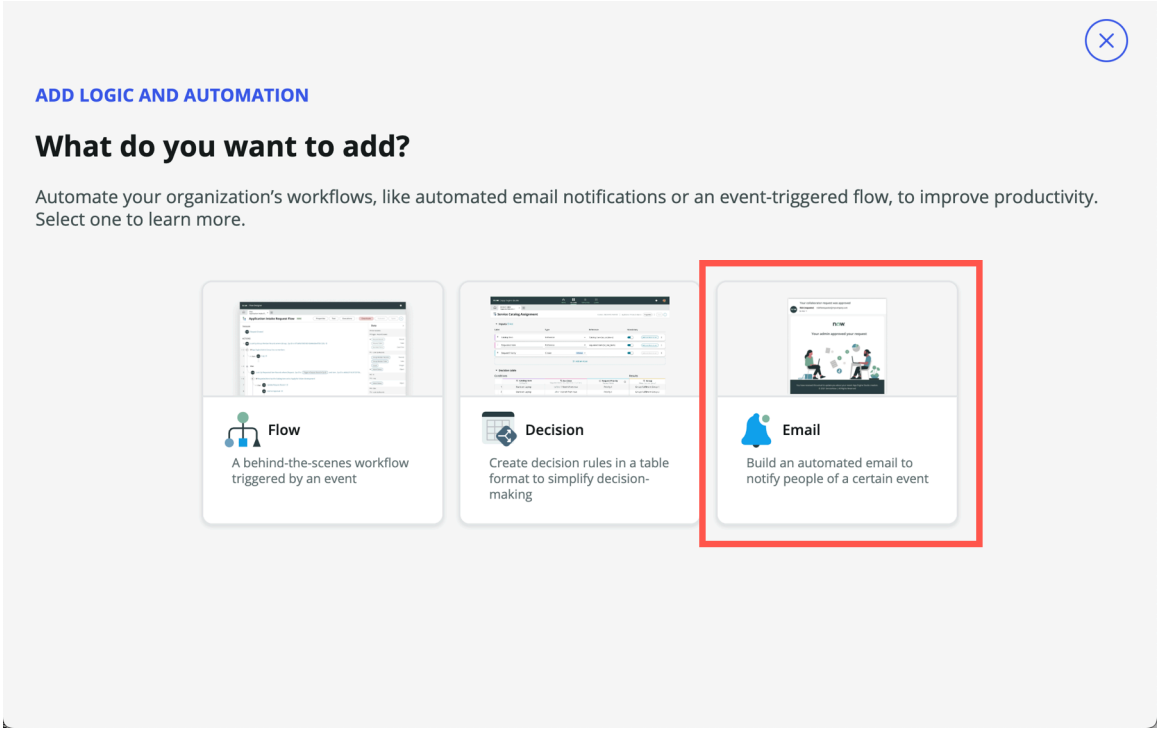
Creating an email notification involves specifying when to send it, who receives it, and what it contains.

If your administrator has created an email template in the ServiceNow AI Platform, you can use it as is or override its content. For more information on email templates, see Email Templates. Also check with your administrator to see if they are using email layouts to control the header, body, and footer. For more information on email layouts, see Email layouts.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, in the Logic and Automation section, select **Add**.
4. Select the card for **Email**.

Add email notification



5. On the form, fill in the fields for the basic settings.

Add notification form basic settings

Field	Description
Name	Name of the email notification. Descriptive names help identify the purpose of the email notification. For example, `Incident Opened & Unassigned`.
Short description	A brief explanation of the purpose of the notification.

6. On the Notification trigger settings section of the form, fill in the fields.

Add notification form Notification trigger settings

Field	Description
Send email notification	Situation where a notification is sent, such as after something happens or when a table is modified. Choices are as follows: ○ **When a record is created or updated** ○ **Only when a record is created** ○ **Only when a record is updated** ○ **When triggered via Flow Action** ○ **When event is fired** This field is automatically set to **When a record is created or updated**. After you create an email notification with a Flow Action as the trigger, you specify the notification when creating a flow in Workflow Studio. For more information, see Notification step.
Table	The database table that hosts the records to link the notification trigger to. For example, the Incident [incident] table. If you set the **Send email notification** field to one of the following values, the table is required: ○ **When a record is created or updated** ○ **Only when a record is created** ○ **Only when a record is updated** You can select from two sections: Tables that are already available in your app, and all tables outside the app scope.
Event name	Event that triggers the notification. This field appears only when **When event is fired** is selected from the **Send email notification** field.

If the same trigger generates multiple notifications, the system only sends one notification. The system considers all other notifications, even if they have a different subject and body, as duplicates. The Ignore Duplicates business rule controls this functionality.

7. Make the trigger conditional by using the condition builder.

Define the condition sets and values that must be met for the notification trigger. For more information, see Condition builder.

Note:
If you specify that the notification trigger is a Flow Action, the condition builder isn't available.

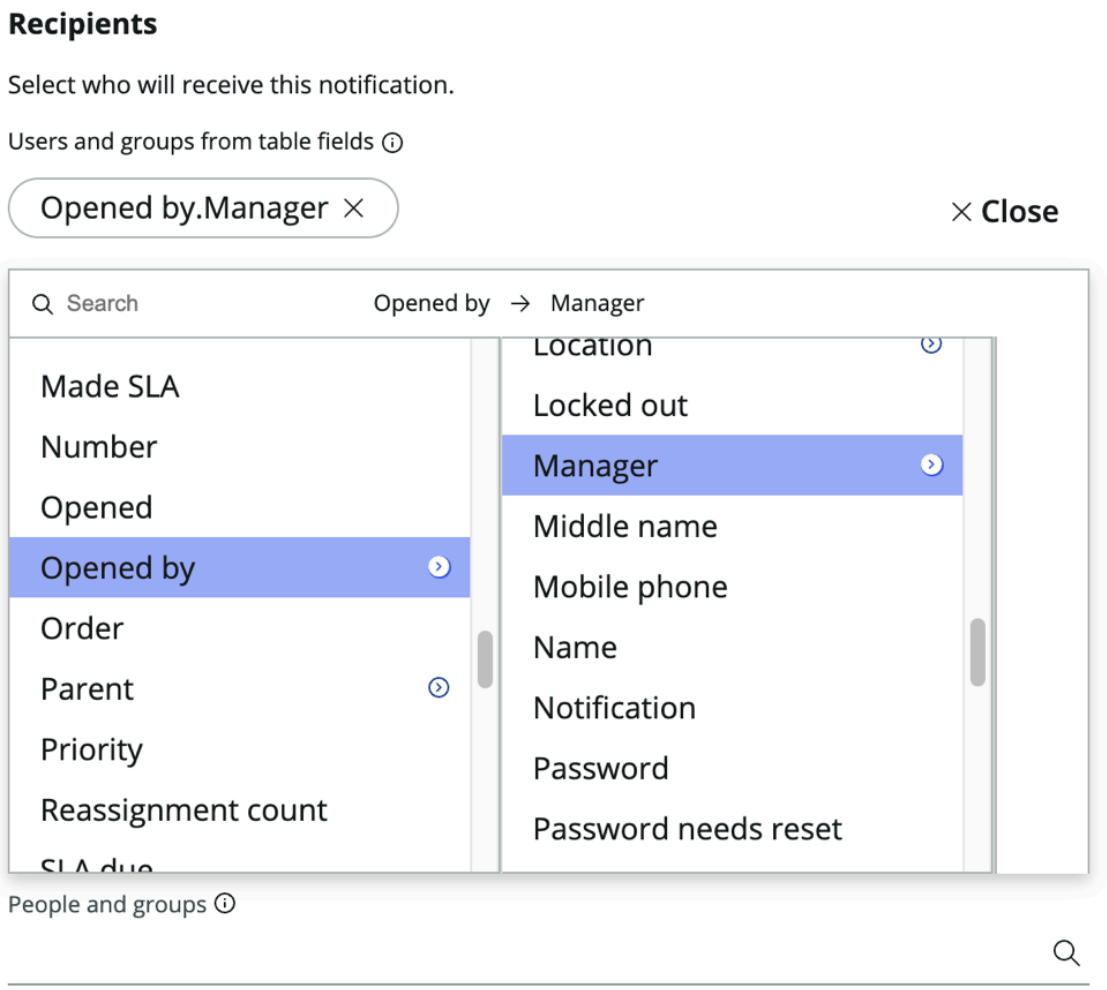
8. In the Recipients section of the form, specify who receives the notification.

   You can:

   - Search for users or groups.
   - Define dynamic recipients by selecting **Add**, which requires you to specify a table in the notification trigger details.

Add notification form Recipients settings

Field	Description
Users and groups from table fields	Dynamic users and groups who receive the email based on the table. For example, if a notification uses the Incident [incident] table, you can select the **Opened by** field to send the notification to users or groups who opened the incident. For some fields, you can also select values contained by a reference field, such as **Opened by** > **Manager**. Select the **Add** button to search for dynamic users and groups based on fields from the specified table. **Note:** If you don't specify a table, the **Add** button isn't available.
People and groups	Static addresses for users and groups who receive the email notification. You can also search for users and groups.



9. In the Email content section of the form, select a template or write original content.

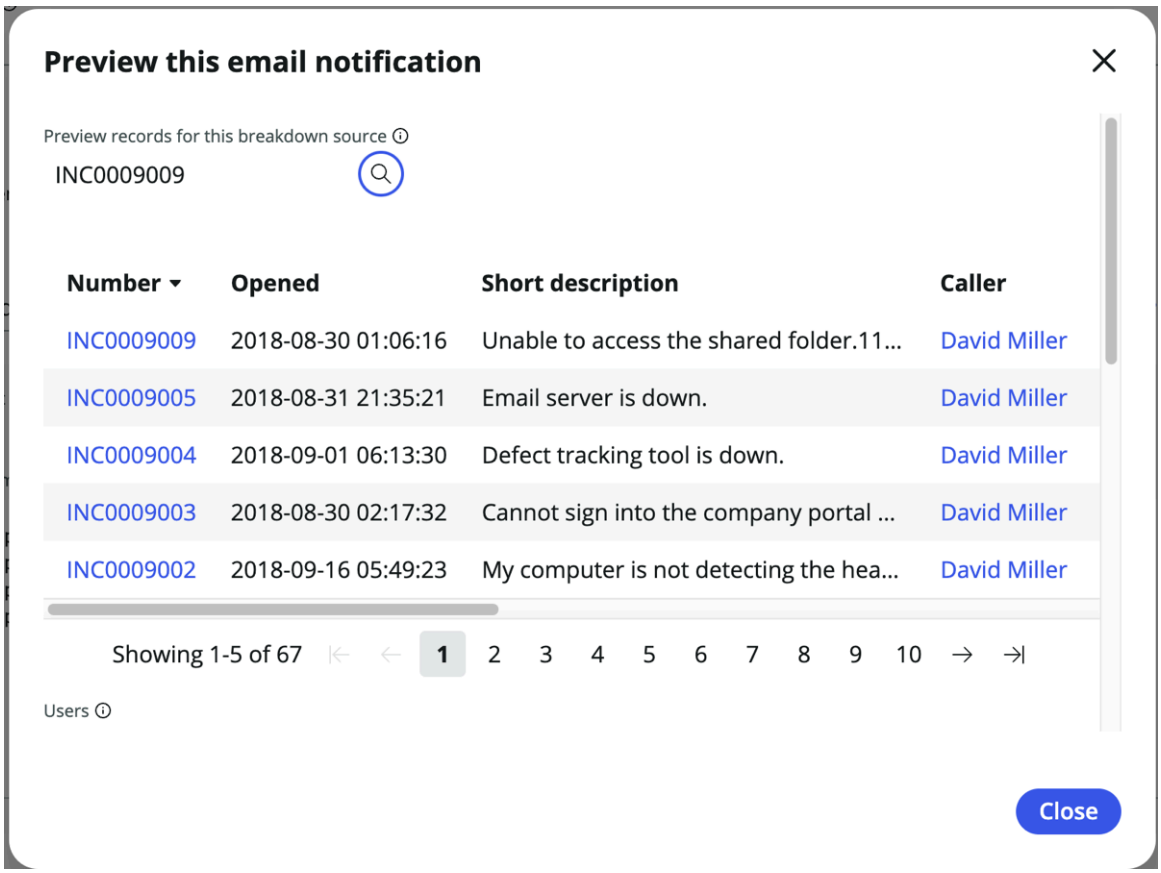
Add notification form Email content settings

Field	Description
Email template	Predefined email template that you can use to apply existing content, which you can override. You can select only templates that have the following: ○ The same table as the notification ○ No specified table If you use a template and don't override it, then when your administrator updates the template, the content of your email notification is also automatically updated.
Override template	Option to override the contents of the selected email template. If you use an email template, any images from the template still belong to the template regardless of whether you override it. Images

Field	Description
	in the notification are automatically updated when administrators update the template. If you override an email template and then change the selected template, the system removes the overrides and replaces them with content from the new template.
Subject	Subject line for the email. To make the subject dynamic, use the **Email variables** field next to the **Email message** to generate variable syntax in the message body. You cam then copy and paste the variable syntax in the subject line. If empty, the system uses the **Subject** value from the email template. If you enter a value in this field, it overrides the template.
Email message	Content of the email notification message, which can include variables. You can format the contents of the email message using the rich text editor icons. If empty, the system uses the **Message** value from the email template. If you enter a value in this field, it overrides the template value.
Add variables	Dynamic variables, or values, derived from fields in the specified table. **Note:** You must specify a table for the **Add variables** button to appear. Select variables in the **Email variables** field and use the arrow to move them into the **Email message**. Use variables to include values from a record in the table, such as an incident short description or comments and work notes. Variables are available fields from the specified table.

10. Select **Create**
    The notification is saved, and you can preview it.
11. View how the email notification appears by selecting **Preview**.

Check the preview that appears. To see how a notification renders, select the search icon in the preview and select the record you want to preview.



Result

When you create a notification in AES, the notification is saved only to the application that you're currently building.

Modify an email notification

Edit an email notification created for an app in App Engine Studio (AES) to change it. For example, modify when to send the email notification, who receives it, and what it contains.

Before you begin

You can perform this task if you're either an administrator or a developer for the application. The required developer permission is **All File Types**. For more information on being a developer for an application, see Delegated development in App Engine Studio.

Role required: admin or delegated_developer

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to a notification, select the menu icon (•••) and then select **Edit**.
4. Edit the notification by taking the appropriate actions.
   For more information on working with notification fields, see Add an email notification.
5. Change the template you're using.

a. Select a different template from the **Email template** field.

   If you override an email template and then change the selected template, the system removes the overrides and replaces them with content from the new template.

b. In the dialog box that appears, select **Change template** to confirm that you want to lose the changes you made by overriding the previous template.

6. To save your changes, select **Save**.

Edit a process

To update or change an existing process for an app built in App Engine Studio (AES), edit it in Playbooks.

Before you begin

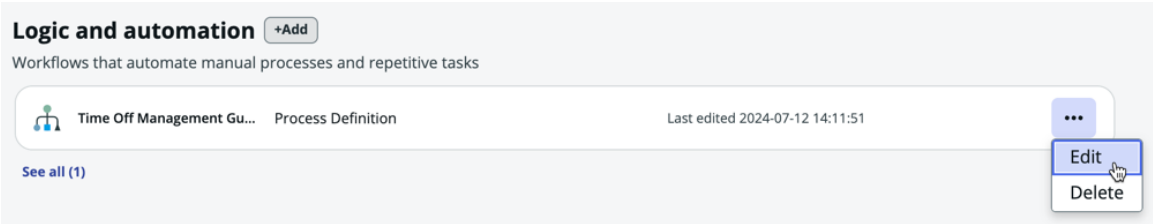
Before you edit a process, you must add a process in Playbooks. For more information, see Create a process definition.

You can edit processes in App Engine Studio, but you must activate Playbooks for App Engine Studio and enable the **Process Automation Designer for App Engine [com.glide.pad.license]** plugin to get started. For more information, see Activate playbooks.

Role required: sn_app_eng_studio.user or delegated_developer. For more information, see Delegate developers using AES.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to a process, select the menu icon (•••) and then select **Edit**.'



4. Take the appropriate actions to edit the process.
5. To save your changes, select **Save**.

What to do next

Test a process to make certain it works the way you expect. For more information on testing processes, see Test a process.

Add application security

Control who is permitted to use or edit your application by configuring roles in App Engine Studio (AES).

Adding security in App Engine Studio, UI Builder, and Catalog Builder

Working with roles

You add security to your application by defining roles. A role is used to limit and control access to your application. The access that you define for a role is granted to all users who are assigned to the role.

Note:
If you don't have permission to work with roles for an app, the **Add** button for the Security section appears, but you can't select it.

An administrator assigns a role to the appropriate user based on the kind of work that the role permits. For example, to enable a manager to read and approve employee requests, an administrator would assign a role that has access to read and update records from the relevant table. The role may also need access to the portal or workspace where the manager would see the request.

Application templates automatically add security to your application. If you use a template to create your application, you can edit the roles that were added or add different roles.

Learn more about AES roles and security	Additional ServiceNow resources
App Engine Studio includes default roles that you can use for your application. Alternatively, you can build custom roles for your application. After you submit your application, an administrator on-boards the requesting team by assigning the roles that you've defined.	What is Security? - ServiceNow Developers site Security and Roles - ServiceNow Developers site Elevating Privileges - ServiceNow Developers site

Build a new role for your application

Create a custom role for your application in App Engine Studio (AES).

Before you begin

Role required: admin, security admin, or delegated_developer (with the **Security Management** permission)

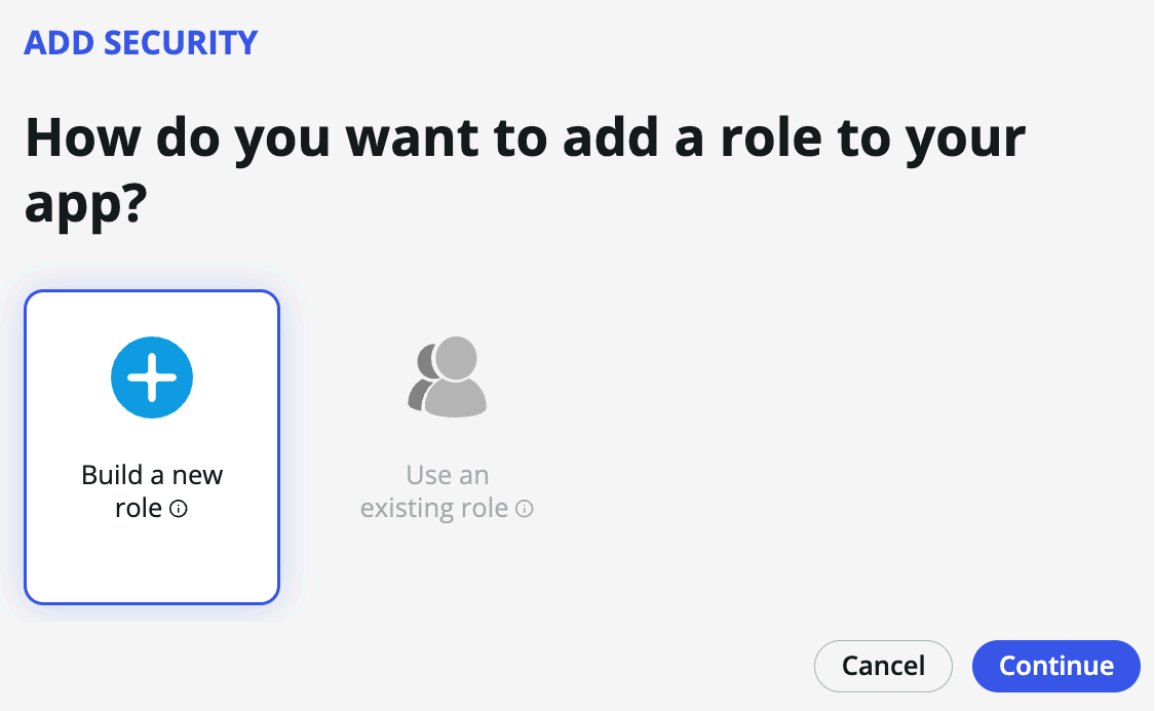
Note:
If you are an admin, be sure to elevate your role.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.

3. In your application, next to Security, select the add icon ( ).
4. Select **Build a new role** and then select **Continue**.

Option to build a new role



5. Enter a name and description for your role, and then select **Continue**.

> **Tip:**
> For consistency with existing role names, enter a role name that is all lower-case and uses underscores instead of spaces. For example, for an office art requester role, you would enter `office_art_requester`.

6. For each table in your application, select one or more access controls for your role.

Create

Users with the role can create new records on the data table.

Read

Users with the role can read the data that is stored in the table.

Write

Users with the role can update existing records in the table.

Delete

Users with the role can delete table records.

7. Select the **Experience** tab, and then select the experiences that users with the role can access.
8. Select **Continue**, and then select **Done** on the summary screen.

Use an existing role for your application

Use a previously created role for your application in App Engine Studio (AES).

Before you begin

Your application must contain either data or experiences in order to add an existing role. For more information about adding data or experiences to your application, see the following guidance:

- Create a data model for your application
- Add an application experience

Role required: admin, sn_app_eng_studio.user, or delegated_developer

About this task

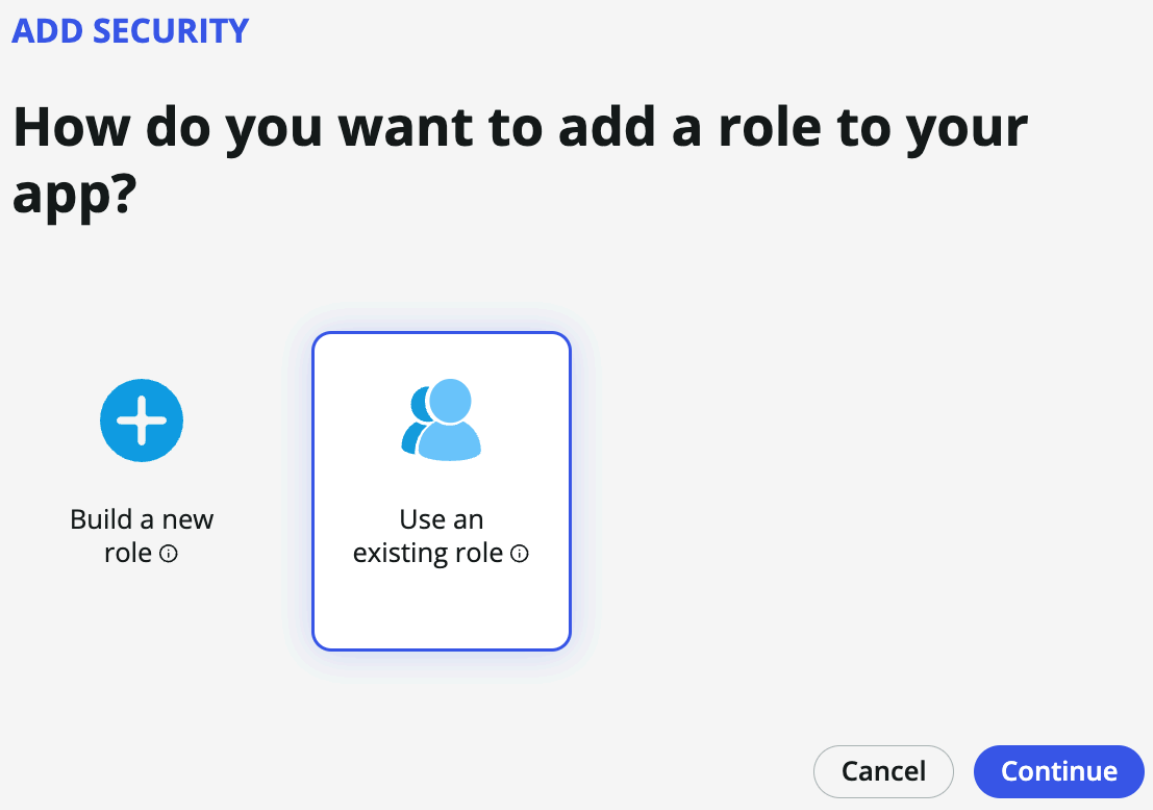
App Engine Studio includes default roles that you can use for your application. For more information on the default roles, see Base system roles.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, next to Security, select the add icon ( ).
4. Select **Use an existing role**, and then select **Continue**.

> **Important:**
> If your application doesn't contain data or experiences, the **Use an existing role option** will appear, but you cannot select it.

Option to use an existing role



5. Select the search field and then select a role from the list.
6. Select **Edit**.
   A new tab opens to set access controls for the existing role.

7. In the Experience section, select the experiences that users with the role can access.
8. In the Data section, set access controls for each available table.

   Create

   Users with the role can create new records on the data table.

   Read

   Users with the role can read the data that is stored in the table.

   Write

   Users with the role can update existing records in the table.

   Delete

   Users with the role can delete table records.

9. Select **Save**.

Change access settings for a role

Control the application permissions for a role in App Engine Studio (AES).

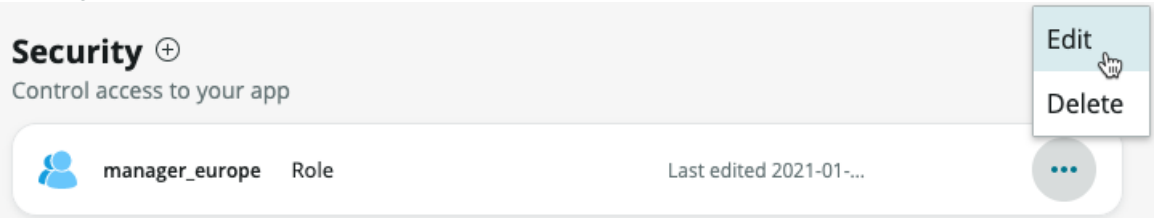
Before you begin

Role required: admin, sn_app_eng_studio.user, or delegated_developer

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to a role, select the menu icon (•••) and then select **Edit**.

Editing a role



A new tab opens to edit the role.

4. In the Experience section, select the experiences that users with the role can access.
5. In the Data section, set the access controls for each available table.

   Create

   Users with the role can create new records on the data table.

   Read

   Users with the role can read the data that is stored in the table.

   Write

   Users with the role can update existing records in the table.

   Delete

   Users with the role can delete table records.

6. Select **Save**.

Delete a role

Delete a role that you no longer need in App Engine Studio (AES).

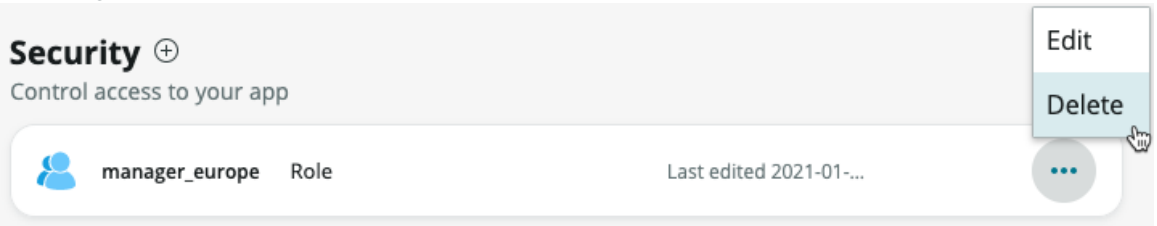
Before you begin

Role required: admin, sn_app_eng_studio.user, or delegated_developer

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Next to a role, select the menu icon (•••) and then select **Delete**.

Deleting a role



4. On the dialog box that appears, enter `delete` and then select **Delete**.

Collaborate with other developers

In App Engine Studio (AES), you can add or remove users and groups to be collaborators on an application.

Users have varying levels of permissions for actions on the Collaboration feature. At a high level:

Users with these permissions	Can perform these actions
Manage Collaborators delegated development permission to the application	Can: • See a list of collaborators and their descriptors • Search for users or groups • Select or change the collaboration descriptor for a user or group (but users can't change customized users or groups) • Add collaborators by sending invitations • Remove users or groups (but users can't remove customized users or groups) Can't: • Customize permissions for a user or group • Deploy via update sets
Invite Collaborators delegated development permission to the application	Can:

Users with these permissions	Can perform these actions
	• See a list of collaborators and their descriptors • Search for users or groups • Add collaborators by sending invitations Can't: • Select or change the collaboration descriptor for a user or group • Remove users or groups • Customize permissions for a user or group
No Collaborator-related roles to the application	Can see a read-only list of collaborators and their descriptors. Can't: • Search for users or groups • Select or change the collaboration descriptor for a user or group • Add collaborators by sending invitations • Remove users or groups • Customize permissions for a user or group
Administrators	Admins must elevate to a security_admin role to work with collaboration features. For more information, see Elevated privilege roles. Administrators can: • See a list of collaborators and their descriptors • Show/hide members of a group • Search for users or groups • Select or change the collaboration descriptor for a user or group (includes changing customized users or groups and changing the owner) • Add collaborators by sending invitations • Remove users or groups (includes removing customized users and groups and removing the owner even if there is only one owner) • Customize permissions for a user or group

Note:
You should create collaboration descriptors in addition to Owner and Editor in the global scope. If you want collaboration descriptors to appear and be used in AES, you should also set them to `standard = TRUE`. AES doesn't support collaboration descriptors that are created in custom scopes, and non-standard collaboration descriptors don't render in AES.

When you add a user or group, a collaboration task is generated and an approval flow kicks off. To find all collaboration tasks, navigate to **All** > **App Engine** > **Collaboration** > **Collaboration Tasks**. The collaboration task provides information on which application a developer is being added to, and what permissions are granted. Approvers sometimes need to review these task records before they add developers to the application.

If you're an admin, you can modify the Collaboration Request flow. The base system Collaboration Request flow handles collaboration requests as follows:

- If the user has AES or delegated developer permissions and isn't new to the platform, the collaboration request approval record is auto-approved.
- If the user does not have AES or delegated developer permissions and is new to the platform, approval is required.

If you're an admin, you can modify the collaboration descriptors that developers use to assign delegated development permissions. The base table provides Owner and Editor collaboration descriptors. By default, Owners have the manage collaborator delegated development permission set, and Editors have the invite collaborator delegated development permission set.

Note:
If you’re using source control to collaborate with other developers, only changes that have been checked in are available to other developers. For example, if an admin creates a new flow for an app that’s linked to Git, the new flow won’t be available in the app for other AES users until the admin checks the flow into Git.

Add a user or group to collaboration

Give users or groups permission to collaborate with other developers in App Engine Studio (AES) using the Collaboration feature.

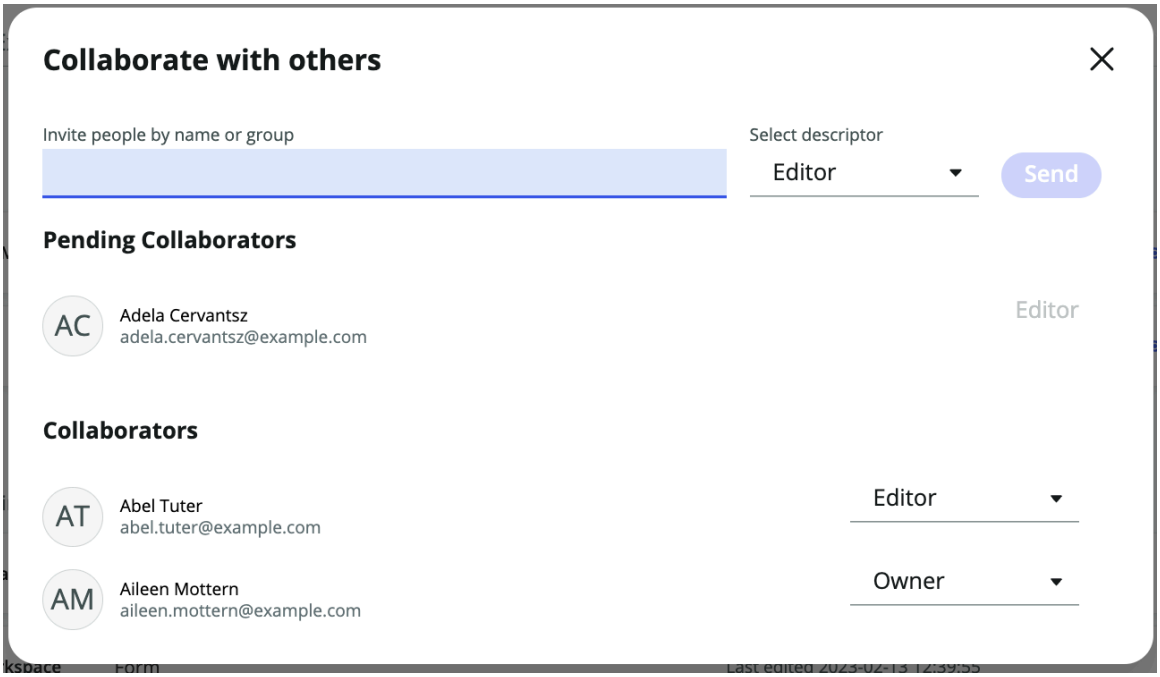
Before you begin

Role required: admin, manage collaborator delegated development role, or invite collaborator delegated development role

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select the Manage collaborators button.

Collaborate with others



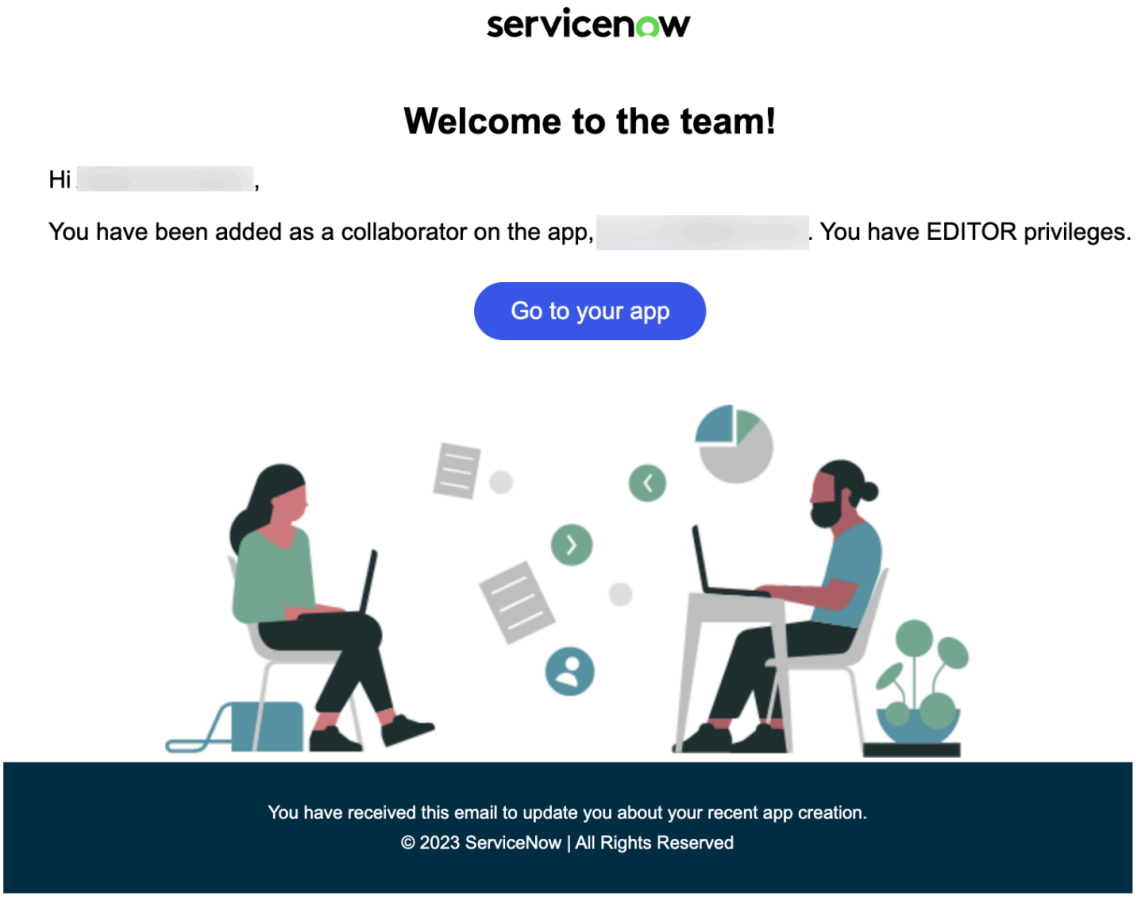
4. To add another user or group as a collaborator, enter the user name or group name in the **Invite people by name or group** field.
5. Search for a specific user or group by entering the first few characters of the name.
   A drop-down list with matching user names and groups appears where you can select the user or group you want to add. If a user or group appears in the drop-down list but you can't select it, it's already been added as a collaborator and can't be re-selected.
6. Select the collaboration descriptor for the user or group that you're adding.
   For a list of collaboration permissions, see Delegated development and collaboration permissions.

   Note:
   Users with Invite Collaborators permissions can't do this, and will default to the Editor option.

   Only App Collaboration Descriptors that are defined in the global scope and have the standard option selected appear in the list.
7. Select **Send**.

   - If the user has AES or delegated developer permissions and is new to the platform, the user is listed under the pending requests section and approval is required. After the request is approved, both the requester and the user

receive an email indicating that the user has been added to the application.



- If the user has AES or delegated developer permissions and is not new to the platform, the collaboration request is auto-approved. Both the requester and the user receive an email indicating that the user has been added to the application.

Note:
If a valid controller has been configured on the instance from which the collaboration request originated, a collaboration request task is created on the controller instance. If the originating instance isn't configured on the controller, work notes are automatically added to the request record indicating that the instance must be configured before approval is granted. If the originating instance is the controller or a valid controller has not been configured, the collaboration request task is created on the requesting instance. For more information, see Configure your controller instance.

Change collaborator permissions

Change the permissions that are assigned to a collaborator or create a custom collaboration permission to enable what people can do in App Engine Studio (AES).

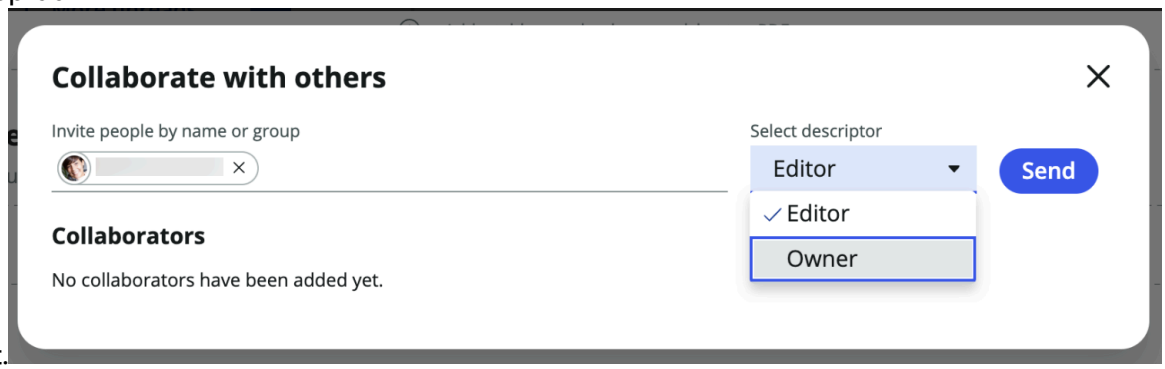
Before you begin

Role required: admin or manage collaborator delegated development role

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select the Manage collaborators button.

4. For the user or group you want to change, select a different collaborator descriptor from the drop-down list.



Customized users and groups are not editable by non-admins.

5. Admin only: Create custom collaboration permissions for specific users in an application.

   a. In AES, select **Customize Permissions** from the drop-down list across from the user's name.

   b. Select or clear delegated development permissions for the user or group.
   For a list of collaboration permissions, see Delegated development and collaboration permissions.

   If the selection matches that of another standard Collaboration descriptor, the system will provide a prompt before proceeding. For details on each delegated development permission, see Delegate development and deployment permissions to personnel.

6. Select **Save**.

Delegated development and collaboration permissions

Collaboration permissions define what users can do in App Engine Studio (AES).

File type access permissions

File type access permissions grant access to application file types.

File type access permissions

Permission	Description
All file types	Grants access to collaborate on all file types. **Note:** This option includes access to additional file types not listed in separate permissions.
Integrations	Grants access to web service APIs, REST APIs, data sources, and Integration Hub - Import.
Reporting	Grants access to reports and scheduled reports.
Mobile builders	Grants access to build mobile experiences, such as with Mobile App Builder.

File type access permissions (continued)

Permission	Description
UI Builder	Grants access to work with UI Builder to build more complex interfaces.
Workflow	Grants access to the Workflow Editor and Activity Creator.
Service Portal	Grants access to work with Service Portal editors and tools.
Workflow Studio	Grants access to the Flows design environment in Workflow Studio to create flows and actions. Script action steps require the **Allow Scripting** permission.
Service Catalog	Grants access to work with catalog-related file types such as catalog items, record producers, and variables to add catalog items to apps.
Tables and forms	Grants access to model and layout-related file types such as table columns, form layout, and list layout.
Playbooks	Grants access to work with the Playbooks design environment to create processes. Editing activity subflows or actions requires the **Flow Designer** permission.
Decision Tables	Grants access to work with Decision Tables to create decision logic based on multiple if-then rules.
Notifications	Grants access to create automatic email notifications in apps.

Security/Entitlement permission

The **Manage ACLs and Roles** permission grants access to security management files, such as Access Control Lists and roles.

Programming tools permission

The **Allow scripting** permission grants access to script fields, such as scripting in business rules, UI actions, and client scripts.

Application management permissions

The application management permissions grant access to basic app management functions, like managing collaborators.

Application management permissions

Permission	Description
Delete application	Grants the collaborator within a scoped app rights to delete the application.

Application management permissions (continued)

Permission	Description
Manage collaborators	Grants access to manage and invite collaborators for apps.
Source control	Grants full access to use source control.
Invite collaborators	Grants access to invite developers to collaborate on an app.

Deployment permissions

The deployment permissions grant access to installing, upgrading, and publishing apps.

Deployment permissions

Permission	Description
Upgrade app	Grants access to upgrade the associated application after it has been installed in the current instance.
Submit for deployment	Grants access to submit the associated application for review and deployment.
Publish to app repo	Grants access to publish the associated application to the application repository in the current instance.
Publish to app store	Grants access to publish the associated application to the ServiceNow Store in the current instance.

Remove a user or group from collaboration

Remove users and groups from collaboration to restrict them from owning or editing an app.

Before you begin

Role required: admin or manage collaborator delegated development role

About this task

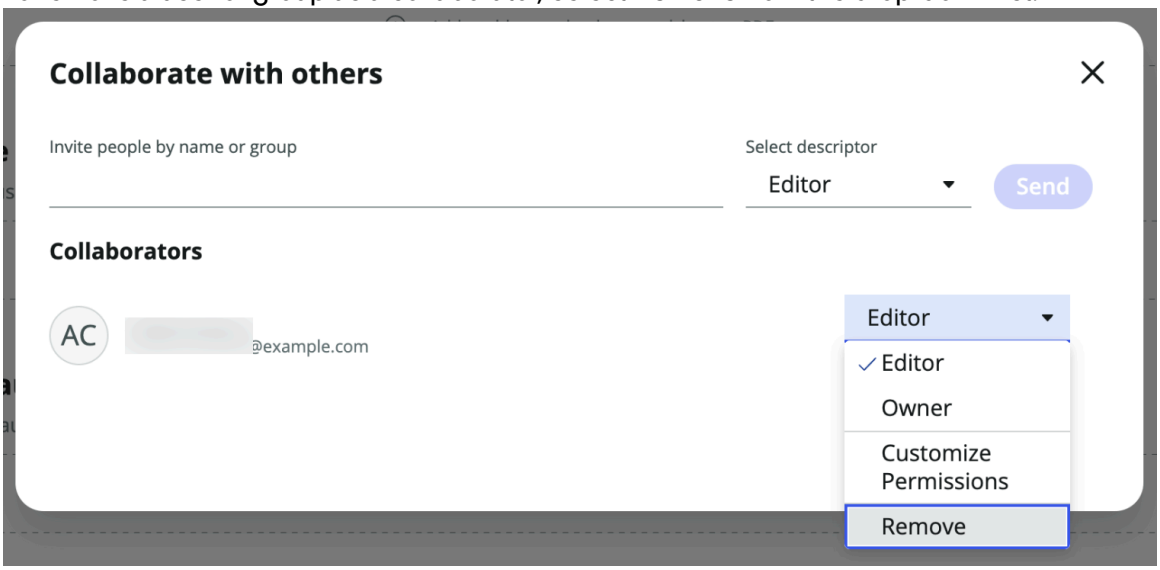
You can remove the final owner and editor for an app. If an app doesn't have any owners and needs one, an admin must add them.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select the Manage collaborators  button.

The Collaborate with others modal appears with a list of the current collaborators.

4. To remove a user or group as a collaborator, select **Remove** from the drop-down list.



Use AES with a Git source control repository

App developers working in App Engine Studio (AES) can manage their data repository in numerous ways.

After your admin has linked an application to Source control, all application developers on a non-production instance can perform these actions:

- Import applications from a Git repository.
- Pull and apply remote changes from a Git repository.
- Commit all local changes on the instance to a Git repository.
- Create tags to permanently link to a given version of an application.
- Create branches to maintain multiple versions of an application simultaneously.

Note:
If you're using source control to collaborate with other developers, only changes that have been checked in are available to other developers. For example, if an admin creates a new flow for an app that's linked to Git, the new flow won't be available in the app for other AES users until the admin checks the flow into Git.

Options available from App Engine Studio

After an application has been linked to source control, application developers can use App Engine Studio to manage the repository. From App Engine Studio, developers can:

- Edit the application repository credentials.
- Commit all local changes on the instance.
- Apply remote changes from the repository.
- Create a branch.
- Switch branches.
- Import an application from a remote repository.

Source control integration does not support managing applications on a production instance. Instead, you can manage applications on a production instance using the application repository,

an update set, or App Engine Studio. For more information about managing applications on a production instance, see Application sharing.

Options available from a Git repository

The ServiceNow platform offers limited support for modifying linked application files outside of an instance. From Git, developers can:

- Move application files to a different Git directory structure.
- Edit application files outside of App Engine Studio.

The system generates a properties text file called `sn_source_control.properties` at the root level of the repository. To move application files to a different Git directory structure, application developers can set the *`path`* parameter to specify the subfolder path containing their application files. For example, if you moved your application to the `src/app` subfolder, set the *`path`* to `path=src/app`.

The system generates a `checksum.txt` file in the Git repository to determine if any application files have been changed outside of App Engine Studio. When the checksum value from the file matches the current checksum value, the integration skips the validation and sanitization process. When the checksum values do not match, the integration validates and sanitizes the application files as part of the source control operation. The sanitization process:

- Creates upgrade log entries for each sanitization action taken.
- Removes unsupported folders and files from the repository.
- Aborts all source control operations when a system application file fails XML schema validation. For example, if a database dictionary record fails XML schema validation, the system aborts all operations.
- Skips the current source control operation when a non-system application file fails XML schema validation.

The source control integration sanitizes only content within the application path listed in the `sn_source_control.properties` file. Repository content outside the application path is ignored.

MID Server support

Use an existing MID Server to connect to a source control repository. Accessing an application through a MID Server enables access to repositories behind a firewall.

Source control operations in App Engine Studio

The source control integration primarily supports operations from App Engine Studio (AES), but can also support some operations directly from the Git repository.

Available source control operations

Operation	Description	Available from
Import from source control	Imports an application from the repository to the local instance. For more information, see Import application or application-customization from source control.	App Engine Studio
Link to source control	Allows developers to manage application changes from a Git repository. For more information, see Link an application or application-customization to source control.	App Engine Studio

Available source control operations (continued)

Operation	Description	Available from
Edit Repository Configuration	Updates the Git repository user credentials. For more information, see Edit a Git repository configuration.	App Engine Studio
Apply Remote Changes	Updates the local version of the application to match the repository version. For more information, see Pull changes from a repository.	App Engine Studio
Commit Changes	Updates the repository version of the application to match the local version. For more information, see Commit changes to a repository.	App Engine Studio
Stash Local Changes	Removes and saves local changes for later work. For more information, see Stash local changes.	App Engine Studio
Switch Branch	Updates the local version of the application to match the repository branch version. For more information, see Switch branches.	App Engine Studio
Create Branch	Creates a branch in the repository to save a different version of the application. For more information, see Create a branch.	• App Engine Studio • Git repository
Create Tag	Creates a tag in the repository to link to a particular application version. For more information, see Create a tag to link to a particular application version.	• App Engine Studio • Git repository
Manage Stashes	Allows developers to apply or delete stashed changes. For more information, see Manage stashes.	App Engine Studio
Create repository	Creates a repository to store application changes.	Git repository
Create credentials	Creates credentials to the repository.	Git repository
Grant access to repository	Provides read and write access to the repository tied to a specific set of credentials.	Git repository

Import application or application-customization from source control

Import an app or app customization from a source control repository into App Engine Studio (AES) to continue developing it on this instance.

Before you begin

- Role required: admin
- Verify that the non-production instance has network access to the Git repository.

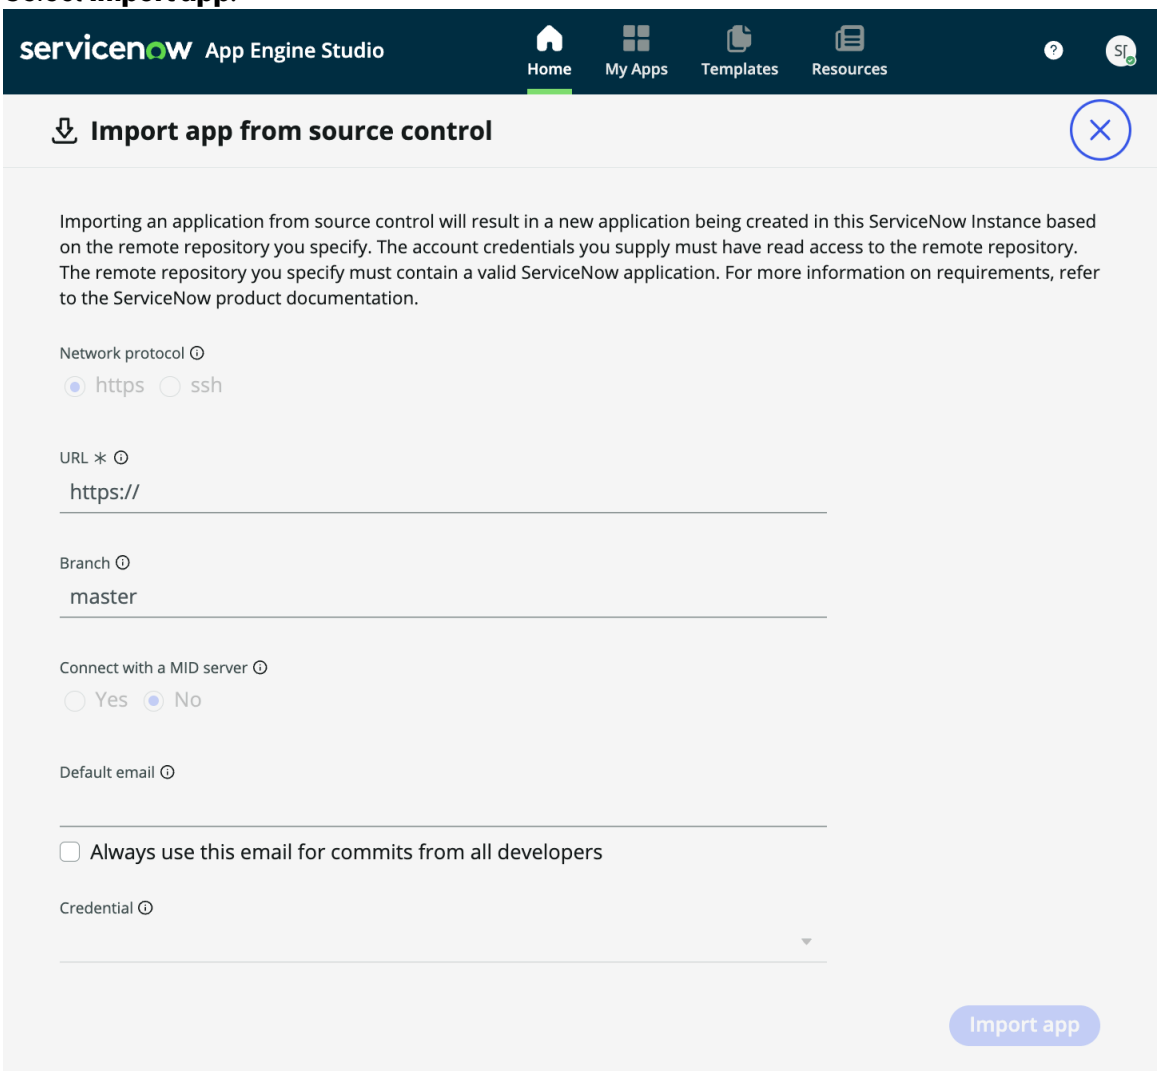
- Verify that the repository contains a valid application.
- Ensure that users add the email address to their respective Users table [sys_user] record that they use in their commits to the Git repository.
- Learn more about application-customizations Manage customizations to applications.

About this task

The source control integration does not support importing an application on a production instance. Instead install applications on a production instance from the application repository, an update set, or the App Engine Studio.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. Select **Import app**.



3. On the form, fill in the fields.

Import from source control fields

Field	Description
Network protocol	Https or ssh credential type that enables secure channel data exchange.

Field	Description
URL	The URL to the Git repository where the application files reside. **Note:** If the Git repo URL for SSH provided by your Git server does not work, check with your Git server owner or provider for the correct URL. There may be additional specifications such as scheme protocol prefixes, port numbers, and so on, required for your Git repo URL to function.
Branch	The repository branch to work on within the application. **Note:** The default branch is named after your instance. If you do not choose a name, the branch defaults to **master**.
MID Server Name	Select an existing MID Server to link to a Git repository stored behind your corporate firewall. **Note:** Use a separate MID Server to prevent conflicts with Discovery activities. See MID Server for more information.
Default email	The committer email address is defined by the sys_user record if available. But if a committer's sys_user record email field is empty, the system generates an alternate email (username@instancename.service-now.com). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.
Credential	Select the credential for your Git repository. For more information, see Getting started with Credentials. **Note:** If you select the ssh network protocol, enter a valid credential of the SSH Private Key type. If you select the https protocol, enter a valid credential of the Basic Auth Credentials type.

Note:
All application developers on the instance share the credential used to link a Git repository to an application.

4. Select **Import app**.
   The system compares the checksum in the `checksum.txt` file to current checksum. When the checksum values match, the integration skips validation and imports the application. When the checksum values do not match, the integration first validates and sanitizes the application files before importing them.
5. Select **Select Application**.
   App Engine Studio displays the application as a new choice in the Switch Applications window.

What to do next

- Review the upgrade logs for any sanitization applied to application files during the import.
- Select the imported application to edit it.

MID Server

Getting started with credentials

Work with changes in Git

Developers using App Engine Studio (AES) can pull and commit changes in their Git repository.

Note:
If you're using source control to collaborate with other developers, only changes that have been checked in are available to other developers. For example, if an admin creates a new flow for an app that's linked to Git, the new flow won't be available in the app for other AES users until the admin checks the flow into Git.

Pull changes from a repository

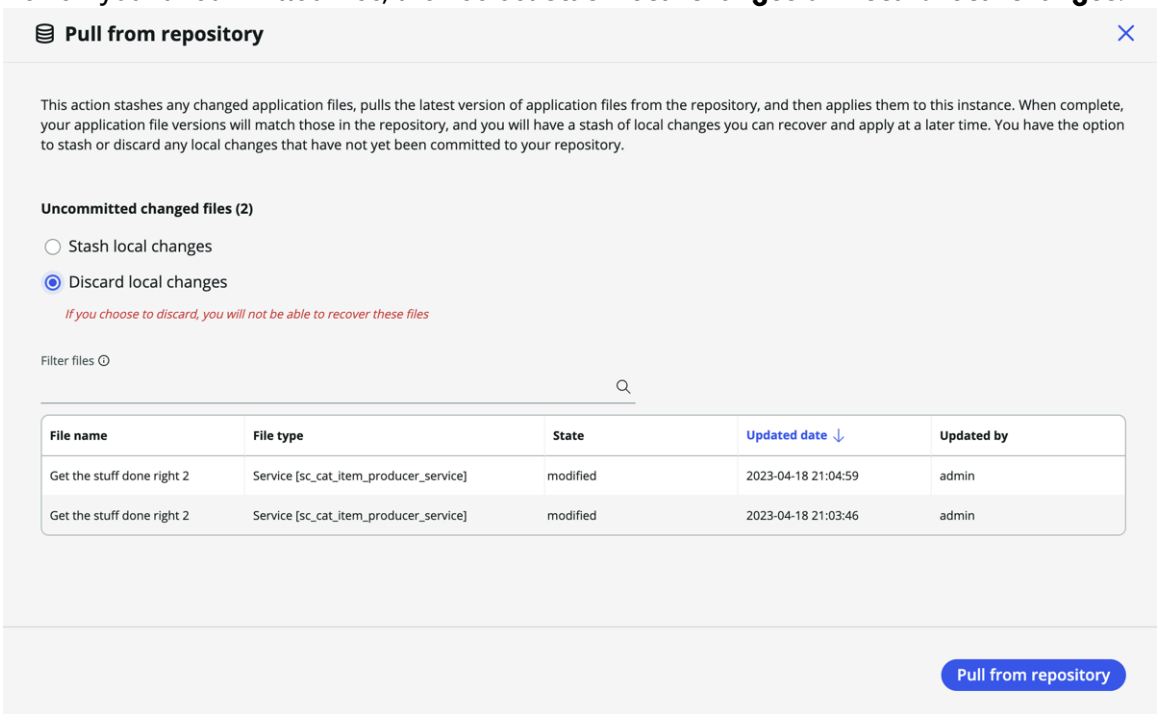
App developers using App Engine Studio (AES) can pull changes from a linked Git repository to apply remote changes to the local instance.

Before you begin

- Role required: admin
- Link an application or application-customization to source control

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select **Source control** > **Pull from repository**.
4. Review your uncommitted files, then select **Stash local changes** or **Discard local changes**.



5. Select **Pull from repository**.
   The following operations occur:

- The system fetches the most recent changes from the remote repository.
- The system applies the remote changes to the instance.
- The system identifies any change conflicts requiring resolution.
  If there are conflicts, the system displays the **Resolve Conflicts** window.

Delta loading is enabled by default in sys properties so your data isn't removed. You can disable this feature if you want data automatically deleted.

What to do next
Resolve any change conflicts.

Commit changes to a repository

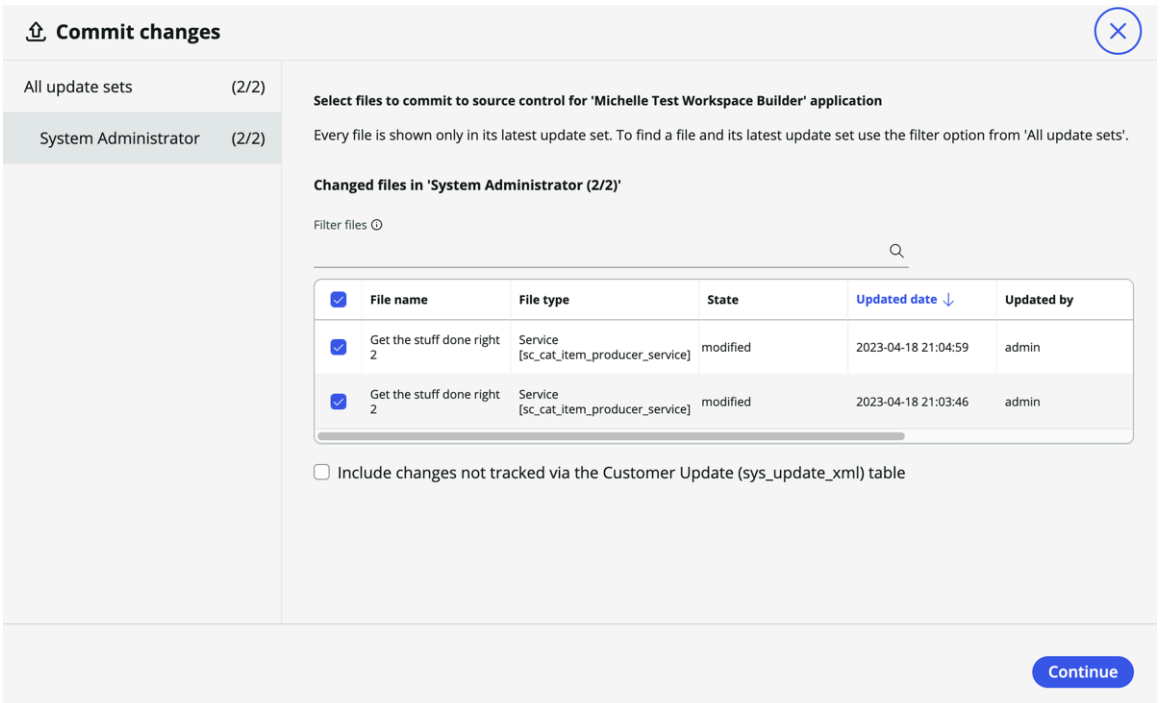
Commit changes made in your application in App Engine Studio (AES) to a linked Git repository. You can either select a few changes to commit, or commit all changes on the instance at once.

Before you begin

- Role required: admin
- Link an application or application-customization to source control

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select **Source control** > **Commit changes**.
   The system displays the **Select files to commit to source control** window. The file changes from all the updates sets display. By default, the file changes from the current update set display.



4. Select the file changes you wish to commit.
5. To include untracked changes, select the **Include changes not tracked via the Customer Update [sys_update_xml] table** check box.

- The default for this check box is set via the **glide.sourcecontrol.default_commit_mode** property.
  - Property can be set to **include_untracked** or **exclude_untracked**.
  - The **include_untracked** mode commits the updates to the application that do not generate sys_update_xml records, as well as any user-selected updates.
  - The **exclude_untracked** mode commits only updates selected by the user in the **Select files to commit to source control** dialog.
- The base system setting for the property is **exclude_untracked**.
- To hide the check box and use the value of the **glide.sourcecontrol.default_commit_mode** property, create the **sn_devstudio.vcs.allow_commit_mode_selection** property and set it to false.
- Checking this check box may incur a performance penalty.

Note:

Commits always occur in **include_untracked** mode in the following cases:

- Linking to source control for the first time. (To learn more, see Link an application or application-customization to source control.)
- Publishing an application that's linked to source control from App Engine Studio.
- Selective commit mode is disabled.

6. Select **Continue**.
7. In **Commit comment**, enter a comment for the changes.
8. Select **Commit Files**.
   The following operations occur:
   - The system identifies all local changes.
   - The system commits all local changes to the remote repository.

Note:
For list of known files that don't have customer update records and are untracked, see Customer Updates table.

Create versions and branches in Git

App developers using App Engine Studio (AES) can create versions and branches in their Git repositories.

Create a tag to link to a particular application version

Create a tag in the repository to link to a particular app version in App Engine Studio (AES).

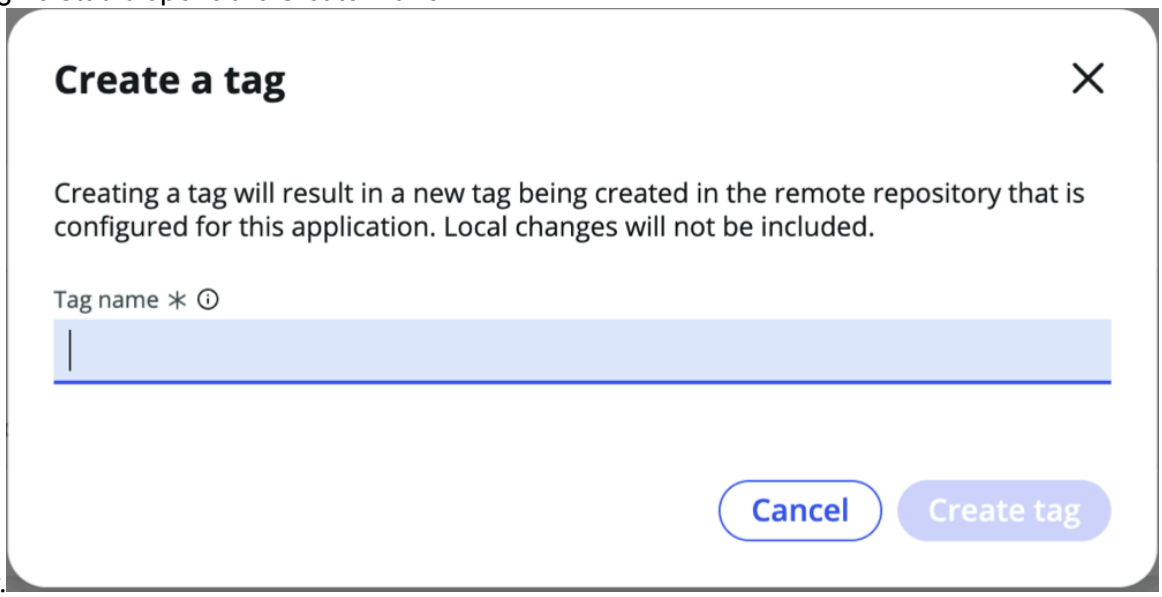
Before you begin

- Role required: admin or sn_group_creator.app_creator
- Link an application or application-customization to source control

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.

3. Select **Source control** > **Create tag**.
   App Engine Studio opens the Create Branch window.



4. Enter the **Tag Name**.
5. Select **Create Tag**.
   App Engine Studio creates the tag.
6. Select **Close**.

What to do next

Commit changes to the new branch.

Switch branches

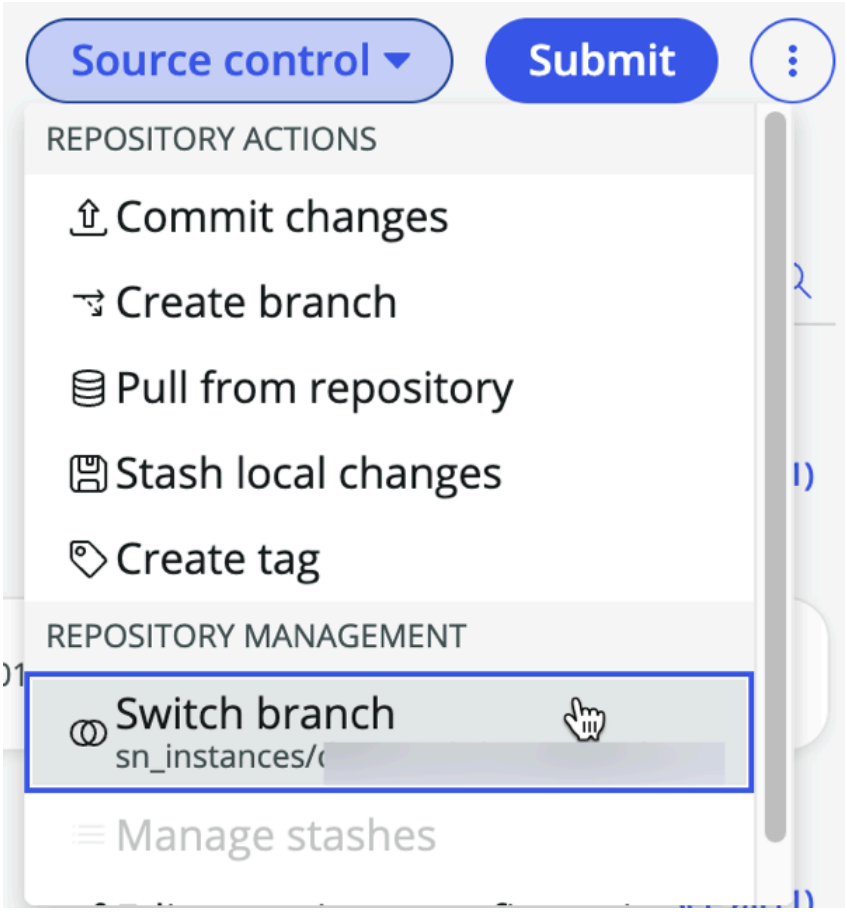
Application developers can switch to a different repository branch to work on another version of the application using App Engine Studio (AES).

Before you begin

- Role required: admin
- Git repository with one or more available branches.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select **Source control** > **Switch branch**.



The system displays the Switch Branch window.

4. **Optional:** If there any local changes on the instance, you can save or discard them.

   Note:
   Use caution when discarding local changes. Since all application developers share repository credentials, there is no way to discard just one set of user changes. Note you cannot later restore discarded changes.

5. Select the branch you want to switch to.
6. Select **Switch Branch**.
   App Engine Studio updates the local application to match the branch version from repository.

Create a branch

Application developers can create a branch to work on a new version of an existing app in App Engine Studio (AES).

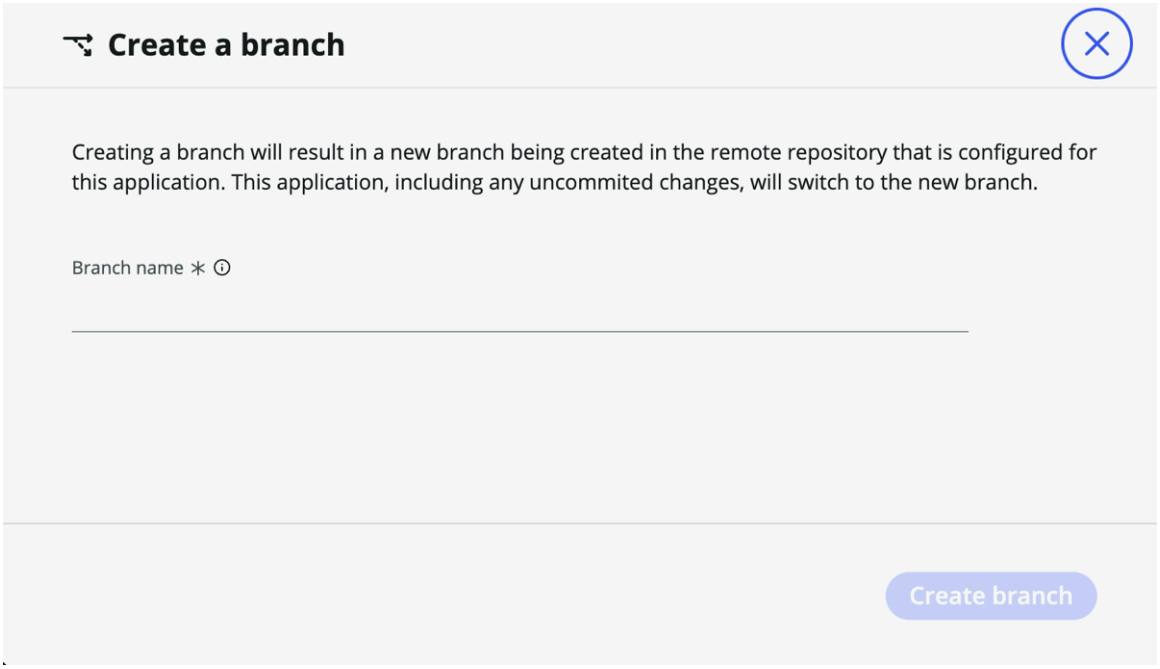
Before you begin

- Role required: admin or sn_group_creator.app_creator
- Link an application or application-customization to source control

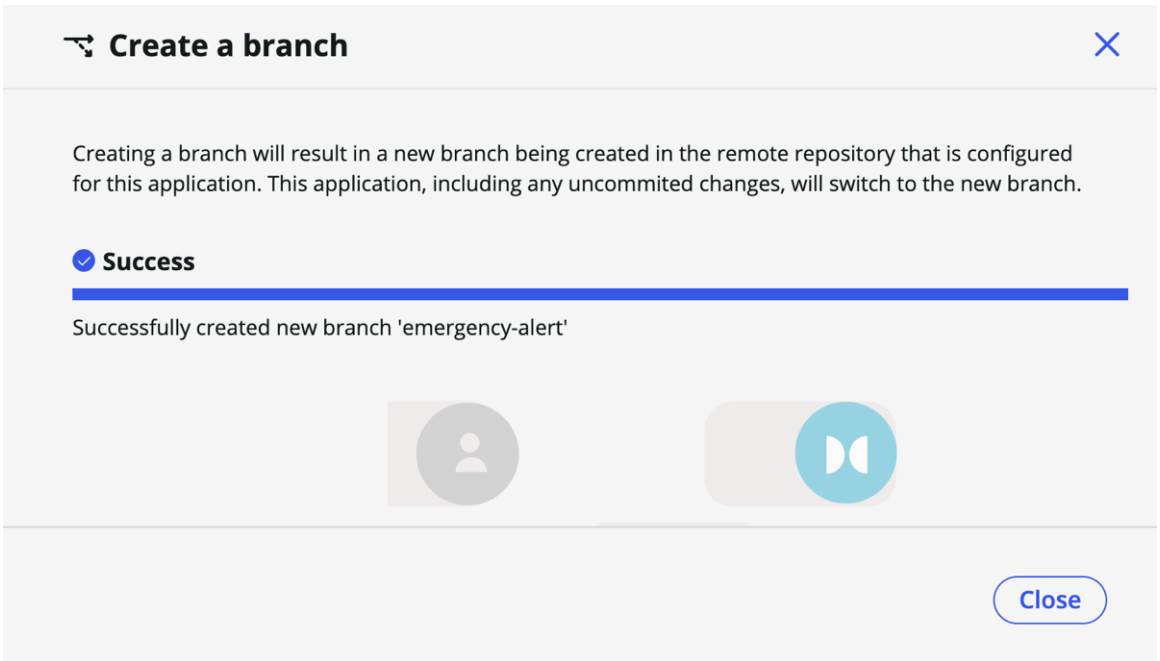
Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select **Source control** > **Create branch**.

App Engine Studio opens the Create Branch window.



4. Enter the **Branch Name**.
5. **Optional:** To create a branch from a tag, select the **Create from Tag** drop-down list and select an existing tag.
6. Select **Create Branch**.
   App Engine Studio creates the branch.



7. Select **Close**.

What to do next

Commit changes to the new branch.

Set the default branch

Set a default branch when you want to use a branch other than main for new changes or for your main App Engine Studio (AES) development repository.

Before you begin

- Role required: admin
- Link an application or application-customization to source control

Procedure

1. Follow the steps to Add a system property.
2. Add the **glide.source_control.default_branch_name** property, and specify the default branch name of the Git source control repository to work from (pull requests, code commits, etc.). Application developers' work is managed from and saved into the default branch if not otherwise specified. If not changed, this value defaults to sn_instances/<instance_name>.

Stash changes

Developers can remove and save changes locally to apply them later, and manage stashed changes from App Engine Studio (AES).

Stash local changes

App developers can remove and save changes locally to apply them later in App Engine Studio (AES).

Before you begin

- Role required: admin
- Link an application to source control
- Change one or more application files

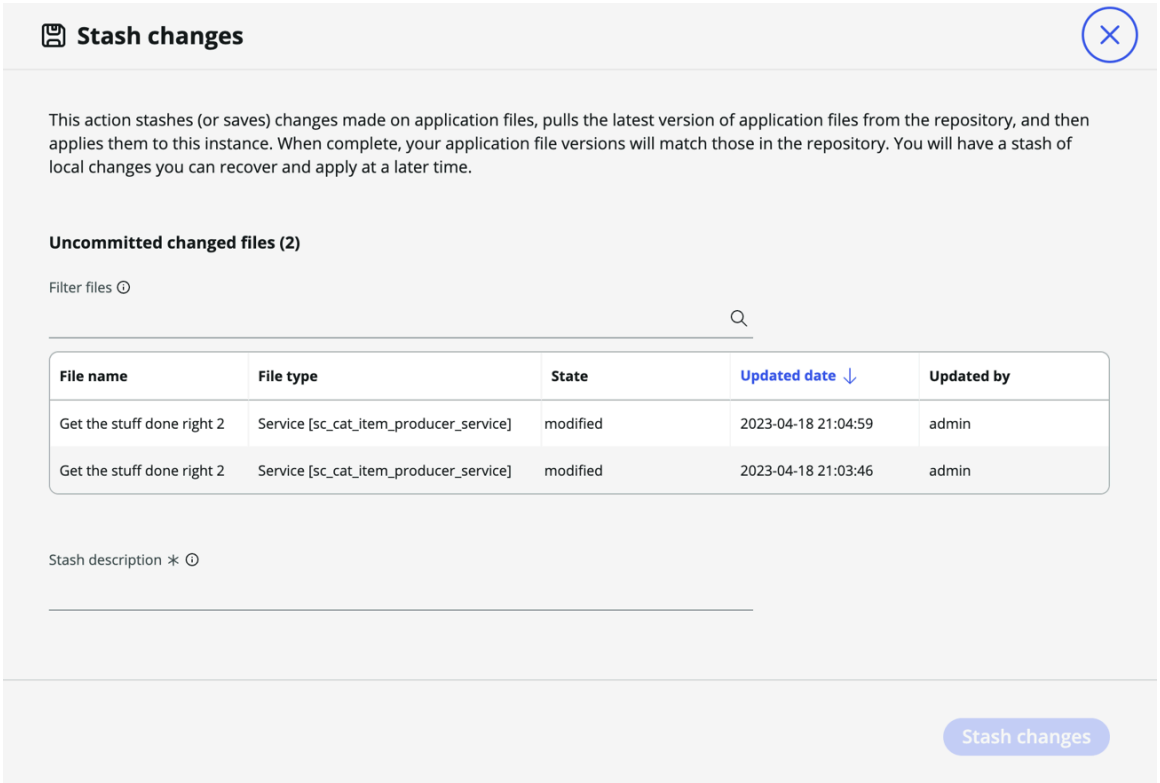
About this task

Stashing changes removes them from the current application and saves them for a developer to later apply or delete.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select **Source control** > **Stash local changes**.
   The system displays a list of locally changed files.
4. Enter your description.
5. Select **Stash Changes**.

The system saves the current changes and displays a success message.



What to do next

- Close dialog
- Manage stashes

To learn more, see Getting started with credentials

Manage stashes

App developers can apply or delete stashed changes from App Engine Studio (AES).

Before you begin

- Role required: admin
- Link an application to source control.
- Stash one or more application file changes.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Select **Source control** > **Manage stashes**.
   The system displays a list of locally stashed changes.
4. Select the action next to the stash you want to manage.

Option	Description
Apply	Commits the stashed changes to the application and checks for conflicts.
Delete	Removes the stashed changes.

Resolve conflicts

App developers can select the app file version to use when applying remote or stashed changes in App Engine Studio (AES).

Before you begin

- Role required: admin
- Link an application to source control
- Apply a stashed change

About this task

Conflicts occur when there are multiple change versions of the same application file: one set of changes in the remote or stashed version and another set of changes in the local version. App Engine Studio requires developers to resolve conflicts before applying remote or stashed changes.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. Pull from a repository or stash local changes.
   If the system identifies a conflict, it displays the Resolve Conflicts dialog.
4. Select how to resolve the conflict.

Option	Description
Select an action	Apply or discard all stashed changes. Go to step 3.
Manually merge changes	Individually select which changes to apply. Go to step 6.

5. If you want to apply or discard all stashed changes, select an **Action**.

Option	Description
Take Stashed Changes	Applies the application file version from the stashed changes.
Discard Stashed Changes	Applies the application file version from the most recent pull from the repository.

6. Select **Apply Stashed Changes**.
   The system applies the selected changes.
7. Select **Close Dialog**.
8. If you want to merge the conflicting changes, select **Manually Apply**.
   The system displays a list of version differences by field.

9. Select the field values you want the merged application file to have.
10. Select **Save Merge**.
    The system applies the selected changes.

View commit history

App developers can view the commit history of apps linked to a source control repository in App Engine Studio (AES).

Before you begin

- Role required: admin
- An existing link to a Git repository

Procedure

1. Navigate to **All** > **Source Control** > **View History** .
   The system displays the History window.

2. Select the commit sort order type.

Option	Description
Date	Sort by commit date.
Committer	Sort by user name.

3. Select the sort order direction.

Option	Description
Descending	Sort dates from the most recent to oldest date. Sort user names reverse-alphabetically from Z to A.
Ascending	Sort dates from the oldest to most recent date. Sort user names alphabetically from A to Z.

   The system sorts commits by the selected sort order.

4. Select a commit.
   The system displays the commit details for the selected commit.
5. Review the commit details.

Commit Details

Field	Description
Committer	The user who committed the change.
Date	The date-time stamp of the commit.
SHA-1	The secure hash value identifying this commit in the repository.
Message	The commit message associated with this commit.

Field	Description
Files	The list of application files changed in this commit.

6. Close the History window.

Move application files in a Git repository

Move application files linked to source control to any folder of the repository when working in App Engine Studio (AES). Allow application developers to store supporting content such as automated tests in the same repository as the applications they support.

Before you begin

- Link an application or application-customization to source control
- Role required: Source control credentials with write access

About this task

Linking an application to source control generates a properties text file called `sn_source_control.properties` at the root level of the repository. The properties file specifies the folder containing the application files. The integration tracks changes to these application files by generating a `checksum.txt` file. When the checksum matches, the integration skips the validation and sanitization process. When the checksum does not match, the integration validates and sanitizes the application files as part of the source control operation. The integration ignores all repository content outside the application path.

Note:
You can set system properties **glide.source_control.checksum_required** to enable optional checksum validations and sanitizations and **glide.source_control.checksum_quick_install** to bypass sanitization steps on checksum matches. See Available system properties for more information.

Procedure

1. Login to the source control repository linked to the application.
2. Create the destination folder where you will move the application files.

   Example
   For example, create the folders `src/app`.
3. Move the folder containing your application files to the destination folder.

   Example
   For example, move the folder `demo_my_app` to `src/app`.
4. Navigate to the root level of the repository.
5. Open the `sn_source_control.properties` text file in a text editor.
6. For the `path=` property, enter the folder path where you moved the application files.

   Example
   For example, enter `path=src/app`.
7. Save the properties file.

What to do next

Login to your instance and perform Source control operations in App Engine Studio from App Engine Studio.

Publish your app

When you have completed your app in App Engine Studio (AES), you need to submit it for approval and publishing. The process you use depends on whether you are linked to source control.

Submit your app for approval and publishing

Start the process of getting the application you built in App Engine Studio (AES) published by submitting it for administrator review.

Before you begin

Role required: delegated developer with permissions (**Submit for deployment**, **Publish to app repo**, or **Publish to app store**, depending on the desired action)

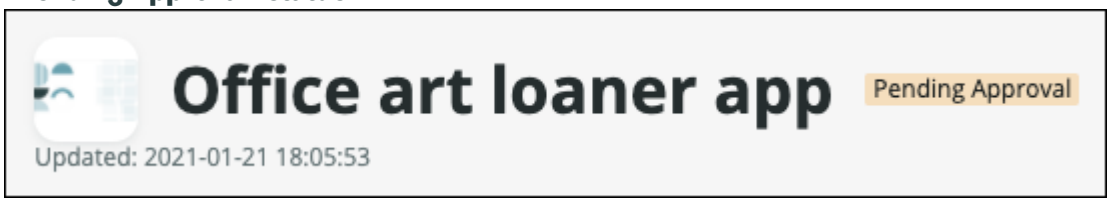
Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. From the app home, select **Submit**.
4. On the dialog box that appears, review the submission details and then select **Submit**.

What to do next

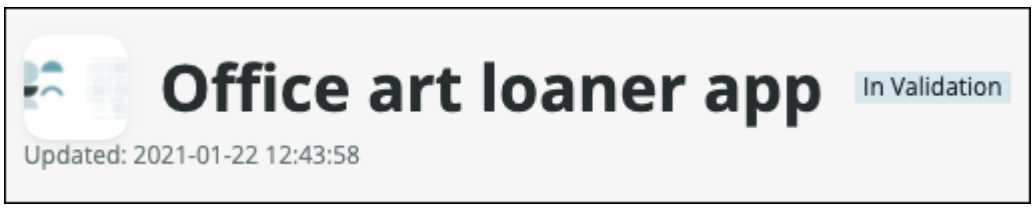
The administrator reviews the submitted application and checks for potential issues. You can check the status of your application from the application home in App Engine Studio.

"Pending Approval" status



After a reviewer begins testing the application, the status changes to `In Validation`.

"In Validation" status



An administrator may provide you with test accounts for different roles in your application. Log in with each of these accounts to check that the application works as expected.

If the reviewer rejects the application, the status changes to `Rejected`. You may also receive an email that includes the reviewer's comments. Use the feedback to improve your application, and then submit the application again.

"Rejected" status

If the application passes testing, the administrator publishes the application and the status changes to `Published`. The administrator on-boards the team that requested the application. For example, if you specified a certain security role for the application, the administrator assigns that role to the relevant users.

"Published" status

Related topics

Delegate developers using AES

Publish an app from App Engine Studio when linked to source control

You can publish a custom application from App Engine Studio (AES) when linked to source control.

Before you begin

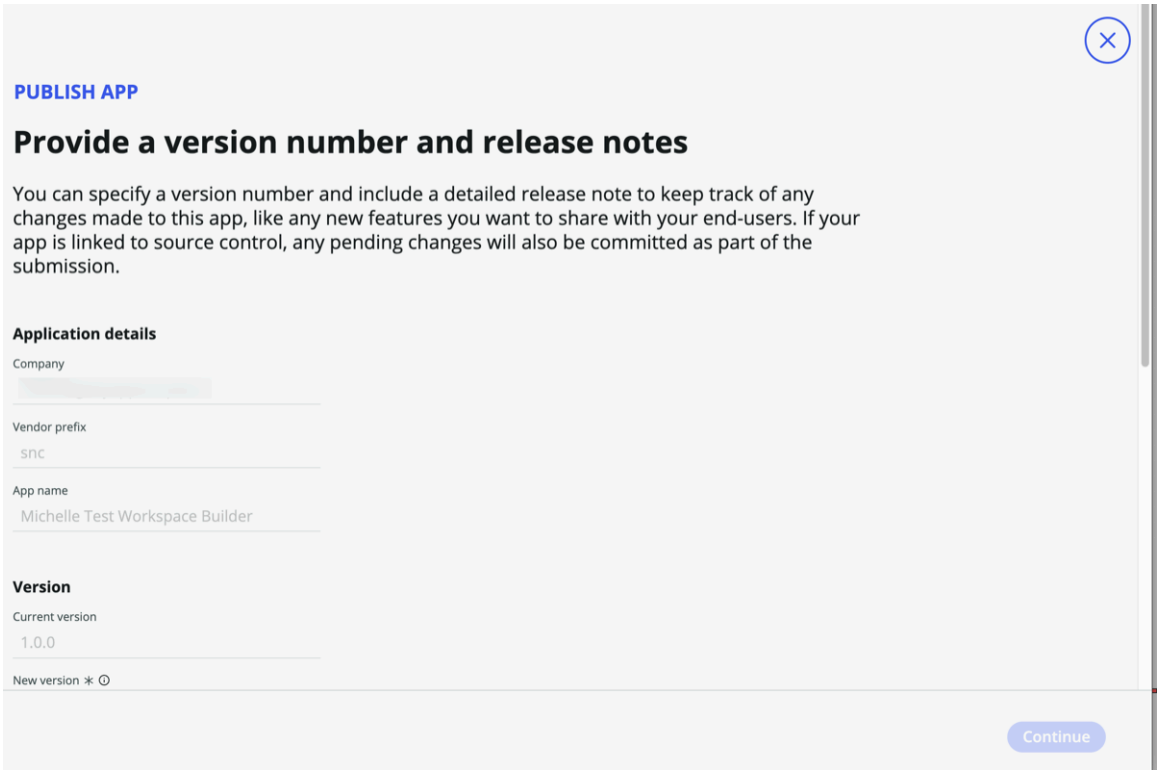
Role required: admin

About this task

When you publish an application from App Engine Studio that is linked to source control, there is a different outcome than when you publish via the sys_app or sys_store_app **Publish** related link.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. From the app home, select **Publish**.
   App Engine Studio displays the publish app fields.



4. Enter the following field values.

Provide a version number and release notes

Field	Description
Version	View your current app version and provide a new version number for your application. **Note:** To change the version number, you must have one of the following deployment permissions: **Submit for deployment**, **Publish to app repo**, or **Publish to app store**
Release notes	Provide a brief description of the changes made to your application.
Publish options	Select if you want the application to be published to your application repository or the ServiceNow Store.

Note:
All application developers on the instance share the credential used to link a Git repository to an application.

5. Select **Continue**.
6. The current state of the application is committed to source control, including any untracked or uncommitted changes.
The value of the **glide.sourcecontrol.default_commit_mode** property is ignored.
This occurs because when the application is published, all the untracked and uncommitted changes are also published. Therefore, the state of the application in the Git repository matches what is published. See the Commit changes to a repository topic for more information about the **glide.sourcecontrol.default_commit_mode** property.

7. A source control tag is created for the new version and the application is published. If needed, the sys_app record is updated with the new store correlation ID.

> **Note:**
> If your application is linked to source control and you publish a new version outside of App Engine Studio, a source control commit and tag are not created.

Managing app deployments using Pipelines and Deployments

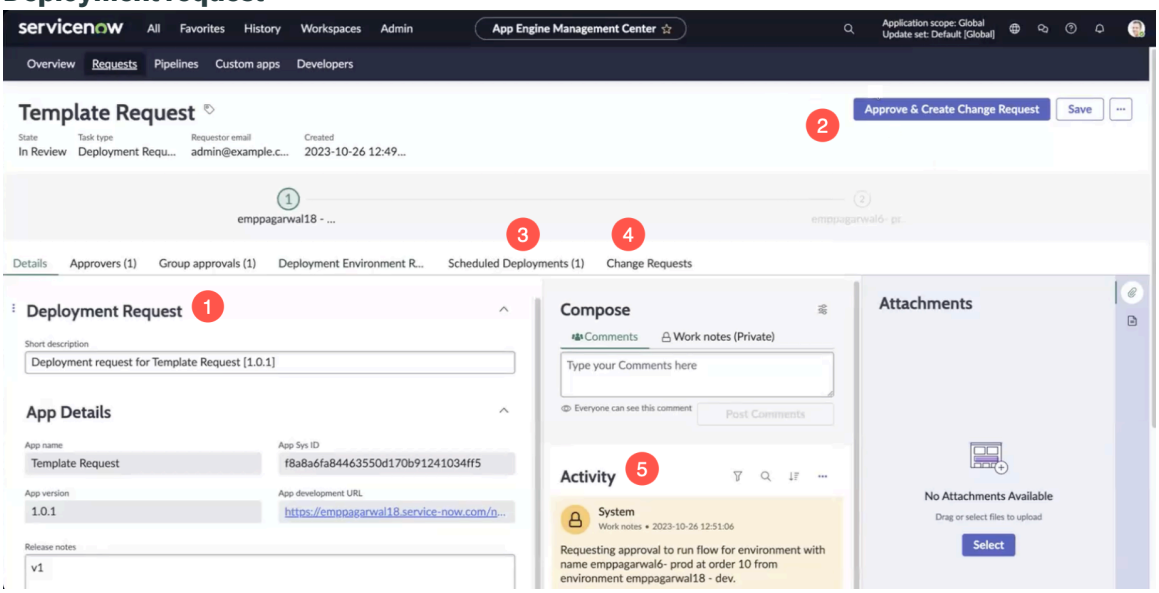
Review the applications developers build using App Engine Studio (AES) so you can deploy with confidence.

Deployment requests

After a developer submits an application in App Engine Studio, a deployment request is created. A deployment request is a record to track the review of submitted applications.

A reviewer can deploy the app to your test environment, reject it, or publish it, all using the App Engine Management Center. If you integrate an existing Change Management program with AEMC, and your app is ready to deploy to production, you can create a change request and deploy the app within a specified change window.

Deployment request



1. View details of the deployment request and the application being deployed.
2. Select **Approve & Create Change Request** when the app is ready for deployment. This action begins the Change Management processes you configure using Guided Setup.

> **Note:**
> If you don't have an existing Change Management program integrated with Pipelines and Deployments, select **Approve & Deploy App** to move the deployment to the next stage.

3. View and edit details of the deployment on the **Scheduled Deployments** tab.
4. View details of the change request on the **Change Request** tab. Depending on the role you have, you may be able to change some details of the request.
5. Watch the **Activity** stream for test results, change request progress, and other deployment details.

Note:
If you submit deployment requests without upgrading all instances in the pipeline, your existing pipeline continues to be used.

For more information on reviewing a deployment request, see Deployment Request form in the Pipelines and Deployments app.

Testing an application

Before you publish a submitted application, test it in a non-production instance. To begin testing, an admin must open the deployment request and select **Approve**. The pipeline record is read and determines the next state for the request.

The goal of testing the application is to ensure the viability of the production instance. When the app has transitioned to the Testing state, ServiceNow Automated Test Framework tests run if you have enabled the appropriate properties.

If the application doesn't pass testing, then you reject the deployment request.

Deploying to a test environment

When you deploy or install an application to a test environment, two jobs are automatically executed:

- Application Deployment Test Suite
- Scoped App Definitions instance scan

These tests can be useful to the administrator for diagnosing issues before an app is deployed. For more information about what goes on during an application deployment, see Pipelines and Deployments workflow version 24.1.2.

Jobs automatically run during deployment

Job	Description
Application Deployment Test Suite	A set of Automated Test Framework (ATF) tests. The suite consists of a single test called **Log**. When the test is run, scan results are logged to the Test Results [sys_atf_test_result] table. **Note:** The following two system properties must be enabled to run the Application Deployment Test Suite: • sn_atf.runner.enabled • sn_atf.schedule.enabled If they aren't enabled, only the instance scan runs. For more information, see Enable Automated Test Framework (ATF) properties.
Scoped App Definitions instance scan	Instance scans aid in diagnosing health issues on a non-production instance, and are

Jobs automatically run during deployment (continued)

Job	Description
	useful for addressing best practices. For more information, see Instance Scan. The instance scan checks all tables in the app that extend Task [task].

The admin can view the results of the scans for troubleshooting purposes by selecting the **Deployment Environment Results** tab in the deployment request.

Simply open the record of the instance. The results are split into three tabs:

- **ATF Results**
  - Test suite name
  - Test URL
  - Success and failure counts
  - Overall error count
- **Instance Scan Results**
  - Scan suite name
  - Scan URL
  - Finding count for the scan
- **Results (JSON)** includes unformatted JSON code of the ATF and instance scan results, as well as any errors identified during the scans. This JSON can also be found in the **Notes** related list.

Publishing an application

If an application passes testing, open the deployment request and deploy the application to your production environment. It is then available to all employees in your organization. For more information, see Managing deployments using pipelines in AEMC.

Guides for more information

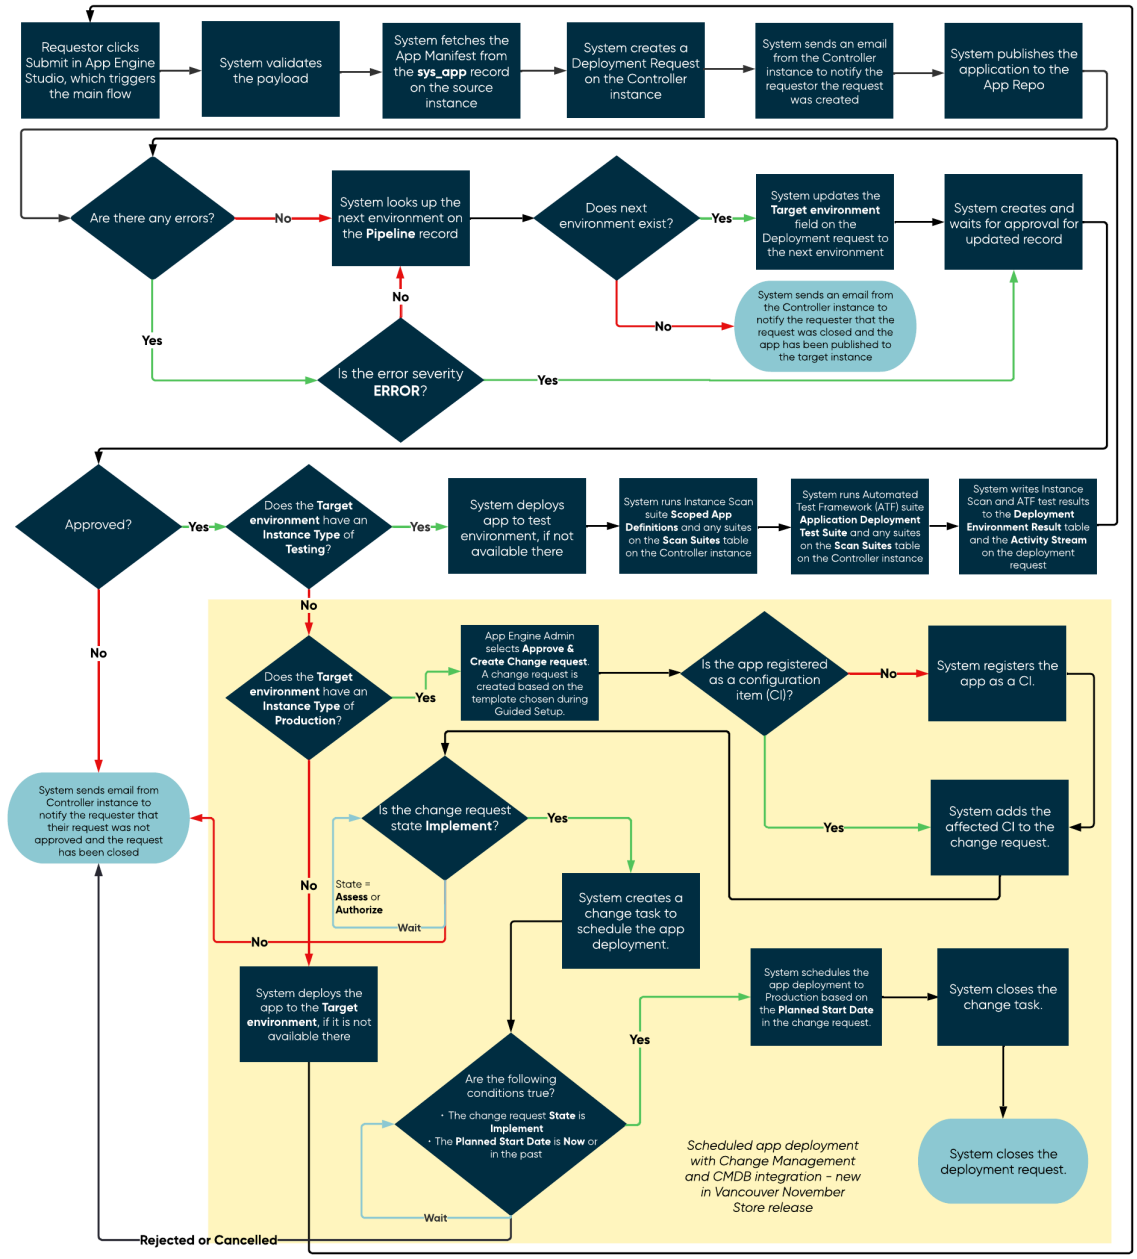
If you need more information, you can try these external guides sponsored by ServiceNow.

Learn more about Pipelines and Deployments	Additional ServiceNow resources
The Pipelines and Deployments app is used to deploy the apps you are creating using App Engine Studio between instances in a pre-defined order. Unlike previous versions, Pipelines and Deployments allows you to deploy your apps to an unlimited number of instances for app creation, testing, staging, and production.	 Promoting apps through the AES pipeline  Create apps fast with App Engine Studio

Pipelines and Deployments workflow version 24.1.2

As you manage requests for app deployment in App Engine Management Center (AEMC), use this workflow to understand how app deployments move through your pipelines in version 24.1.2, released in November 2023.

Pipelines and Deployments workflow



In this workflow:

1. The requester selects **Submit** in App Engine Studio, which triggers the main flow.
2. The system performs the following tasks behind the scenes:
   a. Validates the payload.
   b. Fetches the App Manifest from the **sys_app** record on the source instance.
   c. Creates a deployment request on the controller instance.

d. Sends an email from the controller instance to notify the requester that the request was created.

e. Publishes the application to the Application Repository.

3. The system performs different actions depending on if there are errors or not during publication.

a. If there are errors in the app publication, and the error severity is **Error**, then the system creates and waits for approval for the updated record.

b. If there are no errors, or if there are errors, but the error severity isn't **Error**, then the system looks up the next environment on the Pipeline record.

i. If the next environment doesn't exist, the system sends an email from the Controller instance to notify the requester that the request was closed and the app has been published to the target instance. This action ends the workflow.

ii. If the next environment does exist, the system updates the **Target environment** field on the deployment request to the next environment. Then, the system creates and waits for approval for the updated record.

4. The system performs different actions depending on if the new record was approved.

a. If the record isn't approved, the system sends an email from the Controller instance to notify the requester that the request wasn't approved and the request has been closed. This action ends the workflow.

b. If the record is approved, and if the **Target environment** is **Testing**, then the system performs the following actions:

i. Deploys app to test environment, if the app is not available there.

ii. Runs the Scoped App Definitions Instance Scan and any other suites on the Scan Suites [[scan_suites]] table on the Testing instance.

> **Note:**
> The Scan Suites table should be populated on the Controller instance.

iii. Runs the Application Deployment Test Suite Automated Test Framework (ATF) suite and any suites on the Scan Suites [scan_suites] table on the Testing instance.

iv. Writes Instance Scan and ATF test results to the Deployment Environment Result table and to the Activity Stream on the deployment request.

v. Returns the workflow to step 3, where it checks for errors.

c. If the record is approved, and the **Target environment** is **Production**, the app begins the scheduled deployment process with Change Management integration.

i. The App Engine Admin selects **Approve & Create Change request**. A change request is created based on the template chosen during Guided Setup.

ii. The system performs different actions depending on if the app is registered as a configuration item (CI).

1. If the app is not registered as a CI, the system registers the app as a CI and then adds the affected CI to the change request.

2. If the app is registered as a CI, the system adds the affected CI to the change request.

iii. The system performs different actions depending on if the change request is in the **Implement** state.

1. If the change request state is not **Implement**, and the state is not **Assess** or **Authorize**, the system sends an email from the Controller instance to notify the requester that their request was not approved and has been closed. This ends the workflow.
2. If the change request state is not **Implement**, and the state is **Assess** or **Authorize**, the system waits for the state to be **Implement**.
3. If the change request is in the **Implement** state, the system creates a change task to schedule the app deployment.

iv. If the change request state is **Implement** and the **Planned Start Date** is not **Now** or in the past, the system waits for those two conditions to be true

v. If the change request state is **Implement** and the **Planned Start Date** is **Now** or in the past, but the request is **Rejected** or **Cancelled**, the system sends an email from the Controller instance to notify the requester that their request was not approved and has been closed. This ends the workflow.

vi. If the change request state is **Implement** and the **Planned Start Date** is **Now** or in the past, the system schedules the app deployment to Production based on the **Planned Start Date** in the change request. The system closes the change task, and then closes the deployment request. This ends the workflow.

d. If the record is approved, and the **Target environment** isn't **Testing** or **Production**, then the system deploys the app to the target environment, if it isn't available there.

The workflow starts over when a requester selects **Submit** again in App Engine Studio.

Remove an app from App Engine Studio

If you have the appropriate permissions, you can remove an application from App Engine Studio (AES).

Before you begin

Role required: admin, delete application, or delegated developer with permissions. For more information, see Delegate developers using AES.

About this task

Delegated developers can delete applications based on their permissions. To request delete permissions, contact your administrator.

Procedure

1. Navigate to **All** > **App Engine** > **App Engine Studio**.
2. From the My Apps page, open your application.
3. In your application, select the Edit application properties icon ( ).
4. Select **Delete application**.
5. On the dialog box, enter `delete` and then select **Delete**.

Managing app development using the App Engine Management Center

Track and manage your App Engine Studio (AES) and Creator Studio requests, deployments, applications, and collaborative developers using the App Engine Management Center (AEMC) in your production instance. Additionally, AEMC allows admins to manage app development from intake through production.

AEMC uses Pipelines and Deployments to deploy applications through different instances. Pipelines and Deployments uses the Application Repository to manage these deployments. For more information, see ServiceNow application repository.

Each application can either be deployed using the Application Repository or System Update Sets. If you've used Update Sets in the past, but want to switch to using the Application Repository, you can do a one-time conversion to deploy the app using the Application Repository instead. All apps don't have to follow the same deployment. For more information, see Convert custom applications to upgrade from the application repository and System update sets.

Additional resources for App Engine Management Center

Learn more about App Engine Management Center	ServiceNow resources
Although you can use AEMC in any instance, for full functionality, you must install AEMC in the production instance. You must also set up the deployment pipelines with the controller instance in production. For more information, see Configure Pipelines and Deployments.	 Govern low-code app development at scale with App Engine Management Center  Creator toolbox | App Engine Management Center  Govern low-code app development at scale with App Management Center

Navigating AEMC

From the AEMC Overview screen, you can navigate to four additional views: Requests, Pipelines, Custom apps, and Developers by selecting icons in the primary navigation bar.

AEMC primary navigation bar

Page	Description
Overview	High-level view of all intake, app, collaboration, and deployment requests, with a graph showing new requests of each type over the last 90 days. You can also see a high-level view of your pipelines and application metrics.
Requests	Full list of each request type broken down by approval status.
Pipelines	High-level view of the number of open deployment requests in each instance and within each pipeline. Selecting a pipeline or an environment in a pipeline displays all active deployment requests.

AEMC primary navigation bar (continued)

Page	Description
	Note: If you view deployment requests in a production instance, all **Closed - Published** deployment requests for that environment are listed.
Custom apps	Charts and graphs illustrating the status of your active applications, and a list of all custom apps in development or production. You can view details for individual apps, including usage information, deployment history, and collaborators.
Developers	Charts and graphs illustrating total and active developers, as well as developers by department. You can view details for individual developers, including the apps for which they are collaborators and their request history.

Managing requests using AEMC

You can track and approve or reject Intake, App, Collaboration, and Deployment requests using the App Engine Management Center (AEMC).

To work more efficiently, you can also filter and search for requests.

Manage intake requests

View details of intake requests submitted by developers in App Engine Studio in the App Engine Management Center (AEMC) dashboard, and approve or reject them.

Before you begin

Before intake requests can be displayed in AEMC, you must confirm that the Application Intake application has been properly configured. For more information, see Configure Application Intake. For more information about how to submit intake requests, see Submit your idea for app development.

App requests submitted from Creator Studio restricted users are managed on the App tab on the Requests page. For more information, see Manage app requests from Creator Studio.

Role required: sn_app_eng_notify.app_engine_admin

Procedure

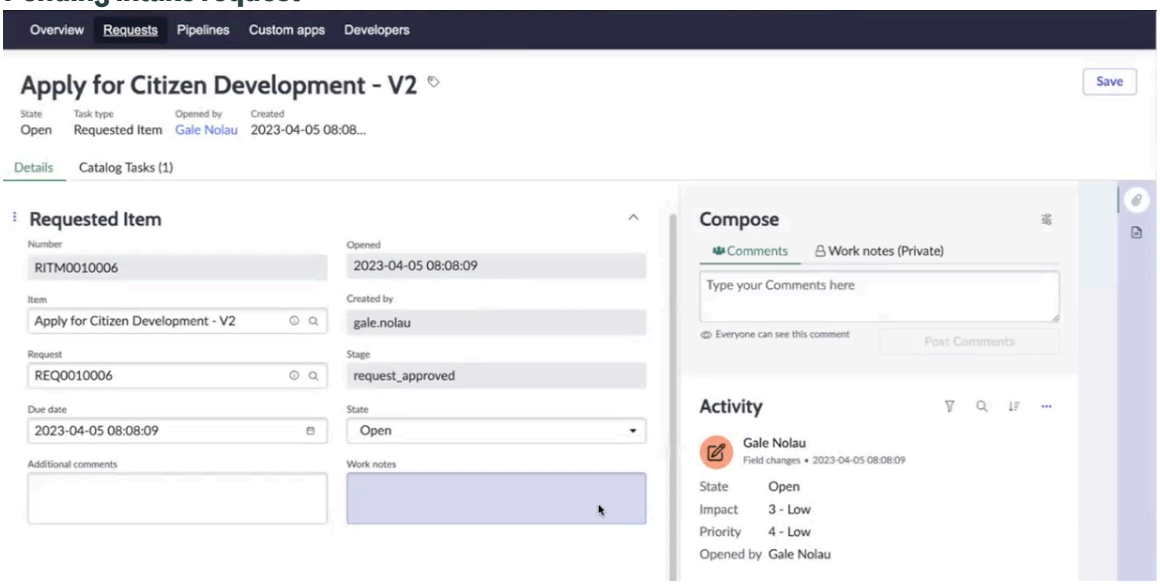
1. Navigate to **All** > **App Engine** > **Administration** > **App Engine Management Center**.

   The AEMC dashboard shows the number of pending intake requests.

   Note: To view a list of all intake requests, either select the number of requests or select the Requests page.

2. Select an intake request to review its details.

Pending intake request



3. Return to the **Details** tab and review the request.

> **Note:**
> The **Administration** section includes a **Development instance** field. Make sure that the development instance the developer intends to use has been selected. Also, if the user isn't defined on that instance, a message displays and you must manually add the user to that instance. For more information, see Create a user.

4. Use the **Permission type** list in the Administration section to select one of the following options for provisioning groups to this application.

5. Approve or reject the request.
   - If the request is approved, the user is added to the App Engine Studio User group and granted the App Engine Studio User role. The AES User role enables developers to begin creating their application in AES in the approved instance. The user also receives an email notification with a link to the provisioned instance. For more information about the AES User role, see Components installed with App Engine Studio.
   - If the request is rejected, a rejection email is sent to the user. The user can submit new requests. However, the rejected request can't be edited.

Manage app requests from Creator Studio

View and manage new app requests in App Engine Management Center (AEMC) that users with the Creator Studio Restricted role (sn_creator_studio_restricted_user) submit for apps they want to create.

Before you begin

Role required: sn_app_eng_notify.app_engine_admin

Procedure

1. Navigate to **All** > **App Engine** > **Administration** > **App Engine Management Center**.
2. View all app requests on the **Requests** page by selecting the **App** tab.
3. Select an app request to view its details.

4. Either approve or reject the request.
   - If the app is useful to your organization, approve the request.
   - If you see issues with the app request, reject the request. If an app request is rejected, the original requestor must put in a new request for the app with changes for reconsideration.

Manage collaboration requests

As an admin, view and approve or reject collaboration requests in the App Engine Management Center (AEMC) from developers who want assistance building their applications.

Before you begin

To view collaboration requests in AEMC, you must first set up Pipelines and Deployments in your production instance. Otherwise, requests are created on the instance where they originated (that is, the instance with App Engine Studio (AES) installed).

Role required: sn_app_eng_notify.app_engine_admin

About this task

Developers with collaboration permissions can access and develop certain parts of an application. Requests for collaboration may come from App Engine Studio or Creator Studio.

Requests from collaborators may be approved automatically depending on permissions or roles they already have.

- For AES collaboration requests, users who have the AES User role are approved automatically.
- Creator Studio users who have already created an app (or have had one created for them) have delegated development permissions, and are automatically approved to collaborate on other apps.
- Current delegated developers without the Creator Studio User or Creator Studio Restricted User roles are automatically approved to collaborate in Creator Studio.

For more information about managing collaboration and permissions, see Collaborate with other developers.

Procedure

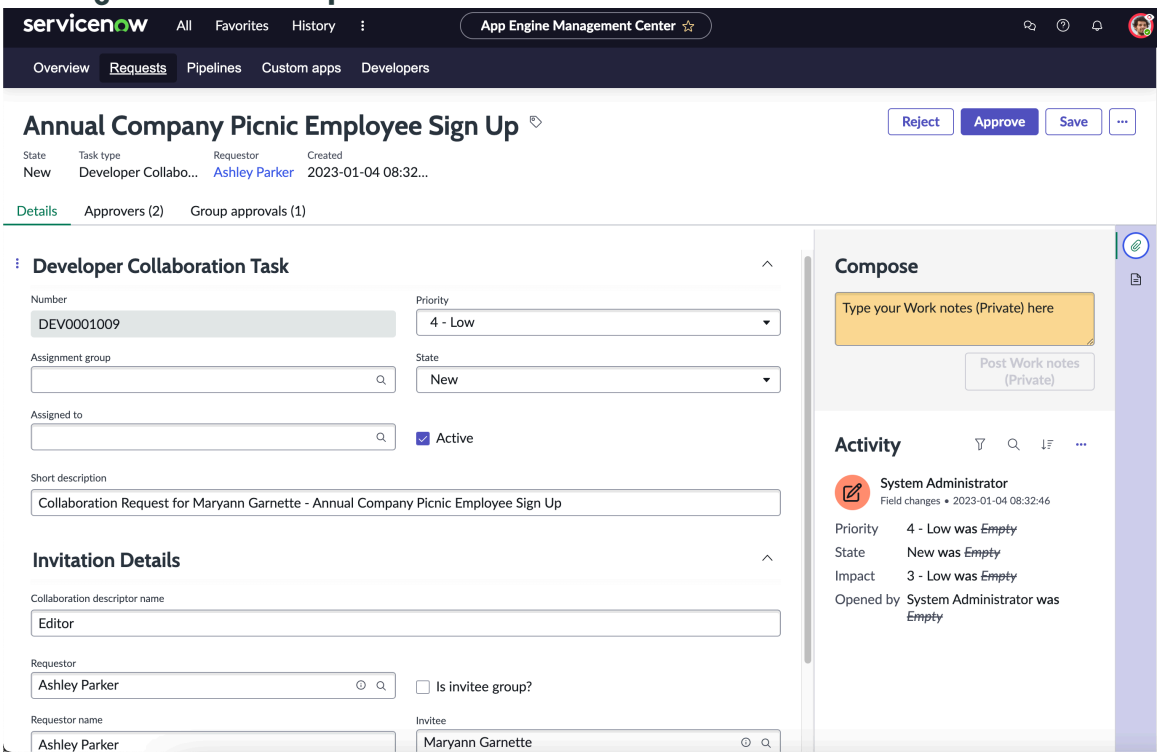
1. Navigate to **All** > **App Engine** > **Administration** > **App Engine Management Center**.

   The AEMC dashboard shows the number of pending collaboration requests.

   Note:
   To view a list of all collaboration requests, either select the number of requests or select the Requests page.

2. Select a collaboration request to review its details.

Pending collaboration request record



3. Return to the **Details** tab and review the request.
4. Approve or reject the request.
   - If the request is approved, the user invited to be a collaborator is added as a developer to the specified app. The collaborator can now work on the parts of the app defined in the Collaboration Descriptor, but cannot concurrently develop other apps in AES. For more information about the AES User role, see Components installed with App Engine Studio.
   - If the request is rejected, the request is closed, and the primary developer is notified by email.

Manage deployment requests

Review and approve or reject deployment requests in the App Engine Studio App Engine Management Center (AEMC) as applications move from development to production.

Before you begin

Role required: sn_app_eng_notify.app_engine_admin

About this task

To view deployment requests in AEMC, pipelines must be configured correctly. For details, see Configure Pipelines and Deployments.

Procedure

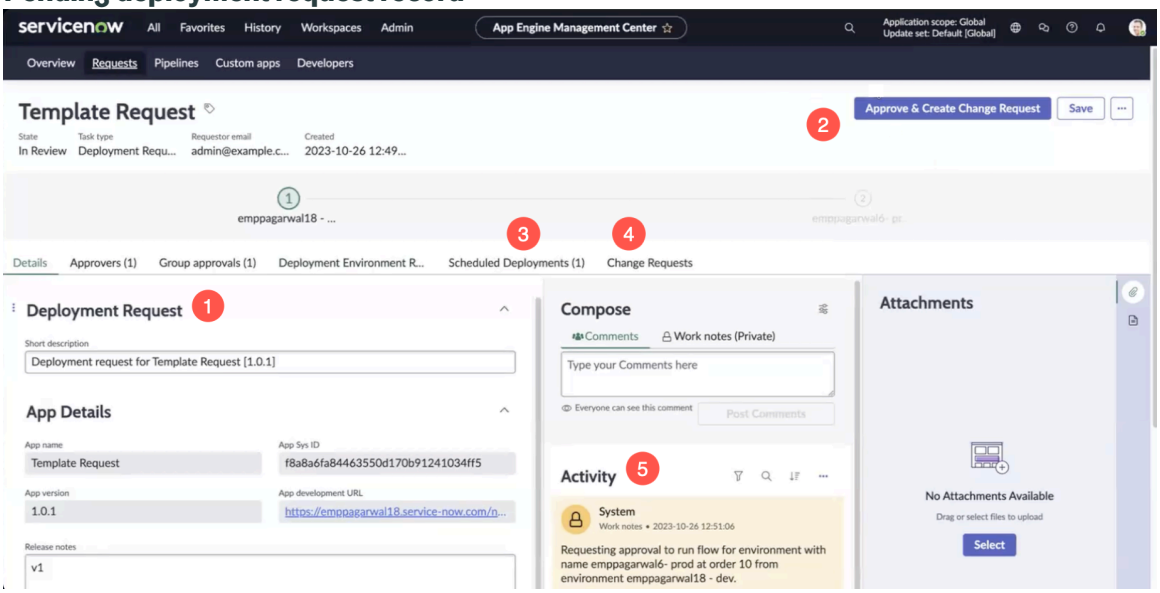
1. Navigate to **All** > **App Engine** > **Administration** > **App Engine Management Center**.

   The AEMC dashboard shows the number of deployment requests.

   Note:
   To view a list of all deployment requests, either select the number of requests or select the Requests page.

2. Select a deployment request to review its details.

Pending deployment request record



3. Review the details of the deployment request, including details about the application, the developer who requested deployment, and the deployment process.

   At the top of each deployment request, you can see the current position of the app in the pipeline.

> **Note:**
> If the request is in a testing environment, you can review the Automated Test Framework (ATF) test and instance scan results in the Activity stream or on the **Deployment Environment Results** tab.

4. Review the notes and application activity for the app manifest and any important details the developer may have added.
5. If a different App Engine Studio (AES) admin must review the deployment request, update the request assignee and select **Save**.
6. Approve or reject the request.
   - To move the application to the next deployment stage, select **Approve & Deploy app**.
   - If you have integrated your existing Change Management processes with AEMC, select **Approve & Create Change Request**. This action creates a change request, which can be seen and monitored on the **Change Requests** tab.
   - If the application is not ready or could potentially cause issues if it was moved on to the next deployment stage, select **Reject**. Add **Work notes** to identify the reasons for the rejection and any changes required to make the application ready for deployment.

> **Note:**
> Unless you are assigned a Change Management role, most of the information on the **Change Request** tab is read-only. You can monitor the change request and see as it changes states. However, if you have Change Management permissions, you may be able to update certain fields on the change request such as the planned start and end date or the state.

Filter and search for requests in AEMC

The App Engine Management Center (AEMC) application provides tools for locating requests. You can perform a global search for request records or filter the list of current requests to locate the ones you want to work on.

Filtering requests

On the Requests, Pipelines, Custom apps, and Developers pages, you can filter the list of requests by several different criteria.

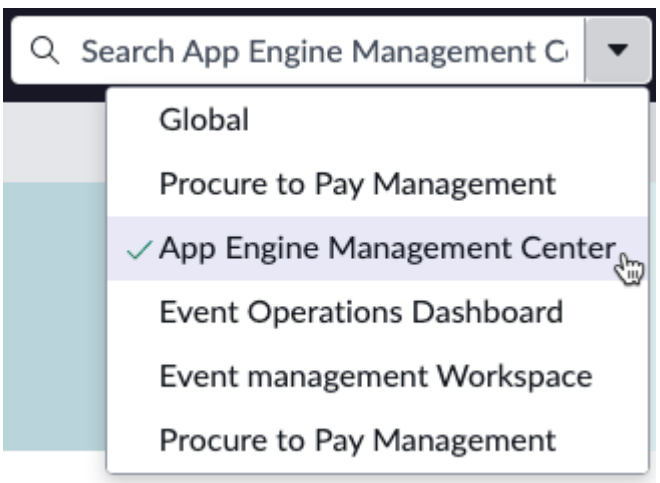
To create a filter, select the filter icon ( ), select **Advanced view**, and add criteria. Build a filter by adding conditions that contain a field, operator, and value(s). You can use an existing filter, save what you create, and limit who can use the filter. Build more complex filters by using the **or** and **and** connectors. Add as many filters as you need, and select **Update**.

When you filter on the Pipelines tab, only instances with requests that match the filtering criteria display information. For example, if your pipeline shows request data in three instances and you filter by an app name used in only one of those instances, only that instance returns results.

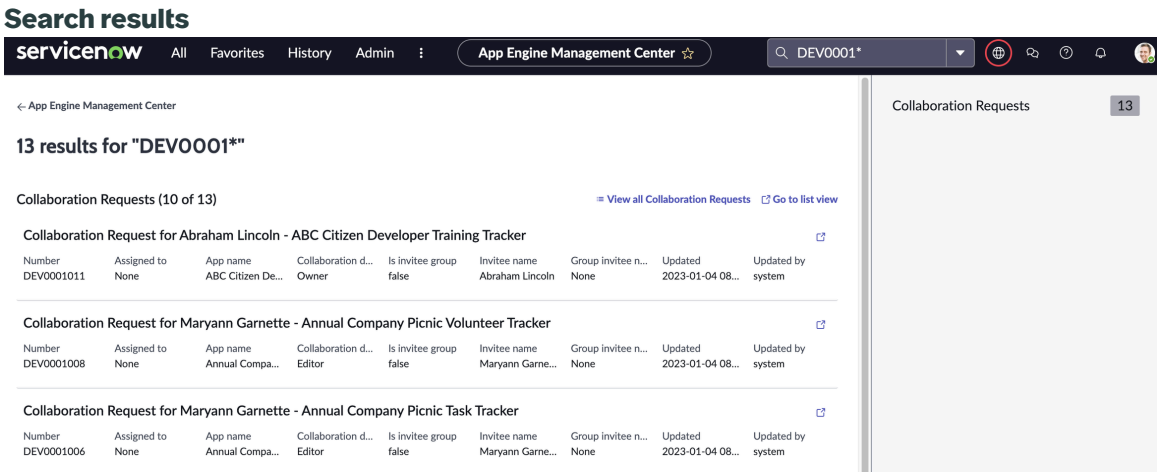
Searching for requests

You can use the **Search** field at the top of any AEMC screen to search for submitted requests. Simply type all or a portion of a request number using an asterisk wild card character, and select **View results**.

Search



For example, you can type DEV0001* and select **View results** (or simply press **Enter**), and a list of all collaboration requests that begin with DEV0001 are returned.

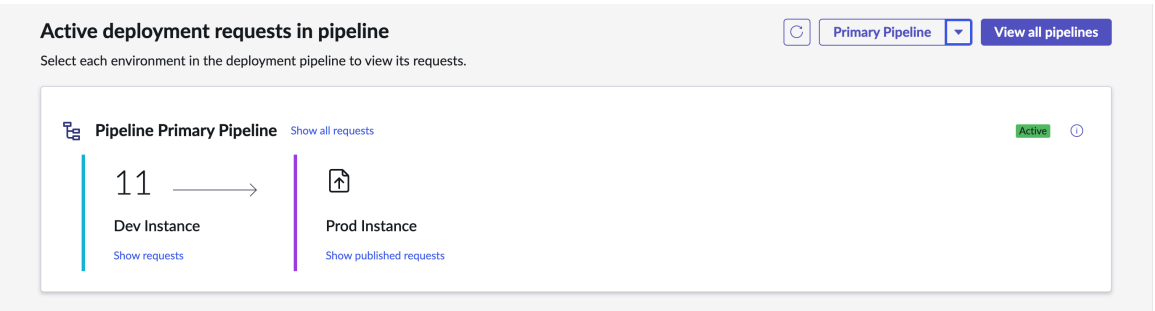


You can then select the record you want to review.

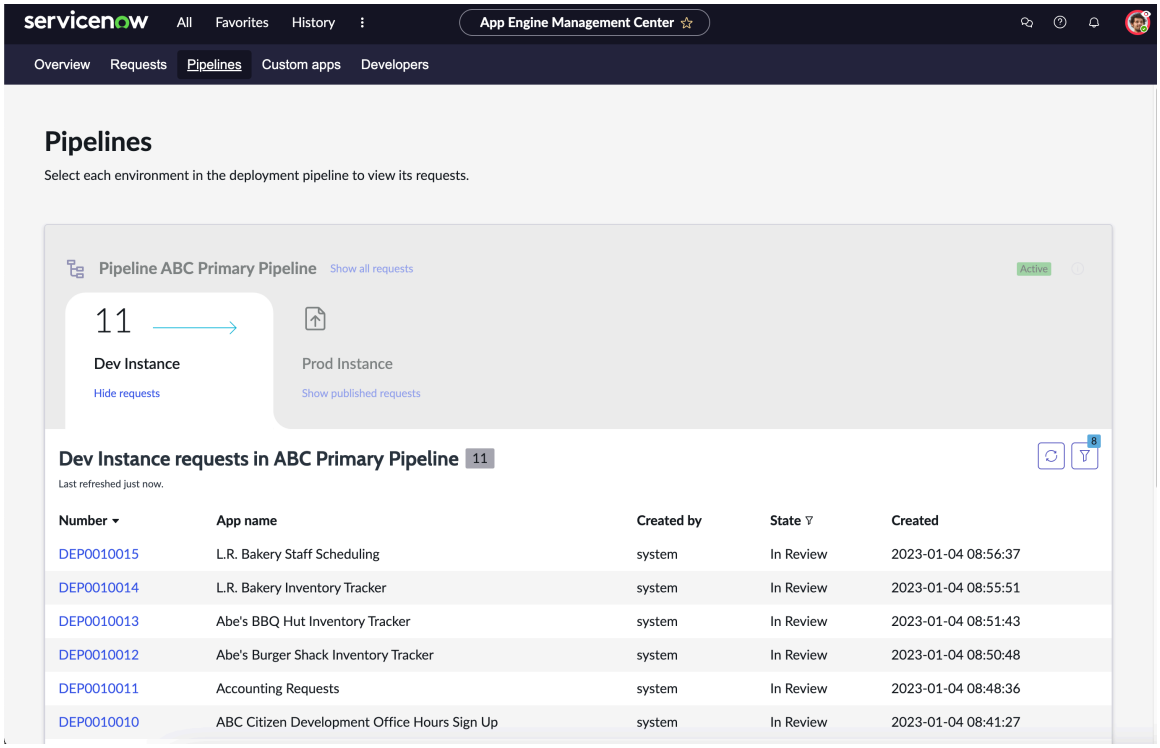
Managing deployments using pipelines in AEMC

Manage applications at all stages of deployment, view multiple pipelines, and approve or reject deployment requests using the App Engine Management Center (AEMC).

The Active deployment requests in the pipeline section of the AEMC Overview page shows the number of apps at each deployment stage within each of your pipelines. You can select **Show all requests**, **Show requests**, or **Show published requests** next to the corresponding sections to see an overview of each group of requests.



For a full picture of all your pipeline deployment requests, access the Pipelines page in AEMC. View all of your pipelines, quickly access each deployment request record, and filter each pipeline section to see only the requests that match your criteria.



Change Management integration

You can integrate an existing Change Management program with your app deployment processes to add oversight into your deployments and have apps deploy according to a scheduled Change window. For more information, see Manage deployment requests.

Schedule app deployments in AEMC

Schedule apps to deploy to production at a future time to load balance your systems using the App Engine Management Center (AEMC).

Before you begin

Role required: admin or app_engine_admin

About this task

Deploying apps through your pipelines requires a certain amount of processing power. Depending on the needs of your organization, you may want to schedule deployments to happen when less processing power is needed elsewhere or when it's generally more convenient.

Procedure

1. Navigate to **All** > **App Engine** > **Administration** > **App Engine Management Center**.
2. On the **Requests** page, select the deployment request for an application that is ready to go to your production environment.
3. Select **Deploy app**.
4. Either deploy your app now or set up a future deployment time.
   - To deploy now, select **Deploy**.
   - To deploy in the future, select **Schedule for later**.
5. **Optional:** If you scheduled the deployment for later, use the date and time picker to select when you want your app to deploy, select **OK**, and select **Deploy**.
   The Activity stream shows the deployment details and the version of the app that will be deployed at the selected date and time. The app is deployed within fifteen minutes of the

selected deployment time. If you want to change this time frame, update how often the deployment workflow checks for a scheduled deployment record by navigating to **All** > **System Definition** > **Scheduled Jobs** > **Scheduled Deployments**.

6. Select **Save**.

Update a deployment request in AEMC

Change the details of a deployment request in App Engine Management Center (AEMC).

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **App Engine** > **Administration** > **App Engine Management Center**.
2. On the **Requests** page, select the deployment request that you want to update.
3. On the **Scheduled Deployments** tab, select the deployment record you want to update.
4. In the **Scheduled Deployment Date** field, select an updated date and time for the app to deploy to production.
5. Select **Save**.

Cancel a scheduled deployment in AEMC

Cancel a scheduled app deployment in App Engine Management Center (AEMC) if you no longer need to deploy the app to production. Canceling the scheduled deployment request cancels the scheduled deployment and also the entire request itself.

Before you begin

Role required: admin

Procedure

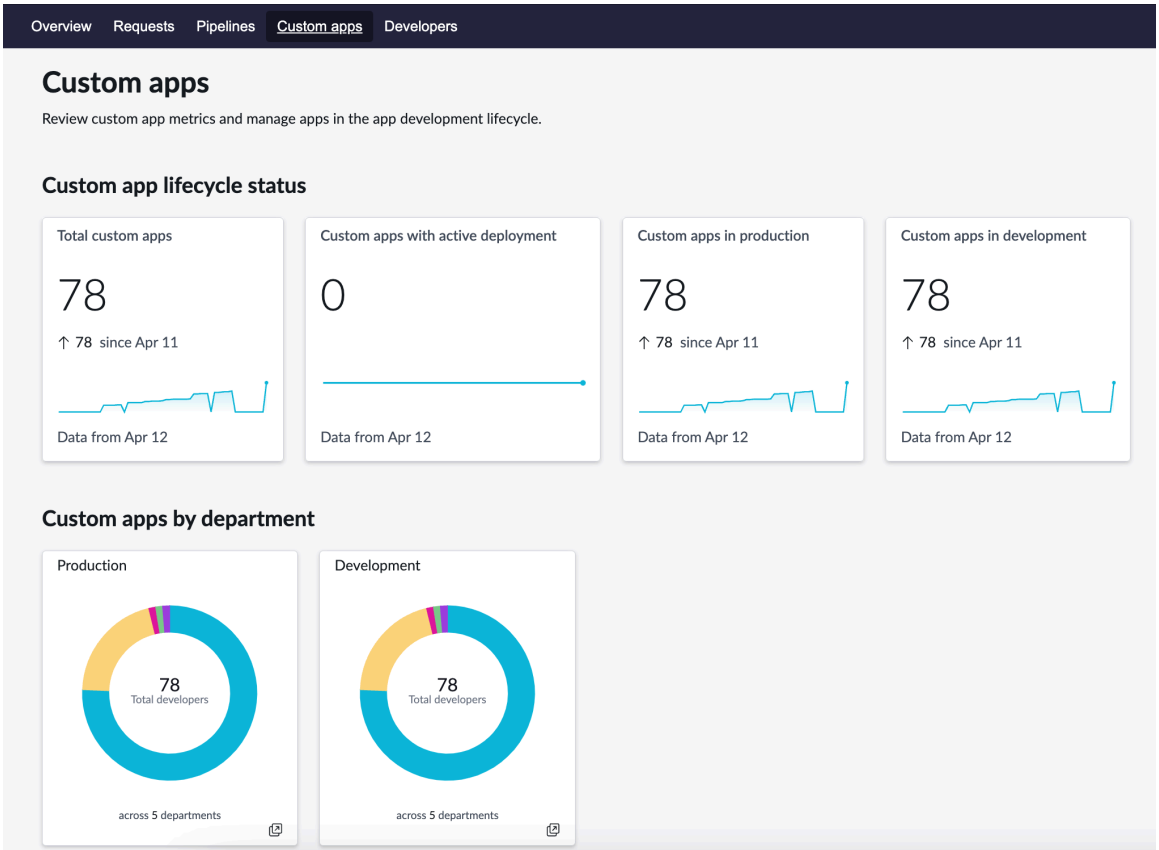
1. Navigate to **All** > **App Engine** > **Administration** > **App Engine Management Center**.
2. On the **Requests** page, select the deployment request that you want to update.
3. On the deployment request, select **Cancel deployment**.

Managing custom apps using AEMC

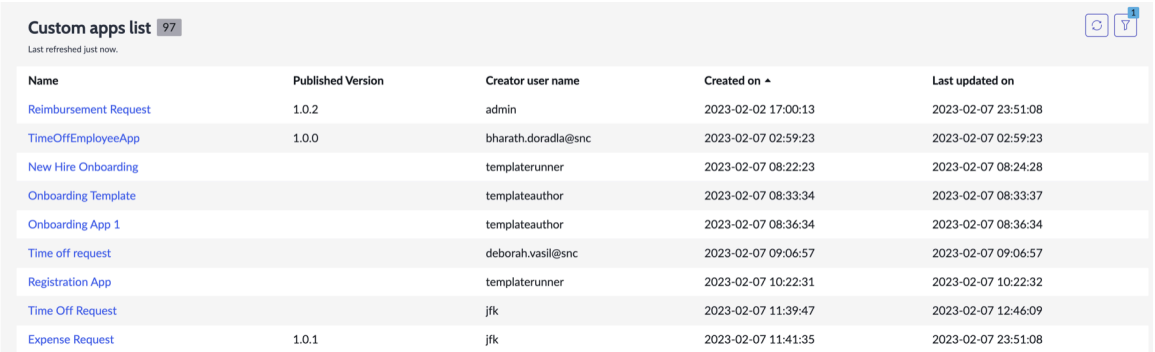
Review custom app metrics and manage apps through the development life cycle using the App Engine Management Center (AEMC).

The App Engine adoption metrics section of the AEMC Overview page shows how many apps you have in development and production environments. Access more information by selecting the large number on each Custom apps card.

The Custom apps page in AEMC shows more detailed metrics and a full list of your applications. In each tile in the Custom app lifecycle status section, you can see trending data for the last 90 days. You can show all apps in the Custom apps list or limit the list to only certain types of applications using the filter. Select a trend chart to filter the list to those criteria.



The Custom app page also lists all the applications individually, with a single record for each application. If the app has been published to production, the **Published Version** column shows the version number. If the **Published Version** column is blank, the app exists in development but has never been published to production.



Custom apps list 97

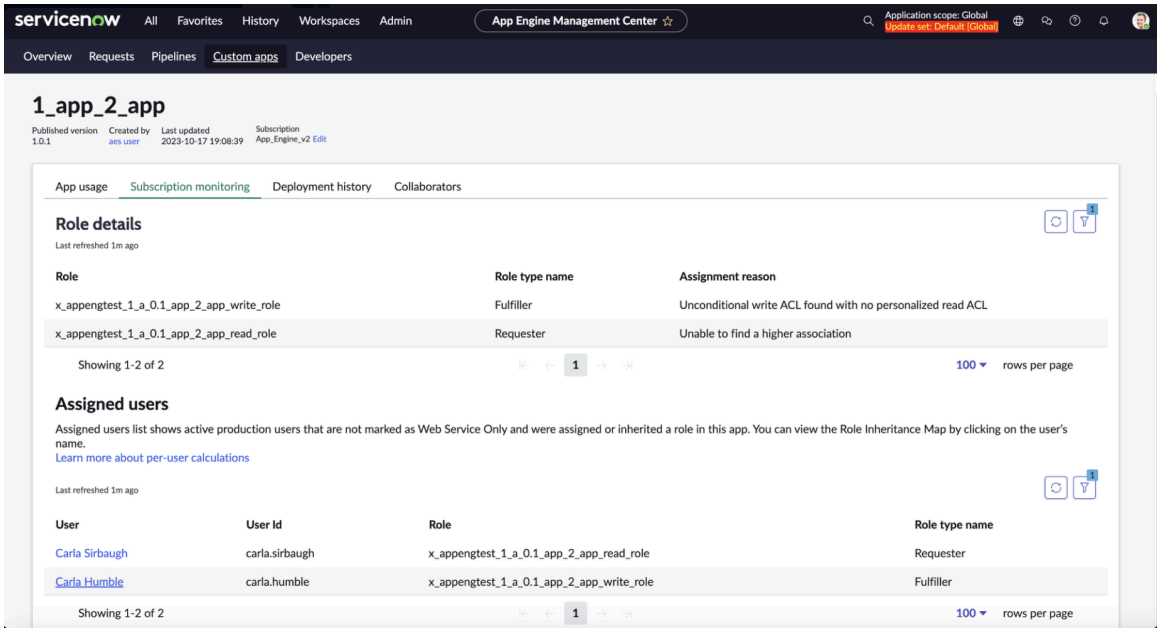
View the app's usage data, subscription monitoring details, deployment history, and collaborators, if any, by selecting an application name from the list.



Select **Open in App Engine Studio** to see the contents of the app and access more information. The App Engine Studio application opens in a new browser window.

App usage

See a high-level view of the usage data for apps on production instances by selecting the **App usage** tab. The data includes the user count, insert count, and update count aggregated for the current month.

- User count: The number of users who have accessed the application.
- Insert count: The number of new records on tables in the application.
- Update count: The number of records in the application that have been updated.

Knowing usage data for your applications has several benefits:

- Discover whether your app is being used. Are people using the app? Are they creating records? If not, consider updating or deleting the app.
- Investigate and fix problems with the app. Knowing when or how data was changed can help identify where something went wrong.
- Determine whether you must load balance the processing power of your instance by seeing when there might be consistently higher traffic in your app.

In the User Experience Analytics dashboards section, see detailed data such as active users, sessions, and page views by selecting an experience. For more information about how to understand and use this data, see User Experience Analytics.

Subscription monitoring

Understand the roles used in your custom application and their implications for licensing and subscriptions. The data in this section includes details about each role and the users assigned to each role.

Knowing subscription and licensing data information for each of your applications has several benefits:

- Discover what roles are active in your custom application.
- Discover which users are assigned each role and the permission levels they have.
- See the cost implications of each license type and where it's used in your apps.

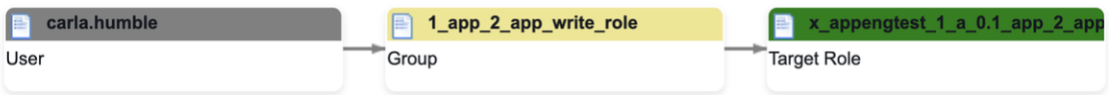
System administrators can see which subscription the app is mapped to and have an option to change the subscription. Several factors affect what you see in this section.

- If the app is mapped to an App Engine subscription, the **Subscription Monitoring** tab is visible.
- If the app is mapped to a different subscription such as ITSM, the **Subscription Monitoring** tab is not visible.
- If the app is mapped to App Engine, is switched to another subscription, and then is changed back to App Engine, the **Subscription Monitoring** tab is visible again.

App Engine admins do not have permissions to change subscriptions. However, if an app is in the production environment, and there is a **Subscription Monitoring** tab, the App Engine admin can infer that the app is mapped to an App Engine subscription. If the **Subscription Monitoring** tab is not there, that app isn't mapped to App Engine.

You can select a user's name in the **Assigned Users** section to see a role inheritance map. This map shows how this user inherited the role, whether from a parent role, a group assignment, or another inheritance. This information can help you take action if someone has a role you believe they shouldn't, and you want to change it.

Role inheritance map



App deployments

View the list of deployments your app has gone through on the **Deployment history** tab.

Knowing deployment history information has several benefits:

- If an app is deployed to production and there’s a defect, you can quickly see when the app was deployed and track down the problem.
- If an app is deployed multiple times, you can quickly track what's changed over multiple deployments.
- If an app is deployed to production, you can quickly see who approved the app deployment.

App collaborators

View the collaborators for the app by selecting the **Collaborators** tab. All collaborators are stored on the Development instance.

If you must take quick action in the application to fix an issue or defect, you can quickly see who has permissions to make changes in an app and what those permissions are.

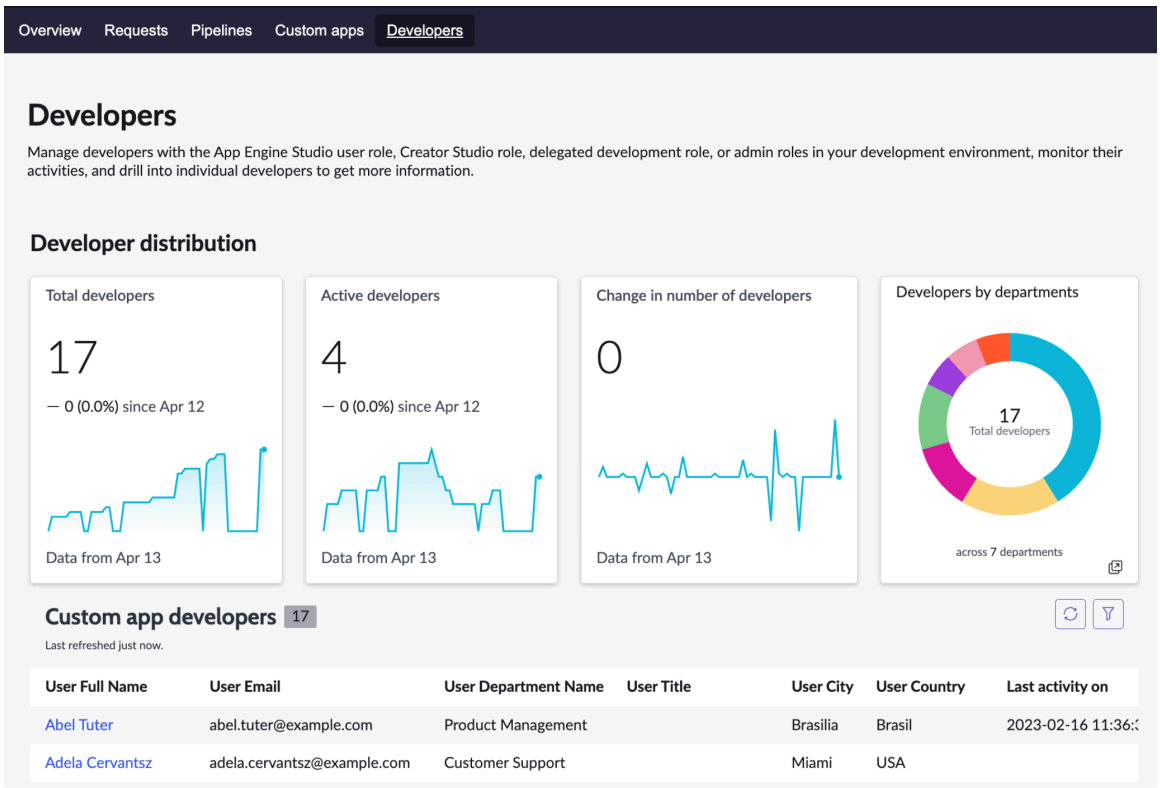
Managing developers using AEMC

View details about developers working on apps in App Engine Studio and Creator Studio using App Engine Management Center (AEMC).

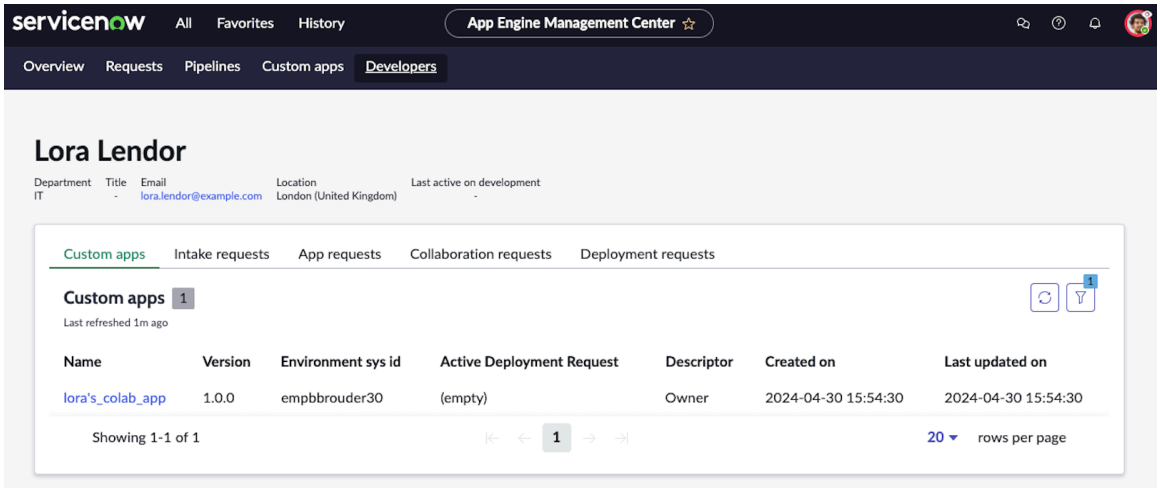
The App Engine adoption metrics section of the AEMC Overview page shows how many developers are working in App Engine Studio (AES) and their departments. Access more information by selecting the **Developers** page.

The Developers page in AEMC shows all developers with the AES Users role, AES User Limited role, Creator Studio Users role, Creator Studio Restricted Users role, or a delegated development role in your development environment. On this page, you can monitor their activities and select individual developers to get more information.

Note:
To remove a developer from the developer tab, you can either revoke all their permissions in Creator Studio, App Engine Studio, Delegated Development, and Admin roles, or deactivate their account on the development instance.



Select a developer record to see more information about the custom apps they have created and their intake requests, app requests, collaboration requests, and deployment requests. You can filter the content on each tab to find specific results, or select an app from this page to see its usage, deployment history, and collaborators. Select any of the displayed records to view the history or to approve, reject, or delete the requests.



App Engine Studio reference

Reference topics provide additional information about the lists and forms that you use to configure and administer App Engine Studio (AES).

AES glossary

Learn about terms and concepts that are unique to App Engine Studio (AES).

Application template

Provides predefined data, experience, logic and automation, and security to support a certain use case. For example, the Travel Request template provides application content for submitting and approving employee travel requests.

For more information on the available templates, see Available templates.

Logic and automation

Automate all the work in your application by adding logic and automation. For example, you can build a flow that sends a notification to the admin when someone makes a request.

Data

Information that is stored in your application. For example, employee phone numbers or office locations. You configure application data using tables.

Deployment request

Ticket to track the review of submitted applications. From the deployment request form, a reviewer can deploy the application to different environments, accept or reject an application, and send feedback to a developer.

Environment

Instance that you use for the developing, testing, or launching an application. To set up App Engine Studio, you must define environments in each of the instances that you're using as environments.

Experience

Graphical interface that your users interact with. For example, you can create a portal where users find information, submit requests, or complete business tasks. For more information on the available application experiences, see Add an application experience.

Pipeline

Configuration for deploying an application to different environments.

Security

Roles and access controls to limit who can use your application.

AES properties

System properties control system behavior. The properties in this section are specific to the App Engine Studio (AES) application. You can access system properties for AES by navigating to **All** > **App Engine Studio** > **Configuration** > **Properties**.

sn_app_eng_studio.show_servicenow_studio_banner

Controls whether the try ServiceNow Studio banner appears on the App Engine Studio home page. Set to true to show the banner or set to false to hide the banner.

- Type: true | false
- Default value: true

sn_app_eng_studio.aes_admin_contact

Defines the contact email for the App Engine Studio administrator. The system sends deployment request notifications to each email address listed in this property. For more information, see Add users to the App Engine Admin group.

- Type: string
- Default value: none

sn_app_eng_studio.illustration_supported_content_types

Defines the supported content types for Taxonomy Category illustrations. This property is read-only.

- Type: string
- Default value: image/svg+xml

sn_app_intake.instance_can_provision_users

Determines if the current instance can support the provisioning of users. The users on this instance will be provisioned to another instance. For more information on provisioning users, see Configure Application Intake.

- Type: true | false
- Default value: false

Deployment Request form in the Pipelines and Deployments app

The Deployment Request form is accessed from within the App Engine Studio (AES) Pipelines and Deployments app.

To view the Deployment Request form, navigate to **All** > **App Engine** > **Pipelines and Deployments** > **Deployment Requests** and open a record.

Deployment Request form

Field	Description
Number	Number to track the deployment request.
Assignment group	Group to which the deployment request is assigned.
State	State of the deployment request. All states are automatically updated by the pipeline flows:

Deployment Request form (continued)

Field	Description
	New The submitted request is new. **In Review** The submitted request is ready for review. **Closed - Published** The submitted request has been deployed to the production instance. **Closed - Rejected** The submitted request is not ready to publish. This state is enabled when you select **Reject** on the associated approval record at any time during the deployment process. The system then prompts you to include the reason why the application is rejected. These comments are then sent via email to the address included in the **Requestor Email** field on the **Requestor Details** related list. **Closed - Failed** This state is enabled when any of the pipeline flows or sub-flows fail for any reason. **Canceled** The submitted request has been canceled.
Assigned to	The user in the assignment group to whom this request is assigned.
Short description	A brief description for the request.
Release notes	Text that appears on the ServiceNow Store for this application after it is published.
App Details	
App name	Name of the submitted application.
App version	Version of the submitted application.
App Sys ID	System ID of the submitted application.
App Development URL	Link to app in App Engine Studio.
Requestor Details	
Requestor First/Last Name	First and last name of the user who requested to the app deployment.
Requestor User ID	Identifier of the user who requested to the app deployment.
Requestor Email	Email address of the user who requested to the app deployment.
Deployment Details	
Originating Environment	The instance of the originating environment.
Pipeline	Pipeline being used for deployment.

Deployment Request form (continued)

Field	Description
Current Environment	The target environment for the app.
Notes	
Additional comments (Customer visible)	Any additional comments to be shared with the customer, including the app manifest, which lists the number of each type of file in the app, and any ATF or instance scan results are shown.
Work notes	Internal notes.

When you have saved the form, additional tabs for approval-related information display. The AES admin can use these tabs to approve the request.

Supported features and metadata in custom templates

Custom templates in App Engine Studio (AES) support most features and metadata, including, but not limited to tables, forms, roles, ACLs, record producers, simple workspaces, flows, and actions.

Custom templates can be created in two ways, either from scratch or using an existing scoped application as a starting point.

When you create a custom template, the pre-scan checks to make sure that everything in the application is supported. There are three possible outcomes.

- All items are supported: The custom template is created. All the objects are available in the custom template and in apps created from the custom template.
- Some items aren't supported: You can continue to create the template but a few items are not available in the custom template. There’s no impact on the custom template or the apps created from the template.
- Some items are denied: You encounter an error message and cannot continue further until the errors are fixed. The author must change the app, if it was created from an existing app or the template, if it was created from scratch.

Note:
Creating an AES template using an application that contains a workspace is not supported.

For more information on the template creation process, see Build a custom template.

ServiceNow CLI

The ServiceNow CLI is a command-line interface that lets you perform instance operations from your local system. You can extend the CLI to include new commands that meet your application's needs.

Benefits

The ServiceNow CLI lets you:

- Perform basic CRUD operations on records in your instance.
- Develop custom components and deploy them to your instance to personalize a UI.
- Create custom commands that enable you to manage custom applications from the command line.
- Use the ServiceNow CLI in scripts to simplify setup tasks and operational activities.

Architecture

Commands are stored in a table on the instance you are connected to. When the ServiceNow CLI connects to the instance, it receives all the available commands supported by that instance.

Commands map to a REST endpoint that executes asynchronously. For more information, see Create a custom command in ServiceNow CLI.

Activating ServiceNow CLI

Install ServiceNow CLI by requesting it from the ServiceNow Store. Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

Configuration file

The ServiceNow CLI stores profile information in a `config.json` file which, by default, is stored in your home directory at the following path:

- Linux and Mac: `~/.snc/config.json`
- Windows: `%USERPROFILE%\.snc\config.json`

The CLI uses this file to determine what information to use to connect to an instance, and what settings to use to generate output. By default, the ServiceNow CLI uses the settings found in the default profile to connect to an instance. To use alternate settings, you can create and reference additional named profiles. For more information, see Configuring and managing your ServiceNow CLI connection profiles.

The following example shows a#configuration#file with a default profile and a named profile. Each profile can use different credentials and specify different hosts and output formats.

```
{
   "profiles":{
      "default":{
         "host":"https://myinstance.service-now.com",
         "loginmethod":"basic",
         "username":"admin",
         "output":"json",
         "hostversion":"Paris",
         "appversion":"1.0"
         },
      "user1":{
         "host":"https://otherinstance.service-now.com",
         "loginmethod":"basic",
         "username":"user1",
         "output":"yaml",
         "hostversion":"Paris",
         "appversion":"1.0"
         }
      }
}
```

Note:
Sensitive credential information is only stored in the OS keychain, not in the configuration file.

Command structure

ServiceNow CLI commands follow this structure:

1. The base call to the `snc` program.
2. The top-level command group followed by any child command groups.
3. The command that specifies which operation to perform.
4. General CLI arguments required by the operation. You can specify arguments in any order.

```
$ snc <command-group> <command> [arguments]
```

Arguments can take various types of input values, such as numbers, strings, and JSON objects. The types supported depend on the command you specify.

Argument values

Many argument values in the ServiceNow CLI are simple string or numeric values, such as the table and table name in the following example.

```
$ snc record create --table incident --data "{short_description:
 'New Incident'}"
```

You can surround strings that do not contain any space characters with quotation marks or not. However, you must use quotation marks around strings that include one or more space characters.

Output formats

The ServiceNow CLI supports four output formats:

- `json`: The output is formatted as JSON. This is the default.

```
{
   "default": {
      "appversion": "1.0.8",
      "host": "https://myinstance.service-now.com",
      "hostversion": "Paris",
      "loginmethod": "basic",
      "output": "json",
      "username": "admin"
   },
   "user1": {
      "appversion": "1.0.8",
      "host": "https://otherinstance.service-now.com",
      "hostversion": "Paris",
      "loginmethod": "basic",
      "output": "yaml",
      "username": "admin"
   }
}
```

- `yaml`: The output is formatted as YAML. Use YAML to handle the output with services and tools that emit or consume YAML-formatted strings.

```
default:
   appversion: 1.0.8
   host: https://myinstance.service-now.com
   hostversion: Paris
   loginmethod: basic
   output: json
   username: admin
user1:
   appversion: 1.0.8
   host: https://otherinstance.service-now.com
   hostversion: Paris
   loginmethod: basic
   output: yaml
   username: admin
```

- `text`: The output is formatted as multiple lines of tab-separated string values. Use this output with traditional UNIX text tools such as grep, sed, and awk, and the text processing performed by PowerShell.

```
default   https://myinstance.service-now.com   Paris   1.0.8
 basic   admin   json
user1   https://otherinstance.service-now.com   Paris   1.0.8
 basic   admin   yaml
```

- `table`: The output is formatted as a table which presents the information in a human-readable format.

```
NAME   HOST   HOST   VERSION   APP   VERSION   LOGIN   METHOD
 USERNAME   OUTPUT
-----------------------------------------------------------------
---------------
```

```
default   myinstance   Paris   1.0.8   basic   admin   json
user1   otherinstance   Paris   1.0.8   basic   admin   yaml
```

- `none`: The CLI does not print the output to the console. Success, error, and progress messages still display.

You can specify command output in two ways:

Use the `output` option in a named profile in the configuration file

The following example sets the default output format to text.

```
{
    "profiles":{
       "default":{
          "output":"text"
       }
}
```

Use the `--output` argument on the command line

The following example sets the output of a single command to JSON. This option on the command overrides any currently set value in the configuration file.

```
$ snc record query --table incident --query
 'active=true' --output json
```

Install the ServiceNow CLI

Install the ServiceNow CLI on a Mac, Windows, or Linux machine.

The latest version of the ServiceNow CLI is 1.1.0. To find your installed version and see if you must update, run `snc version`.

Installing the ServiceNow CLI requires:

- Admin rights to install software on your machine.
- Software to extract or unzip the downloaded package.

The sn_cli_metadata plugin needs to be installed on your instance to support full CLI functionality.

Role required: admin

Available for the following operating systems:

- Mac
- Windows
- Linux

Install the ServiceNow CLI on Mac

Install ServiceNow CLI on a Mac OS using the installer.

Before you begin

You must have an Apple-supported version of 64-bit Mac OS.
Role required: admin

Procedure

1. In your browser, download the installer bundle from the ServiceNow Store.
2. Extract the OS-specific installers.
3. Open the `snc-1.0.0-osx-installer` file.
4. Follow the on-screen instructions.
   a. When prompted, ensure the **Add to PATH** option is selected.
   This option requires root account access.
5. To verify that the installation succeeded, use the following commands.

```
$ which snc

/usr/local/bin/snc
```

```
$ snc version

{
 "extensions": {},
 "snc": "1.0.0"
}
```

Install the ServiceNow CLI on Windows

Install ServiceNow CLI on a Windows OS using the installer.

Before you begin

You must have a 64-bit version of Windows 10 or later.
Role required: admin

Procedure

1. In your browser, download the installer bundle from the ServiceNow Store.
2. Extract the OS-specific installers.
3. Open the `snc-1.0.0-windows-x64-installer.exe` file.
4. Follow the on-screen instructions.
   By default, the CLI installs to `C:\Program Files\ServiceNow CLI`.
5. To confirm the installation, check the version in the command line using the following command.

```
C:\>snc version

{
 "extensions": {},
 "snc": "1.0.0"
}
```

   If Windows is unable to find the program, close and reopen the command prompt window to refresh the path.

Install the ServiceNow CLI on Linux

Install ServiceNow CLI on a Linux machine using the installer.

Before you begin

You must have a 64-bit version of a recent distribution of CentOS or Ubuntu.
Role required: admin

Procedure

1. In your browser, download the installer bundle from the ServiceNow Store.
2. Extract the OS-specific installers.
3. Open the `snc-1.0.0-linux-x64-installer.run` file.
4. Follow the on-screen instructions.
   a. When prompted, ensure the **Add to PATH** option is selected.
   This option requires root account access.
5. To verify that the installation succeeded, use the following commands.

```
$ which snc

~/ServiceNow CLI/bin/snc
```

```
$ snc version

{
 "extensions": {},
 "snc": "1.0.0"
}
```

Configuring and managing your ServiceNow CLI connection profiles

Create a connection profile to connect with your instance, view connection profiles, refresh your connection and available commands, or delete profiles you no longer need.

The ServiceNow CLI stores profile information in a `config.json` file which, by default, is stored in your home directory at the following path:

- Linux and Mac: `~/.snc/config.json`
- Windows: `%USERPROFILE%\.snc\config.json`

The CLI uses this file to determine what information to use to connect to an instance, and what settings to use to generate output. By default, the ServiceNow CLI uses the settings found in the default profile to connect to an instance. To use alternate settings, you can create and reference additional named profiles. For more information, see Configuring and managing your ServiceNow CLI connection profiles.

The following example shows a#configuration#file with a default profile and a named profile. Each profile can use different credentials and specify different hosts and output formats.

```
{
   "profiles":{
      "default":{
         "host":"https://myinstance.service-now.com",
         "loginmethod":"basic",
         "username":"admin",
         "output":"json",
         "hostversion":"Paris",
```

```
         "appversion":"1.0"
         },
      "user1":{
         "host":"https://otherinstance.service-now.com",
         "loginmethod":"basic",
         "username":"user1",
         "output":"yaml",
         "hostversion":"Paris",
         "appversion":"1.0"
         }
      }
}
```

Create a default profile

Create a connection profile that the ServiceNow CLI uses by default. You must create a default profile to set up the CLI's initial connection with an instance.

About this task

By default, the information in this profile is used when you run a command that does not explicitly specify a profile to use.

> **Note:**
> Sensitive credential information is only stored in the OS keychain, not in the configuration file.

Procedure

1. Open your system's command-line tool and execute this command.

   ```
   $ snc configure profile set
   ```

   The CLI prompts you for more information.

2. Enter the requested values.
   When prompting for information, the CLI displays current values in brackets []. To keep an existing value, press the Enter key.

Requested information	Description
Host	The host name of the instance to connect to. Supports both the full URL (https://my-instance.service-now.com) or just the host name (my-instance).
Login method	The login method to use to connect to the instance. Supports `Basic`, `OAuth`, and `OAuth + MFA`.
Username	The user name to use to connect to the instance.
Password	The password to use to connect to the instance.
Client id	The client ID to use to connect to the instance when the login method is OAuth or OAuth + MFA.
Client secret	The client secret to use to connect to the instance when the login method is OAuth or OAuth + MFA.
Authentication code	The authentication code to use to connect to the instance when the login method is OAuth + MFA.

Requested information	Description
Default output format	Specifies how to format the command results. Options are `json`, `yaml`, `text`, and `table`.

Example

```
$ snc configure profile set

Host:
https://myinstance.service-now.com

Login Method (Basic, OAuth, OAuth + MFA):
Basic

Username:
myusername

Password:
mypassword
```

3. Run any command using the values specified in your default profile by omitting the `--profile` attribute from your command.

   Example

   ```
   $ snc record create
   ```

   The command creates a record in the instance specified in the default profile with the specified connection options.

Create a named profile

Create a named connection profile to use with specific commands. This allows you to specify a different instance or connection protocol for a specific command.

Before you begin

A default profile must first exist to communicate with an instance.

About this task

Note:
Sensitive credential information is only stored in the OS keychain, not in the configuration file.

Procedure

1. Open your system's command-line tool and execute this command.
2. Specify the name of the named profile in the *`profile-name`* argument.

   ```
   $ snc configure profile set [--profile profile-name]
   ```

   The CLI prompts you for more information.
3. Enter the requested values.
   When prompting for information, the CLI displays current values in brackets []. To keep an existing value, press the Enter key.

Requested information	Description
Host	The host name of the instance to connect to. Supports both the full URL (https://my-instance.service-now.com) or just the host name (my-instance).
Login method	The login method to use to connect to the instance. Supports `Basic`, `OAuth`, and `OAuth + MFA`.
Username	The user name to use to connect to the instance.
Password	The password to use to connect to the instance.
Client id	The client ID to use to connect to the instance when the login method is OAuth or OAuth + MFA.
Client secret	The client secret to use to connect to the instance when the login method is OAuth or OAuth + MFA.
Authentication code	The authentication code to use to connect to the instance when the login method is OAuth + MFA.
Default output format	Specifies how to format the command results. Options are `json`, `yaml`, `text`, and `table`.

Example

```
$ snc configure profile set --profile user1

Host:
https://mytestinstance.service-now.com

Login Method (Basic ,OAuth ,OAuth + MFA):
Basic

Username:
myusername

Password:
mypassword
```

4. Run any command using the values specified in your named profile by adding the`#--profile# <profile-name>` attribute to your command.

Example

```
$ snc record create --profile user1
```

The command creates a record in the instance specified in the `user1` profile with the specified connection options.

View profiles

View all connection profiles set in the configuration file, or view information about a specific profile.

Before you begin

A default profile must first exist to communicate with an instance.

About this task
For each profile, the CLI displays host information, version details, user name, login method, and preferred output format. It does not display sensitive information such as passwords or client IDs.

Procedure

Open your system's command-line tool and execute this command.

Include the `[--profile profile-name]` argument to view the connection information for a single profile. Otherwise, the CLI lists information for all profiles.

```
$ snc configure profile list [--profile profile-name]
```

Example

This command displays all configured profiles.

```
$ snc configure profile list
```

The CLI provides the following output.

```
{
   "profiles":{
      "default":{
      "host":"https://myinstance.service-now.com",
      "loginmethod":"basic",
      "username":"admin",
      "output":"json",
      "hostversion":"Paris",
      "appversion":"1.0"
   }
}
```

Remove a profile

Remove a named connection profile that you no longer need from the configuration file.

Before you begin
A default profile must first exist to communicate with an instance.

About this task
You cannot remove the default connection profile using this command. To remove the default connection profile, edit the configuration file manually.

Procedure

1. Open your system's command-line tool and execute this command.
2. Specify the name of the named profile in the *`profile-name`* argument.

```
$ snc configure profile remove [--profile profile-name]
```

Result
The CLI removes the specified profile from the configuration file.

Refresh your connection

Update the available commands from the instance for the given profile. Refresh your connection after modifying any of the commands on the corresponding instance in order to keep the CLI up-to-date.

Before you begin

A default profile must first exist to communicate with an instance.

Procedure

Open your system's command-line tool and execute this command.

Include the `[--profile profile-name]` argument to refresh connection information from a named profile. If you do not include the argument, the CLI refreshes the default profile.

```
$ snc configure profile refresh [--profile profile-name]
```

Result

The CLI connects to the instance in the designated connection profile and updates any commands that may have changed.

Get help with ServiceNow CLI

See available commands, command options, and examples, or generate debug logging output.

Before you begin

- Install the ServiceNow CLI
- Configuring and managing your ServiceNow CLI connection profiles
- Role required: none

About this task

In addition to the debug logging output option, the CLI logs all command executions to a log file at the following locations:

- Linux and Mac: `~/.snc/.logs`.
- Windows:`%USERPROFILE%\.snc\.logs`.

Procedure

1. To see the available commands and arguments, open your system's command-line tool and enter the command you need help with, followed by the `--help` argument.

   Example

   The following example displays help for the available top-level commands.

   ```
   $ snc --help
   ```

   Example

   The following example displays the available profile-specific commands.

   ```
   $ snc configure profile --help
   ```

   The CLI displays help for the requested command divided into eight sections:

Name

The name of the command.

```
Name
     set
```

Description

The description of what the command does and its return values.

```
Description
     Configure connection profiles. This command
 is interactive and will prompt you for each
 configuration value.
```

Synopsis

The basic syntax for using the command and its options.

```
Synopsis
     snc configure profile set [arguments]
```

Available commands

The commands available under the current command group.

```
Available Commands
 list    : Lists the configured connection profiles.
 refresh : Updates the available commands from the
 instance for the given profile.
 remove  : Removes the specified connection profile.
 set     : Configures connection profiles in order to
 communicate with an instance.
```

Command groups

The command groups available under the current command group.

```
Command Groups
     profile : Set, view, and remove connection
 profiles.
```

Arguments

A description of each of the arguments the command accepts.

```
Arguments
     -p, --profile string : Use a specific connection
 profile when executing a command.
```

Global arguments

The global arguments that the command accepts.

```
Global Arguments
     -d, --debug Print logs to console.
     -h, --help Display detailed help information.
     -o, --output string Set the format for printing
 command output.
```

Examples

Examples of the requested command.

```
Examples
   Create a new profile to save as the default:
      $ snc configure profile set
         Host:
         Login method:
         Username:
         Password:
         Client id:
         Client secret:
```

2. To generate debug logging output, open your system's command-line tool and enter the command you want to debug, followed by the `--debug` argument.

Example

The following example generates debug logging output when trying to perform the operation.

```
$ snc record delete --table incident --sysid
 552c48888c033300964f4932b03eb092 --debug
```

The CLI generates debug logging output when executing the command.

Perform record operations using ServiceNow CLI

Create, read, update, delete, and query records in your instance using the ServiceNow CLI command-line tool.

- Install the ServiceNow CLI
- Configuring and managing your ServiceNow CLI connection profiles

Note:
To perform record operations, install the CLI Metadata application from the ServiceNow Store on the instance you want to connect to.

Create a record

Inserts a single record in a specified table.

Before you begin

Role required: sn_cli_metadata.cli_admin, sn_cli_metadata.cli_user, or admin

About this task

Note:
You cannot insert multiple records using this command.

Procedure

Open your system's command-line tool and execute this command.

```
$ snc record create [--table table --data data]
```

Pass in values for these arguments.

Parameter	Description
table	Required. Name of the table in which to save the record.
data	Required. Field name and the associated value for each field to define in the specified record in JSON string format.

Result

The system creates a record in the designated table and returns field-value pairs of the new record.

Example:

```
$ snc record create --table incident, --data
 "{'short_description': 'Unable to open file', 'impact':'3'}"
```

The system returns the record in JSON format.

```

Delete a record

Deletes the specified record from the specified table.

Before you begin

Role required: sn_cli_metadata.cli_admin, sn_cli_metadata.cli_user, or admin

Procedure

Open your system's command-line tool and execute this command.

```
$ snc record delete [--table table --sysid sys_id]
```

Pass in values for these arguments.

Parameter	Description
table	Required. Name of the table in which to delete the record.
sysid	Required. Sys_id of the record to delete.

Example:

```
$ snc record delete --table incident --sysid
 552c48888c033300964f4932b03eb092
```

Get a record

Retrieves a single record based on the specified sys_id from the specified table.

Before you begin

Role required: sn_cli_metadata.cli_admin, sn_cli_metadata.cli_user, or admin

Procedure

Open your system's command-line tool and execute this command.

```
$ snc record get [--table table --sysid sys_id]
```

Pass in values for these arguments.

Parameter	Description
table	Required. Name of the table from which to retrieve the record.
sysid	Required. Sys_id of the record to retrieve.

Example:

```
$ snc record get --table incident --sysid
 552c48888c033300964f4932b03eb092
```

The system returns the record in JSON format.

```

}
```

Query records

Retrieves multiple records from a specified table.

Before you begin

Role required: sn_cli_metadata.cli_admin, sn_cli_metadata.cli_user, or admin

Procedure

Open your system's command-line tool and execute this command.

```
$ snc record query [--displayvalue displayValue --fields fields
 --limit limit --offset offset --query query --table table]
```

Pass in values for these arguments.

Parameter	Description
displayValue	Include `--displayvalue` to retrieve the display value from the database for reference and choice fields. Do not include this parameter to retrieve the actual values.
fields	Comma-separated list of field names to return from the database.
limit	Maximum number of records to return.
offset	Starting record index for which to begin retrieving records. Use this value to paginate record retrieval.
query	Required. Encoded query used to filter the result set in the following format: `--query '<column_name><operator><value>'`.
table	Required. Name of the table in which to query the records.

Example:

```
$ snc record query --displayvalue --fields
 short_description,state --query '123TEXTQUERY321=email' --table
 incident
```

The CLI returns any records that match the query.

```
{
   "result": [
      {
         "short_description": "Unable to connect to email",
         "state": "Closed"
      }
   ]
}
```

Update a record

Updates the specified record with the given data attributes.

Before you begin

Role required: sn_cli_metadata.cli_admin, sn_cli_metadata.cli_user, or admin

Procedure

Open your system's command-line tool and execute this command.

```
$ snc record update [--sysid sys_id --table table --data data]
```

Pass in values for these arguments.

Parameter	Description
table	Required. Name of the table in which to save the record.
sysid	Required. Sys_id of the record to update.
data	Required. Field name and the associated value for each field to define in the specified record in JSON string format.

Example:

```
$ snc record update --sysid 9ef81de2db0d6090d7055268dc961978
 --table incident --data "{'short_description': 'Email servers
 down', 'urgency':'1'}"
```

The system returns field-value pairs for the updated record.

```
{
   "result": {
      "active": "true",
      "activity_due": "",
      "additional_assignee_list": "",
      "approval": "not requested",
      "approval_history": "",
      "approval_set": "",
      "assigned_to": "",
      "assignment_group": {
         "link":
 "https://my-instance.service-now.com/api/now/table/sys_user_gro
up/287ebd7da9fe198100f92cc8d1d2154e",
         "value": "287ebd7da9fe198100f92cc8d1d2154e"
      },
      "business_duration": "",
      "business_service": "",
      "business_stc": "",
      "calendar_duration": "",
      "calendar_stc": "",
      "caller_id": "",
      "category": "inquiry",
      "caused_by": "",
      "child_incidents": "0",
      "close_code": "",
      "close_notes": "",
      "closed_at": "",

Create a custom command in ServiceNow CLI

Manage your custom application from the command line by creating custom commands in the ServiceNow CLI.

Before you begin

Role required: admin

About this task

A ServiceNow CLI command maps to a scripted REST endpoint in the End Point [sn_cli_metadata_end_point] table. You can define a scripted REST endpoint to perform a function in your custom application, or use any existing REST endpoint. Then map a CLI command to execute the REST call.

Procedure

1. Make a REST endpoint available to a ServiceNow CLI command.

   a. Navigate to **Command Line Interface (CLI)** > **End Points**.

   b. Select **New** and complete the form.

Field	Description
Resource Path	Required. Path to the endpoint on the instance to map a command to. Can be the path to an inbound REST API, or a scripted REST API. For example, `api/now/table/{table}/{sysid}`. For more information, see Available REST APIs and Scripted REST APIs.
HTTP Method	Required. HTTP method to use when the user runs the associated command.
Application	Read-only application scope for the endpoint.

2. **Optional:** Create a command group.
   Alternatively, you can add your new command to an existing command group.

a. Navigate to **Command Line Interface (CLI)** > **Command Groups**.

b. Select **New** and complete the form.

Field	Description
Name	Required. Name of the command group.
Parent Group	Parent command group.
Reference Group	Command group to reference. For example, you can create a new command group as an alias for an existing command group. When the user calls a referenced command using the new command group, the original command executes. This enables you to create a command group specific to your custom application that includes both new and existing commands.
Short Description	Required. Short description for the command group.
Description	Description of the command group used as help text when the user runs the `--help` command on the command group.
Application	Read-only application scope for the command group.
Active	When selected, the command group is active.

3. Create a command.

a. Navigate to **Command Line Interface (CLI)** > **Commands**.

b. Select **New** and complete the form.

Field	Description
Name	Required. Name of the command.
Command Group	Required. Command group that the command is a part of.
Reference Command	Command to reference. For example, you can create a new command as an alias for an existing command. When the user calls the new command, the original command executes. This enables you to create a command specific to your custom application that executes existing functionality. **Note:** A command cannot reference a command that references another command, or reference a descendant command, an ancestor command, or a callback command.
API Endpoint	Required. API call to execute when the user runs the command.
Short Description	Required. Short description of the command.
Application	Read-only application scope for the command.

Field	Description
Active	When selected, the command is active.
Is Callback Command	When true, designates the command as a callback command. Select this option to hide the command from the CLI client and prevent users from calling it from the command line. Use this field with the **Callback** section of a primary command. The callback command executes when the primary command is complete.
Help Text	
Description	Description of the command used as help text when the user runs the `--help` command.
Examples	Examples of the command used as help text when the user runs the `--help` command.
Expressions	
Success Expression	Expression used to evaluate the response from the server and determine if the command succeeded. For example, `result.code = 1`.
Failure Expression	Expression used to evaluate the response from the server and determine if the command failed.
Messages	
Success Message	Message displayed on the CLI client when the command is successful.
Progress Message	Message displayed on the CLI client when the command is in progress.
Failure Message	Message displayed on the CLI client when the command fails.
Callback	
Callback Expression	Expression used to determine whether to execute the callback command. For example, you can write an expression that checks on a long-running process. If the expression produces a certain result, the callback executes.
Callback Command	Command to execute when the **Callback Expression** is satisfied. Must be a command with the **Is Callback Command** field selected.
Callback Interval	The interval between callback command executions. Unit: Milliseconds Default: 1,000
Max Retries	Maximum number of times the callback command executes. Default: 10

c. In the Command Arguments related lists, create any command arguments needed for the command.

Create a command argument to allow users to set options when running a command.

Field	Description
Name	Required. Name of the command argument, for example `data`.
Short Name	Short dame of the command argument, for example `d`.
Data Type	Required. Type of data expected for the command argument. Options include: ▪ String: Allows users to enter a string as input. ▪ Integer: Allows users to enter a number as input. ▪ Boolean: Allows users to enter `true` or `false` as input. ▪ File Input: Allows users to upload a file as input. Map this argument to a Body **Parameter Type** in the API Endpoint Arguments related list in the next step. Users can pass plain text, YAML, JSON, or another file type accepted by the REST API. When the user submits a YAML file, the CLI client converts to file to JSON format by default. Use the **Skip Pre-processing** field to disable this behavior. ▪ Password: Allows users to securely enter a password as input. **Note:** For File Input data types, the file size limit is 10 MB by default. However, you change this limit using the *`glide.rest.scripted.max_inbound_content_length_mb`* system property.
Skip Pre-processing	Set this flag to prevent the CLI client from converting YAML files into JSON format before sending them in the request. When **Data Type** is set to **File Input** and the user submits a YAML file, the CLI client converts the file to JSON before executing the command by default. **Note:** Only applies when **Data Type** is set to **File Input**.
Default Value	Default value to use when the user does not pass a value.
Short Description	Required. Short description of the command argument. Used as help text when the user runs the `--help` command.
Application	Read-only application scope for the argument.
Command	Required. Command that the argument applies to.
Mandatory	When selected, the user must provide a value for the argument when running the associated command.
Prompt	Prompt to request information from the user. The CLI prompts for information when the user does not include a required argument in a command.
Visibility Expression	Expression used to determine whether the CLI should prompt for the argument. Typically used to display an argument based on the value provided to a previous argument.

Field	Description
Order	Order in which to prompt for the argument.

d. In the API Endpoint Arguments related lists, create any API endpoint arguments needed for the command.

Map command arguments from the Command Arguments related list to parameters in your REST endpoint.

Field	Description
Name	Required. Name of the argument.
Value	Required. The value from the command that you want to pass to the REST endpoint. You can pass a static value, or an expression such as `{flags.table}`. Use the `flags` global variable to access the command arguments.
Parameter Type	Required. The type of parameter in the REST endpoint that you want to pass the **Value** to. For example, if you select **Body**, the CLI passes the value of the **Value** field to the REST endpoint body. Options include: ▪ Body ▪ Header ▪ Path ▪ Query
Application	Read-only application scope for the argument.
Command	Required. Command that the argument applies to.

e. In the Return Values related lists, create any return values needed for the command.

Create return values to only return certain keys from the response.

Field	Description
Path Expression	Required. Expression representing the path to the key that you want to return.
Alias	Variable name to assign the return value to.
Application	Read-only application scope for the command.
Command	Required. Command that the return value applies to.

Result

When the user runs the ServiceNow CLI command, the system executes the associated REST API call and returns the result to the ServiceNow CLI.

Manage ServiceNow CLI extensions

Add extensions to the ServiceNow CLI to load additional functionality and commands, update existing extensions, or remove extensions you no longer need.

Procedure

1. Find available extensions.

   a. Open your system's command-line tool and execute this command.

   ```
   $ snc extension list-available -o table
   ```

   The system lists available extensions and associated details.

   ```
   NAME       DESCRIPTION
    VERSION            INSTALLED
   ------------------------------------------------------------------
   -------------------------
   ui-component        Build and deploy components
       19.0.0-alpha.15     false
   ```

2. Install an extension.

   a. Open your system's command-line tool and execute this command.

   ```
   $ snc extension add --name <extension-name>
   ```

3. **Optional:** Update an extension.

   a. Open your system's command-line tool and execute this command.

   ```
   $ snc extension update --name <extension-name>
   ```

4. **Optional:** Remove an extension.

   a. Open your system's command-line tool and execute this command.

   ```
   $ snc extension remove --name <extension-name>
   ```

ServiceNow CLI available commands

Commands and command arguments available to the base system ServiceNow CLI.

Global command arguments

Use command arguments to set options for any CLI commands.

--help

Provides help information for the specified command, which includes the description, supported arguments, and examples. For more information, see Get help with ServiceNow CLI.

```
$ snc --help
```

--debug

provides debug logging output when executing a command. For more information, see Get help with ServiceNow CLI.

```
$ snc record delete --table incident --sysid
 552c48888c033300964f4932b03eb092 --debug
```

--profile

Specifies the named profile to use for a command. For more information, see Configuring and managing your ServiceNow CLI connection profiles.

```
$ snc configure profile set --profile <profilename>
```

--output

Specifies the output format to use for a command. The ServiceNow CLI supports the following output formats.

- `json`: The output is formatted as JSON. This is the default.

```
{
   "default": {
      "appversion": "1.0.8",
      "host": "https://myinstance.service-now.com",
      "hostversion": "Paris",
      "loginmethod": "basic",
      "output": "json",
      "username": "admin"
   },
   "user1": {
      "appversion": "1.0.8",
      "host": "https://otherinstance.service-now.com",
      "hostversion": "Paris",
      "loginmethod": "basic",
      "output": "yaml",
      "username": "admin"
   }
}
```

- `yaml`: The output is formatted as YAML. Use YAML to handle the output with services and tools that emit or consume YAML-formatted strings.

```
default:
   appversion: 1.0.8
   host: https://myinstance.service-now.com
   hostversion: Paris
   loginmethod: basic
   output: json
   username: admin
user1:
   appversion: 1.0.8
   host: https://otherinstance.service-now.com
   hostversion: Paris
   loginmethod: basic
   output: yaml
   username: admin
```

- `text`: The output is formatted as multiple lines of tab-separated string values. Use this output with traditional UNIX text tools such as grep, sed, and awk, and the text processing performed by PowerShell.

```
default   https://myinstance.service-now.com   Paris
 1.0.8   basic   admin   json
user1   https://otherinstance.service-now.com   Paris
  1.0.8   basic   admin   yaml
```

- `table`: The output is formatted as a table which presents the information in a human-readable format.

```
NAME   HOST   HOST   VERSION   APP   VERSION   LOGIN
 METHOD   USERNAME   OUTPUT
-------------------------------------------------------
-------------------------
default   myinstance   Paris   1.0.8   basic   admin
 json
user1   otherinstance   Paris   1.0.8   basic   admin
  yaml
```

- `none`: The CLI does not print the output to the console. Success, error, and progress messages still display.

```
$ snc record query --table incident --query
 'active=true' --output json
```

--no-interactive

Prevents the CLI from prompting the user for argument values. If the user does not pass a value for a required argument, the system uses the default value. If no default value is defined, the system throws an error.

--no-verbose

The command executes silently without messages. Use this argument in automated testing scenarios.

Configure profile

Create a connection profile to connect with your instance, view connection profiles, refresh your connection and available commands, or delete profiles you no longer need. For more information about configuring your profile, see Configuring and managing your ServiceNow CLI connection profiles.

Set up a default profile

Create a connection profile that the ServiceNow CLI uses by default. You must create a default profile to set up the CLI's initial connection with an instance.

```
$ snc configure profile set
```

The system prompts you for the following information:

Requested information	Description
Host	The host name of the instance to connect to. Supports both the full URL (https://my-instance.service-now.com) or just the host name (my-instance).

Requested information	Description
Login method	The login method to use to connect to the instance. Supports `Basic`, `OAuth`, and `OAuth + MFA`.
Username	The user name to use to connect to the instance.
Password	The password to use to connect to the instance.
Client id	The client ID to use to connect to the instance when the login method is OAuth or OAuth + MFA.
Client secret	The client secret to use to connect to the instance when the login method is OAuth or OAuth + MFA.
Authentication code	The authentication code to use to connect to the instance when the login method is OAuth + MFA.
Default output format	Specifies how to format the command results. Options are `json`, `yaml`, `text`, and `table`.

Set up a named profile

Create a named connection profile to use with specific commands. This allows you to specify a different instance or connection protocol for a specific command.

```
$ snc configure profile set [--profile profile-name]
```

The system prompts you for the following information:

Requested information	Description
Host	The host name of the instance to connect to. Supports both the full URL (https://my-instance.service-now.com) or just the host name (my-instance).
Login method	The login method to use to connect to the instance. Supports `Basic`, `OAuth`, and `OAuth + MFA`.
Username	The user name to use to connect to the instance.
Password	The password to use to connect to the instance.
Client id	The client ID to use to connect to the instance when the login method is OAuth or OAuth + MFA.
Client secret	The client secret to use to connect to the instance when the login method is OAuth or OAuth + MFA.
Authentication code	The authentication code to use to connect to the instance when the login method is OAuth + MFA.
Default output format	Specifies how to format the command results. Options are `json`, `yaml`, `text`, and `table`.

View profiles

View all connection profiles set in the configuration file, or view information about a specific profile.

```
$ snc configure profile list [--profile profile-name]
```

Remove a profile

Remove a named connection profile that you no longer need from the configuration file.

```
$ snc configure profile remove [--profile profile-name]
```

Refresh a profile

Update the available commands from the instance for the given profile. Refresh your connection after modifying any of the commands on the corresponding instance in order to keep the CLI up-to-date.

```
$ snc configure profile refresh [--profile
 profile-name]
```

Perform record operations

Create, read, update, delete, and query records in your instance using the ServiceNow CLI command-line tool. For more information about performing record operations, see Perform record operations using ServiceNow CLI.

Create a record

Inserts a single record in a specified table.

```
$ snc record create [--table table --data data]
```

Pass in values for these arguments.

Parameter	Description
table	Required. Name of the table in which to save the record.
data	Required. Field name and the associated value for each field to define in the specified record in JSON string format.

Delete a record

Deletes the specified record from the specified table.

```
$ snc record delete [--table table --sysid sys_id]
```

Pass in values for these arguments.

Parameter	Description
table	Required. Name of the table in which to delete the record.
sysid	Required. Sys_id of the record to delete.

Get a record

Retrieves a single record based on the specified sys_id from the specified table.

```
$ snc record get [--table table --sysid sys_id]
```

Pass in values for these arguments.

Parameter	Description
table	Required. Name of the table from which to retrieve the record.
sysid	Required. Sys_id of the record to retrieve.

Query records

Retrieves multiple records from a specified table.

```
$ snc record query [--displayvalue displayValue
 --fields fields --limit limit --offset offset --query
 query --table table]
```

Pass in values for these arguments.

Parameter	Description
displayValue	Include `--displayvalue` to retrieve the display value from the database for reference and choice fields. Do not include this parameter to retrieve the actual values.
fields	Comma-separated list of field names to return from the database.
limit	Maximum number of records to return.
offset	Starting record index for which to begin retrieving records. Use this value to paginate record retrieval.
query	Required. Encoded query used to filter the result set in the following format: `--query '<column_name><operator><value>'`.
table	Required. Name of the table in which to query the records.

Update a record

Updates the specified record with the given data attributes.

```
$ snc record update [--sysid sys_id --table table
 --data data]
```

Pass in values for these arguments.

Parameter	Description
table	Required. Name of the table in which to save the record.
sysid	Required. Sys_id of the record to update.
data	Required. Field name and the associated value for each field to define in the specified record in JSON string format.

Work with extensions

Add extensions to the ServiceNow CLI to load additional functionality and commands, update existing extensions, or remove extensions you no longer need. For more information, see Manage ServiceNow CLI extensions.

Find available extensions

```
$ snc extension list-available -o table
```

Install an extension

```
$ snc extension add --name <extension-name>
```

Update an extension

```
$ snc extension update --name <extension-name>
```

Remove an extension

```
$ snc extension remove --name <extension-name>
```

Use the ui-component extension

Add the ui-component extension

Add the ui-component extension to the ServiceNow CLI.

```
$ snc extension add --name ui-component
```

Set up your project

Create the component project and the set of files required to develop a component. You can connect to your instance and create an application scope for your component, or you can reserve a scope to verify later.

```
$ snc ui-component project [--name name --description
 description --scope scope --offline]
```

Pass in values for these arguments.

Name	Description
name	Required. The project name. Must be a valid and unique npm package name.
description	The project description to be available in the npm registry and the plugins list in your instance.
scope	Suggested application scope to assign to this project and its components. If provided, the instance validates the name. Use the namespace identifier guidelines for application development on the instance. For more information, see Application scope. Maximum: 18 characters. Case: snake case. Default: `x_customerprefix_componentname`, where: • `customerprefix` is the value in the *`glide.appcreator.company.code`* system property on your instance. • `componentname` is the value provided in the component's `name` parameter when you created the project.

Name	Description
	Alternatively, you can add a value to the `scopeName` parameter in the `now-ui.json` file. For more information, see Change a component's application scope.
offline	When true, creates and scaffolds a component while disconnected from your instance. Skips validation of the given scope name. Default: `false`.

Run the development server

Add your component code and test it using a local development server.

```
$ snc ui-component develop [--entry entry --open --port
 port --host host]
```

Pass in values for these arguments.

Name	Description
entry	Path to the test module in your component project. Default: `example/index.js`.
open	Opens the default browser and navigates to the test page. Default: false.
port	Port where the development server runs. Default: 8081.
host	Host address to use if you want your local development server to be accessible externally by others. Typically set to `0.0.0.0`

Deploy a component to an instance

Deploy your component to display in your instance as an application plugin.

```
$ snc ui-component deploy [--open --force]
```

Pass in values for these arguments.

Name	Description
open	When true, opens the default browser and navigates to UI Builder in your instance. Default: false
force	Deploys component changes and overwrites any existing component records. Default: false.

Commands installed with CMDB Application CLI and API

Commands and command groups available to the ServiceNow CLI when the app-cmdb-api-cli plugin is installed.

Request apps on the Store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

To script critical operations which support automation across the enterprise, you can leverage APIs or run command line operations that the CMDB Application CLI and API store app provide instead of using the user interface. The CMDB Application CLI and API store app provides a robust framework which consolidates all the APIs that are related to application services and the command lines that let you access the interface to those APIs.

CMDB Application CLI and API commands enable the following tasks:

- Registering and creating an application service and establishing upstream relationships
- Getting details of a given application service and its upstream relationships
- Connecting higher level constructs such as business applications and business service offerings
- Populating an application service with a given population type
- Changing the state of an application service

For the REST API solution, see SG Services API.

Convert Application Service

Converts a manual or empty type application service to a calculated application service. During conversion, the application service record moves into the [cmdb_ci_service_calculated] table with the newly assigned class.

Command group:

- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure for Mac OS

```
snc service-graph app-service convert --data '{JSON}'
```

Command structure for Windows OS

```
snc service-graph app-service convert --data "{JSON}"
```

Arguments

This command passes a JSON object using the *data* parameter.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

JSON object properties

Name	Description
<IRE field name>	One or more IRE fields identifying the application service. For example, name or version. Data type: String
levels	Number of levels to include in the conversion. Data type: String
number	Unique number that identifies the application service. Data type: String
sys_id	Sys_id of the application service. Data type: String

Example on Mac OS

```
snc service-graph app-service
 convert --data '{"name":"Test
 Register","environment":"Test","version":"1.0","levels
":8}'
```

Example on Windows OS

```
snc service-graph app-service
 convert --data "{"name":"Test
 Register","environment":"Test","version":"1.0","levels
":8}"
```

Return value

```
{
  "result": {
  "status": "success"
  }
}
```

Create Application Service Relationship

Constructs upstream relations such as business applications, business service offerings, and other application services. Running this command creates a relationship, taking input with a single parent and a corresponding child object.

Command group:

- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure for Mac OS

```
snc service-graph app-service create-relationship
 --data '{JSON}'
```

Command structure for Windows OS

```
snc service-graph app-service create-relationship
 --data "{JSON}"
```

Arguments

This command passes a JSON object using the *data* parameter.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

JSON object properties

Name	Description
child	Information identifying the child application service with which to create a relationship. The child is located in the Service Instance [cmdb_ci_service_auto] table. A dynamic CI group can be added as a child but cannot be parent. Data type: Object `"child": { "<IRE field name>": "String", "number": "String", "sys_id": "String" }`
child.<IRE field name>	One or more IRE fields identifying the child application service. For example, name or version. Data type: String

JSON object properties (continued)

Name	Description
child.number	Unique number that identifies the child application service. Data type: String
child.sys_id	Sys_id of the child application service listed in the Service Instance [cmdb_ci_service_auto]. Data type: String
parent	Details identifying the parent application service with which to create a relationship. Data type: Object `"parent": {` `  "<IRE field name>": "String",` `  "number": "String",` `  "sys_id": "String",` `  "class_name": "String"` `}`
parent.<IRE field name>	One or more IRE fields identifying the application service. For example, name or version. Data type: String
parent.number	Unique number that identifies the application service. Data type: String
parent.sys_id	Sys_id of the application service listed in the Service Instance [cmdb_ci_service_auto]. Data type: String
parent.class_name	Name of the class that contains the application service. The parent class name should be from one of the following tables: • cmdb_ci_service_auto • cmdb_ci_service_discovered • cmdb_ci_service_by_tags • cmdb_ci_service_calculated • service_offering • cmdb_ci_business_app Default: cmdb_ci_service_auto Data type: String

Example on Mac OS

```
snc service-graph app-service
 create-relationship --data
 '{"child":{"name":"wdfsdf","environment":"Test","versi
on":"1.0"},"parent":{"sys_id":"abcdefg","name":"busin
ess App1","class_name":"service_offering"}}'
```

Example on Windows OS

```
snc service-graph app-service
 create-relationship --data
 "{"child":{"name":"wdfsdf","environment":"Test","versi
on":"1.0"},"parent":{"sys_id":"abcdefg","name":"busin
ess App1","class_name":"service_offering"}}"
```

Return value

```
{
  "result": {
  "status": "success"
  }
}
```

Delete Application Service

Deletes an application service.

Command group:

- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure for Mac OS

```
snc service-graph app-service delete --data '{JSON}'
```

Command structure for Windows OS

```
snc service-graph app-service delete --data "{JSON}"
```

Arguments

This command passes a JSON object using the *data* parameter.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

JSON object properties

Name	Description
<IRE field name>	One or more IRE fields identifying the application service. For example, name or version. Data type: String
number	Unique number that identifies the application service. Data type: String
sys_id	Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table. Data type: String

Example on Mac OS

```
snc service-graph app-service
 delete --data '{"name":"Test
 Register","environment":"Test","version":"1.0"}'
```

Example on Windows OS

```
snc service-graph app-service
 delete --data "{"name":"Test
 Register","environment":"Test","version":"1.0"}"
```

Return value

```
{
  "result": {
  "status": "success"
  }
}
```

Delete Application Service Relationship

Deletes an application service upstream relationship.

Command group:

- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure for Mac OS

```
snc service-graph app-service delete-relationship
 --data '{JSON}'
```

Command structure for Windows OS

```
snc service-graph app-service delete-relationship
 --data "{JSON}"
```

Arguments

This command passes a JSON object using the *data* parameter.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

JSON object properties

Name	Description
child	Information describing the child relationship to be deleted from the service application. Data type: Object `"child": { "<IRE field name>": "String", "number": "String", "sys_id": "String" }`
child.<IRE field name>	One or more IRE fields identifying the child application service. For example, name or version. Data type: String
child.number	Unique number that identifies the child application service. Data type: String
child.sys_id	Sys_id of the child application service listed in the Service Instance [cmdb_ci_service_auto]. Data type: String
parent	Details identifying the parent application service from which to remove a relationship. Data type: Object `"parent": { "<IRE field name>": "String", "number": "String", "sys_id": "String", "class_name": "String" }`

JSON object properties (continued)

Name	Description
parent.<IRE field name>	One or more IRE fields identifying the application service. For example, name or version. Data type: String
parent.number	Unique number that identifies the application service. Data type: String
parent.sys_id	Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table. Data type: String
parent.class_name	Name of the class that contains the application service. The parent class name should be from one of the following tables: • cmdb_ci_service_auto • cmdb_ci_service_discovered • cmdb_ci_service_by_tags • cmdb_ci_service_calculated • service_offering • cmdb_ci_business_app Default: cmdb_ci_service_auto Data type: String

Example on Mac OS

```
snc service-graph app-service delete-relationship
 --data '{"child":{"name":"Test
 Register","environment":"Test","version":"1.0"},"paren
t":{"name":"business Service
 Offering1","class_name":"service_offering"}}'
```

Example on Windows OS

```
snc service-graph app-service delete-relationship
 --data "{"child":{"name":"Test
 Register","environment":"Test","version":"1.0"},"paren
t":{"name":"business Service
 Offering1","class_name":"service_offering"}}"
```

Return value

```
{
  "result": {
  "status": "success"
```

```
    }
}
```

Find Application Service

Finds the details of a given application service and its upstream relationships.

Command group:

- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin – This role provides unlimited viewing of application services.

app_service_user – This role only provides viewing application services in Operational status.

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure for Mac OS

```
snc service-graph app-service find --data '{JSON}'
```

Command structure for Windows OS

```
snc service-graph app-service find --data "{JSON}"
```

Arguments

This command passes a JSON object using the *data* parameter.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

JSON object properties

Name	Description
<IRE field name>	One or more IRE fields identifying the application service. For example, name or version. Data type: String
number	Unique number that identifies the application service. Data type: String
sys_id	Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table.

JSON object properties (continued)

Name	Description
	Data type: String

Example on Mac OS

```
snc service-graph app-service find --data '{"name" :
 "Test App Service1"}'
```

Example on Windows OS

```
snc service-graph app-service find --data "{"name" :
 "Test App Service1"}"
```

```

Populate Application Service

Populates an application service with a service population method.

Command group:

- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure for Mac OS

```
snc service-graph app-service populate --data '{JSON}'
```

Command structure for Windows OS

```
snc service-graph app-service populate --data "{JSON}"
```

Arguments

This command passes a JSON object using the *data* parameter.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

JSON object properties

Name	Description
<IRE field name>	One or more IRE fields identifying the application service. For example, name or version. Data type: String
number	Unique number that identifies the application service. Data type: String
population_method	Required. Identifies the population method and its accompanying property to identify the content for population. Only one accompanying object is valid per type. Data type: Object
population_method.group_id	Group ID of the CMDB group configured with the cmdb_group population type. Data type: "String" `"population_method": { "group_id": "String", "type": "cmdb_group" }` Associated population type: cmdb_group
population_method.levels	Number of levels to use in building the service. If the level value is

JSON object properties (continued)

Name	Description
	not provided, the system checks the sys_property for the value. If svc.manual.convert.levels.default_value is not populated, a default value of 3 is used. Data type: Number `"population_method": { "levels": Number, "type": "dynamic_service" }` Associated population type: dynamic_service Default: 3 if no level value is set for the sys_property
population_method.service_candidate	Unique identifier of the service candidate. Data type: String `"population_method": { "service_candidate": "String", "type": "tag_based_service_family" }` Associated population type: tag_based_service_family
population_method.service_relations	List of objects containing hierarchy data for the CIs within the application service. All CIs form pairs with a parent and child CI. The top-level CI, referred to as the entry point of an application service, does not have a parent CI. Data type: Array `"population_method": { "service_relations":[ { "child": "String", "parent": "String" } ],`

JSON object properties (continued)

Name	Description
	<pre>"type": "service_hierarchy" }</pre> Associated population type: service_hierarchy
population_method.service_relations.child	Name of a child CI related to the CI. Data type: String
population_method.service_relations.parent	Name of a parent CI related to the CI. Data type: String
population_method.tags	List of objects containing tags to associate with the CI. This information is located in the Key Values [cmdb_key_value] table. Data type: Array <pre>"population_method": { "tags": [{ "tag": "String", "value": "String" }], "type": "tag_list" }</pre> Associated population type: tag_list
population_method.tags.tag	Tag name. Data type: String
population_method.tags.value	Tag value. Data type: String
population_method.type	Required. Population type to add to the application service. Data type: Object Valid values: • cmdb_group • service_hierarchy • dynamic_service

JSON object properties (continued)

Name	Description
	• tag_list • tag_based_service_family
sys_id	Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table. Data type: String

Example on Mac OS

```
snc service-graph app-service
 populate --data '{"name":"Test
 Register","environment":"Test","version":"1.0","popula
tion_method":{"group_id":"String","type":"cmdb_group"
}}'
```

Example on Windows OS

```
snc service-graph app-service
 populate --data "{"name":"Test
 Register","environment":"Test","version":"1.0","popula
tion_method":{"group_id":"String","type":"cmdb_group"
}}"
```

Return value

```
{
  "result": {
  "status": "success"
  }
}
```

Register Application Service

Creates an application service, tags and constructs upstream relationships such as business applications, business service offerings, and other application services.

Command group:

- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure for Mac OS

```
snc service-graph app-service register --data '{JSON}'
```

Command structure for Windows OS

```
snc service-graph app-service register --data "{JSON}"
```

Arguments

This command passes a JSON object using the *data* parameter.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

JSON object properties

Name	Description
<IRE field name>	One or more IRE fields identifying the application service. For example, name or version. Data type: String
number	Unique number that identifies the application service. Data type: String
relationships	Upstream relationships categorized by type. Data type: Object `"relationships": { "business_app": [Array], "business_service_offering": [Array], "parent_app_service": [Array], "technical_service_offering": [Array] }` Maximum number of relationships is 25.
relationships.business_app	List of objects representing Business Application relationship types. These values can be defined using one of the following items as key-value pairs. • <IRE field name> • number • sys_id

JSON object properties (continued)

Name	Description
	Data type: Array
relationships.business_service_offering	List of objects representing Business Service Offering relationship types. These values can be defined using the following items as key-value pairs. • <IRE field name> • number • sys_id Data type: Array
relationships.parent_app_service	List of objects representing Application Service relationship types. These values can be defined using the following items as key-value pairs. • <IRE field name> • number • sys_id Data type: Array
relationships.technical_service_offering	List of objects representing Technical Service Offering relationship types. These values can be defined using the following items as key-value pairs. • <IRE field name> • number • sys_id Data type: Array
sys_id	Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table. Data type: String
tags	List of objects containing tag definitions as key-value pairs. `"tags": [ { "key": "String", "value": "String" }]`

JSON object properties (continued)

Name	Description
	Data type: Array
tags.key	Tag category name. Data type: String
tags.value	Tag value. Data type: String

Example on Mac OS

```
snc service-graph app-service
 register --data '{"name":"Test
 Register","environment":"Test","version":"1.0","number
":"
 SNSVC0001014","relationships":{"business_applicatio
n":[{"sys_id":"0250a94040697410f87713b656474250"},{"num
ber":"APM0001002"},{"name":"Test Biz
 App1"}],"business_service_offering":[{"sys_id":"ed32e9
8040697410f87713b656474259"}],"technical_service_offeri

 Offering2"}],"parent_app_service":[{"sys_id":"a2f06180
40697410f87713b656474255"}]},"tags":[{"key":"key1","val
ue":"value1"},{"key":"key2","value":"value2"}]}"
```

Return value

```
{
  "result": {
    "app_service": {
      "sys_id": "99b2a54040697410f87713b6564742ad",
      "name": "Test Register",
      "number": "SNSVC0001014"
    },
    "message": "Service registered successfully",
```

```
    "status": "INSERT"
  }
}
```

Update Application Service

Updates an existing application service provided and creates tags for the given application service.

Command group:

- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure for Mac OS

```
snc service-graph app-service update --data '{JSON}'
```

Command structure for Windows OS

```
snc service-graph app-service update --data "{JSON}"
```

Arguments

This command passes a JSON object using the *data* parameter.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

JSON object properties

Name	Description
<fields or tags to update>	Use key-value pairs to identify each field or tag to be updated. Only basic information can be updated, no upstream relationships can be updated. Data type: String
<IRE field name>	One or more IRE fields identifying the application service. For example, name or version. Data type: String
number	Unique number that identifies the application service.

JSON object properties (continued)

Name	Description
	Data type: String
sys_id	Sys_id of the application service listed in the Service Instance [cmdb_ci_service_auto]. Data type: String

Example on Mac OS

```
snc service-graph app-service update --data '{"name":
 "Test Register", "version": "2.0"}'
```

Example on Windows OS

```
snc service-graph app-service update --data "{"name":
 "Test Register", "version": "2.0"}"
```

Return value

```
{
  "result": {
    "sys_id": "99b2a5404069741 0f87713b6564742ad",
    "name": "Test Register",
    "number": "SNSVC0001014",
    "version": "2.0"
  }
}
```

Update Application Service State

Changes the application service lifecycle state to activate, deactivate, or retire.

Command group:

- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure for Mac OS

```
snc service-graph app-service update-state --data
 '{JSON}'
```

Command structure for Windows OS

```
snc service-graph app-service update-state --data
 "{JSON}"
```

Arguments

This command passes a JSON object using the *data* parameter.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

JSON object properties

Name	Description
<IRE field name>	One or more IRE fields identifying the application service. For example, name or version. Data type: String
number	Unique number that identifies the application service. Data type: String
state	Required. Lifecycle state of the application service. These values are updated in the Service Instance [cmdb_ci_service_auto] table. Valid values: • ACTIVATE – Life cycle is operational and in use. ○ operational_status=Operational ○ life_cycle_stage=Operational ○ life_cycle_stage_status=In Use • DEACTIVATE – Life cycle is not operational and is in the design stage. ○ operational_status=Non-Operational ○ life_cycle_stage=Design ○ life_cycle_stage_status=Build • RETIRE – End of life. ○ operational_status=Retired ○ life_cycle_stage=End Of Life ○ life_cycle_stage_status=Retired Data type: String
sys_id	Sys_id of the application service listed in the Service Instance [cmdb_ci_service_auto]. Data type: String

Example on Mac OS

```
snc service-graph app-service
 update-state --data '{"name":"Test
 Register","environment":"Test","version":"1.0"}'
```

Example on Windows OS

```
snc service-graph app-service
 update-state --data "{"name":"Test
 Register","environment":"Test","version":"1.0"}"
```

Return value

```
{
  "result": {
  "status": "success"
  }
}
```

App Engine for ERP with the ServiceNow AI Platform

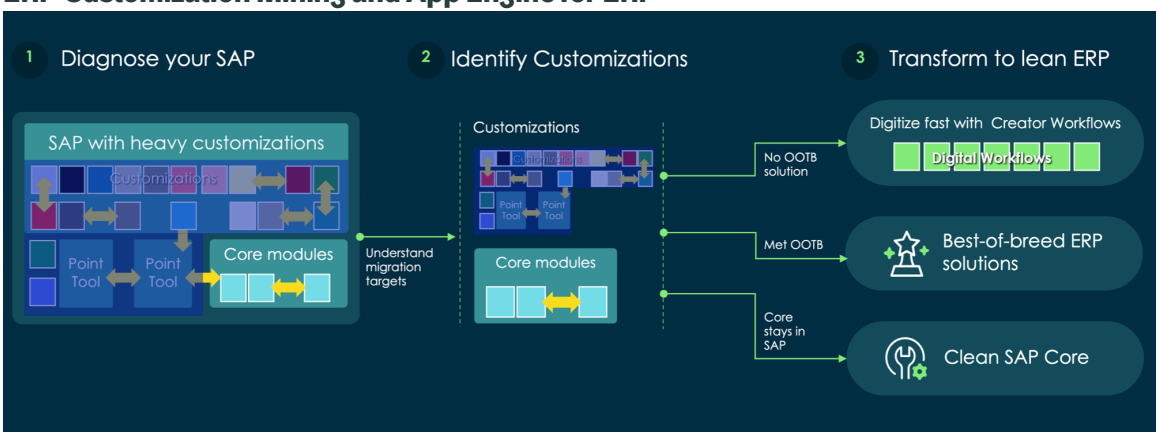
Read and update your legacy ERP (Enterprise Resource Planning) system using ERP Data Hub and identify customizations with ERP Customization Mining (ERP-CM). You can then use additional ServiceNow AI Platform apps, such as App Engine Studio (AES), to organize and replatform ERP data.

Replatforming is the process of scanning legacy ERP system code to find potential candidates to move onto your ServiceNow AI Platform instance as new apps. You can use data from the ERP system as a source for apps built on the ServiceNow AI Platform, improving performance, enhancing security, and reducing maintenance.

Combined benefits of integrating ERP Data Hub and ERP-CM to replatform apps

Legacy systems of records, such as SAP, can have old, complex custom code and data that require more time and effort to move to newer versions of the system of record. Use ERP Data Hub and ERP Customization Mining (ERP-CM) to scan the system of record to find and replace custom code with digitized workflows, resulting in a clean ERP core.

ERP Customization Mining and App Engine for ERP



The replatforming of legacy code enables innovation on top of the system of record without knowledge of the legacy system. Database administrators and developers are then relieved of time-consuming efforts to create database views or endpoints in the system of record, freeing them to work on other projects, such as migration.

Replatformed data is immediately available, mirrored in easy-to-manage tables and apps. Users no longer need to request information from database administrators, which can take weeks. Replatformed apps use the ERP system of record as the live data source.

Workflow for ERP Data Hub and ERP-CM

Using ERP Data Hub and ERP-CM together enables Solutions Integration consultants to implement the following workflow:

1. Have your administrator use the Connections and Credentials app to configure credentials to connect ERP Data Hub to the ERP system of record. For more information, see Connections and Credentials.
2. Create an ERP system in ERP Data Hub using the connection and credentials alias that you configured. For more information, see Create an ERP system in ERP Data Hub.
3. In ERP Data Hub, build your ERP systems, ERP models, and tables in a development instance.
   a. Create or clone an ERP model that scans the specified ERP module in the system of record for available tables and fields. Note the tables and fields in the ERP model for use in extraction and remote tables. For more information, see Clone an ERP model in ERP Data Hub.
   b. Add new tables, fields, and table joins to include additional data in the ERP model. For more information, see the following topics:
      - Managing how models read and update the ERP system
      - Add joins between ERP tables
   c. Create update operation using a BAPI (Business Application Programming Interface) to update data on the ERP system as needed.
   d. Build and customize remote tables to make them available for use as a data source, such as when building apps. Remote tables get their records from running an associated script against an external data source. For more information, see:
      - View and edit ERP remote table details with ERP Data Hub
      - Customize fields for an ERP remote table in ERP Data Hub
      - Query a remote table using ERP Data Hub
   e. Work with ETL extraction tables to regularly scan the system of record and extract data to a staging table. Extraction tables retrieve large amounts of data using a scheduled query, and use transform tables to process data for use on the ServiceNow AI Platform.
      - Create as many separate extraction tables as needed, such as one for each supported country. For more information, see Extracting and transforming data in ERP Data Hub.
      - You must first create the table transform map that connects the source table (on the system of record) to a Glide table on the ServiceNow AI Platform. For more information on creating table transform maps, see Create a transform map.
      - Extraction processes are configured in the ServiceNow app that uses them. For example, Workflow Studio.
      - After the extraction process is run, use import sets to map imported data into ServiceNow AI Platform tables. For more information, see Import sets.
4. Identify legacy ERP system customizations to modernize and replatform with ERP-CM.
5. Move the ERP Data Hub systems, ERP models, and tables to a production environment when they are ready. For more information, see Managing ERP development pipelines in ERP Data Hub.

a. Meet with a customer and agree to run an analysis with ERP Customization Mining on their ERP system of record.

b. Connect the customer ERP system of record to the ServiceNow instance using ERP Data Hub.

> **Note:**
> Most customers have their own instance.

ERP-CM uses the system connections configured in ERP Data Hub. For more information, see Working with ERP systems in ERP Data Hub.

c. Use ERP Data Hub to build ERP models from fields on the available remote tables as specified in previous workflow steps.

d. Run ERP Customization Mining to find candidates. Candidates are custom code in the system of record that you can replace with ServiceNow apps. For more information, see Browse an overview of candidates in ERP-CM.

e. Choose candidates to replatform. For more information, see Save potential candidates to replatform.

f. Use the candidate details in ERP-CM as a central place to enter comments and save attachments relating to the candidate. For more information, see View and work with candidate details in ERP-CM.

g. In the candidate details, identify any similar candidates that you could combine into a single replatformed app. For more information, see How ERP Customization Mining determines candidate score and potential.

h. Return to ERP Data Hub to continue building data models with remote tables and extraction tables. Ensure that all the necessary data is available in the ServiceNow AI Platform. For more information, see Building and managing ERP models to work with ERP data.

6. Use the ERP data that is now available as the data source when building apps on the ServiceNow AI Platform, such as:
   - App Engine Studio: For more information, see Create a data model for your application.
   - Flows in Workflow Studio: For more information, see Configuring flows.
   - Table Builder: For more information, see Data in Table Builder.
   - UI Builder: For more information, see Dynamically expose data in UI Builder pages (advanced feature).
   - Workflow Studio: For more information, see Configuring flows.
   - Workspace Builder: For more information, see Configure a record page for a workspace in Workspace Builder.
7. Measure and monitor the performance of the new app using applicable metrics and parameters with your preferred analytic tools.

Requirements for integrating ERP Data Hub and ERP-CM

1. Requirements for installing ERP Data Hub include the following:
   - A valid license
   - ServiceNow AI Platform plugins
   - MID server configuration

- Spoke integration
- SAP configuration

For more information, see Requirements for installing ERP Data Hub.

2. Requirements for installing ERP-CM include the following:
   - License and entitlement. For more information, see Install ERP Data Hub.
   - ServiceNow AI Platform plugins. For more information, see Install ERP Data Hub.
   - SAP configuration. For more information, see Configure SAP for ERP-CM.

Get started with ERP Data Hub and ERP-CM

Get started with ERP Data Hub and ERP-CM by completing these tasks:

1. Install and configure ERP Data Hub. For more information, see Configuring ERP Data Hub.
2. Install and configure ERP-CM. For more information, see Configuring ERP Customization Mining.
3. Install and configure any additional ServiceNow AI Platform apps and builders that consume ERP data, such as the following:
   - Installing App Engine Studio
   - Configuring Flows in Workflow Studio
   - Exploring Table Builder
   - Getting started with Playbooks
   - UI Builder quick start
   - Workflow Studio
   - Workspace Builder

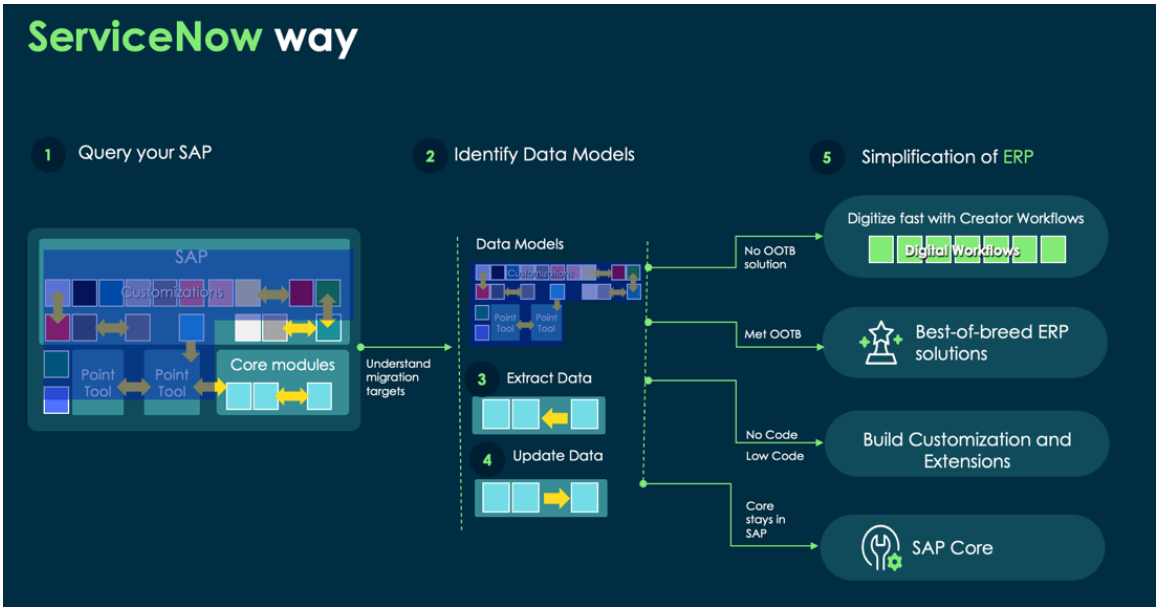
ERP Data Hub

ERP Data Hub (Enterprise Resource Planning) is a ServiceNow scoped app that enables you to retrieve and update ERP data from the system of record, such as SAP.

Legacy systems of records, such as SAP, can have old, complex custom code and data that require more time and effort to move to newer versions of the system of record. Use ERP Data Hub and ERP Customization Mining (ERP-CM) to scan the system of record to find and replace custom code with digitized workflows, resulting in a clean ERP core.

The replatforming of legacy code enables innovation on top of the system of record without knowledge of the legacy system. Database administrators and developers are then relieved of time-consuming efforts to create database views or endpoints in the system of record, freeing them to work on other projects, such as migration.

ERP Data Hub



Use ERP models as the data foundation for ERP apps. These models include ERP system data in remote tables and extraction tables, and enable you to read and update the ERP system. After you create ERP models, you can use the extracted and transformed data to build apps that access the ERP models, for example in App Engine Studio or Creator Studio, or use the ERP data in flows in Workflow Studio.

Note:
For information about new and updated features in the Xanadu release, see ERP Canvas release notes.

Learning resources for ERP Data Hub

Learn more about ERP Data Hub	ServiceNow resources
ERP Data Hub has a several training and learning resources for you to get started. (Some of these resources require logging in to the ServiceNow Learning site.)	Partner Essentials: Clean Core for App Engine ERP Clean Core with App Engine Overview ERP modernization: Working toward a clean core

Request ERP Data Hub on the store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

Before you can use ERP Data Hub, you must first download the application from the ServiceNow Store. After you've completed the download, you may need to clear your local cache before ERP Data Hub appears on your instance.

Exploring ERP Data Hub

ERP Data Hub enables you to connect to the ERP (Enterprise Resource Planning) system to send updates and extract data to remote tables and extraction tables for use on the ServiceNow AI Platform.

Overview of ERP Data Hub

ERP Data Hub functions as a platform within ServiceNow, offering a unified data model for ERP systems. ERP Data Hub enables you to manage tables that contain both standard and custom fields grouped within ERP models. You can send updates to and extract data from ERP tables on the system of record and store it in a remote table or an extraction table, depending on the size of data sets and refresh needs.

- Remote tables get their records from running an associated script against an external data source.
- Extraction tables retrieve large amounts of data using a scheduled query, and use transform tables to process data for use on the ServiceNow AI Platform.

In addition to retrieving data, ERP Data Hub can also update the ERP system using a BAPI (Business Application Programming Interface) or OData and an HTTP connection. (OData option available starting in Xanadu Store Release 2.)

The unified data model of the ServiceNow AI Platform ensures seamless integration of ERP data into the ServiceNow AI Platform. ERP Data Hub streamlines ERP data management, making it accessible and actionable within the ServiceNow AI Platform and ServiceNow instances.

Note:
ERP Data Hub doesn't replicate data into the ServiceNow AI Platform. It mirrors data that lives in the ERP system of record, and remains protected there.

ERP Data Hub workflow

1. Have your administrator use the Connections and Credentials app to configure credentials to connect to the ERP system of record. For more information, see Configure the ERP Data Hub credentials and connection.
2. Create an ERP system in ERP Data Hub using the connection and credentials alias that you configured. For more information, see Create an ERP system in ERP Data Hub.

   Note:
   The rest of the workflow steps are in ERP Data Hub. Build your ERP systems, ERP models, and tables in a development instance, and then promote them to a production instance when you're ready. For more information, see Managing app deployments using Pipelines and Deployments.

3. Clone or create an ERP model that scans the specified ERP module in the system of record for available tables and fields. Note the tables and fields in the ERP model for use in extraction and remote tables, as well as for mapping parameters to read and update the system of record. For more information, see Clone an ERP model in ERP Data Hub.
4. Create read and update operations to connect to the ERP system by adding tables, mapping fields, and building table joins to include additional data in the ERP model. For more information, see the following topics:
   - Managing how models read and update the ERP system
   - Add joins between ERP tables
5. Work with remote tables to make them available for use as a data source, such as when building apps in App Engine Studio. Remote tables get their records from running an associated script against an external data source. For more information, see the following topics:
   - View and edit ERP remote table details with ERP Data Hub
   - Customize fields for an ERP remote table in ERP Data Hub
   - Query a remote table using ERP Data Hub
6. Work with ETL extraction tables to regularly scan the system of record and extract data to a staging table. Extraction tables retrieve large amounts of data using a scheduled query, and use transform tables to process data for use on the ServiceNow AI Platform.
   - Create as many separate extraction tables as needed, such as one for each supported country. For more information, see Extracting and transforming data in ERP Data Hub.
   - You must first create the table transform map that connects the source table (on the system of record) to a Glide table on the ServiceNow AI Platform. For more information on creating table transform maps, see Create a transform map.
   - Extraction processes are configured in the ServiceNow app that uses them, for example, Workflow Studio.
   - After the extraction process is run, use import sets to map imported data into ServiceNow AI Platform tables. For more information, see Import sets.

7. Build flows in Workflow Studio to specify details for when you query or update the ERP (Enterprise Resource Planning) system. For more information, see Building flows to read or update the ERP system.
8. Move the ERP systems, ERP models, tables, operations, and flows to a production environment when they're ready. For more information, see Managing ERP development pipelines in ERP Data Hub.
9. Use the ERP data as the data source when building apps on the ServiceNow AI Platform using:
   - App Engine Studio: For more information, see Create a data model for your application.
   - Flows in Workflow Studio: For more information, see Configuring flows.
   - Playbooks in Workflow Studio: For more information, see Getting started with Process Automation.
   - Table Builder: For more information, see Data in Table Builder.
   - UI Builder: For more information, see Dynamically expose data in UI Builder pages (advanced feature).
   - Workspace Builder: For more information, see Configure a record page for a workspace in Workspace Builder.

Benefits of ERP Data Hub

ERP Data Hub key benefits

Benefit	Feature	Role
Configure connections to the system of record	Working with ERP systems in ERP Data Hub	sn_erp_integration.erp_admin
Build ERP models to create read and update operations and organize mirrored ERP data	Building and managing ERP models to work with ERP data	sn_erp_integration.erp_admin
Work with and query remote tables to view ERP data on the system of record	Using ERP remote tables in ERP Data Hub	• To modify remote tables: sn_erp_integration.erp_admin • To read remote tables: sn_erp_integration.erp_user
Access standard remote tables	Standard remote tables for ERP Data Hub	• sn_erp_integration.erp_user • Additional, table-specific roles are required. For more information, see ERP Data Hub roles.
Configure extraction tables to regularly pull custom data from the ERP system	Extracting and transforming data in ERP Data Hub	sn_erp_integration.erp_admin

Additional resources for ERP Data Hub

Identifying ERP candidates to replatform with ERP Data Hub and ERP-CM

ERP Data Hub enables you to connect to your ERP (Enterprise Resource Planning) system of record, and to organize its data.

Replatforming legacy ERP apps onto the ServiceNow AI Platform

Replatforming is the process of scanning legacy ERP system code to find potential candidates to move onto your ServiceNow AI Platform instance as new apps. You can use data from the ERP system as a source for apps built on the ServiceNow AI Platform, improving performance, enhancing security, and reducing maintenance.

Using ERP Data Hub, you can access standard fields for remote tables and ERP extraction tables, while ERP Customization Mining (ERP-CM) enables you to find good candidates for replatforming from the system of record to the ServiceNow AI Platform.

ERP-CM suggests candidates and possible next steps, such as updating remote tables and extraction tables to access ERP data. Remote tables send data to the ServiceNow instance as an attachment, which is then analyzed using AI/ML to identify similar candidates to replatform.

Using remote tables and extraction tables with ERP Data Hub and ERP-CM

You can use a combination of remote tables and extraction tables to retrieve data from your legacy ERP system.

- Remote tables get their records from running an associated script against an external data source.
- Extraction tables retrieve large amounts of data using a scheduled query, and use transform tables to process data for use on the ServiceNow AI Platform.

Remote tables describe the schema for the data that you want to retrieve from an external source, such as the system of record. Use remote tables to connect the ServiceNow AI Platform to third-party sources, or to another instance, so that you can retrieve external data and optionally cache it in the memory. You can view external data in lists or forms and process it with standard Glide scripts. You can also group, sort, aggregate, and filter the data just like you would for standard internal tables.

By using a remote table, you can retrieve the data from external sources or from another instance with REST or SOAP services. The external data lives in the memory in read-only mode, which makes the data temporary, or transient, within the ServiceNow AI Platform. You can then view and manipulate the external data without importing or storing it. For more information, see Remote tables.

Use an extraction table to work with large amounts of ERP data. ERP extraction tables regularly save data to a local transform table on the ServiceNow AI Platform, which you can then process and use as the data foundation of a replatformed app.

ERP Data Hub custom field example

ERP Data Hub helps you identify custom ERP (Enterprise Resource Planning) apps and fields in the system of record to access their data on the ServiceNow AI Platform. The ERP system can have both standard and custom fields that are accessed by ERP Data Hub.

Example of ERP custom data replatforming

In this example, a farmer grows grain to sell. The farmer has entries in a table for standard values, such as weight and sales price.

However, the sale price of grain depends on the moisture content of the grain. If it rains the day before grain is harvested, the farmer must adjust the sale price to reflect the moisture content. Thus, in addition to standard fields like **Date** and **Weight**, the legacy table that tracks the grain harvest on the ERP system must have a custom **Moisture %** field.

The farmer can use ERP Data Hub to connect to the legacy system of record and identify the table that contains the custom field. Then they can create an ERP model in ERP Data Hub with a remote table or an extraction table that contains the **Moisture %** field.

After they have the ERP model with custom data, they can use App Engine Studio or other ServiceNow products to quickly build an app that tracks their grain sales. The data that the grain sale app consumes still lives on the legacy system of record.

ERP Data Hub and security

In addition to role-based security and access control, ERP Data Hub protects personally identifiable data in other ways.

Personally identifiable data is secured with ERP Data Hub and ERP-CM in several ways.

- You can customize ERP models and remote tables to exclude personal data in a specified field, such as email address.
- All remote tables are secured using access control rules (ACLs). If you have a remote table that contains sensitive data, use ACLs to restrict that table from ServiceNow users. For more information, see ServiceNow® access control.

Configuring ERP Data Hub

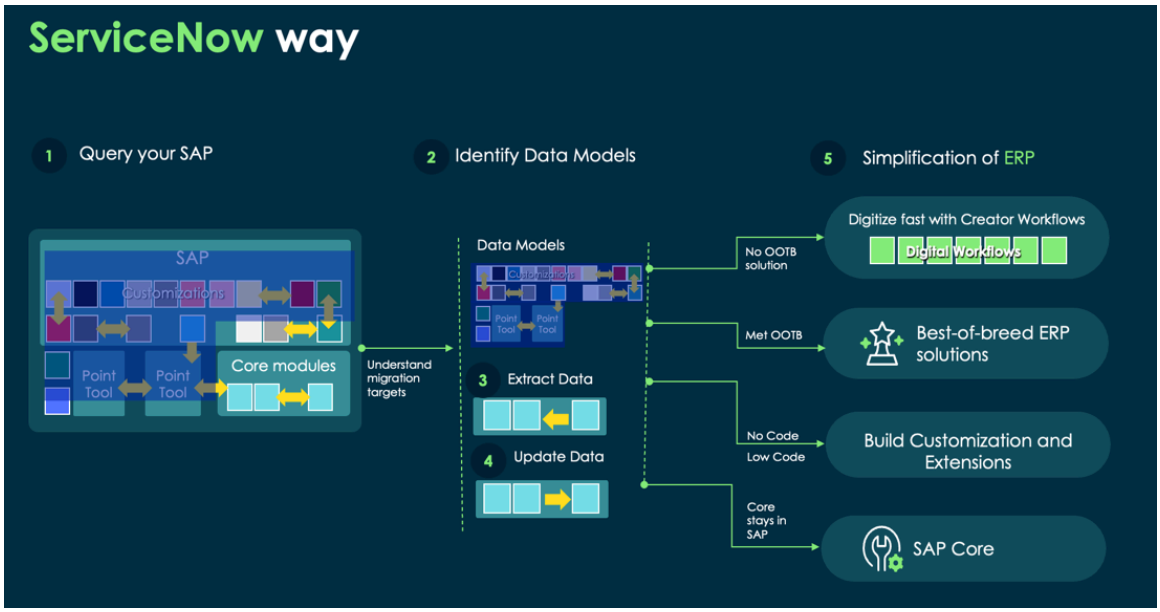
Install ERP Data Hub to configure connections to ERP (Enterprise Resource Planning) systems of record, as well as other ServiceNow products, such as ERP Customization Mining, Procurement for Field Service Management, and Process Mining.

ERP Data Hub uses basic authentication to connect a ServiceNow instance with an instance on the system of record (such as SAP).

After you configure a connection, you can read and update the system of record with ERP Data Hub using ERP models, and create remote tables and extraction tables.

Additionally, you can use ERP Customization Mining (ERP-CM) to identify legacy applications that are good candidates for replatforming, making their data immediately available on the ServiceNow AI Platform. For more information, see ERP Customization Mining (ERP-CM).

ERP Data Hub



Connecting to multiple instances

The number of ERP connections you can have per ServiceNow instance depends on your license. If you have the ERP-CM license, you get one connection per instance.

Requirements for installing ERP Data Hub

Before you install ERP Data Hub, you must complete several configurations, on both the ERP (Enterprise Resource Planning) system and on the ServiceNow AI Platform.

Licensing

You must have a license and get entitlement to ERP Data Hub for installation. For more information, see Licensing.

ServiceNow AI Platform plugins

The following plugins and servers are required for installing ERP Data Hub:

- Integration Hub plugin (for more information, see Request Integration Hub)
- Remote Tables plugin (for more information, see Activate the remote tables plugin)
- MID Server: The MID Server must be configured to install ERP Data Hub. See the following section for more information.

MID Server requirements

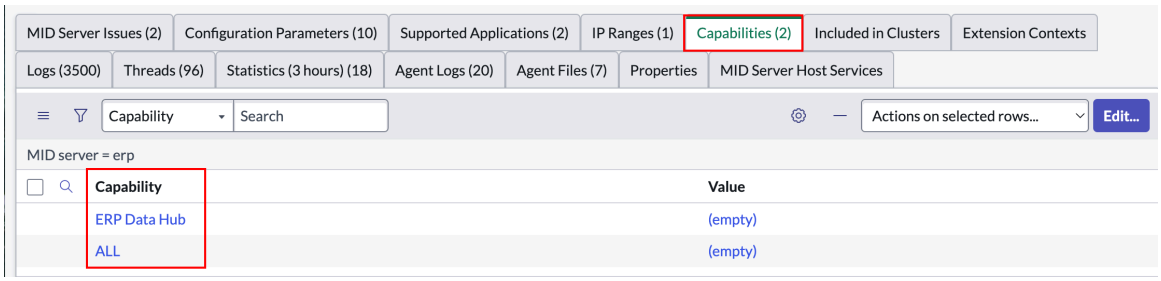
Communicating with the system of record through a MID Server requires a valid connection and credential alias.

Note:
The credentials you specify for the ERP Data Hub connection must match the service user credentials in the system of record.

ERP Data Hub and ERP-CM currently support ECC (minimum SAP Netweaver 7.31) and S/4HANA SAP systems.

Find your MID Server on the ServiceNow AI Platform in **All** > **MID Server** > **Servers**. Select it and add the following:

1. In the **Supported applications** tab, edit the list to include ERP Data Hub.
2. In the **Capabilities** tab, in addition to **ALL**, edit the list to include ERP Data Hub.



For more information, see MID Server.

Assign the mid_user user the sn_erp_integration.erp_mid_server role. The role enables the MID Server to use the ImportSet API to send data to the ServiceNow instance.

1. Navigate to **All** > **User Administration** > **Users**
2. Find and select the **mid_user**.
3. Select the **Roles** tab.
4. Select **Edit**.
5. Find and assign the **sn_erp_integration.erp_mid_server** role.

Required SAP authorizations in development system

For the credentials, use an SAP service type user account in your system of record that requires the following SAP authorization objects:

- S_RFC with Activity = 16 (Execute) for the following Function Modules:
  - RFCPING
  - BAPI_MONITOR_GETLIST
  - RFC_METADATA_GET

- RFC_GET_FUNCTION_INTERFACE
- RFC_READ_TABLE
- DDIF_FIELDINFO_GET

- S_TABU_NAM with Activity 03 (Display) for the following tables:
  - DD01L
  - DD02L
  - DD02T
  - DD03L
  - DD04L
  - DD04T
  - DD12L
  - DD17S
  - DD40L
- S_DEVELOP with Activity 03 (Display)

Required SAP authorizations in production and test system

For the credentials, use an SAP service type user account in your system of record that requires the following SAP authorization objects:

- S_RFC with Activity = 16 (Execute) for the following Function Modules:
  - RFCPING
  - BAPI_TRANSACTION_COMMIT
  - BAPI_TRANSACTION_ROLLBACK
  - RFC_METADATA_GET
  - RFC_GET_FUNCTION_INTERFACE
  - RFC_READ_TABLE
- S_TABU_NAM with Activity 03 (Display) for the tables you have used in models.

Spoke integration

For required spokes, contact the admin of your SAP ECC RFC account to obtain the following SAP proprietary JARs and other required files:

- Create a record called "SAP Jco Dll" and attach `sapjco3.dll`. Use this file if your MID Server is installed on a Windows server.
- Create a record called "SAP Jco so" and attach `libsapjco3.so`. Use this file if your MID Server is installed on a Linux server.
- Create a record called "SAP Eco Jar" and attach `sapjco3.jar`. Use this file for both Windows and Linux.

> **Note:**
> Create the records at **All** > **MID Server** > **JAR Files**. For more information about creating JAR files and adding attachments, see Synchronize a JAR file to MID Servers.

The MID Server restarts multiple times during this process.

For more information on spoke integration, see SAP ECC RFC Spoke.

SAP configuration

You must configure the JCO connector before you install ERP Data Hub. See the SAP documentation for more information.

You must add the DuckDB JDBC jar as a MID Server jar. For more information and to download, see DuckDB JDBC Driver 1.1.1 on the Maven web site.

Additionally, you need the following on your ERP system:

- SAP ECC (minimum SAP Netweaver 7.31)
- SAP S/4HANA (all versions supported)
- SAP Java Connector

Install ERP Data Hub

Install the ERP Data Hub (Enterprise Resource Planning) application (sn_erp_integration) if you have the admin role from the ServiceNow Store.

Before you begin

For a complete list of prerequisites for installing ERP Data Hub, including licensing information, see Requirements for installing ERP Data Hub.

Role required: admin

Procedure

1. Go to the ServiceNow Store.
2. In search type, `ERP Data Hub`.
3. Select the **ERP Data Hub** tile.
4. Select **Get**.
5. Log in using your ServiceNow credentials.
   Federal customers should select **Are you a federal customer?** and follow the instructions.
   If you don't have ServiceNow credentials and aren't a federal customer, select **Are you a customer who doesn't have ServiceNow ID?** and follow the instructions.
6. Check that you have entitlements (or licenses) to the product and dependent applications by viewing **Your Subscription Status**.
7. Select **Request Install**.
   When complete, confirm the installation of ERP Data Hub and select **Close** to return to the ServiceNow Store.

What to do next

After you install ERP Data Hub, you must enable the *sn_erp_integration.enableModelModification* property so users can customize ERP models. After you enable the *sn_erp_integration.enableModelModification* property, ERP Data Hub retrieves all tables and BAPIs (Business Application Programming Interface) to use when managing models. System properties are maintained in the System Property table [sys_properties], which you can access using the module navigator, or by directly typing `sys_properties.list` in the Navigator Filter.

Run Guided Setup for ERP Data Hub

Run the Guided Setup to configure ERP Data Hub.

Before you begin

You must first download and install ERP Data Hub from the ServiceNow Store. For more information, see Install ERP Data Hub.

Role required: sn_erp_integration.erp_admin

About this task

For more information on using Guided Setup, see Guided setup.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Guided Setup**.
2. Set up the MID Server in the MID Server setup section.
   a. Select **Create MID user** and create the user account on the ServiceNow instance that will connect to the MID Server.
   For example, you can create mid.user.
   b. Select **Download and install MID** and follow the instructions to download the appropriate MID Server installer archive for the operating system.
   c. Select **Configure MID server files** and follow the instructions to configure the required MID Server files, which are detailed in the Guided Setup.
   For more information, see Install ERP Data Hub.
3. Set up the connection and credentials.
   a. Select **Create credential record for the ERP system** and follow the steps.
   b. Select **Create a connection record for ERP Data Hub** and follow the steps.
   c. Select **Configure connection and capabilities** and complete the steps.
   Alternatively, you can configure without Guided Setup. For more information, see Configure the ERP Data Hub credentials and connection.
4. Create and validate the ERP system.
   a. Select **Create system** and follow the steps.
   b. Select **Validate system** and follow the steps.
   Alternatively, you can configure without Guided Setup. For more information, see Create an ERP system in ERP Data Hub.
5. Configure remote tables and extraction sources.
   a. Select **Configure remote tables** and follow the steps.
   Alternatively, you can configure without Guided Setup. For more information, see View and edit ERP remote table details with ERP Data Hub.
   b. Select **Configure extraction sources** and follow the steps.
   Alternatively, you can configure without Guided Setup. For more information, see Add a new ERP extraction table in ERP Data Hub.

Configure the ERP Data Hub credentials and connection

Connect ERP Data Hub to a system of record (such as SAP) directly or using a load balancer to enable access to the ERP (Enterprise Resource Planning) system. You must select an existing, configured connection when you set up an ERP system.

Before you begin

You must first create the alias for ERP Data Hub. For more information, see Create a Connection & Credential alias.

Role required: admin

About this task

ERP Data Hub and ERP-CM currently support ECC (minimum SAP Netweaver 7.31) and S/4HANA SAP systems.

Note:
The credentials you specify for the ERP Data Hub connection must match the service user credentials in the system of record.

Alternatively, you can run Guided Setup. For more information, see Run Guided Setup for ERP Data Hub.

Procedure

1. Navigate to **All** > **Connections & Credentials** > **Connection & Credential Aliases**.
2. Select the alias that you created for the new connection.
3. Create a connection and credential.
4. On the form, fill in the fields.
   You must specify a connection and login credential to be used simultaneously. That is, the connection you configure uses the defined login credentials for the connection.

   For a description of the field values, see ERP Data Hub connection and credentials field descriptions. If you're creating an HTTP connection, see Create an HTTP(s) connection for field and MID Server details.
5. Set up the ERP Data Hub connection.
   a. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
   b. Open the ERP systems list by selecting the systems icon () in the side panel.
   c. In the **Connection** column, select the **(empty)** cell.

      Important:
      You must select the empty row instead of creating a new row.

   d. In the search box that appears, select the search icon ().
   e. On the Connection & Credential Aliases dialog, select **sn_erp_integration.ERP_Integration**.
   f. Select the selection icon ( ).

ERP Data Hub roles

Administrators assign roles to give team members permission to configure or use ERP Data Hub.

Important:
When you assign ERP Data Hub (Enterprise Resource Planning) roles to a user, you must include the scope. For example, assign the `sn_erp_mining.erp_admin` role, not just `erp_admin`.

For more on assigning roles, see Assign a role to a user.

To learn more about managing per-user subscriptions, see Managing per-user subscriptions in Subscription Management and contact your account representative.

ERP Data Hub roles

Note:
All required roles are the same across development and production instances. However, only sn_erp_integration.erp_user is required to read data in a production instance.

ERP Data Hub roles

Role	Description	Additional access
sn_erp_integration.erp_admin	Grants the user access to updating the application setup.	Contains sn_erp_integration.erp_user.
sn_erp_integration.erp_data_pill	Grants the user read access to all the tables needed for making Remote Tables requests. This role can be combined with any single Remote Tables role. For example, combining sn_erp_integration.erp_data_pill and sn_erp_integration.sap_company_code_user enables the list of SAP Company Codes.	--
sn_erp_integration.erp_mid_server	Grants the user access to use the API to enable the MID Server to send attachments back to the ServiceNow instance.	--
sn_erp_integration.erp_user	Grants the user read access for all remote tables.	Contains sn_erp_integration.erp_data_pill and all Remote Tables roles. • sn_erp_integration.sap_company_code_user • sn_erp_integration.sap_country_user • sn_erp_integration.sap_currency_user • sn_erp_integration.sap_customer_invoice_us • sn_erp_integration.sap_distribution_channel • sn_erp_integration.sap_division_user • sn_erp_integration.sap_language_user

ERP Data Hub roles (continued)

Role	Description	Additional access
		• sn_erp_integration.sap_material_stock_user • sn_erp_integration.sap_purchase_document • sn_erp_integration.sap_purchasing_organiza • sn_erp_integration.sap_sales_customer_user • sn_erp_integration.sap_sales_delivery_user • sn_erp_integration.sap_sales_document_use • sn_erp_integration.sap_sales_organization_u • sn_erp_integration.sap_sales_revenue_recog • sn_erp_integration.sap_vendor_invoice_user • sn_erp_integration.sap_vendor_user

Additional ERP data model roles

If users need access to work with specific ERP data models, such as purchasing or invoices, assign them the following roles and access for ERP Data Hub.

ERP data model-specific roles for ERP Data Hub

Persona	Role	Access
ERP MID Server user	erp_mid_server	• sys_attachments • sn_erp_integration_queue
Customer invoice user	sap_customer_invoice_user	sn_erp_integration_st_sap_customer_invoice
Material stock user	sap_material_stock_user	sn_erp_integration_st_sap_material_stock
Purchase document user	sap_purchase_document_user	sn_erp_integration_st_sap_purchase_documer
Purchasing organization user	sap_purchasing_organization_user	sn_erp_integration_st_sap_purchasing_organiz
Sales customer user	sap_sales_customer_user	sn_erp_integration_st_sap_sales_customer
Sales delivery user	sap_sales_delivery_user	sn_erp_integration_st_sap_sales_delivery
Sales document user	sap_sales_document_user	sn_erp_integration_st_sap_sales_document
Sales organization user	sap_sales_organization_user	sn_erp_integration_st_sap_sales_organization
Sales revenue recognition user	sap_sales_revenue_recognition_user	sn_erp_integration_st_sap_sales_revenue_reco
Vendor invoice user	sap_vendor_invoice_user	sn_erp_integration_st_sap_vendor_invoice
Vendor user	sap_vendor_user	sn_erp_integration_st_sap_vendor

Working with ERP systems in ERP Data Hub

An ERP (Enterprise Resource Planning) system represents a connection to a section of your ERP system of record. For example, sales orders or vendor invoices.

ERP systems organize connections to the system of record

The system plays a crucial role in data synchronization, sharing, and collaboration, enabling seamless integration and operation between the ERP model and the connected ERP system.

ERP Data Hub provides a standard set of ERP models, such as SAP Material Stock and SAP Purchase Document. You can also build new models. For a list of standard ERP models, which you must clone to modify, see Standard ERP models and extraction tables for ERP Data Hub.

Configuring ERP systems and checking connections

ERP systems are configured by ServiceNow admins. The ERP system is set on the extraction table or remote table. ERP Data Hub supports connecting to multiple systems.

ERP Data Hub regularly scans all connected ERP systems for the latest heartbeat, which indicates whether a ping to the ERP system connection is currently successful.

Create an ERP system in ERP Data Hub

Configure an ERP (Enterprise Resource Planning) system in ERP Data Hub to organize your connections to the system of record.

Before you begin

Role required: sn_erp_integration.erp_admin

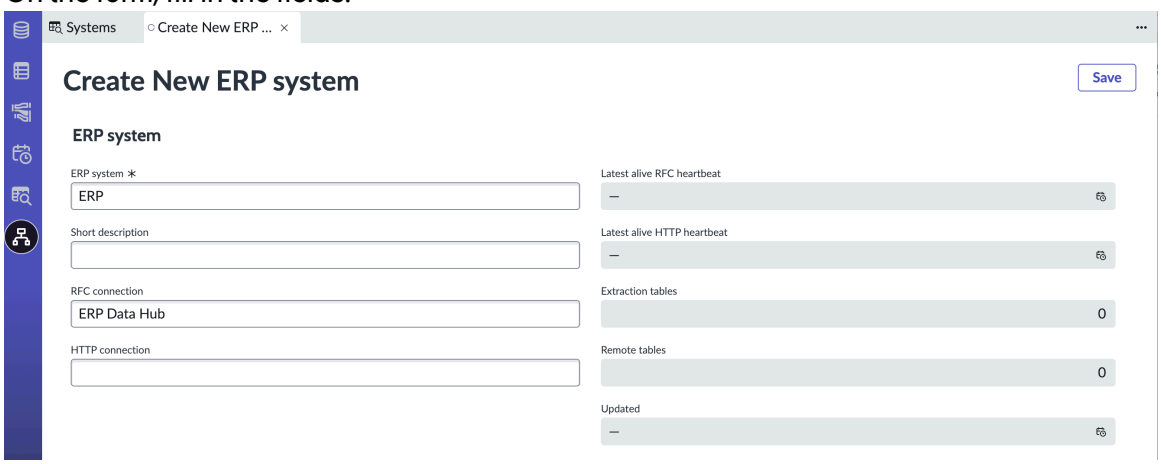
About this task

The ERP system is set on the extraction table or remote table. ERP Data Hub supports connecting to multiple systems.

Alternatively, you can run Guided Setup. For more information, see Run Guided Setup for ERP Data Hub.

Procedure

1. Navigate to **All** > **ERP Data Hub**.
2. Open the ERP systems list by selecting the systems icon ( ) in the side panel.
3. Select **New**.
4. On the form, fill in the fields.



Note:
The HTTP connection option is available starting in Xanadu Store Release 2. You must have an SAP system that is enabled to make an OData connection.

For a description of the field values, see ERP Data Hub new system field descriptions.

5. Select **Save**.

Result

After you create a system, you can view heartbeat and retrieval status on the ERP systems list page. For more information, see View a list of ERP Data Hub systems.

View a list of ERP Data Hub systems

Check the ERP (Enterprise Resource Planning) systems list in ERP Data Hub to view the heartbeats and retrieval status of your ERP systems.

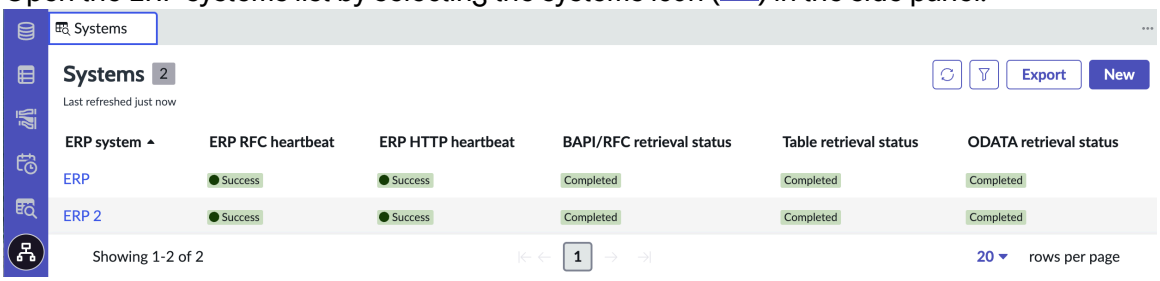
Before you begin

Role required: sn_erp_integration.erp_admin

Note:
Users with the sn_erp_integration.erp_admin role can view the list of ERP systems, but can't create a system. For more information, see Create an ERP system in ERP Data Hub.

Procedure

1. Navigate to **All** > **ERP Data Hub**.
2. Open the ERP systems list by selecting the systems icon ( ) in the side panel.



Note:
The HTTP connection option and ODATA option are available starting in Xanadu Store Release 2.

3. Check the information for each system to confirm that there are no connectivity issues.
   For a description of the field values, see ERP Data Hub system list field descriptions.

View ERP Data Hub system heartbeat information

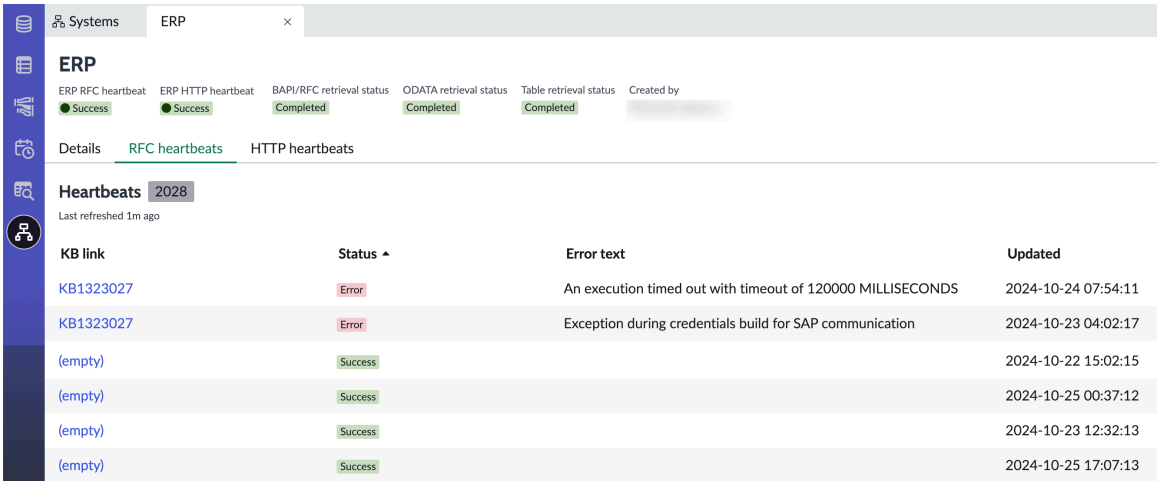
In ERP Data Hub, the heartbeat shows the status, date, and time of connections to the ERP system, along with error information.

Before you begin

Role required: admin and sn_erp_integration.erp_user

Procedure

1. Navigate to **All** > **ERP Data Hub**.
2. Open the ERP systems list by selecting the systems icon ( ) in the side panel.
3. Open a system.
4. Select the **RFC heartbeats** or **HTTP heartbeats** tab.



View information about the heartbeats, including updated date and time, and status. If there's an error, the error text is displayed and a link to a knowledge base article (if available) is provided. For more information, see ERP Data Hub new system field descriptions.

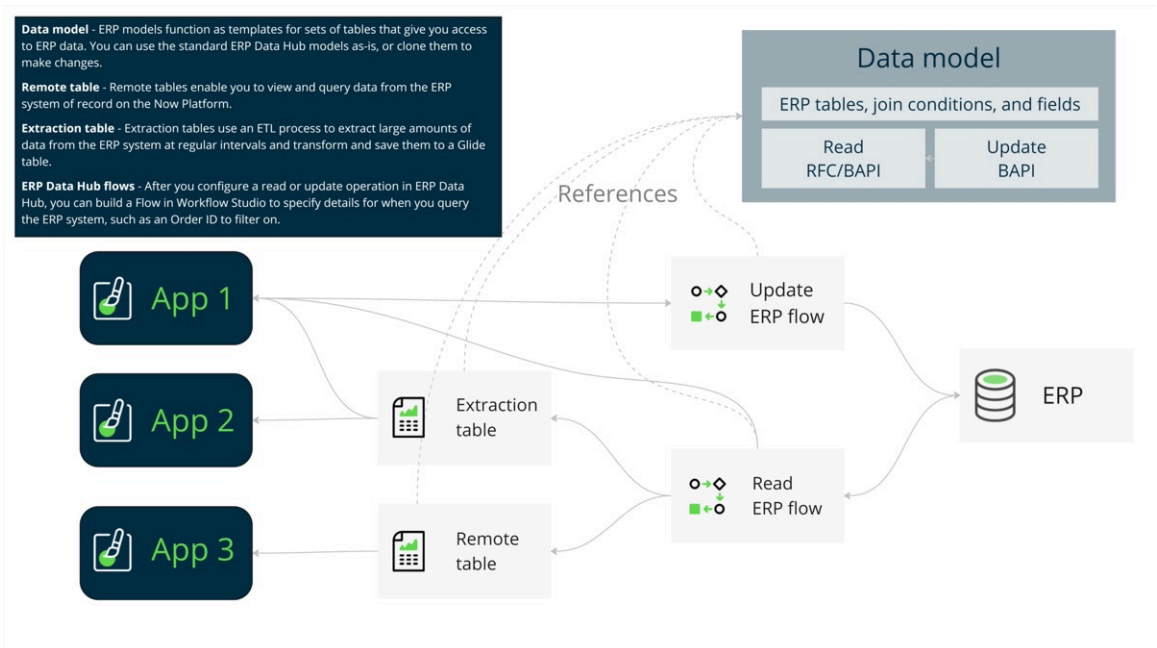
By default, all heartbeat information is kept for one week. To change that setting, go to **All** > **Data Management Policies**, open the sn_erp_integration_log_heartbeat policy, select the **Table Cleanup Rules** tab, select the **Tablename**, and edit the **Age in seconds**.

Using ERP models, extraction tables, and remote tables

Use ERP Data Hub to work with ERP (Enterprise Resource Planning) models, remote tables, and extraction tables to integrate ERP data from the system of record onto the ServiceNow AI Platform.

The workflow of ERP Data Hub generally follows its main sections, each of which you access by selecting the section icon in the contextual side panel.

Data models and ERP data



You can also build flows in Workflow Studio to use retrieved ERP data for processes or tasks outside of ERP Data Hub. For more information, see Building flows to read or update the ERP system.

Build an ERP model using remote tables and extraction tables to organize, load, and transform ERP data, as well as flows to query the ERP system.

Parts of ERP Data Hub

ERP Data Hub section	Description
ERP models	ERP models function as templates for sets of tables that give you access to ERP data. You can use the standard ERP Data Hub models as-is, or clone them to make changes. Manage models to map input and output data for reading and updating the ERP system using wither table read operations or BAPIs (Business Application Programming Interface). For more information, see Building and managing ERP models to work with ERP data.
Flows to query ERP data	Build a flow in Workflow Studio to specify details for querying the ERP system using the parameters specified in the model.
Remote tables	Remote tables enable you to view and query data from the ERP system of record on the ServiceNow AI Platform. For more information, see Using ERP remote tables in ERP Data Hub.
ERP extraction tables	Extraction tables use an ETL process to extract large amounts of data from the ERP system at regular intervals and transform and save them to a Glide table. For more information, see Extracting and transforming data in ERP Data Hub.

Building and managing ERP models to work with ERP data

ERP (Enterprise Resource Planning) models function as templates for sets of tables that give you access to ERP data. Use model management to create read and update operations that access the ERP system with specified inputs and outputs to map fields for use on the ServiceNow AI Platform.

ERP models represent data sets and create a staging area

An ERP model represents the logical structure and organization of data coming from the Enterprise Resource Planning system. ERP models define the entities, attributes, read/update operations, and table join relationships that capture and represent business processes and data elements in the ERP system. When you first open ERP Data Hub, you view a list of the ERP models for your instance.

ERP Data Hub provides a standard set of ERP models, such as SAP Material Stock and SAP Purchase Document. You can also build new models. For a list of standard ERP models, which you must clone to modify, see Standard ERP models and extraction tables for ERP Data Hub.

The ERP model serves as a blueprint for configuring, customizing, and integrating the ERP system to meet your business requirements. An ERP model functions as a staging area that contains all potential fields you can add to remote and extraction tables, and read and update operations. You can then use the tables and queried data as a data source on the ServiceNow AI Platform.

You can also build flows in Workflow Studio to use retrieved ERP data for processes or tasks outside of ERP Data Hub. For more information, see Building flows to read or update the ERP system.

You can view the list of existing ERP models or add a new one to create a custom data set. After you add a remote table, you can manage models to map input and output parameters, update the ERP system using BAPIs (Business Application Programming Interface), and create table joins. You can also create extraction tables that regularly pull large amounts of filtered data from the ERP system. Another option is to use a custom ERP action in Workflow Studio to use queried ERP data in other ServiceNow AI Platform processes.

You can create as many ERP models as needed, though you can't edit their field names.

How ERP models are structured

Each model is linked to ERP tables on the system of record, as well as remote tables and ERP extraction tables on the ServiceNow AI Platform. You can connect the same table to multiple, different ERP models.

ERP models are connected to an ERP system, one ERP system for each model. The connected ERP system:

- Enables access to field and table information.
- Helps coordinate data synchronization, sharing, and collaboration, enabling seamless integration and operation between the ERP model and the ERP system.

ERP models in ERP Data Hub encompass remote tables from the system of record, as well as APIs and ERP extraction tables and read/update operations, to create a holistic data set. For example, you can have one ERP model for sales orders and another for inventory.

Note:

After you install ERP Data Hub, you must enable the *sn_erp_integration.enableModelModification* property so users can customize ERP models. After you enable the *sn_erp_integration.enableModelModification* property, ERP Data Hub retrieves all tables and BAPIs (Business Application Programming Interface) to use when managing models. System properties are maintained in the System Property table [sys_properties], which you can access using the module navigator, or by directly typing `sys_properties.list` in the Navigator Filter.

Managing models to read and update ERP systems

After you create or clone an ERP model, you can specify how ERP Data Hub reads and writes to the ERP system using the ERP model manager page. When managing models, you have the option to use a BAPI, which is a remote procedure SAP function call that's similar to an API.

Each model can have only one read and one update operation defined.

For more information, see Managing how models read and update the ERP system.

View and edit the foundation of ERP models

Create a holistic data set by building ERP (Enterprise Resource Planning) models in ERP Data Hub, which encompasses remote tables and extraction tables from the ERP system, as well as read and update operations.

Before you begin

Your administrator must enable the *sn_erp_integration.enableModelModification* property for you to edit, customize, and clone ERP models and tables. After you enable the *sn_erp_integration.enableModelModification* property, ERP Data Hub retrieves all tables and BAPIs (Business Application Programming Interface) to use when managing models. The property must be configured for either a non-production or production state. System properties are maintained in the System Property table [sys_properties], which you can access using the module navigator, or directly typing `sys_properties.list` in the Navigator Filter.

Note:
You must enable the *sn_erp_integration.enableModelModification* property on the correct scope. Enabling the *sn_erp_integration.enableModelModification* on a production instance can create new metadata records when new models and fields are added in ERP Data Hub.

Role required: sn_erp_integration.erp_admin, sn_erp_integration.erp_user

About this task

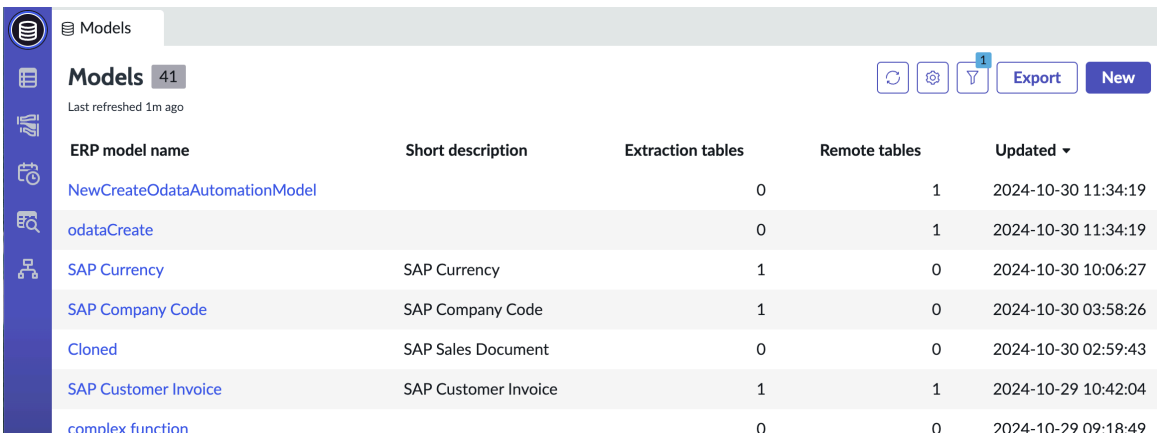
ERP Data Hub provides a standard set of ERP models, such as SAP Material Stock and SAP Purchase Document. You can also build new models. For a list of standard ERP models, which you must clone to modify, see Standard ERP models and extraction tables for ERP Data Hub.

An ERP model functions as a staging area that contains all potential fields you can add to remote and extraction tables, and read and update operations. You can then use the tables and queried data as a data source on the ServiceNow AI Platform.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP models page by selecting the ERP models icon ( ) in the side panel.

ERP Data Hub models



3. Review the list of ERP models.

ERP model columns

Column	Description
ERP model name	Name of the ERP model.
Short description	Brief description of what the ERP model represents.
ERP tables	Number of ERP tables on the system of record.
Extraction tables	Number of extraction tables on the ServiceNow AI Platform that are linked to the ERP model.
Remote tables	Number of remote tables on the ServiceNow AI Platform that are linked to the ERP model.
Updated	Date and time the model was last updated.

4. Select an ERP model to view and edit the details of the model.

ERP model Details tab

Field	Description
ERP model name	Name of the ERP model.
ERP module	Brief name of the ERP business area on the system of record.
ERP system	ERP system that represents a connection to a business section of your ERP system of record.
Application	Application scope the ERP model is linked to. For example, if you create a custom model, the model will be in that scope.
Short description	Brief description of what the ERP model represents.
Long text	Any longer description or information about the ERP data model.

5. **Optional:** View and work with the following on the **Details** tab of an ERP model:
   - Public comments and private work notes.
   - The Activity stream for the model.
   - File attachments.
6. Select **Save**.
7. View and confirm that the table entities included in the model by selecting the **Model entities** tab of the ERP model record.
   View details for an individual table by selecting the table name in the **Model entities** tab.

   ERP Data Hub automatically scans the linked ERP system to retrieve the latest entity data. However, you can select the refresh icon to update the data on demand.

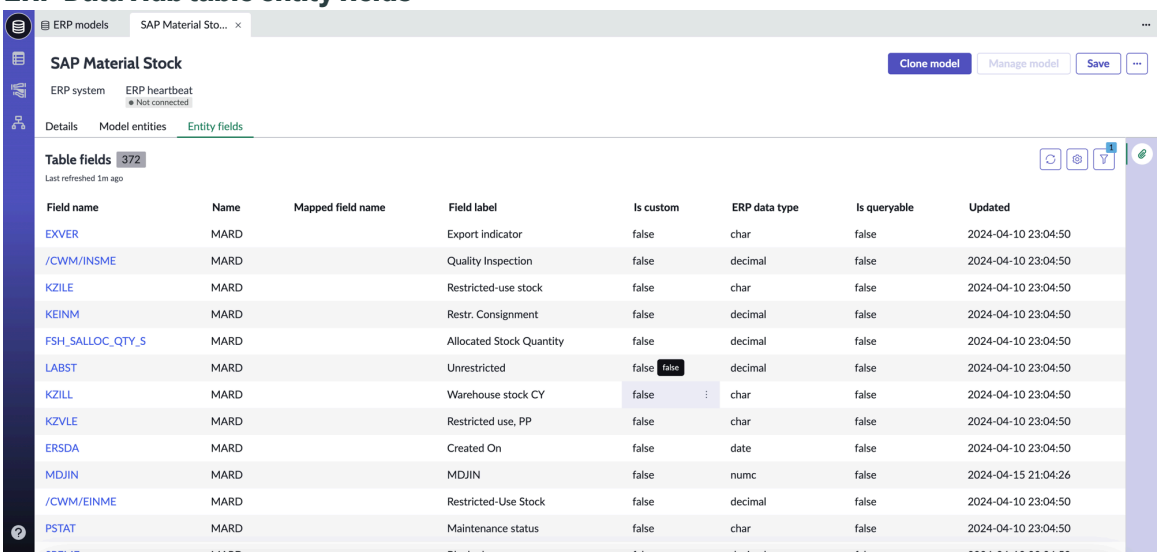
ERP Model entities tab details

Field	Description
Name	Name of the model table on the system of record.
Alias	Alias for the table. The alias refers to an alternative or substitute name for the table. An alias enables you to assign and customize a recognizable name for easier reference and identification. The alias can be a maximum of 40 characters, and contain a-z, A-Z, 0-9, and underscores.
Status	Status of the data synchronization, such as **Retrieved table data**.
Updated	Date and time the model entity was last updated.

8. **Optional:** Export the list of tables in the model by selecting the **Export** button. You can select the **File type**, such as **JSON** or **Excel**, and the **Delivery type**, such as **Download**.
9. View and confirm the table entity fields included in the ERP model by selecting the **Entity fields** tab of the ERP model record.

   For a description of the field values, see ERP Data Hub ERP model table field descriptions.

ERP Data Hub table entity fields



What to do next

After you have noted the available fields and tables, you can add new table entities to a model by managing the model. When you manage the model, you can also create read and update operations using table reads and BAPIs (Business Application Programming Interface). For more information, see Managing how models read and update the ERP system.

Clone an ERP model in ERP Data Hub

Clone a standard ERP (Enterprise Resource Planning) model that ships with ERP Data Hub. After you clone the model you can make modifications, for example, by adding new fields or tables.

Before you begin

Your administrator must enable the *sn_erp_integration.enableModelModification* property for you to edit, customize, and clone ERP models and tables. After you enable the *sn_erp_integration.enableModelModification* property, ERP Data Hub retrieves all tables and BAPIs (Business Application Programming Interface) to use when managing models. The property must be configured for either a non-production or production state. System properties are maintained in the System Property table [sys_properties], which you can access using the module navigator, or directly typing `sys_properties.list` in the Navigator Filter.

Note:
You must enable the *sn_erp_integration.enableModelModification* property on the correct scope. Enabling the *sn_erp_integration.enableModelModification* on a production instance can create new metadata records when new models and fields are added in ERP Data Hub.

Role required: sn_erp_integration.erp_admin, sn_erp_integration.erp_user

About this task

ERP Data Hub provides a standard set of ERP models, such as SAP Material Stock and SAP Purchase Document. You can also build new models. For a list of standard ERP models, which you must clone to modify, see Standard ERP models and extraction tables for ERP Data Hub.

Cloning ERP models to make customizations ensures that your changes don't break connections to other ServiceNow AI Platform applications.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP models page by selecting the ERP models icon ( ) in the side panel.
3. Select the name of ERP model that you want to clone.
4. Select the **Clone model** button.
5. In the **Clone this model** modal, enter the new **ERP model name**.
6. Select **Clone this model**.
   ERP Data Hub clones the model and displays a success message.
7. Open the ERP models page by selecting the ERP models icon ( ).
8. In the **ERP model name** column, select the cloned model you created.
9. Change the details for the ERP model on the **Details** tab, such as by updating the name.

Warning:
Changing the ERP system connected to the ERP model affects the available remote tables and extraction tables. If you change the ERP system, you must confirm the change on a warning modal.

For a description of the field values, see ERP Data Hub clone model field descriptions.

What to do next

Next, manage the model to specify additional criteria, such as which tables it reads and joins, as well as defining read and update operations and input/output parameters. For more information, see Managing how models read and update the ERP system.

Add a new ERP model

Add an ERP (Enterprise Resource Planning) model in ERP Data Hub to create a data set that contains ERP tables from the system of record, and enables you to read and send updates to the ERP system.

Before you begin

Role required: sn_erp_integration.erp_admin, sn_erp_integration.erp_user

About this task

An ERP model functions as a staging area that contains all potential fields you can add to remote and extraction tables, and read and update operations. You can then use the tables and queried data as a data source on the ServiceNow AI Platform.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP models page by selecting the ERP models icon ( ) in the side panel.
3. Select **New**.
4. On the new model tab, fill in the fields.
   For a description of the field values, see ERP Data Hub new model field descriptions.
5. Select **Save**.
6. Open the ERP models page again by selecting the ERP models icon ( ).
7. Update the page by selecting the refresh list icon.
   The new model is displayed in the list.

What to do next

After you add a new ERP model, you can manage it to specify additional criteria, such as which tables it reads and joins, any parameters for inputs and outputs, and whether it uses a BAPIs (Business Application Programming Interface) to update the system of record. For more information, see the following topics:

- Managing how models read and update the ERP system
- Add joins between ERP tables

Managing how models read and update the ERP system

After you create an ERP (Enterprise Resource Planning) model in ERP Data Hub, you can specify how it reads and updates the ERP system using parameters.

When creating a read or update operation, first add the operation. Then define operation entities and parameters in the following tabs of the ERP model manager page.

- **Manage entities**: Specify the table to read or BAPI (Business Application Programming Interface, a remote procedure call that's similar to an API) to use for reading or updating the ERP system.
- **Specify inputs**: Define how fields on the ERP system map to parameters to specify how data is queried. If parameters can't be retrieved, you can also define any default values to pass to the ERP system.
- **Choose output**: Define parameters for how returned data is stored on the ServiceNow AI Platform by specifying outputs.

Read and update operations for ERP system

ERP Data Hub contacts the ERP system using read and update operations.

- You can use either a table read or BAPI to read the ERP system.
- You must use a BAPI for update operations.
- You can add either table reads or a BAPI function call to a model for read operations, but not both.
- You can add multiple tables to a table read operation, but you can specify only one BAPI for a function call read operation.

Managing tables and entities for ERP operations

An entity is the foundation of how the operation accesses the ERP system to read or update it. Use the **Manage entities** tab to define requests and the content of their responses by specifying the BAPI or name of the table.

When you add an entity to an operation, you must specify the following information:

- How ERP Data Hub retrieves data from or sends updates to the ERP system.
  - For read operations, you must specify whether you're reading tables on the ERP system or using a pre-defined BAPI to read the system.
  - For update operations, you must use a BAPI.
- The name of the table to read or BAPI to use.

For instructions on adding entities, see Add an operation to a model in ERP Data Hub.

Managing operation input parameters

After you specify the operation's tables or BAPI, ERP Data Hub automatically populates the **Specify inputs** tab with the required input parameters.

ERP Data Hub uses parameters as part of the method/function call to define and map data that's passed to the ERP system.

- The Output parameters section is where you enter optional default values for parameters that are used to query the ERP system. If no input value is provided when querying the model, the **Default value** for each parameter is used as a fallback. Default values can also be utilized for mapping constants.
- The Tables (for read operations)/Function call (for BAPI operations) section is where you define and map fields from the ERP system that ERP Data Hub sends as parameters in the operation. When you select a field, use the automap functionality to automatically update its **Mapped value** and add a row for the parameter to the Output parameters section. If you define

a `Constant` as the **Type** and enter the constant value in the **Mapped value** field, mapped inputs can act as filter criteria. You can add and nest as many related parameters as needed.

If you're adding a complex, nested parameter, such as an address that includes several other parameters (one for street, one for city, one for country), ERP Data Hub automatically identifies that it needs additional related parameters and creates new, nested parameter rows that you must then populate with the related values. You can nest only parameters with **Object** or **Array** as the **Data type**.

The available data types for parameters are:

- Object
- Array
- String
- Date Time
- Date
- Time
- Char
- Decimal

Note:

An example use case is running a sales order BAPI to find out what items are in an order. You must specify the order ID as a mapped field in the Tables (for read operations)/ Function call (for BAPI operations) section, using the automap option to define which field is referenced in the **Mapped value** field. After defining all operation inputs and outputs, you can build a flow in Workflow Studio. In the flow, enter the order ID as the parameter in use when the flow runs to call the ERP system.

Another example would be adding a parameter for **Order billing dates** in the Table fields (for table read operations)/Function call (for BAPI operations) section. Then build a flow in Workflow Studio that enables you to specify a date or date range to retrieve all orders from that time period.

Note:
It doesn't matter what order you define parameters in. ERP Data Hub displays optional parameters in alphabetical order when you save.

For instructions on managing inputs, see Manage input parameters for an ERP Data Hub model operation.

Selecting outputs for a read operation

You must create output parameters to define how the data is mapped to the ERP system and stored on the ServiceNow AI Platform.

For instructions on managing outputs, see Choose output parameters for an ERP model.

Adding retrieved ERP fields to tables

When you add mapped fields or parameters as outputs and successfully read or update the ERP system, each parameter appears as a field that you can then add to a remote table or an extraction table. Manage the fields for the remote table or extraction table to add the retrieved parameters. For more information, see the following topics:

- Customize fields for an ERP remote table in ERP Data Hub
- Select fields for an extraction table in ERP Data Hub

Building flows to call the ERP system

After all parameters are defined and you have built and run the read or update operation, build a flow in Workflow Studio that uses the defined parameters.

Enter any filter criteria by specifying a value when you select the parameter in the **Mandatory Field** of the flow's action. For more information, see Building flows to read or update the ERP system.

Add an operation to a model in ERP Data Hub

Add an operation to an ERP (Enterprise Resource Planning) model in ERP Data Hub to define how it retrieves data from or writes data to the ERP system, or creates a new instance of the business object.

Before you begin

Role required: sn_erp_integration.erp_admin, sn_erp_integration.erp_user

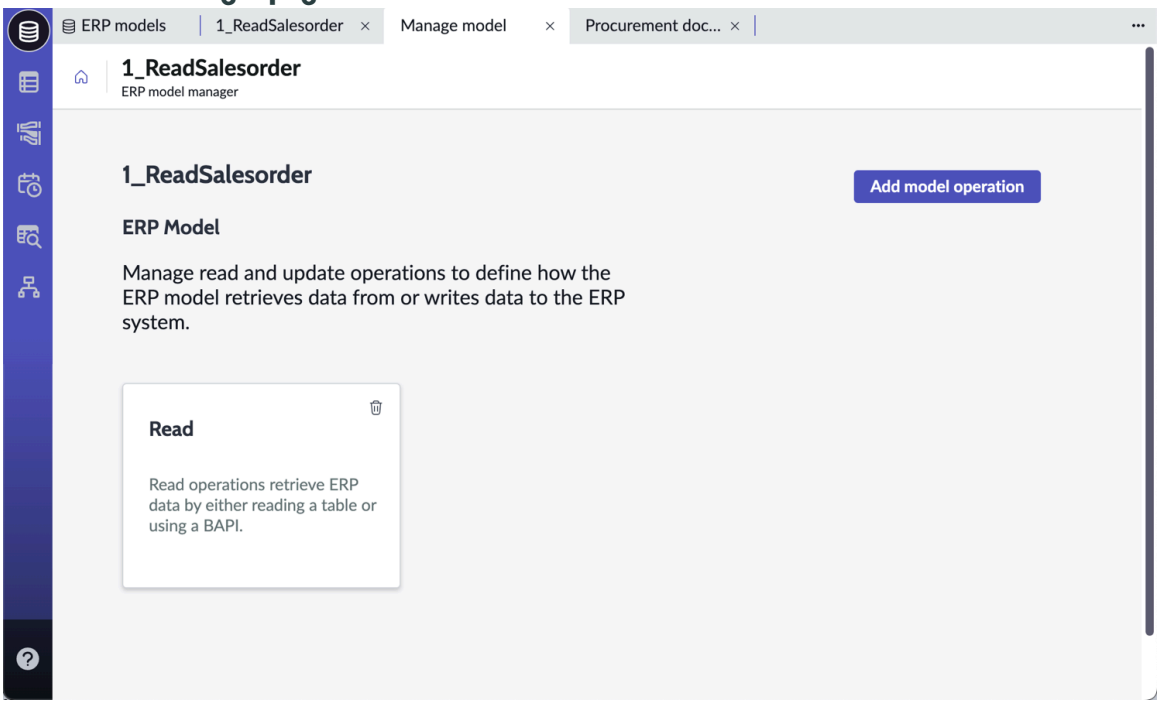
About this task

- Read operations retrieve ERP data by either reading a table or using a BAPI.
- Update operations use a BAPI to write updates to the ERP system.
- Create operation creates a new instance of the business object in the SAP system. (Available starting in Xanadu Store Release 2)

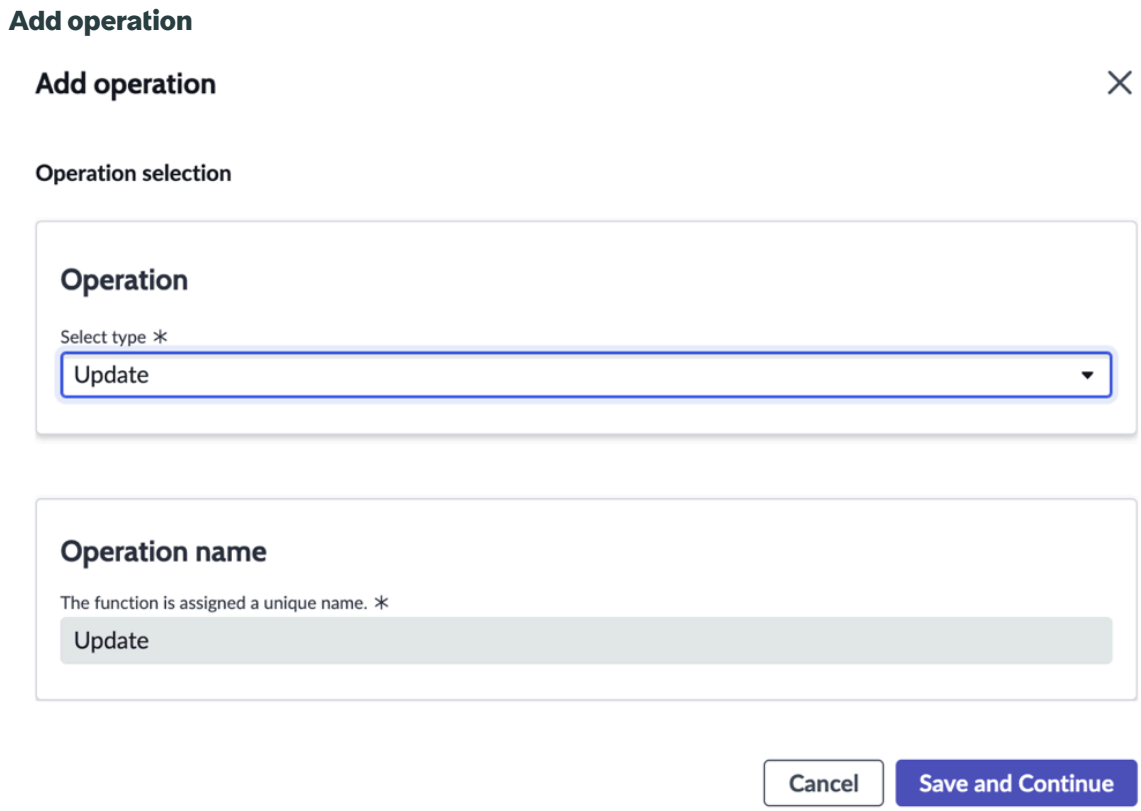
Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP model page by selecting the ERP model icon ( ) in the side panel.
3. Select the model to which you want to add an operation.
4. Select the **Manage model** button.

ERP model manager page



5. Select **Add model operation**.
6. Specify the type of operation that you're adding in the **Select type** field of the **Add operation** modal.
   - **Update** sends data back to write to the ERP system.
   - **Read** reads and retrieves data from the ERP system and brings it onto the ServiceNow AI Platform.
   - **Create** is used to create a new instance of the business object in the SAP system. (Available starting in Xanadu Store Release 2)



7. Select **Save and continue**.

Result
The foundation of the operation is created.

What to do next
Next, you must add the read or update entity to the operation. For more information, see Add a read, update, or create entity to a model in ERP Data Hub

You can select the delete icon (🗑) on the operation's card to remove any operations you don't need, or to start over.

Add a read, update, or create entity to a model in ERP Data Hub

Specify the operation entity, which is the table or BAPI (Business Application Programming Interface) that ERP Data Hub uses for read, update, or create operations.

Before you begin
You must have already added the read, write, or create operation before you can add an entity to it. For more information, see Add an operation to a model in ERP Data Hub.

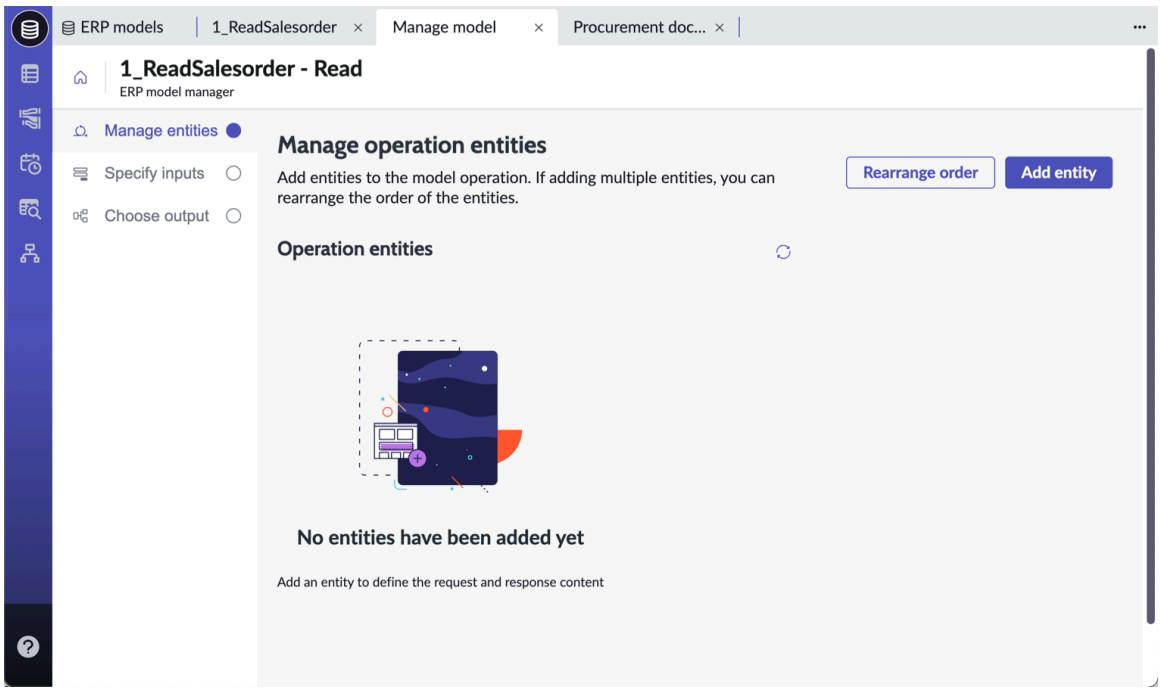
Role required: sn_erp_integration.erp_admin, sn_erp_integration.erp_user

About this task
- Read operations retrieve ERP data by either reading a table or using a BAPI.
- Update operations use a BAPI to write updates to the ERP system.
- Create operation creates a new instance of the business object in the SAP system. (Available starting in Xanadu Store Release 2)

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP model page by selecting the ERP model icon ( ) in the side panel.
3. Select the model that you want to add an operation entity to.
4. Select the **Manage model** button.
5. Select **Add entity** on the **Manage entities** tab.

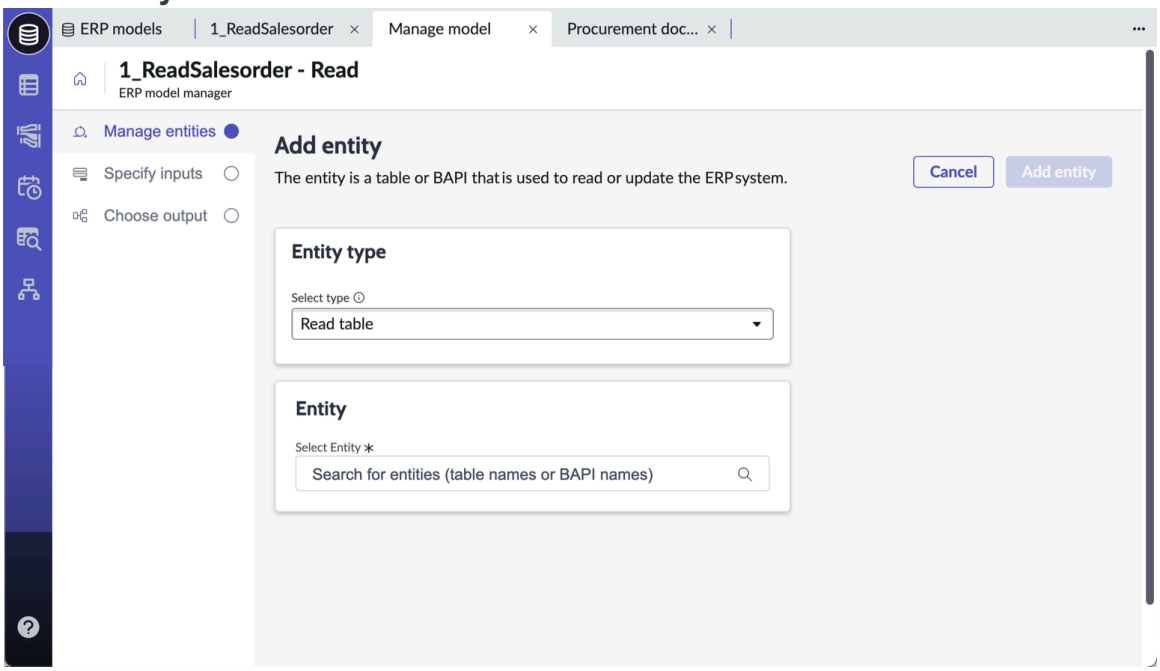
Manage entities tab



6. For read operations, specify the type of read operation in **Select type**.
   - **Read table** defines a read operation entity that retrieves data by reading it directly from a table on the ERP system.
   - **Function call (BAPIs)** defines a read operation entity that uses a BAPI remote procedure call.
   - **Function call (RFCs)** defines a read operation entity that uses an RFC call.
   - **OData** enables you to work with various business objects (for example, read, create, update, and delete) defined in the ERP system.

> **Note:**
> Update operation entities must use a BAPI Function call, so this field is read only for update operations.

Add an entity



7. Define the entity by specifying the name of the table to read or BAPI to use in **Select entity**.

   The AI Search for this field can help you find what you're looking for faster, for example by entering `Countries` instead of `T005`. AI Search also suggests tables and BAPIs that are in the connected ERP system.

   For table read operations, you may need to check the **Model entities** tab of the current or another, related model to get the table name, or ask your SAP admin. For more information, see View and edit the foundation of ERP models.

8. When you're finished, select **Add entity**.
9. **Optional:** Rearrange and delete table entities as needed.

   Important:
   Reordering deletes any existing table joins for the reordered entities.

   a. Select **Rearrange order**.

   b. Drag the tables to the order that you want.

   c. Select the delete icon (🗑) on the card for a table to remove any tables you don't need. Deleting an entity removes all of its related field mappings and table joins.

   d. Select **Confirm reorder**.

Result

The entity is added to the operation. ERP Data Hub connects to the ERP system using the specified entity and retrieves data that you can use to define input and output parameters.

When you view the entity on the **Manage operation entities** page, a status shows whether the ServiceNow AI Platform is retrieving data or has finished retrieving data.

If you added a **Read table** operation, you can repeat this process to add as many tables as necessary to the operation. Then you can add joins to create relationships between tables.

Note:
If you have more than one table for an operation, you must join the tables.

For more information, see Add joins between ERP tables.

The **Entity fields** tab for the ERP model automatically populates for the new table when the table is connected to an ERP system. View their details as needed. For more information, see ERP Data Hub ERP model table field descriptions.

What to do next
Next, you must specify the input parameters for the operation. For details, see Manage input parameters for an ERP Data Hub model operation.

Add joins between ERP tables

Link multiple ERP (Enterprise Resource Planning) tables from the system of record to build an ERP model in ERP Data Hub using table joins.

Before you begin
Table joins require a read operation that uses table read entities. For more information, see Add an operation to a model in ERP Data Hub.

When you add table joins, the parent table is the first table listed on the **Manage entities** tab of the ERP model manager page. Child tables pull information from the parent table.

Note:

- If you have more than one table for an operation, you must join the tables.
- You can create table joins only for table read operations, not for operations that use a BAPI (Business Application Programming Interface).

Role required: sn_erp_integration.erp_admin, sn_erp_integration.erp_user

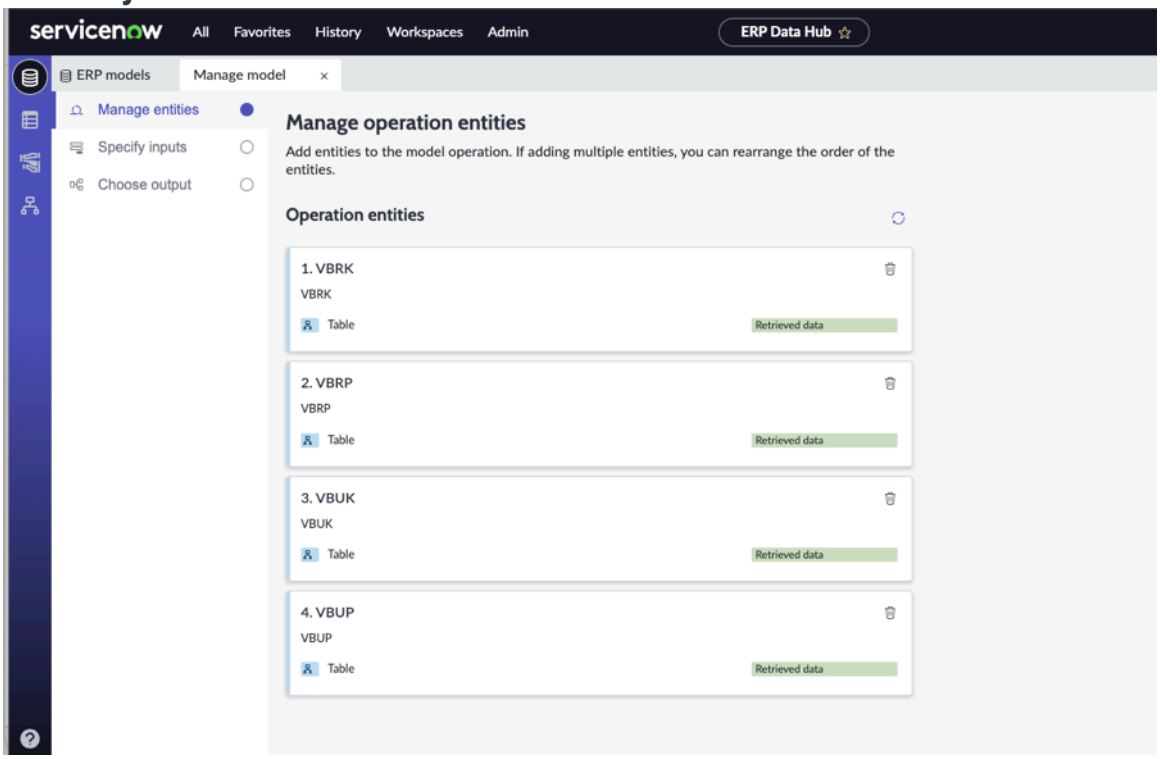
About this task
Table joins link different tables through shared fields. Joins enable you to access data from multiple tables based on logical relationships between them. The relationship can be conditional, which you specify using join conditions.

Join fields defines the common attribute or key used to connect records in a child table with their corresponding parent records.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP model page by selecting the ERP model icon () in the side panel.
3. Select the model that you want to add a join to.
4. Select the **Manage model** button.
5. Select the **Read** operation that you're adding the table join to.
6. **Optional:** Add the tables to join as **Table read** operation entities if they haven't yet been added to the model.
   For more information, see Add a read, update, or create entity to a model in ERP Data Hub.

Tables to join



7. Rearrange the tables on the **Manage entities** tab to place the parent table for the join as the first table listed on the ERP model manager page.

> **Important:**
> Reordering deletes any existing table joins for the reordered entities.

   a. Select the **Rearrange order** button.

   b. Drag the tables to the order that you want, with the parent table as the first table listed on the page.

   c. Select the **Confirm reorder** button.

8. Select the **Specify inputs** tab, which is where you update input parameters to specify table join as a parameter.
   The input parameters for each table appear.

9. Create a table join parameter.

   a. Find the parameter that will be the parent join field in the Output parameters section and note its name.

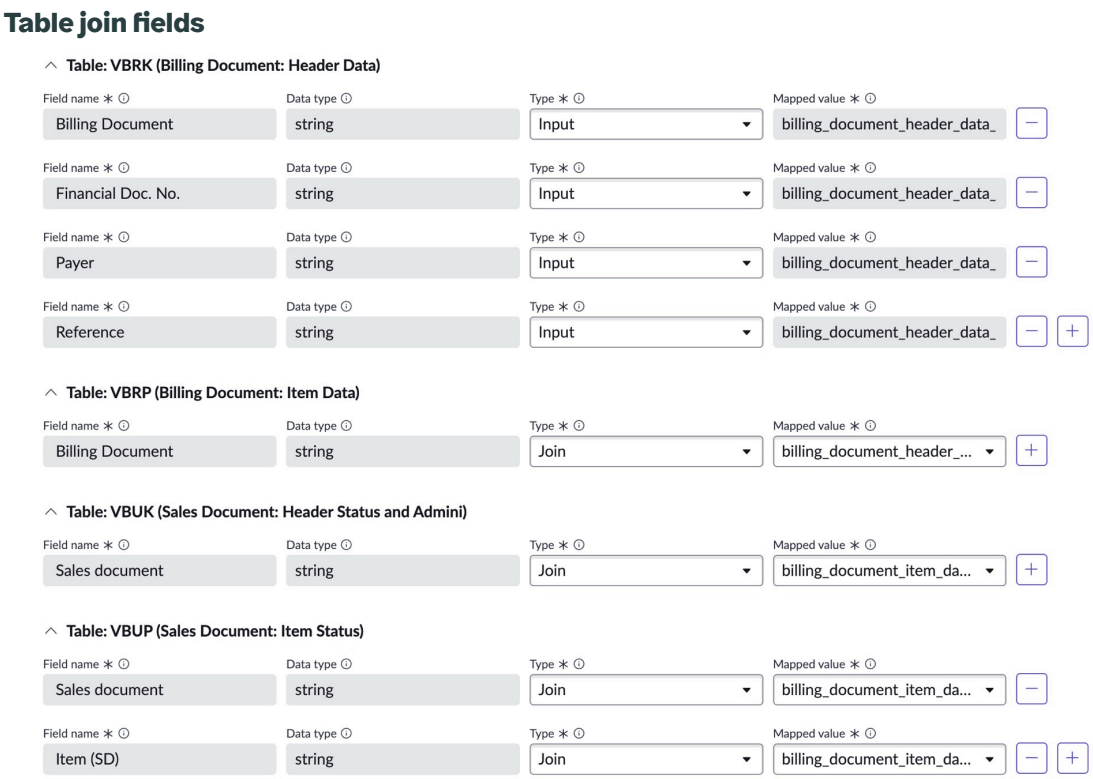
   b. Add a new mapped field row in the table by selecting the add (+) icon.

   c. Enter or select the parent join **Field name** in the new field row.

   d. Select **Join** from the **Type** field.
   The value in the child table **Mapped value** field updates automatically with the joined field name.

For example, in the SAP Material Stock model, you can specify **Material** as the parent field in the **Field name** field, and join it to the material ID by entering `mard_material_matnr` in the parent **Mapped value** field.

e. Select **Save**.



10. **Optional:** Add or update any output parameters as needed in the Output parameters section. The joined parameter that you added to as an input is automatically added to the **Choose output** tab.

    For more information, see Choose output parameters for an ERP model.

Result

After you're done creating table joins, you can specify where the returned ERP data goes, and build flows that retrieve and output the data. For more information, see the following topics:

- Specifying where the ERP system data is saved
- Building flows to read or update the ERP system

Manage input parameters for an ERP Data Hub model operation

Specify how fields on the ERP (Enterprise Resource Planning) system map to input parameters and their values to define the inputs for an operation that reads or updates the system of record from ERP Data Hub.

Before you begin

Role required: sn_erp_integration.erp_admin, sn_erp_integration.erp_user

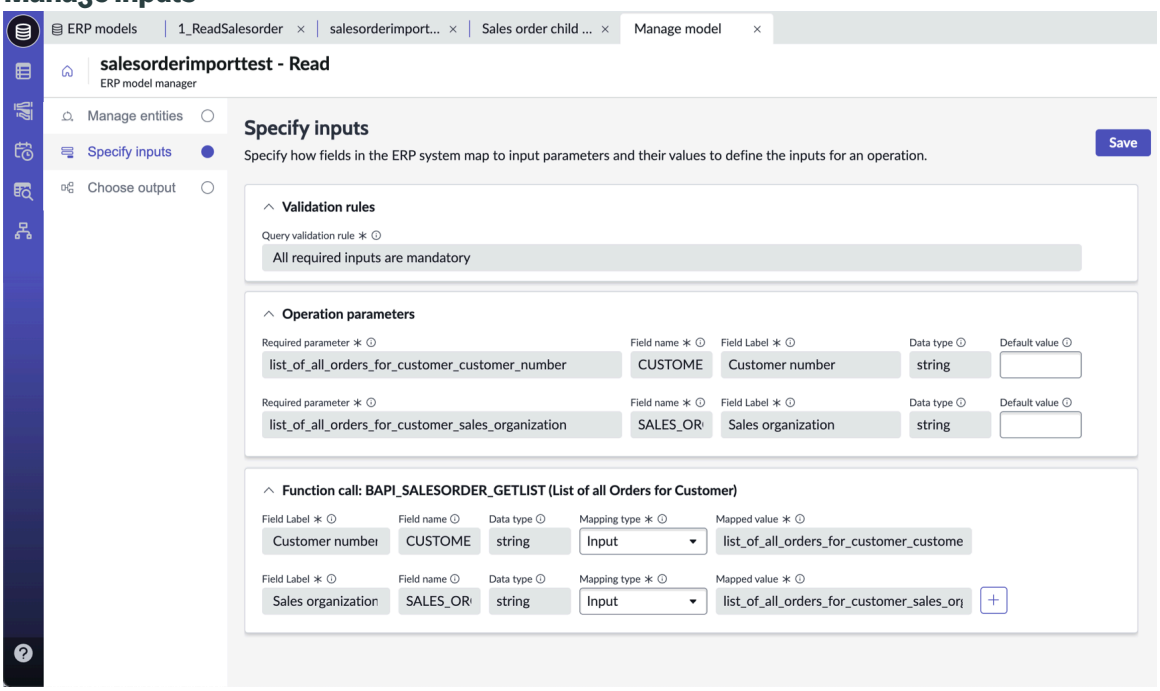
About this task

If you're already in the process of managing a model and ready to specify inputs, you can skip to step 5.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP model page by selecting the ERP model icon ( ) in the side panel.
3. Select the model with the operation that you want to add inputs to.
4. Select the **Manage model** button.
5. Open a model operation.
   If you do not have a model operation, add one to the model. For more information, see Add an operation to a model in ERP Data Hub.
6. Open an entity.
   If you do not have an entity, add one to the operation. For more information, see Add a read, update, or create entity to a model in ERP Data Hub
7. Select **Specify inputs**.
   The required parameters for the operation appear in both of the following places:
   - The Operation parameters section, where you define any default values to use if the operation fails.
   - The Tables/Function call section, where you define the parameters the operation uses. The Table section appears for read operations, and the Function call section appears for BAPI (Business Application Programming Interface) operations.

Manage inputs



8. Define whether the operation inputs are required in the **Query validation rule** field.
   - **All inputs are mandatory**
   - **At least one input is mandatory**
   - **No inputs are mandatory**
9. Review the required and optional parameters that are already defined for the operation and note what you must add.
10. Define a new input parameter to be sent when querying the ERP system.

For table read operations, a Tables section appears in the mapped table fields section for each defined table entity. Make sure that you're adding the parameter for the correct table.

Note:
It doesn't matter what order you define parameters in. ERP Data Hub displays optional parameters in alphabetical order when you save.

a. Select the add icon (+) next to the last-defined parameter.

b. Fill in the fields to define the parameter.

Fields to define an input parameter

Field	Description
Field name	Name of the field from the ERP system that you're defining as a parameter. ERP Data Hub automatically retrieves fields from the table defined in the operation entity.
Data type	(Read-only) Automatically populated value that specifies the type of data the parameter contains.
Type	Definition of how the parameter is sent. ▪ **Input** parameters have their **Mapped value** automatically populated. ▪ **Constant** defines a parameter whose value never changes, for example, to use as filter criteria. You must specify the value in the parameter's **Mapped value** field. ▪ **Join** (Table read operations only) indicates that you're creating a table join. For more information, see Add joins between ERP tables.
Mapped value	Specific value of the parameter. ▪ For **Input** parameters, accept the system-generated name. ▪ For **Constant** parameters, enter a set value that's always sent for the parameter. ▪ For **Join** parameters, select the field to join the parameter with. For details on creating joins, see Add joins between ERP tables.

If you're adding a complex, nested parameter, such as an address that includes several other parameters (one for street, one for city, one for country), ERP Data Hub automatically identifies that it needs additional related parameters and creates new, nested parameter rows that you must then populate with the related values. You can nest only parameters with **Object** or **Array** as the **Data type**.

11. Include the newly defined parameter in the Output parameters section by selecting the automap icon ( ).

ERP Data Hub automatically updates the **Mapped value** for the Tables/Function call parameter, and adds a row for the parameter to the Output parameters section.

12. **Optional:** Specify a **Default value** to be used for the parameter in the newly added **Optional parameter** row in the Output parameters section.
    The **Default value** is used when the input parameter isn't specified in the query.
13. **Optional:** Remove any optional parameters that you don't need when querying the ERP system by selecting the remove (-) icon.
    You can't remove any **Required parameters**.
14. Make any additional edits to existing parameters.
15. Select **Save**.

What to do next

Next, check the output parameters for the operation and update as needed. For more information, see Choose output parameters for an ERP model.

Choose output parameters for an ERP model

Specify output parameters for an ERP (Enterprise Resource Planning) system read or update operation in ERP Data Hub to define how fields and parameters are mapped from the ERP system to the ServiceNow AI Platform. Output parameters also define how returned data is stored on the ServiceNow AI Platform.

Before you begin

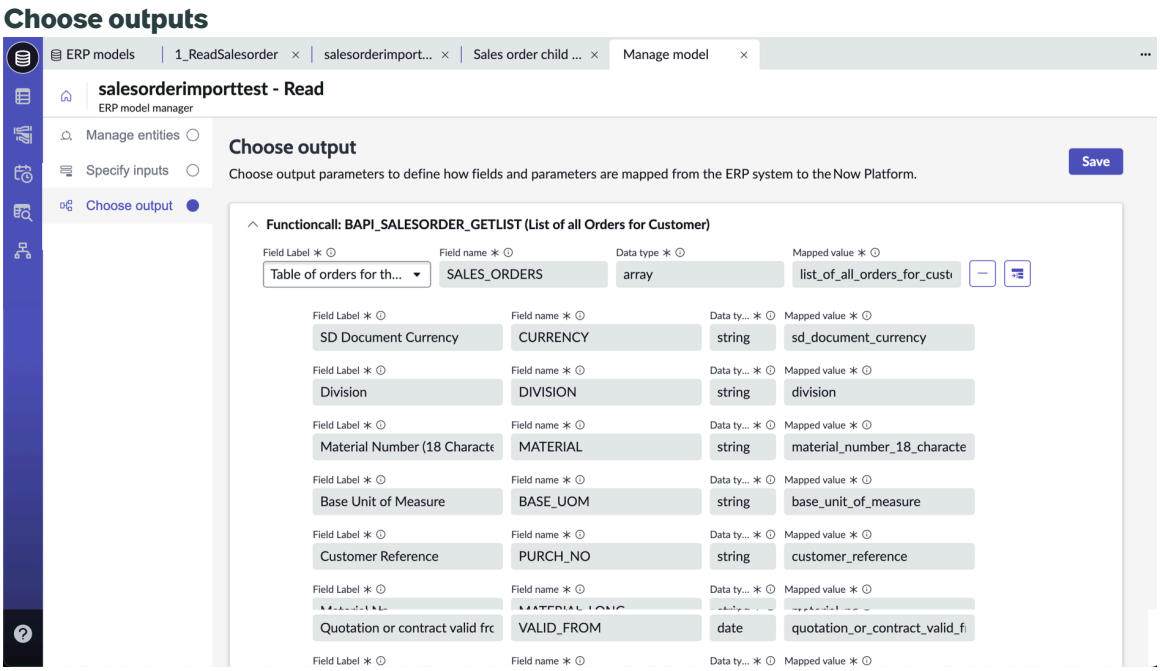
Role required: sn_erp_integration.erp_admin, sn_erp_integration.erp_user

About this task

If you're already in the process of managing a model and ready to specify outputs, you can skip to step 5.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP model page by selecting the ERP model icon ( ) in the side panel.
3. Select the model that you want to add a read operation to.
4. Select the **Manage model** button.
5. Select the **Choose outputs** tab.
6. Review the existing outputs to see if you must add any additional parameters.



7. Add a new output field or parameter.

   a. Select the added icon (+) next to the last-defined parameter.
   If you're adding a mapped field for a table read operation, make sure to add the field to the applicable table section.

   b. Search for and select the **Field name** for table reads or **Parameter name** for BAPI (Business Application Programming Interface) operations.
   The **Data type** field is automatically updated with the applicable values for your selection.

   c. Enter the corresponding value in the **Mapped value** field.

   If you're adding a complex, nested parameter, such as an address that includes several other parameters (one for street, one for city, one for country), ERP Data Hub automatically identifies that it needs additional related parameters and creates new, nested parameter rows that you must then populate with the related values. You can nest only parameters with **Object** or **Array** as the **Data type**.

8. **Optional:** Add any nested output fields or parameters to choose what data to include from a complex parameter.
   For example, you may have a full billing address in the object parameters, but only need to include the city and postal code as output.

   a. Specify the parent output field or parameter.

   b. Select the settings ( ) or add icon (+) for the parent row.

   c. In the modal that appears, select any additional, related fields or parameters to include.
   The parent automatically updates with the related, nested fields or parameters you selected.

9. Select **Save**.

Result

When you add mapped fields or parameters as outputs and successfully read or update the ERP system, each parameter appears as a field that you can then add to a remote table or an

extraction table. Manage the fields for the remote table or extraction table to add the retrieved parameters. For more information, see the following topics:

- Customize fields for an ERP remote table in ERP Data Hub
- Select fields for an extraction table in ERP Data Hub

Specifying where the ERP system data is saved

Data that ERP Data Hub retrieves from ERP (Enterprise Resource Planning) systems can be used in remote tables, extraction tables, and added to flows as data pills in Workflow Studio.

Adding retrieved data to remote tables and extraction tables

Use the JSON contents of the **Response** in a flow's output to save the ERP data in the following ways:

- Store the data in a remote table. Remote tables get their records from running an associated script against an external data source.
- Store the data in an extraction table. Extraction tables retrieve large amounts of data using a scheduled query, and use transform tables to process data for use on the ServiceNow AI Platform.

When you add mapped fields or parameters as outputs and successfully read or update the ERP system, each parameter appears as a field that you can then add to a remote table or an extraction table. Manage the fields for the remote table or extraction table to add the retrieved parameters. For more information, see the following topics:

- Customize fields for an ERP remote table in ERP Data Hub
- Select fields for an extraction table in ERP Data Hub

Using retrieved ERP data in flows

The **Use ERP Data** action returns ERP data in an output data pill called **Response**. The **Response** pill is available when you build a flow in Workflow Studio with the **Use ERP Data** action. The **Response** data pill is available in the following places of the action:

- The **Outputs** tab
- The **Output** section in the **Data** pane

You can then add the **Response** data pill or any of the child **record** data pills to a flow to parse the returned JSON.

For example, you can generate a record for each response from the ERP system, making that data available for use on the ServiceNow AI Platform. For more information, see Building flows to read or update the ERP system.

Next steps after extracting data from your ERP system using ERP Data Hub

After you identify and extract ERP (Enterprise Resource Planning) data with ERP Data Hub, you can use that data on the ServiceNow AI Platform as the data source for products and apps.

Use retrieved ERP data in flows

Build flows in Workflow Studio to specify details for when you query or update the ERP (Enterprise Resource Planning) system.

For example, you can generate a record for each response from the ERP system, making that data available for use on the ServiceNow AI Platform. For more information, see Building flows to read or update the ERP system.

Build a ServiceNow app that consumes ERP data

ERP data from the system of record is available in the remote tables and ERP extraction tables that you configure in ERP Data Hub. You can also use table transform maps to put extracted ERP data into a Glide table.

After ERP data is available on tables in the ServiceNow AI Platform, you can use those tables as the foundation for app builders. For example, you can use ERP tables as a data source when you add data in App Engine Studio. For more information, see Create a data model for your application.

ServiceNow low- and pro-code builders

Use any of the following ServiceNow builders to create apps using custom data:

- App Engine Studio
- Flows in Workflow Studio
- Playbooks in Workflow Studio
- Table Builder
- UI Builder
- Workspace Builder

Using Glide to query ERP data

You can also access data from the system of record through the Glide API.

For more information, see Sample Glide query for ERP data in ERP Data Hub.

Managing ERP development pipelines in ERP Data Hub

Move your ERP (Enterprise Resource Planning) systems, ERP models, tables, operations, and flows from a development instance to a production environment when they're ready.

Changes that you could promote from a development instance to a production instance include adding:

- Fields to tables
- Tables or BAPIs (Business Application Programming Interface) to ERP models
- Table joins and fields to link tables
- Read and update operations
- Flows built with the **Use ERP Data** action to query and update the system of record

> **Note:**
> You should do your development on a non-production instance. If you make changes on a production instance, and then promote changes from a non-production instance to the production instance, any changes you previously made on the production instance are overwritten.

There are several ways to move changes to your production instance on the ServiceNow AI Platform:

1. Use System Update Sets to transfer changes from a development instance to a non-production and then production instance. For more information, see System update sets.
2. Add the changes to the ServiceNow Store and use the **Share with others** option to install the updates on the production instance. For more information, see Publish an application to an Update Set.

For more information on ways to publish your ERP updates, see Application sharing.

Building flows to read or update the ERP system

After you configure an operation in ERP Data Hub, you can build a flow in Workflow Studio to specify details for querying the ERP (Enterprise Resource Planning) system. For example, build a flow that filters by Order ID.

Actions in Workflow Studio for calling the ERP system

A Use ERP Data action is automatically available in Workflow Studio after installing ERP Data Hub.

The Use ERP Data action enables you to use ERP data outside of ERP Data Hub for other processes. For example, you could create a task or an incident based on ERP data using the Use ERP Data action.

After you're done creating and managing your model in ERP Data Hub, go to Workflow Studio and use the Use ERP Data action to test your model's inputs and outputs.

When you test the action, you must specify the model you're using, which fields to read or update, and the ERP system. For more information on the action, see ERP Data Hub Use ERP Data action details for flows.

Using parameters to filter data requests

After you successfully test the Use ERP Data action, build a flow that uses that action to retrieve or update the specified data in the ERP system.

When you add the Use ERP Data action to a flow, you can specify any **Mandatory Field(s)** and **Optional Field(s)** defined as inputs when you managed the model. Required and optional fields must already be configured as required and optional input parameters.

If you select a field that was defined as a parameter for the system query, you can then enter a value to filter on. For example, if you build a flow that uses the Use ERP Data action and specify the SAP Stock Movement model, you can select **iseg_fiscal_year** as a required field, and then enter a year to filter the data returned, for example 2023.

Process for building flows to retrieve ERP data

If you want to use ERP data for processes or tasks outside of ERP Data Hub, use the following workflow:

1. In Workflow Studio, test the **Use ERP Data** action by selecting the model in the **System** field of the Test Action modal and then specifying the inputs.
   - For more information on testing actions, see Test an action.
   - For more details on inputs for the action, see ERP Data Hub Use ERP Data action details for flows.
2. After the test runs, view the action execution details. For more information, see Flow execution details.
3. The returned data from testing the action appears in the **Response** field of the output data.

- For more information on outputs for the action, see ERP Data Hub Use ERP Data action details for flows.
- For details on incorporating returned ERP data, see Specifying where the ERP system data is saved.

4. Build a flow that runs the Use ERP Data action.

   The **Use ERP Data** action returns ERP data in an output data pill called **Response**. The **Response** pill is available when you build a flow in Workflow Studio with the **Use ERP Data** action. The **Response** data pill is available in the following places of the action:

   - The **Outputs** tab
   - The **Output** section in the **Data** pane

   You can then add the **Response** data pill or any of the child **record** data pills to a flow to parse the returned JSON.

   For more information, see Building flows.

Note:
ERP Data Hub appears as **ERP Integration** when you work with it in Workflow Studio.

Connect ERP Data Hub to SAP using OData and HTTP

Extract data securely from ERP OData APIs using ETL for use in remote tables and extraction tables. OData connects to SAP via HTTP.

Important:

OData v2 does not use snapshot isolation so you might experience some data consistency issues when retrieving data from an external ERP source.

Providing OData access to users

You must have an SAP system that has been enabled to make an OData connection.

As of Xanadu Store Release 2, extract data using OData and an HTTP connection. To give users OData access, see the following instructions on the SAP help site Back-End Server: Assign OData Service Authorization to Users.

New properties

The following are properties related to OData available for ERP in Xanadu Store Release 2.

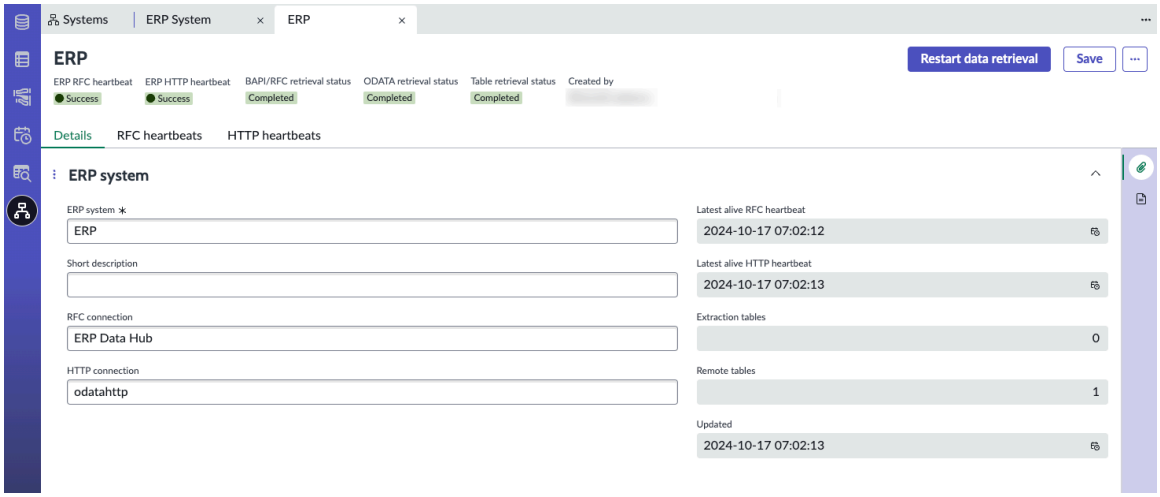
Property	Type	Description	Create manually?
sn_erp_integration.response_timeout	integer	Specifies the timeout value for OData response. If OData calls are timed out frequently, increase the timeout value. Specify the value in seconds. The default is 100 seconds. This value is used for responses both from	No

Property	Type	Description	Create manually?
		external web and from a MID Server.	
sn_erp_integration.use_csrf_token	true | false	Indicates if CSRF token should be sent for OData calls in ERP Data Hub operations.	No
sn_erp_integration.catalog_service_path	string	After the hostname and port, this is the path to connect with any SAP catalog service. The default is: /sap/opu/odata/iwfnd/CATALOGSERVICE;v=2/ServiceCollection. After creating the property and setting it to true, a list of all services are retrieved from SAP. The information is stored in an XML file and attached to the system record. The XML can be used later. For example, parse the XML while offline with no connection to SAP.	Yes
sn_erp_integration.odata_service_path	string	After the hostname and port, this is the path to connect with any SAP OData service. Add a URL in **Value** to specify the OData service. The default is: /sap/opu/odata/sap.	Yes

Note:
To add a new property manually, verify that your scope is set to ERP Data Hub, then navigate to sys_properties.list and select **New**.

Heartbeat information

For an ERP system, there are separate heartbeat indicators for RFC and HTTP. When a system is established, the heartbeats become active and the status is updated, including any errors. If the heartbeat calls are successful, BAPI and OData retrieval is triggered in parallel and the status can be seen on the system record. BAPI and table list retrieval is done via RFC. OData retrieval is done via HTTP.



More information

For more information about using OData in ERP Data Hub, see Create an OData connection in ERP Data Hub and OData capabilities supported by ERP Data Hub.

OData capabilities supported by ERP Data Hub

Details about the OData query capabilities supported in ERP Data Hub.

For information about OData connections in ERP Data Hub, see Connect ERP Data Hub to SAP using OData and HTTP and Create an OData connection in ERP Data Hub.

OData query capabilities

OData query	
$select, $filter, $count	Available in the **Use ERP** flow. When using the inputs and outputs parameters in the model, $select and $filter are applied. Use $count when invoking the **Use ERP** flow.
$orderby	Supported only via encoded query while executing the remote tables or extraction tables.
$top and $skip	When doing the internal operations, $top and $skip are supported only while pagination is done. Cannot send $top and $skip via any flow.

Create an OData connection in ERP Data Hub

Create an OData v2 connection to link to SAP via HTTP so data can be extracted for use in remote tables and extraction tables.

Before you begin

Role required: sn_erp_integration.erp_admin

For information about OData connections in ERP Data Hub, see Connect ERP Data Hub to SAP using OData and HTTP and OData capabilities supported by ERP Data Hub.

About this task

Your administrator must enable the *sn_erp_integration.enableModelModification* property for you to edit, customize, and clone ERP models and tables. After you enable the *sn_erp_integration.enableModelModification* property, ERP Data Hub retrieves all tables and BAPIs (Business Application Programming Interface) to use when managing models. The property must be configured for either a non-production or production state. System properties are maintained in the System Property table [sys_properties], which you can access using the module navigator, or directly typing `sys_properties.list` in the Navigator Filter.

Note:
You must enable the *sn_erp_integration.enableModelModification* property on the correct scope. Enabling the *sn_erp_integration.enableModelModification* on a production instance can create new metadata records when new models and fields are added in ERP Data Hub.

Procedure

1. Confirm that you have an SAP system that has been enabled to make an OData connection.
2. Create a connection and credential alias, specifying HTTP as the **Connection type**.
   For more information, see Create a Connection & Credential alias.
3. Create an HTTP connection and associate it with the new alias.

   Note:
   For more information, see Create an HTTP(s) connection. If you choose to use a MID Server, users with access to the services can use the same credential for RFC and HTTP.

4. Create a system with the HTTP connection.
   For more information, see Create an ERP system in ERP Data Hub.
5. On the system record, confirm that the heartbeats are successful and the retrieval status is complete.
   If any have failed, select **Restart data retrieval**. Any data retrieval that failed (BAPI, OData, or tables) is fetched again.
6. Create a model and, after saving, open the model record.
   For more information, see Add a new ERP model.
7. Select **Manage model**.
8. Select **Add model operation**.
   a. Choose a **Select type**.
   b. Select **Save and Continue**.
9. Select the new operation.
10. Select **Add entity**.
    a. In **Select type**, choose **OData**.
    b. In **Select entity**, search for and select a service, for example **API_BUSINESS_PARTNER (Remote API for business partner)** in the OData service catalog.
    When you specify the service, a call is made to the SAP service to read its metadata. The default service is /sap/opu/odata/iwfnd/CATALOGSERVICE;v=2/ServiceCollection. If you

must change the service, create a property named sn_erp_integration.odata_service_path and set the value.

c. In **Select the endpoints**, search for and select an endpoint, for example **A_BusinessPartnerType**.

d. Select **Add entity**.
The flow named **GET SAP BAPIs and tables when system becomes active** runs to retrieve the data. The BAPI, table, and catalog tables are populated.

11. Select **Specify inputs** to check the information and edit as needed.
For more information, see Manage input parameters for an ERP Data Hub model operation.
12. Select **Choose output** to check the information and edit as needed.
For more information, see Choose output parameters for an ERP model.
13. Open the ERP systems list by selecting the systems icon ( ) in the side panel.
14. Select the system.
15. Check the heartbeat and retrieval status, and select the refresh list icon as needed until the heartbeats are successful and the retrieval status completed.
16. Create a model.
    a. Open the ERP models page by selecting the ERP models icon ( ) in the side panel.
    b. Select **New**.
    c. Add an **ERP model name**, **ERP module**, and **ERP system**, and select **Save**.
    d. Select the new model in the list.
    e. Select **Manage model**.
    f. Select **Add model operation**.
    g. Select a **Select type**.
    h. Select **Save and Continue**.
17. Select the new operation.
18. Select **Add entity**.
    a. In **Select type**, select **OData**.
    b. Select a **Select entity**, select an entity, for example **API_BUSINESS_PARTNER (Remote API for Business Partner) OData service catalog**.
    c. In **Select the endpoints**, search for and select an endpoint, for example **A_BusinessPartnerType Entity Name: Business Partner --- Return Type: Business Partner**.
    d. Select **Add entity** and wait for retrieval to complete.
19. Select **Specify inputs** to check the information and edit as needed.
    a. If there are required fields, select **Select mandatory fields**.
    b. Select any mandatory inputs listed and select **OK**.
    c. Select **Save**.
20. Select **Choose output**.

a. Select **+ New output**.

b. Select fields, for example **BusinessPartnerName** and **Full Name**.

c. Select **Save**.

21. Test with Workflow Studio.

a. Navigate to **All** > Workflow Studio.

b. On the homepage, select **Actions**.

c. In the **Name** column, filter for **contains Value** and type `Use ERP`.

d. Select **Apply**.

e. Select **Use ERP data**.

f. Select **Test**.

g. Specify the **ModelName**, **ModelOperation**, **Mandatory fields** (provide a value for the mandatory field if necessary), select a **System**, and select **Run Test**.

h. When complete, select the link **Your test has finished running. View the Action execution details**.

i. View and check the output, for example, in **Output Data**, select the **Response** to view the output.

Using ERP remote tables in ERP Data Hub

ERP (Enterprise Resource Planning) remote tables in ERP Data Hub enable you to view and query data from the ERP system of record on the ServiceNow AI Platform.

Note:
ERP Data Hub doesn't replicate data into the ServiceNow AI Platform. It mirrors data that lives in the ERP system of record, and remains protected there.

Remote tables are linked to ERP models

Each ERP remote table is connected to one ERP model, which links the remote table to the ERP system and other related values. When you build a remote table, you can add any of the fields that ERP Data Hub finds when scanning the ERP system of record, which is connected through the ERP model. Scanning for and adding fields ensures that all necessary fields are available, such as when using the table as a data source when building an app.

The connected ERP model, which is defined on the remote table **Details** tab, controls the available fields on the remote table. If you change the ERP model for a remote table, the available fields change as well.

Limitations of remote tables

To ensure data integrity, you can't create new remote tables in ERP Data Hub, but you can clone existing ERP models and extend standard ERP remote tables to customize them. For more information, see Clone an ERP model in ERP Data Hub.

ERP remote tables have a limit of 1,000 records. If you need a larger amount of data, use an ERP extraction table. For more information, see Extracting and transforming data in ERP Data Hub.

View and edit ERP remote table details with ERP Data Hub

View and edit details for ERP (Enterprise Resource Planning) remote tables in ERP Data Hub, such as their attachment settings and short descriptions.

Before you begin

Role required:

- To modify remote tables: sn_erp_integration.erp_admin
- To read remote tables: sn_erp_integration.erp_user

About this task

To ensure data integrity, you can't create new remote tables in ERP Data Hub, but you can clone existing ERP models and extend standard ERP remote tables to customize them. For more information, see Clone an ERP model in ERP Data Hub.

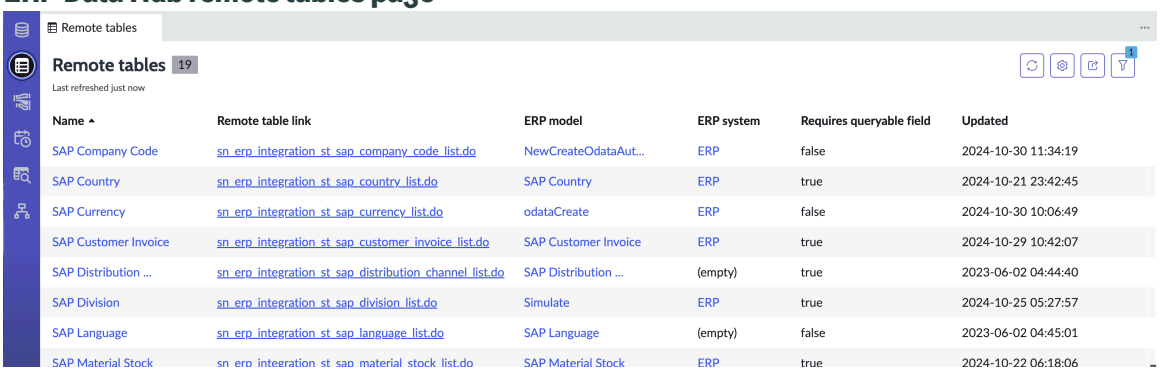
For information on adding and removing fields to and from remote tables, see Customize fields for an ERP remote table in ERP Data Hub.

ERP remote tables have a limit of 1,000 records. If you need a larger amount of data, use an ERP extraction table. For more information, see Extracting and transforming data in ERP Data Hub.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the Remote tables page by selecting the remote tables icon ( ) in the side panel.

ERP Data Hub remote tables page



3. View the details for a remote table by selecting the remote table **Name**.
4. **Optional:** Refresh the data stored in the remote table attachment outside of the scheduled cycle by selecting the **Refresh attachment data** button.
   The remote table attachment is the cached response from the ERP system. If the remote table **Attachment setting** field is set to **Use attachment**, ERP Data Hub doesn't call the ERP system when someone fetches data from the remote table.
5. Edit the remote table details as needed.
   For a description of the field values, see ERP Data Hub remote table form field descriptions.
6. View the fields in the remote table by selecting the **Remote table fields** tab.
7. **Optional:** View the ERP remote table as a list on the ServiceNow AI Platform by selecting the **Open remote table list** button.
8. Select **Save**.

Customize fields for an ERP remote table in ERP Data Hub

Add or remove columns in remote tables in ERP Data Hub to create your ERP (Enterprise Resource Planning) model. For example, remove fields with sensitive information, such as birthdays.

Before you begin

Role required:

- To modify remote tables: sn_erp_integration.erp_admin
- To read remote tables: sn_erp_integration.erp_user

About this task

ERP Data Hub scans the system of record for the ERP model to find all available fields that you can add to a remote table. You can view all available fields from the ERP system in the ERP model. Using the **Manage fields** modal to add available columns from the ERP system to a remote table automatically creates them in the remote table.

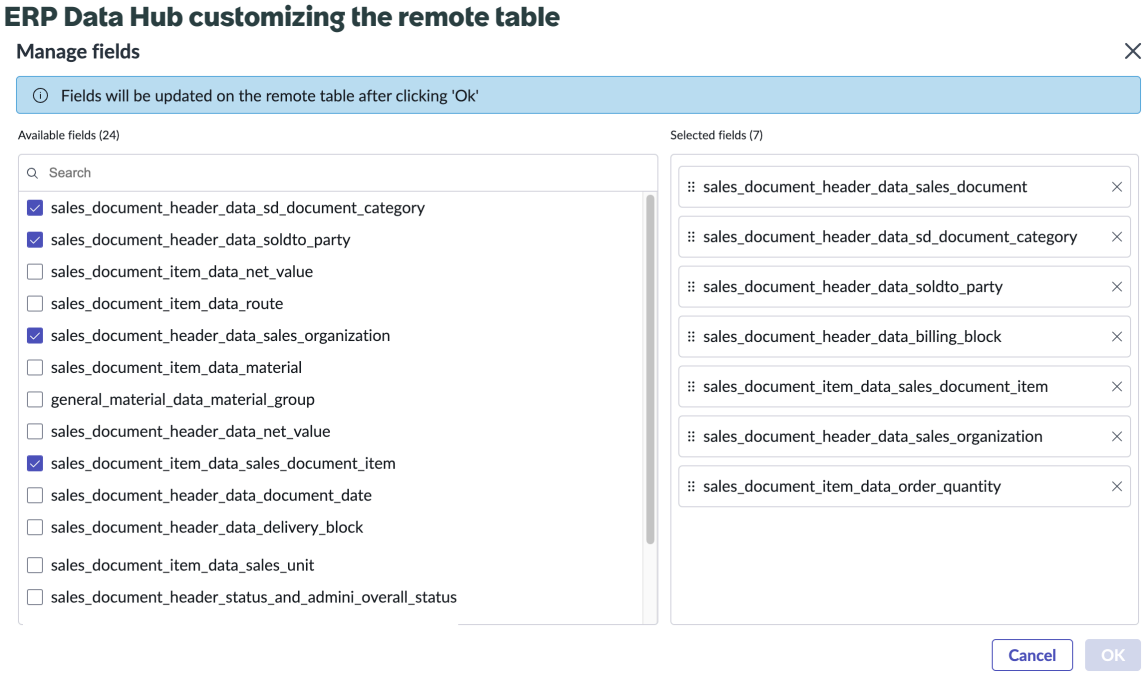
If you don't see the fields that you want to add to the remote table, you must first add them to the model. For more information, see Choose output parameters for an ERP model.

The connected ERP model, which is defined on the remote table **Details** tab, controls the available fields on the remote table. If you change the ERP model for a remote table, the available fields change as well.

Note:
You can't edit field names in remote tables, but you can add a new label for a field.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the Remote tables page by selecting the remote tables icon () in the side panel.
3. Select a table to work with by selecting the **Name**.
4. Manage the columns to build the remote table by selecting the **Manage fields** button.
   a. On the modal, find and select the field that you want to add to the remote table using the search box.
   b. Select the button to move the field from the **Available fields** list to the **Selected fields** list.
   c. Drag to rearrange how fields appear in the table.
   d. After you finish adding all the fields, select **OK** to save your changes.
   The ServiceNow AI Platform updates the fields on the remote table with your changes.



5. Confirm that the fields appear correctly as columns on the remote table by selecting the **Remote table fields** tab.

Query a remote table using ERP Data Hub

Query ERP (Enterprise Resource Planning) remote tables from a system of record directly from the **All** menu using ERP Data Hub.

Before you begin

Role required: sn_erp_integration.erp_user

About this task

You can query the system of record to create an ERP model for your ERP processes. For more information, see Building and managing ERP models to work with ERP data.

Note:
ERP Data Hub doesn't replicate data into the ServiceNow AI Platform. It mirrors data that lives in the ERP system of record, and remains protected there.

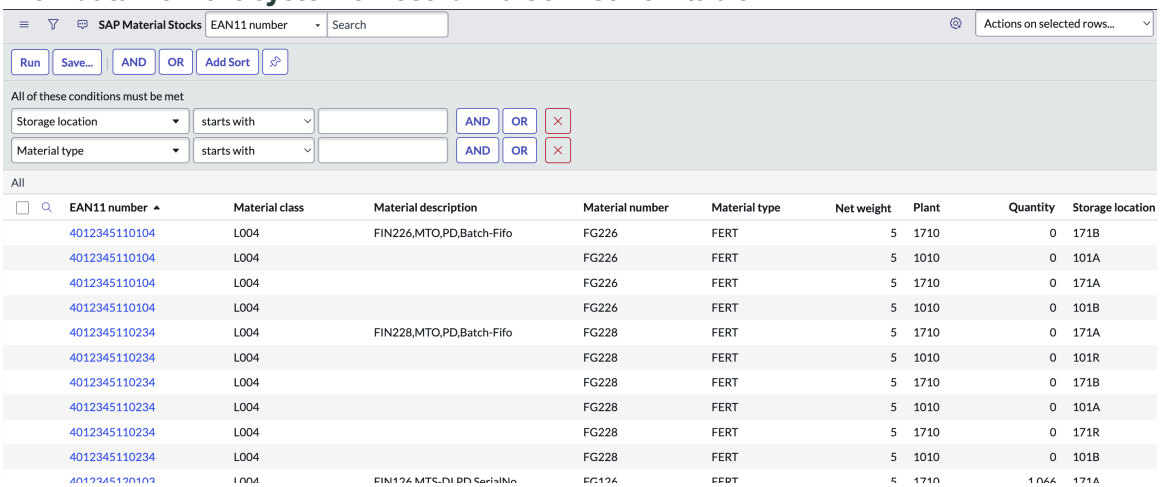
Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the Remote tables page by selecting the remote tables icon ( ) in the side panel.
3. Select the remote table from the navigation menu, such as **SAP Material Stock**.
4. Query the remote table using Glide for SAP.

   For example, you can select and hold (or right-click) on a column, such as **Storage location**, and select **Show Matching** records.

The SAP data is accessible for you to work with using standard ServiceNow AI Platform searching, sorting, and filtering, such as the condition builder. For more information, see Condition builder.

View data from the system of record in a ServiceNow table



EAN11 number	Material class	Material description	Material number	Material type	Net weight	Plant	Quantity	Storage location

Extracting and transforming data in ERP Data Hub

ERP (Enterprise Resource Planning) extraction tables enable you to create daily processes that extract large amounts of data. You can then include the extracted data in an ERP model in ERP Data Hub.

Hold large amounts of data in extraction tables

Use extraction tables, which are ETL (extract, transform, and load) data sources, to extract large amounts of data on a regular basis.

For example, you can extract all open purchase orders for the current month from an SAP system into a Glide table once a day at a set time. You can then access that data via ServiceNow AI Platform, such as Source-to-Pay Operations or a PO workspace created in App Engine Studio.

After the extraction process is run, use import sets to map imported data into ServiceNow AI Platform tables. For more information, see Import sets.

Extraction tables use transform table maps

ERP extraction tables save data to a local transform table on the ServiceNow AI Platform. The transform table is a temporary table that holds data during the data integration or transformation process. Transform tables are an intermediary step before data is further processed, cleaned, or loaded into the target destination. For example, after import, the extraction table can run a Glide query on a transform table and save the output to several different target tables.

If you use a custom transform table, you must first create the table on the ServiceNow AI Platform, and the table must be in the application scope. For more information on creating table transform maps, see Create a transform map.

ETL processes in ERP Data Hub are configured in the ServiceNow AI Platform app that needs the data, not ERP Data Hub. For example, you can configure an extraction process in a flow in Workflow Studio.

Automatically available standard extraction tables

When you install ERP Data Hub, the ServiceNow AI Platform automatically loads standard ERP extraction tables for you to work with. For example, sales, delivery, and procurement tables. For a list of standard extraction tables, see Standard ERP models and extraction tables for ERP Data Hub.

If you installed ERP Customization Mining, that app populates some additional extraction tables, such as ERP application activity, Collector directory data, and Namespace data.

View ERP extraction tables

Work with ETL (extract, transform, and load) processes in ERP Data Hub to extract large amounts of ERP (Enterprise Resource Planning) data from the ERP system. Extracted data is stored in Glide tables in the ServiceNow AI Platform.

Before you begin

Role required: sn_erp_integration.erp_user

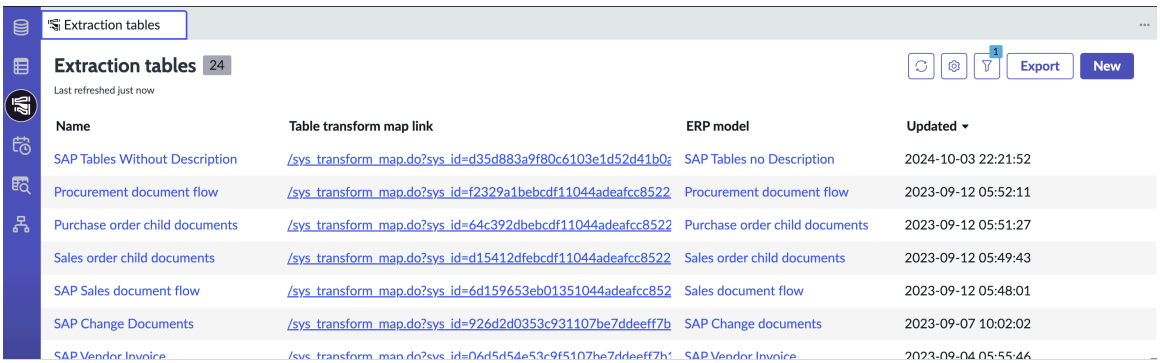
About this task

ERP extraction tables extract and save data to a transform table on the ServiceNow AI Platform. The transform table is a temporary table that holds data during the data integration or transformation process. Transform tables are an intermediary step before data is further processed, cleaned, or loaded into the target destination.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP extraction tables page by selecting the ERP extraction tables icon ( ) in the side panel.

Extraction tables in ERP Data Hub



3. View the list of ERP extraction tables and note of the tables that you can use to build your ERP model.

ETL source columns

Column	Description
Name	Name of the ETL process.
Short description	Brief description of the purpose of the ETL process.
Tables transform map link	Table that the extracted data is cached and stored in.

Column	Description
	Select the table name to view the table on the ServiceNow AI Platform in a new browser tab. For more information on creating table transform maps, see Create a transform map.
ERP model	ERP model used in the ETL extraction. Select the ERP model name to view the details. For more information, see View and edit the foundation of ERP models.

4. **Optional:** View the details for an extraction table by selecting the table name.

What to do next

After the extraction process is run, use import sets to map imported data into ServiceNow AI Platform tables. For more information, see Import sets.

Add a new ERP extraction table in ERP Data Hub

Create an ERP (Enterprise Resource Planning) extraction table to capture large amounts of data from the system of record every day, and save the data to a transformation (staging) table. The data is then available on the ServiceNow AI Platform, and you can add the extracted data to an ERP model or remote table.

Before you begin

You must first configure the source table, target table, and table transform map before those tables can be added to an ERP extraction table. For more information on creating table transform maps, see Create a transform map.

Role required:

- To modify extraction tables: sn_erp_integration.erp_admin
- To read extraction tables: sn_erp_integration.erp_user

About this task

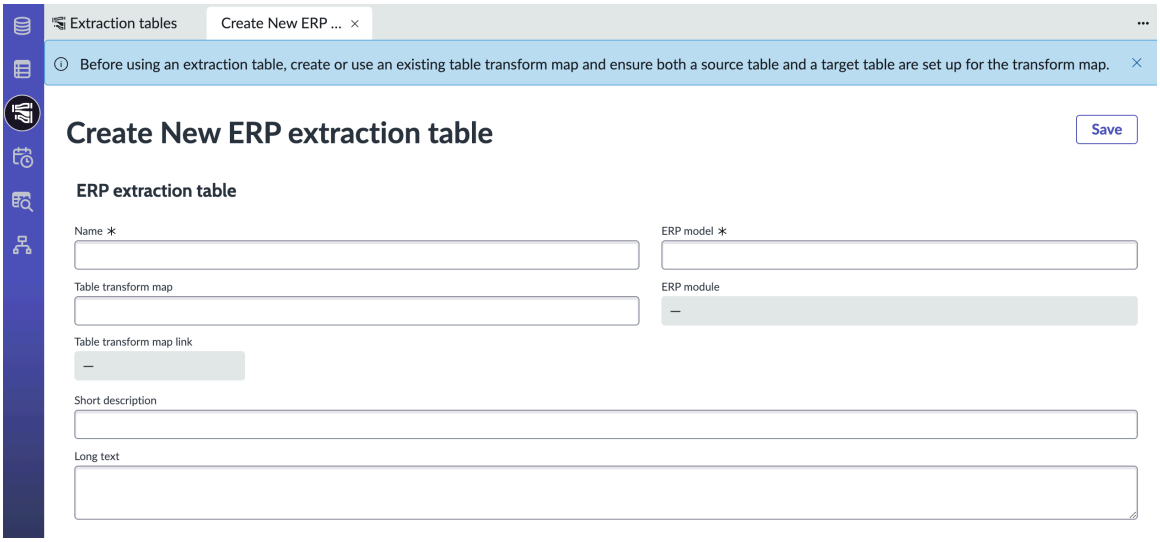
ERP Data Hub provides a number of standard extraction tables, which you can use as-is. If you must change a standard extraction table, copy the table and then update the copied version.

You can create multiple ERP extraction tables, and multiple extraction tables can use the same ERP model. For example, create separate extraction tables for sales contracts, sales inquires, and old sales orders.

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP extraction tables page by selecting the ERP extraction tables icon ( ) in the side panel.
3. Select the **New** button.

Add an extraction table in ERP Data Hub



4. On the form, fill in the fields.
   For a description of the field values, see ERP Data Hub extraction table field descriptions.
5. Select **Save**.

Select fields for an extraction table in ERP Data Hub

Add or remove fields for an extraction table in ERP Data Hub. For example, you may want to remove fields with sensitive information, such as birthdays.

Before you begin

If you don't see the fields that you want to add to the extraction table, you must first add them to the model. For more information, see Choose output parameters for an ERP model.

Role required:

- To modify extraction tables: sn_erp_integration.erp_admin
- To read extraction tables: sn_erp_integration.erp_user

Procedure

1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP extraction tables page by selecting the ERP extraction tables icon ( ) in the side panel.
3. Select an extraction table to work with by selecting the **Name**.
4. Manage the columns to build the extraction table by selecting the **Select fields** button.
   a. On the modal, find and select the field that you want to add to the extraction table using the search box.
   b. Select the button to move the field from the **Available columns** list to the **Selected columns** list.
   c. Drag to rearrange how fields appear in the table.

d. After you finish adding all the fields, select **OK** to save your changes.
The ServiceNow AI Platform updates the fields on the extraction table with your changes.

5. Confirm that the fields appear correctly as columns on the extraction table by selecting the **Extraction table fields** tab.

Create a scheduled extraction

Schedule extraction of information for an ERP (Enterprise Resource Planning) extraction table to capture large amounts of data from the system of record at a regular interval.

Before you begin

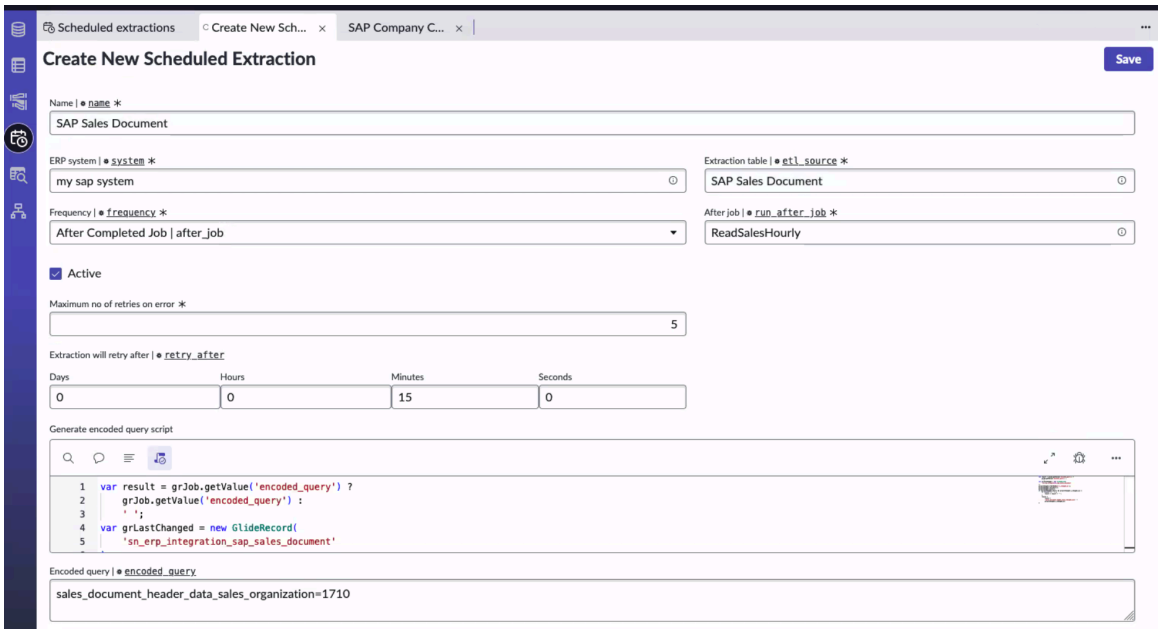
You must have a standard or custom ERP extraction table in place to use. For more information, see Add a new extraction table in ERP Data Hub.

The system property sn_erp_integration.enableJobModification must be set to true to enable creation and modification of scheduled jobs in ERP Data Hub.

Role required: en_erp_integration.erp_user

Procedure

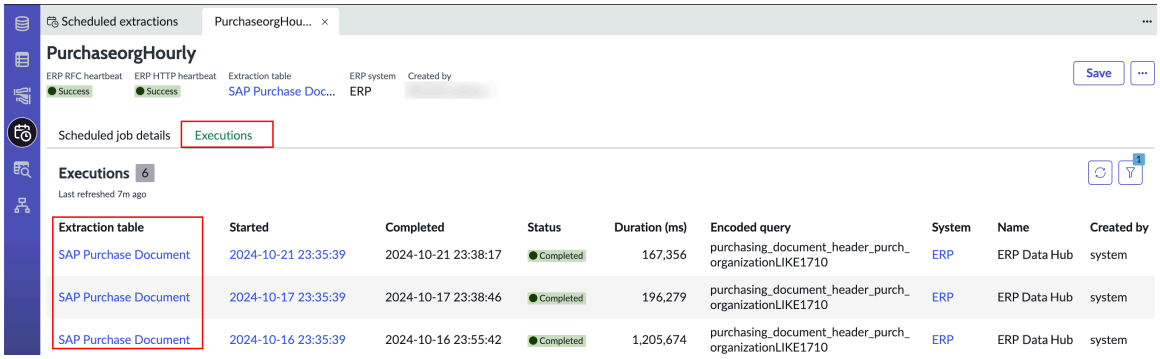
1. Navigate to **All** > **ERP Data Hub** > **ERP Data Hub Home**.
2. Open the ERP scheduled extractions page by selecting the Scheduled extractions icon ( ) in the side panel.
3. Select the **New** button.



4. On the form, fill in the fields.
For a description of the field values, see ERP Data Hub scheduled extraction field descriptions.
5. Select **Save**.

What to do next

Check the executions. After the scheduled job has run, select the **Executions** tab. For details about an extraction, select any line item in the **Extraction table** column.



Monitor ERP Data Hub logged extraction and remote lookup transactions

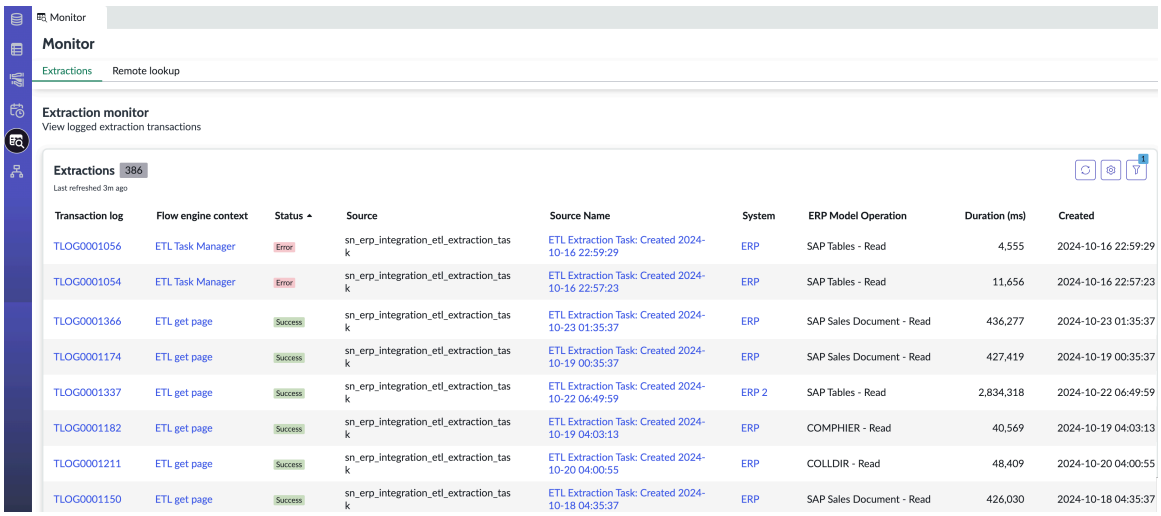
Use the new monitoring feature to track each ERP transaction and its progress. Filter the ERP Data Hub task information, such as successes, failures, and more, as needed.

Before you begin

Role required: admin and sn_erp_integration.erp_user

Procedure

1. Navigate to **All** > **ERP Data Hub**.
2. Open the ERP monitor page by selecting the Monitor icon ( ) in the side panel.
3. Select the **Extractions** and **Remote lookup** tabs to view transaction information.



For a description of the field values, see ERP Data Hub Monitor field descriptions.

ERP Data Hub reference

Find reference information for ERP Data Hub, including ERP (Enterprise Resource Planning) table details.

ERP Data Hub and domain separation

Domain separation is unsupported for ERP Data Hub (Enterprise Resource Planning). Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

Domain separation for service providers

Sample Glide query for ERP data in ERP Data Hub

Access data from the ERP (Enterprise Resource Planning) system of record through the Glide API.

The following is an example of a Glide query that fetches a customer name.

```
var sap_customer_gr = new
 GlideRecord('sn_erp_integration_st_sap_sales_customer');
sap_customer_gr.get('customer_number', '100032');
sap_customer_gr.getValue('name');
```

ERP Data Hub standard tables, fields, and models

Find details on standard ERP (Enterprise Resource Planning) remote tables, extraction tables, fields, and models in ERP Data Hub.

Standard remote tables for ERP Data Hub

ERP Data Hub accesses several standard remote tables for ERP (Enterprise Resource Planning) models.

The following remote tables are available through ERP Data Hub and ERP-CM.

Remote tables for ERP Data Hub and ERP-CM

Label	Name	ERP module
SAP Company Code	sn_erp_integration_st_sap_company_code	Basis
SAP Country	sn_erp_integration_st_sap_country	Basis
SAP Currency	sn_erp_integration_st_sap_currency	Basis
SAP Language	sn_erp_integration_st_sap_language	Basis
SAP Material Stock	sn_erp_integration_st_sap_material_stock	Plant maintenance
SAP Purchase Document	sn_erp_integration_st_sap_purchase_document	Purchasing document
SAP Purchasing Organization	sn_erp_integration_st_sap_purchasing_organization	Purchasing organization
SAP Customer Invoice	sn_erp_integration_st_sap_customer_invoice	Sales invoice
SAP Distribution Channel	sn_erp_integration_st_sap_distribution_channel	Sales
SAP Division	sn_erp_integration_st_sap_division	Sales
SAP Sales Customer	sn_erp_integration_st_sap_sales_customer	Sales
SAP Sales Delivery	sn_erp_integration_st_sap_sales_delivery	Sales
SAP Sales Document	sn_erp_integration_st_sap_sales_document	Sales

Remote tables for ERP Data Hub and ERP-CM (continued)

Label	Name	ERP module
SAP Sales Organization	sn_erp_integration_st_sap_sales_org	Sales_organization
SAP Sales Revenue Recognition	sn_erp_integration_st_sap_sales_rev	Sales_revenue_recognition
SAP Vendor	sn_erp_integration_st_sap_vendor	Sales
SAP Vendor Invoice	sn_erp_integration_st_sap_vendor_inv	Sales_invoice
SAP Transport	sn_erp_integration_st_sap_transport	Transport

For more details on working with remote tables, see Remote tables.

You can use any of the standard remote tables as data sources when building apps in ServiceNow products, such as:

- App Engine Studio
- Flows in Workflow Studio
- Playbooks in Workflow Studio
- Table Builder
- UI Builder
- Workspace Builder

You can also access data from the system of record through the Glide API.

The following is an example of a Glide query that fetches a customer name.

```
var sap_customer_gr = new
 GlideRecord('sn_erp_integration_st_sap_sales_customer');
sap_customer_gr.get('customer_number', '100032');
sap_customer_gr.getValue('name');
```

Standard ERP Data Hub fields within remote tables

The standard ERP (Enterprise Resource Planning) remote tables available for use in ERP Data Hub contain fields from additional SAP tables.

The standard remote tables contain the following additional fields. For details on the standard tables, see Standard remote tables for ERP Data Hub.

Standard ERP Data Hub and ERP-CM tables within remote tables

Remote table	Source table	ERP field name	Mapped field name
SAP Sales Document	VBAK	VBELN	document_number

Standard ERP models and extraction tables for ERP Data Hub

ERP Data Hub provides a number of standard extraction tables that you can link to ERP (Enterprise Resource Planning) models.

ERP models function as templates for sets of tables that give you access to ERP data. You can use the standard ERP Data Hub models as-is, or clone them to make changes.

The following extraction tables are available through ERP Data Hub.

Extraction tables for ERP Data Hub

Label	ERP module
SAP Company Code	Basis
SAP Country	Basis
SAP Currency	Basis
SAP Language	Basis
SAP Material Stock	Procurement
SAP Purchase Document	Procurement
SAP Purchasing Organization	Procurement
SAP Customer Invoice	Sales
SAP Distribution Channel	Sales
SAP Division	Sales
SAP Sales Customer	Sales
SAP Sales Delivery	Sales
SAP Sales Document	Sales
SAP Sales Organization	Sales
SAP Sales Revenue Recognition	Sales
SAP Vendor	Sales
SAP Vendor Invoice	Sales
SAP Transport	Transport

For more details on working with remote tables, see Remote tables.

ERP Data Hub field descriptions

Some tables of field descriptions in ERP Customization Mining (ERP-CM) are too large to maintain in task topics. Find information on the those large tables in this section.

ERP Data Hub connection and credentials field descriptions

The Connection and Credential Alias modal contains connection and credential details that specify how ERP Data Hub connects to the ERP (Enterprise Resource Planning) system.

Enter the Connection Information field descriptions

Enter the Connection Information field descriptions

Field	Description
Connection Name	Label or alias for the connection.
Host name or IP Address to SAP Application server or the Load Balancer	Host name or IP address of the ERP system server or load balancing host that connects to the ERP system.
Login Language	Two-character language code of the language of the ERP server you're connecting to.

Enter the Connection Information field descriptions (continued)

Field	Description
SAP Client	Client value of the connection host where the SAP instance is installed.
SAP System Number	System number of the connection host where the SAP instance is installed. Don't enter anything in this field if the connection you're specifying is for a load balancer.
Load Balancing: SAP Message Server Port number or logical name	Port number or name of the message server host. Enter this value only if the connection you're specifying is for a load balancer.
Load Balancing: SAP R3 Name	Three-character system ID of the ABAP system to be addressed. Enter this value only if the connection you're specifying is for a load balancer.
Load Balancing: SAP Load Balancing Group	Name of load balancer. Enter this value only if the connection you're specifying is for a load balancer.

Enter the Credential Information field descriptions

Enter the Credential Information field descriptions

Field	Description
User Name	User name to log in to the system of record to access ERP data.
Password	Password to authenticate and log in to the system of record.
Credential Name	Alias or name for the login credential.

ERP Data Hub new system field descriptions

The Create new system form in ERP Data Hub contains information on connection details for the ERP (Enterprise Resource Planning) system.

Create new ERP system fields

Field	Description
ERP system	Name of the ERP system to help identify the business area.
Short description	Brief description of what the ERP system is for, such as sales orders.

Create new ERP system fields (continued)

Field	Description
Connection (HTTP connection available starting in Xanadu Store Release 2)	Alias of the connection credential that you configured to connect to the system of record. You can select only from connections in the ERP Data Hub scope. For more information, see Configure the ERP Data Hub credentials and connection.
Latest alive heartbeat (HTTP heartbeat available starting in Xanadu Store Release 2)	Date and time that the ServiceNow AI Platform most recently connected to the ERP system. This field isn't editable and has a value only if the ERP system has been successfully saved and contacted.
ETL data sources/Extraction tables	Number of ERP extraction tables in the ERP system. Link a system to an extraction table by adding the system to the ERP extraction table record in ERP Data Hub. For more information, see Add a new ERP extraction table in ERP Data Hub.
Remote tables	Number of remote tables in the ERP system. Link a system to a remote table by adding the system to the ERP remote table record in ERP Data Hub. For more information, see View and edit ERP remote table details with ERP Data Hub.
Updated	Date and time the ERP system record was most recently saved.
KB link (on heartbeat tabs)	If there's an error and a relevant knowledge base article is available, a link to the article is provided.
Status (on heartbeat tabs)	State of the heartbeat: **Started**, **Success**, or **Error**.
Error text (on heartbeat tabs)	Details about the error.
Updated (on heartbeat tabs)	Date and time when the heartbeat was last changed.

ERP Data Hub system list field descriptions

The Create new system form in ERP Data Hub contains information on connection details for the ERP (Enterprise Resource Planning) system.

ERP system list details

Column	Description
ERP system	Name of the ERP system.
ERP heartbeat (HTTP connection available starting in Xanadu Store Release 2)	Latest status of the SAP system connection, either **Success** or **Error**. The connection is checked every 5 minutes automatically.
Retrieval status (OData available starting in Xanadu Store Release 2)	When the system is first set up and connects to the SAP system, metadata is retrieved. • BAPI/RFC: For BAPI, a list of functions available to call on the system are collected. For RFC, a check is done to determine the tables available on the database. • Table: The tables from the database are retrieved. • Odata: The models available on the HTTP protocol are retrieved.

ERP Data Hub ERP model table field descriptions

The **Entity fields** tab for an ERP (Enterprise Resource Planning) model in ERP Data Hub displays the table fields that are included in the ERP model.

ERP Data Hub automatically scans the linked ERP system to retrieve the latest entity data. However, you can select the refresh icon to update the data on demand.

Entity fields tab details

Column	Description
Field name	Name of the field on the system of record.
Name	Name of the table on the system of record that contains the field.
Mapped field name	Name of the mapped field. The ServiceNow AI Platform automatically creates this mapped field name in the ERP model after scanning the linked tables on the system of record.
Field label	Natural language field name for the automatically mapped field on the ServiceNow AI Platform.
Is custom	Option to indicate whether the field on the system of record is standard or customized.
ERP data type	Type of data the field contains. The options are: • char (character) • date

Entity fields tab details (continued)

Column	Description
	• decimal • numc (number) • time
Is queryable	Option to indicate whether you can retrieve data from the field without querying the source table. Smaller tables, such as a currency table, can have data stored locally and thus don't require a query to retrieve fields.

ERP Data Hub clone model field descriptions

The Clone ERP (Enterprise Resource Planning) model form in ERP Data Hub enables you to clone an ERP model so you can edit the new model.

ERP model fields

Field	Description
ERP model name	Name of the ERP model.
ERP module	ERP module in the system of record. For example, sales orders or inventory. ERP modules represent a distinct set of features and functionalities tailored to address business processes or activities.
ERP system	ERP system the ERP model connects to. The connected ERP system enables access to information about fields and tables and interaction between the model and the connected ERP system. For more information, see Create an ERP system in ERP Data Hub and View a list of ERP Data Hub systems.
Application	Application scope the ERP model is linked to. For example, if you create a custom model, the model will be in that scope.
Short description	Brief description of what the ERP model represents.
Long text	Any longer description or information about the ERP data model.
Work notes	Notes on the ERP model. Work notes are private, and not viewable by other ServiceNow AI Platform users.

ERP model fields (continued)

Field	Description
Comments	Comments on the ERP model. Comments are public, and visible to other ServiceNow AI Platform users.

ERP Data Hub new model field descriptions

The Create new system form in ERP Data Hub contains details for the ERP (Enterprise Resource Planning) model.

ERP model fields

Field	Definition
ERP model name	Name of the ERP model.
ERP module	ERP module in the system of record, for example, sales orders or inventory. ERP modules represent a distinct set of features and functionalities tailored to address business processes or activities.
ERP system	ERP system the ERP model connects to. The connected ERP system enables access to information about field and tables and interaction between the model and the connected ERP system. For more information, see Create an ERP system in ERP Data Hub and View a list of ERP Data Hub systems.
Application	Application scope the ERP model is linked to. For example, if you create a custom model, the model will be in that scope.
Short description	Brief description of what the ERP model represents.
Long text	Any longer description or information about the ERP data model.
Work notes	Notes on the ERP model. Work notes are private, and not viewable by other ServiceNow AI Platform users.
Comments	Comments on the ERP model. Comments are public, and visible to other ServiceNow AI Platform users.

ERP Data Hub remote table form field descriptions

The Remote table form in ERP Data Hub enables you to create and edit remote tables in the ERP (Enterprise Resource Planning) model.

Remote table details

Field	Description
Name	Name of the remote table on the ServiceNow AI Platform.
ERP model	ERP model connected to the remote table. The ERP model controls the available fields on the remote table. **Note:** Changing the ERP model removes any previously configured table fields that aren't available on the new model. To change the model for an ERP remote table, you must select the **Unlock ERP model field** button and then select the **Unlock model change** button on the confirmation dialog.
ERP module	Functional area or component within an ERP system. The module represents a distinct set of features and functionalities tailored to address a set of business processes or activities.
ERP system	ERP system that the remote table is linked to. The connected system represents the ERP instance that is linked to the model, enabling data flow and interaction between the model and the connected ERP system. For more information, see Create an ERP system in ERP Data Hub.
Remote table link	Name of and link to the remote table on the ServiceNow AI Platform. Selecting the remote table link opens a new browser tab, where you can explore, query, and manage the remote table.
Attachment setting	How the remote table uses attachments, which contain the remote data from the ERP system. The options are: • **None**: No attachment is used for the remote table. • **Save attachment**: Generate a new attachment when specified in the scheduled query or by selecting the **Refresh attachment data** button. • **Use attachment**: The current attachment, if available, is used locally.

Remote table details (continued)

Field	Description
Short description	Brief description of the ERP remote table.
Long text	Additional details on the contents of the remote table.
Requires queryable field	Indicates whether you can retrieve data from the remote table without querying the source table. Smaller tables, such as a currency table, can have data stored locally and thus don't require a query to retrieve fields.
Enable schedule	Option to create a scheduled query (ETL extraction) to fetch a new version of the attachment data. **Note:** The **Attachment setting** field must be set to **Save attachment** or **Use attachment** for this option to be available.
Daily schedule time	Time, in 24-hour format, for when the schedule runs every day.
Scheduled encoded query	Details on any scheduled extraction queries for the remote table. Create an encoded query string using a filter on the remote table list and paste the string into the **Encoded query** field. For more information on creating encoded queries, see Encoded query strings.

ERP Data Hub extraction table field descriptions

The Extraction table form in ERP Data Hub enables you to create and edit extraction tables in the ERP (Enterprise Resource Planning) model.

New ERP extraction table fields

Field	Description
Name	Name of the ERP extraction table.
ERP model	ERP model for the extraction table source, which must be configured for you to select.
Table transform map	Table that the extracted data is cached and stored in. The transform table is a temporary table that holds data during the data integration or transformation process. Transform tables are an intermediary step before data is further

New ERP extraction table fields (continued)

Field	Description
	processed, cleaned, or loaded into the target destination. The specified Glide table connects the source ERP extraction table and the target table for the extracted data. If you use a custom transform table, you must first create the table on the ServiceNow AI Platform, and the table must be in the application scope. For more information on creating table transform maps, see Create a transform map.
ERP module	Name of the ERP module linked to the ERP extraction table, which is controlled by the ERP model.
Table transform map link	Link to the Glide table that the extracted ERP data is cached and stored in. After you save the extraction table, when you select the link, the ServiceNow AI Platform table opens in a new browser tab.
System	ERP system that the ETL (extract, transform, and load) process extracts data from on the system of record. The system must already be configured.
Short description	Brief description of the ETL source.
Long text	Any additional text to describe the ERP extraction table.
Comments	Public comment that is visible to anyone working on the ERP extraction table.
Work notes	Private notes that only you can view.

ERP Data Hub scheduled extraction field descriptions

The Scheduled extraction form in ERP Data Hub enables you to create and edit jobs to extract data at regular intervals.

ERP scheduled extraction table fields

Field	Description
Name	A unique name that identifies this scheduled extraction.
ERP system	ERP system that the extraction table is linked to. The system must already be configured.
Extraction table	Name of the ERP extraction table from which to pull data.

ERP scheduled extraction table fields (continued)

Field	Description
Frequency	When to run the extraction. • Hourly: Specify the next scheduled start in hours, minutes, and seconds to repeat hourly. For example, adding 20:30:00 starts the scheduled extraction the next time the clock reaches 20:30:00 (9:30 pm) and then hourly after that (21:30:00, 22:30:00, 23:30:00, and so on). • Daily: Specify the next scheduled start in hours, minutes, and seconds to repeat daily. For example, adding 20:30:00 starts the scheduled extraction the next time the clock reaches 20:30:00 (9:30 pm) and then every subsequent day at 20:30:00. • Weekly: In **Weekday**, select the day of the week to run the scheduled extraction. Specify the next scheduled start in hours, minutes, and seconds to repeat weekly. For example, selecting Sunday and specifying 03:00:00 starts the scheduled extraction the next Sunday at 3:00 am and then every subsequent week on Sunday at 3:00 am. • After Completed Job: In **After job**, select an existing job that, when it completes, the new job you're creating should start. The job you specify must be active. **Note:** If you don't see the job that you want to use listed in **After job**, check if the job is already scheduled before or after another job. Only jobs that won't create a loop are permitted.
Next scheduled start	Time, in 24-hour format, for when the scheduled extraction should run.
Active	Option that indicates the scheduled extraction is active and should be executed at the specified frequency and time.
Maximum no of retries on error	If the job fails, set the maximum number of retries (from 0 through 10) the scheduled job should attempt before stopping.

ERP scheduled extraction table fields (continued)

Field	Description
	Note: Each retry uses the same query and retries the entire job. For example, if the total job contains 5000 records and the job fails after 2000 records are successfully processed, the entire job is rerun again on the next retry. For more information, see Import sets key concepts.
Extraction will retry after	If the **Maximum no of retries on error** field is set to a number between 1-10, specify the amount of time (in days, hours, minutes, and seconds) the system should wait before attempting the extraction again.
Generate encoded query script	Generate an encoded query script to use on the extraction table to fetch the data. For example:  The script entered in **Generate encoded query script** takes precedence over information entered into the **Encoded query** field. You can append the encoded query to the script (as in the example).
Encoded query	Create an encoded query string using a filter on the extraction table list and paste the string into this field. For example:

```
// var result (in lower case) is where the encoded query is returned.
// has to be declared as a string
// grJob is a GlideRecord of the scheduled Extraction. The encoded_query is a
// column in the scheduled extraction table. on screen labelled as "Encoded query"

// this is a delta load sample of sales doc records.
// the query will get everything changed at or after the last date received.
// first we grab the encoded query from the Job definition if any exists
var result = grJob.getValue('encoded_query')
    ? grJob.getValue('encoded_query')
    : ' ';

// look up the latest changed on date in table sn_erp_integration_sap_sales_document
var grLastChanged = new GlideRecord('sn_erp_integration_sap_sales_document');
grLastChanged.orderByDesc('u_changed_on');
grLastChanged.setLimit(1);
grLastChanged.query();
if (grLastChanged.next() && grLastChanged.u_changed_on) {
    if (result != ' ') {
        // if encoded query is not empty we use ^ to separate fields
        result = result + '^';
    }
    // sales document changed on should be at or after the last record we have.
    result =
        result +
        'sales_document_header_data_changed_on>=' +
        grLastChanged.u_changed_on;
}
```

ERP scheduled extraction table fields (continued)

Field	Description
	Encoded query | encoded_query sales_document_header_data_sales_organization=1710 {SAPTODAY} {SAPYESTERDAY} {TODAY} {YESTERDAY} For more information, see Encoded query strings.

ERP Data Hub Monitor field descriptions

The ERP Data Hub Monitor enables you to track ERP transactions and their progress.

ERP Monitor Extractions and Remote lookup tab fields

Transaction log	A unique, system-assigned transaction log identification number. Select the number for details.
Flow engine context	If the transaction occurs in a flow, the specific flow is logged and displayed here. Select the context name to open the flow in Workflow Studio and obtain more information. **Note:** System-provided flows are logged. Custom flows aren't logged.
Status	Extraction or remote lookup state: Started, Success, or Error.
Source	Source table in ERP Data Hub. For example, sn_erp_integration_etl_extraction_task or sn_erp_integration_remote_table.
Source Name	System ID of the source identified in the **Source** field. Select the name to obtain more information.
System	ERP system on which the transaction took place.
ERP Model Operation	Operation called by the transaction. For example, if you're creating an ERP model with a read operation and call it, the model's read operation is displayed here.
Duration (ms)	Amount of time (in milliseconds) that the transaction took to process.
Created	The date and time the transaction completed.

ERP Monitor Extractions and Remote lookup tab fields (continued)

Async	If Async is true, the job runs in the background, for example, extractions are asynchronous. If Async is false, the user initiates the job, for example, remote lookup is synchronous.
Encoded query	Encoded query being used for the specific transaction. For more information, see Encoded query strings.
Logged on	UNIX timestamp for transaction start time.
Response item count	The number of records that were read.

ERP Data Hub Use ERP Data action details for flows

After you're done creating and managing your model in ERP Data Hub, go to Workflow Studio and use the Use ERP Data action to test your model's inputs and outputs. You can then build a flow with the action to incorporate ERP (Enterprise Resource Planning) data into the ServiceNow AI Platform.

For information on using the Use ERP Data action to retrieve ERP data, see Building flows to read or update the ERP system.

Roles and availability

Available as part of ERP Data Hub.

Role requirements

This action requires roles granted by delegated development or assigned to the user. For more information, see User access to Workflow Studio flows.

Inputs

Provide a value for each input that your action needs. To add dynamic values, you can also select data pills using the pill picker.

ModelName

Data type: *Dynamic Choice*

Name of the ERP model that contains the read or update operation. The model must already be created, and have the read or update operation defined in ERP Data Hub. For more information, see Managing how models read and update the ERP system.

ModelOperation

Data type: *Dynamic Choice*

Whether to **Read** or **Update** the ERP system. The read or update entity must already be defined in ERP Data Hub. For more information, see Add a read, update, or create entity to a model in ERP Data Hub.

Mandatory Field(s)

Data type: *Dynamic Template*

Fields that are required for the operation. Fields must already be defined as required input parameters when you manage the model in ERP Data Hub. For more information, see Manage input parameters for an ERP Data Hub model operation.

Optional Field(s)

Data type: *Dynamic Template*

Fields that are optional for the operation. Fields must already be defined as optional input parameters when you managed the model. For more information, see Manage input parameters for an ERP Data Hub model operation.

System

Data type: *Reference*

Name of the connected ERP system. For more information, see Working with ERP systems in ERP Data Hub.

Outputs

You can use these outputs as inputs for other items.

Action status

Data type: *Object*

Data pill that contains the current runtime details about the action. The **Action Status** object consists of a code and a message.

Don't Treat As Error

Data type: *True/False*

Option to report the Action Status as an error or a success when returned to a flow.

Error Message

Data type: *String*

String data pill containing the error message produced by the action, step, or system operation.

Response

Data type: *Dynamic Object*

Requested data that's returned from the ERP system. For more information, see Choose output parameters for an ERP model.

Flows that ship with ERP Data Hub

ERP Data Hub includes two ERP (Enterprise Resource Planning) flows that run automatically.

You don't need to do anything to activate the flows, but you can customize them in Workflow Studio if you want. For example, to change the time that they run daily. For more information, see Edit a flow.

Note:
ERP Data Hub appears as **ERP Integration** when you work with it in Workflow Studio.

The flows that ERP Data Hub automatically runs are:

- **Get SAP BAPIs and tables when system becomes active**: This flow is triggered automatically as soon as the ERP heartbeat for an ERP system is live. It detects and retrieves the available BAPIs (Business Application Programming Interface) and tables for use when managing models. This flow also reads the OData catalog service if the OData heartbeat is successful.
- **ETL SAP BAPIs and Tables From all systems**: This flow calls the **Get SAP BAPIs and tables when system becomes active** flow every night to retrieve any changes to available BAPIs and tables on the ERP system.

The flows save their changes to the following tables:

- sn_erp_integration_sap_tables_list
- sn_erp_integration_sap_bapi_list_list

ERP Data Hub and ERP-CM glossary

Learn about ERP (Enterprise Resource Planning) terminology and concepts that apply to ERP Data Hub and ERP Customization Mining (ERP-CM).

BAPI

A Business Application Programming Interface (BAPI) is a standard interface to the business object models in SAP products, similar to an API.

candidate

A candidate is a group of recommended remote tables that you can use to create an application based on a custom transaction (ERP root) in the system. Candidates can also be existing applications that sit on top of the legacy ERP system of record.

Good candidates for replatforming tend to be smaller applications that use data from the system of record.

candidate score

A metric for how well a custom application (ERP root) fits to a remote table in ERP Customization Mining.

connection and credential alias

The credential alias is the system connection access enabler that's maintained in the ServiceNow credential alias. The credential alias is used to access the ERP system of record.

custom fields

Custom fields are values added to a table by the customer.

entity

The table or Business Application Programming Interface (BAPI) function call that ERP Data Hub uses to read or update the system of record.

ERP application

The ERP (Enterprise Resource Planning) custom application that you choose to replatform using ERP Customization Mining is an ERP root in the ERP system.

ERP model

The ERP model represents a distinct set of features and functionalities tailored to address specific business processes or activities. An ERP model encompasses multiple tables from

the system of record, as well as APIs and ETL processes, to create a holistic data set. For example, you can have one ERP model for sales orders and another for inventory.

ERP module

The functional business area on the ERP system. The ERP root can only have one selected business area.

ERP system

An ERP system represents a connection to a section of your ERP system of record. The system plays a crucial role in data synchronization, sharing, and collaboration, enabling seamless integration and operation between the ERP model and the connected ERP system.

ERP table

Individual tables (both custom and standard) in the ERP system are part of the remote tables. For example, in sales, ERP tables could include VBAK, VBAP, VBFA, VBPA, VBEP, MKPF, or MSEG.

extraction table

Extraction tables retrieve large amounts of data using a scheduled query, and use transform tables to process data for use on the ServiceNow AI Platform.

mapped value

Value of the field on the ERP system that's being mapped as an operation parameter in ERP Data Hub.

odata

In ERP Data Hub, create an OData connection to link to SAP via HTTP so data can be extracted for use in remote tables and extraction tables.

operation

Individual maintenance task performed to read or update the system of record.

remote table

A remote table is an aggregation of the system of record tables that provide value when gathered in one table. The remote table is the foundation of the ERP model. A candidate can consist of several remote tables.

system of record

The ERP system of record is where the data lives and is distributed from, for example, SAP.

ERP Customization Mining (ERP-CM)

The ServiceNow® ERP Customization Mining (ERP-CM) product enables Solution Integration consultants to find application candidates with customized code in their ERP (Enterprise Resource Planning) system. ERP-CM ranks the candidate suitability for replatforming onto the ServiceNow AI Platform.

ERP Data Hub and ERP Customization Mining (ERP-CM) are App Engine for ERP products of ServiceNow. They help organizations modernize and orchestrate legacy code, complimenting processes and integrations that are underserved with the existing system of record, such as SAP. Together, ERP Data Hub and ERP-CM make it faster and easier for you to build applications on the ServiceNow AI Platform using data from a legacy ERP system.

Replatforming is the process of scanning legacy ERP system code to find potential candidates to move onto your ServiceNow AI Platform instance as new apps. You can use data from the ERP system as a source for apps built on the ServiceNow AI Platform, improving performance, enhancing security, and reducing maintenance.

The replatforming of legacy code enables innovation on top of the system of record without knowledge of the legacy system. Database administrators and developers are then relieved of time-consuming efforts to create database views or endpoints in the system of record, freeing them to work on other projects, such as migration.

Note:
For information about new and updated features in the Xanadu release, see ERP Customization Mining release notes.

Learning resources for ERP Customization Mining

Learn more about ERP Customization Mining	ServiceNow resources
ERP Customization Mining has a number of training and learning resources for you to get started. (Some of these resources require logging in to the ServiceNow Learning site.)	Partner Essentials: Clean Core for App Engine ERP Customization Mining Overview ERP Clean Core with App Engine Overview Get to a clean ERP core with ServiceNow ERP Customization Mining

Request ERP Customization Mining on the store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

Before you can use ERP-CM, you must first download ERP-CM from the ServiceNow Store. After you have completed the download, you may need to clear your local cache before ERP-CM appears on your instance.

After you download ERP-CM, install it on your instance. For more information, see Install ERP Customization Mining.

Exploring ERP Customization Mining

ERP Customization Mining (ERP-CM) enables you to identify candidates for replatforming. These candidates can be custom applications that were built on legacy ERP (Enterprise Resource Planning) systems that you want to quickly replatform.

Identifying candidates to replatform with ERP-CM

Legacy ERP systems can contain old tables with custom fields that have become difficult to maintain. Use ERP Data Hub and ERP-CM to identify candidates with custom fields to extract onto their instance as remote tables or extraction tables. Low-code developers can then use

the legacy ERP fields as data sources for apps created on the ServiceNow AI Platform, using a builder such as App Engine Studio, to replatform them.

You can use a combination of remote tables and extraction tables to retrieve data from your legacy ERP system.

- Remote tables get their records from running an associated script against an external data source.
- Extraction tables retrieve large amounts of data using a scheduled query, and use transform tables to process data for use on the ServiceNow AI Platform.

Replatforming is the process of scanning legacy ERP system code to find potential candidates to move onto your ServiceNow AI Platform instance as new apps. You can use data from the ERP system as a source for apps built on the ServiceNow AI Platform, improving performance, enhancing security, and reducing maintenance.

When you find ERP candidates to replatform, ERP-CM also provides suggestions for next actions and similar candidates. ERP-CM supports any ERP modules, or functional areas that admins configure in ERP Data Hub. Some example modules are Finance, Procurement, and Sales. For more information, see Building and managing ERP models to work with ERP data.

Replatformed data is immediately available, mirrored in easy-to-manage tables and apps. Users no longer need to request information from database administrators, which can take weeks. Replatformed apps use the ERP system of record as the live data source.

Workflow for replatforming customized ERP applications

Complete the following workflow to replatform legacy ERP data with custom code from the system of record on the ServiceNow AI Platform using ERP Customization Mining (ERP-CM).

1. Meet with the customer and agree to run an analysis with ERP Customization Mining on their ERP system of record.
2. Connect the customer ERP system of record to the ServiceNow instance using ERP Data Hub.

   Note:
   Most customers have their own instance.

   ERP-CM uses the system connections configured in ERP Data Hub. For more information, see Working with ERP systems in ERP Data Hub.

3. Use ERP Data Hub to build ERP models from fields on the available remote tables. For more information, see the following topics:
   - Building and managing ERP models to work with ERP data
   - Using ERP remote tables in ERP Data Hub
4. Run ERP Customization Mining to find candidates. Candidates are custom code in the system of record that you can replace with ServiceNow apps. For more information, see Browse an overview of candidates in ERP-CM.
5. Choose the candidate to replatform. For more information, see Save potential candidates to replatform.
6. Use the candidate details in ERP-CM as a central place to enter comments and save attachments relating to the candidate. For more information, see View and work with candidate details in ERP-CM.
7. In the candidate details, identify any similar candidates that you could combine into a single replatformed app. For more information, see How ERP Customization Mining determines candidate score and potential.

8. Return to ERP Data Hub to continue building data models with remote tables and extraction tables. Confirm that all the necessary data is available in the ServiceNow AI Platform. For more information, see Building and managing ERP models to work with ERP data.
9. In App Engine Studio (AES) or another ServiceNow application, build a scoped app by using the replatformed data as a source. For more information, see Build apps using App Engine Studio.
10. Measure and monitor the performance of the new app using applicable metrics and parameters with your preferred analytic tools.

Benefits of ERP Customization Mining

Benefits of ERP-CM

How ERP-CM extracts and processes data

ERP Customization Mining (ERP-CM) retrieves data from the ERP (Enterprise Resource Planning) system using extractors and processes it before the data is available on the ServiceNow AI Platform.

Use an SAP extractor to analyze the ERP data sources and validate the syntax. The following extractors are available to retrieve data from the ERP system:

- APPstats
- COMPHIER
- SQLM

The supported extractors process data using ServiceNow AI Platform tables.

SAP data extractors

Extractor	Full name	Description	ServiceNow AI Platform processing tables	Populated ServiceNow AI Platform tables
APPstats	Application Statistics	Collects and analyzes system-level statistics and performance metrics from the ERP application.	sn_erp_mining_erp_appstat_data_staging sn_erp_mining_erp_appstat_data_agg	sn_erp_mining_erp_application sn_erp_mining_erp_user
COMPHIER	Component Hierarchy	Analyzes the hierarchy and relationships among different components at SAP, including business processes and module configurations.	sn_erp_mining_erp_comp_hier_data_staging sn_erp_mining_erp_comp_hier_data_agg	sn_erp_mining_erp_application sn_erp_mining_erp_module
SQLM	SQL Monitor	Enables the monitoring of all SQL statements and operations that are executed by running ABAP applications. The data collected by SQLM provides aggregated performance indicators (such as the number of executions, execution time, or number of effected rows) for all executed	sn_erp_mining_erp_sqlm_data_staging sn_erp_mining_erp_sqlm_data_agg	sn_erp_mining_erp_application sn_erp_mining_erp_table sn_erp_mining_erp_application_ta sn_erp_mining_erp_application_us

SAP data extractors (continued)

Extractor	Full name	Description	ServiceNow AI Platform processing tables	Populated ServiceNow AI Platform tables
		database operations.		

How ERP Customization Mining determines candidate score and potential

ERP Customization Mining (ERP-CM) generates a score to rank the potential for replatforming legacy ERP (Enterprise Resource Planning) candidates onto the ServiceNow AI Platform.

Every candidate has an ERP module specified in the candidate details in ERP-CM. The ERP module is used to evaluate the potential score of the candidate for replatforming, as well as the remote tables and extraction tables the model contains.

- Remote tables get their records from running an associated script against an external data source.
- Extraction tables retrieve large amounts of data using a scheduled query, and use transform tables to process data for use on the ServiceNow AI Platform.

Note:

Admins must first configure the connection to the ERP system in ERP Data Hub. For more information, see Working with ERP systems in ERP Data Hub.

High and low scores for candidate potential

ERP-CM evaluates candidates based on how well their tables and fields are supported by the ServiceNow AI Platform.

- A high potential indicates that ERP-CM can immediately use remote tables and extraction tables that match the ERP model for the application candidate without making additional changes.
- A low potential indicates that the application candidate matches few of the remote tables and extraction tables in the ERP models in ERP Data Hub.

How scores are calculated

The candidate potential score is calculated using the following metrics:

- ERP models: The number of ERP models that the candidate uses remote tables and extraction tables from.
- Similar candidates: The number of candidates with a similarity score above the threshold, which accounts for both table-based similarity and model-based similarity.

  The threshold can be adjusted in the System Properties [sys_properties] table, and the default `OR` condition can be changed to `AND`.

- Supported table score: The ratio of the number of custom app tables that are supported by any ERP model relative to the number of custom app tables.

Note:
Tables from either the Technical or ServiceNow table clusters are ignored from these computations.

- Supported table usage: The ratio of tables supported by the relevant ERP models that are used by the custom app.
- Unsupported model penalty: A penalty for the number of unsupported operations on tables in ERP models. The number of unsupported operations is passed through a sigmoid function, so it ranges from 0.0 and 1.0.
- Unsupported table extensions: The number of custom app tables that are also suggested as model extensions.
- Model inaccuracy: The number of tables supported by relevant ERP models that aren't used by custom apps, and are passed through a sigmoid function.

How ERP-CM works with ERP Data Hub and remote tables

ERP Data Hub enables you to connect to your ERP (Enterprise Resource Planning) system of record, and to organize its data.

Using ERP Data Hub, you can access standard fields for remote tables and ERP extraction tables, while ERP Customization Mining (ERP-CM) enables you to find good candidates for replatforming from the system of record to the ServiceNow AI Platform.

ERP-CM suggests candidates and possible next steps, such as updating remote tables and extraction tables to access ERP data. Remote tables send data to the ServiceNow instance as an attachment, which is then analyzed using AI/ML to identify similar candidates to replatform.

After you've identified candidates to replatform and taken the recommended action in ERP-CM, you need to use only ERP Data Hub to access the remote tables and extraction tables. These tables are data sources for building apps, flows, and workspaces.

Using remote tables and extraction tables with ERP Data Hub and ERP-CM

You can use a combination of remote tables and extraction tables to retrieve data from your legacy ERP system.

- Remote tables get their records from running an associated script against an external data source.
- Extraction tables retrieve large amounts of data using a scheduled query, and use transform tables to process data for use on the ServiceNow AI Platform.

Remote tables describe the schema for the data that you want to retrieve from an external source, such as the system of record. Use remote tables to connect the ServiceNow AI Platform to third-party sources, or to another instance, so that you can retrieve external data and optionally cache it in the memory. You can view external data in lists or forms and process it with standard Glide scripts. You can also group, sort, aggregate, and filter the data just like you would for standard internal tables.

By using a remote table, you can retrieve the data from external sources or from another instance with REST or SOAP services. The external data lives in the memory in read-only mode, which makes the data temporary, or transient, within the ServiceNow AI Platform. You can then view and manipulate the external data without importing or storing it. For more information, see Remote tables.

Use an extraction table to work with large amounts of ERP data. ERP extraction tables regularly save data to a local transform table on the ServiceNow AI Platform, which you can then process and use as the data foundation of a replatformed app.

Recommendations and similar candidates in ERP-CM

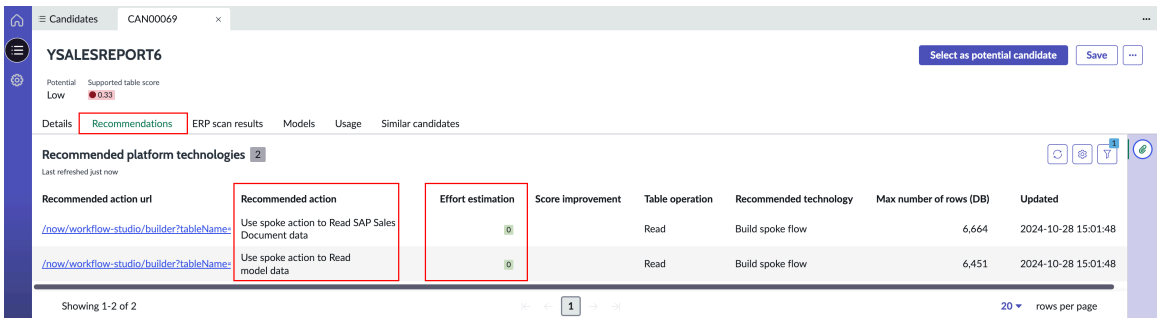
The record for each candidate in ERP Customization Mining (ERP-CM) displays information on suggested next steps and similar candidates to help you in replatforming an ERP (Enterprise Resource Planning) app.

Recommended actions for candidates

When you view a candidate, ERP-CM displays the number of recommended actions or next steps to take. The candidate details also have a **Recommendations** tab where you can view the suggested actions, and select them to open the associated app on the ServiceNow AI Platform.

For example, you may need to create a workflow in Workflow Studio for one candidate, update an integration spoke for another, and read an extraction table or remote table for a third candidate.

Each recommended action has an estimated effort, which is a numerical score that assesses how well the ServiceNow AI Platform has matching functionality. Green actions require little-to-no effort, while red actions are more difficult.



For more information on recommended actions, see Check candidate recommendations in ERP-CM.

Similar candidates in candidate details

For each candidate, ERP-CM displays a **Similar candidates** tab, which lists each similar candidate, a numerical score to represent how closely the two candidates are related, and a link to other similar candidates.

Similar candidates are helpful when planning how to best replatform a legacy app. When you replatform a custom app from the system of record, you don't have to replicate the old app exactly. Use the replatforming process to design a better app, perhaps one that addresses the needs of multiple similar candidates in a single, new app built using low-code tools on the ServiceNow AI Platform.

Next steps when replatforming apps to ServiceNow using ERP-CM

After you use ERP Customization Mining (ERP-CM) to identify legacy ERP (Enterprise Resource Planning) candidates, use additional ServiceNow AI Platform products and resources to replatform your app.

First, identify the customization you want to replatform from the ERP system with ERP-CM.

Then, use the remote tables and extraction tables linked in the candidate mining results for fast access to ERP data.

That ERP data can be used as a data source when you build new apps on the ServiceNow AI Platform, for example, with App Engine Studio.

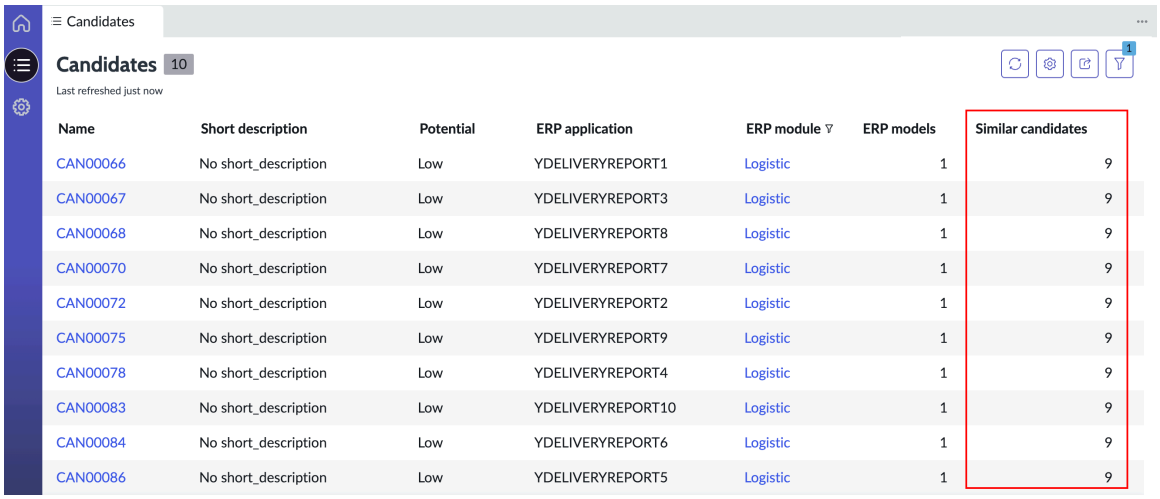
Build a ServiceNow app that consumes ERP data

The next step in replatforming with App Engine for ERP (Enterprise Resource Planning) is to build an app on the ServiceNow AI Platform that consumes the ERP data.

As you plan to replatform a legacy app on the ServiceNow AI Platform, consider where the data is coming from. For example, an old app may retrieve data from a third party into the system of record. When you build a new, replatformed app on the ServiceNow AI Platform, you can configure the new app to pull data directly from that third party instead of having the ERP Data Hub model pull it from the ERP system, which adds an extra step of retrieval.

Working with similar candidates when replatforming apps

If ERP-CM shows that a candidate has a number of similar candidates, consider building one app that meets the needs of some or all similar candidates when you replatform.



Name	Short description	Potential	ERP application	ERP module	ERP models	Similar candidates
CAN00066	No short_description	Low	YDELIVERYREPORT1	Logistic	1	9
CAN00067	No short_description	Low	YDELIVERYREPORT3	Logistic	1	9
CAN00068	No short_description	Low	YDELIVERYREPORT8	Logistic	1	9
CAN00070	No short_description	Low	YDELIVERYREPORT7	Logistic	1	9
CAN00072	No short_description	Low	YDELIVERYREPORT2	Logistic	1	9
CAN00075	No short_description	Low	YDELIVERYREPORT9	Logistic	1	9
CAN00078	No short_description	Low	YDELIVERYREPORT4	Logistic	1	9
CAN00083	No short_description	Low	YDELIVERYREPORT10	Logistic	1	9
CAN00084	No short_description	Low	YDELIVERYREPORT6	Logistic	1	9
CAN00086	No short_description	Low	YDELIVERYREPORT5	Logistic	1	9

When you replatform a custom app from the system of record, you don't have to replicate the old app exactly. Use the replatforming process to design a better app, perhaps one that addresses the needs of multiple similar candidates in a single, new app built using low-code tools on the ServiceNow AI Platform. App Engine Studio is the quickest app to use, but there are other builders available to you, depending on your licensing.

ServiceNow low- and pro-code builders

After you identify ERP data to replatform, citizen developers can use ServiceNow builders to create apps quickly from the data. Any custom fields that exist in the ERP system of record, such as SAP, can be leveraged by the apps you build using the ServiceNow AI Platform. For more on citizen development, see Delegated development and deployment.

Use any of the following ServiceNow builders to create apps using custom data:

- App Engine Studio
- Flows in Workflow Studio
- Playbooks in Workflow Studio
- Table Builder
- UI Builder
- Workspace Builder

For example, in App Engine Studio, use a template (or build the app from the ground up) and incorporate remote tables using ERP models and remote tables. You can combine legacy data from the ERP models and remote tables with other ServiceNow data in tables.

Using Glide to query ERP data

You can also access data from the system of record through the Glide API.

For an example Gilde query, see Sample Glide query for ERP data in ERP Customization Mining.

After you replatform custom code to a ServiceNow app

Replatformed apps on the ServiceNow AI Platform use live data from the system of record without writing any code back to it.

After you've identified candidates to replatform and taken the recommended action in ERP-CM, you need to use only ERP Data Hub to access the remote tables and extraction tables. These tables are data sources for building apps, flows, and workspaces.

If you're sure that the legacy code on the system of record isn't referenced anywhere else, you can remove it from the system after it's replatformed to a ServiceNow instance.

Configuring ERP Customization Mining

Set up ERP Customization Mining (ERP-CM) to enable the app to scan the system of record for candidates to replatform. Administrators can also quickly check the health of the ERP (Enterprise Resource Planning) connection and investigate any issues, and view knowledge articles related to errors.

You must install ERP Data Hub and configure connections and ERP data models before you can install ERP Customization Mining.

Server requirements

For the credentials, use an SAP service type user account in your system of record that requires the following S_RFC SAP authorization objects:

- S_RFC with Activity = 16 (Execute) for the following Function Modules:
  - SAPWL_WORKLOAD_GET_STATISTIC
  - SWNC_COLLECTOR_GET_AGGREGATES
  - SWNC_COLLECTOR_GET_DIRECTORY
  - SQLM_API_GET_NEXT_DATA_PACKAGE
- S_TABU_NAM with Activity 03 (Display) for the following table: TRNSPACET

There are additional authorizations needed for ERP Data Hub. For more information, see Configuring ERP Data Hub.

Note:
The credentials you specify for the ERP Data Hub connection must match the service user credentials in the system of record.

Types and number of available connections

ERP Data Hub and ERP-CM currently support ECC (minimum SAP Netweaver 7.31) and S/4HANA SAP systems.

Note:
Each installation of ERP-CM supports adding up to 10 systems. However, ERP-CM can connect to only one live ERP system at a time.

You should install ERP Data Hub and add credentials there before you install and configure ERP-CM. For more information, see Configure the ERP Data Hub credentials and connection.

The number of ERP connections you can have per ServiceNow instance depends on your license. If you have the ERP-CM license, you get one connection per instance.

For details on Connections and Credentials, see Connections and Credentials.

Plugins for ERP Customization Mining

You must have the following plugins installed:

Plugins for ECM

Plugin	Full name	Dependencies
ERP Data Hub	com.snc.sn_erp_integration	com.glide.script.vtable
ERP Customization Mining	com.snc.uib.sn_erp_mining	• com.snc.sn_erp_integration • com.glide.platform_ml

Request apps on the Store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

Configure SAP for ERP-CM

Enable SQLM (SQL Monitor) on the productive system and confirm that ST03 (Workload Monitor) is collected for daily workloads before you can install ERP Customization Mining (ERP-CM).

Before you begin
Role required: none

About this task

Warning:
If you don't perform the SAP configurations from this procedure, and if there's no data in SAP, then ERP-CM won't work.

Procedure

1. Collect SQLM information from the productive environment by enabling SQLM in the SAP system.

   a. In the production system, start the transaction SQLM.
   For more information, refer to the SAP SQL Monitor documentation.

   b. Confirm that the **Activation state** field is set to **Globally active**.

   c. If SQLM isn't active, start the transaction SQLM again.

d. Navigate to **SQL Monitor** > **Setting** > **General Settings**.

e. Confirm that the **Delete Older Than [Days]** option is set to a minimum of `365` days, and select **Confirm**.

f. Activate the setting by selecting **All Servers**.

2. Verify that ST03 is collected for daily workloads from the productive environments.
   a. In the production system, start the transaction ST03.
   b. Verify that the **Workload data** field is set to **Daily**.

Install ERP Customization Mining

Install the ERP Customization Mining (ERP-CM) application (sn_erp_mining) if you have the admin role from the ServiceNow Store.

Before you begin

You must:

- Have a license and get entitlement to ERP-CM before you can install the application.

  For more information, see Licensing.
- Install ERP Data Hub. Use the application to configure connections to the system of record, as well as ERP (Enterprise Resource Planning) data models.
- Configure the JCO connector before you install ERP-CM. See the SAP documentation for more information.

The following plugins are required:

- ERP Data Hub
- Predictive Intelligence

Role required: admin

About this task

Procedure

1. In the ServiceNow Store, confirm that you have entitlements (or licenses) to the product and dependent applications.
   You can access the Store by navigating to **System Applications** > **All Available Applications** > **Available To Obtain From Store**.
2. Search for ERP Customization Mining and select **Install**.
3. **Optional:** Select **Load demo data** to create demo data in the app.
4. Select **Install** to confirm the installation of ERP-CM.

Result

The installation is complete. Select **Close** to return to the ServiceNow Store.

What to do next

After you install ERP-CM, ERP data from the connected system of record populates the ERP extraction tables in ERP Data Hub. For example, ERP application activity, Collector directory data, and Namespace data. You can then incorporate extracted data into ERP data models and remote

tables for use as a data source when building apps on ServiceNow. For more information, see the following topics:

- View ERP extraction tables
- Standard ERP models and extraction tables for ERP Data Hub

Run Guided Setup for ERP Customization Mining

Run the Guided Setup to configure ERP Customization Mining (ERP-CM).

Before you begin

You must first download and install ERP-CM from the ServiceNow Store.

Role required: sn_erp_integration.erp_admin, sn_erp_mining.erp_admin

About this task

For more information on using Guided Setup, see Guided setup.

Alternatively, you can configure ERP-CM without Guided Setup. For more information, see Configure a new ERP Customization Mining connection.

Procedure

1. Navigate to **All** > **ERP Customization Mining** > **ERP Customization Mining Guided Setup**.
2. Complete the Guided Setup for ERP Data Hub by selecting **Configure ERP Data Hub**.

   ERP Data Hub is required by ERP-CM to connect to systems.

   Follow the steps to configure ERP Data Hub, and select **Continue**. For more information, see Run Guided Setup for ERP Data Hub.
3. Connect ERP Customization Mining to the ERP system.
   a. Select **Select the ERP system to connect**, follow the steps, and select **Continue**.
   b. Select **Validate the connection status**, follow the steps, and select **Continue**.

Configure a new ERP Customization Mining connection

Specify the Connections and Credentials alias for ERP Customization Mining (ERP-CM) to connect to the ERP (Enterprise Resource Planning) system.

Before you begin

You should install ERP Data Hub and add credentials there before you install and configure ERP-CM. For more information, see Configure the ERP Data Hub credentials and connection.

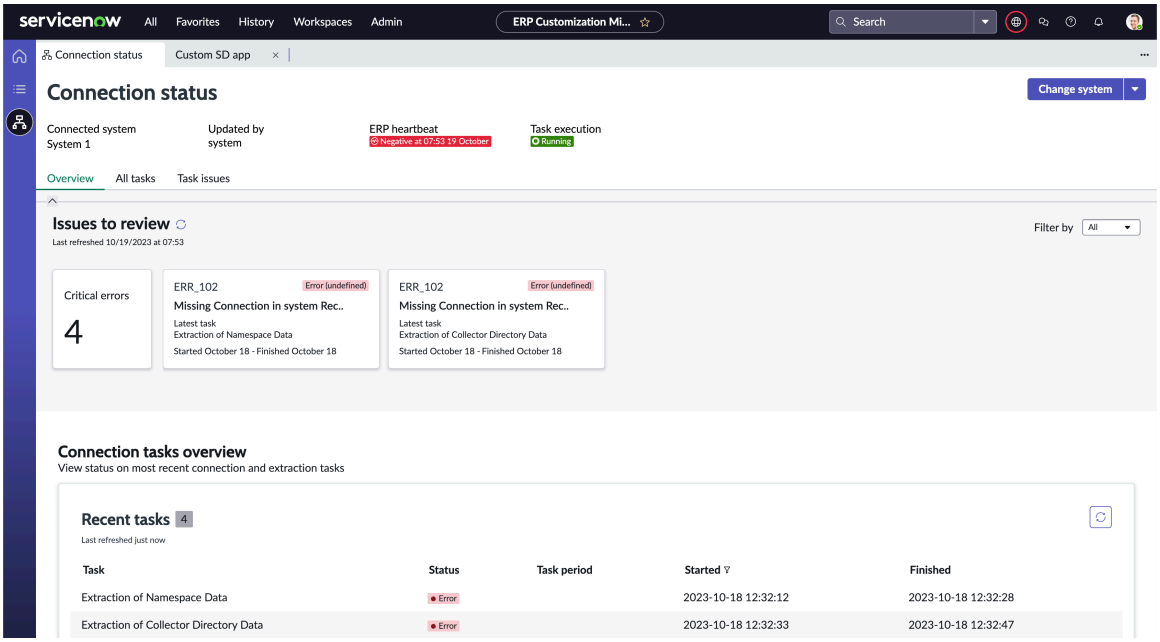
Role required: sn_erp_integration.erp_admin, sn_erp_mining.erp_admin

Procedure

1. Navigate to **All** > **ERP Foundation** > **ERP Customization Mining**.
2. Select the connection status icon () in the side panel.
3. Select the **Select connection** button.
   If you have already configured a system connection and want to use a different connection and credential, see Update an ERP-CM connection.
4. In the Connections and Credentials alias box, choose the credentials you configured in ERP Data Hub from the **Select connection & credential alias** field.
5. Select **Connect**.

ERP-CM begins extracting data from the connection.

6. Refresh the Issues to review list and the Executed tasks list by selecting their respective refresh icons ( ).



What to do next

After the system is connected, you can check the connection status and investigate errors at any time on the Connection status page. For more information, see Check and troubleshoot the data refresh status for ERP Customization Mining.

Update an ERP-CM connection

Update the Connections and Credentials alias for ERP Customization Mining (ERP-CM) to change the connection to the ERP (Enterprise Resource Planning) system. For example, you may want to change from a non-production system to a production system.

Before you begin

You should install ERP Data Hub and add credentials there before you install and configure ERP-CM. For more information, see Configure the ERP Data Hub credentials and connection.

Role required: sn_erp_integration.erp_admin, sn_erp_mining.erp_admin

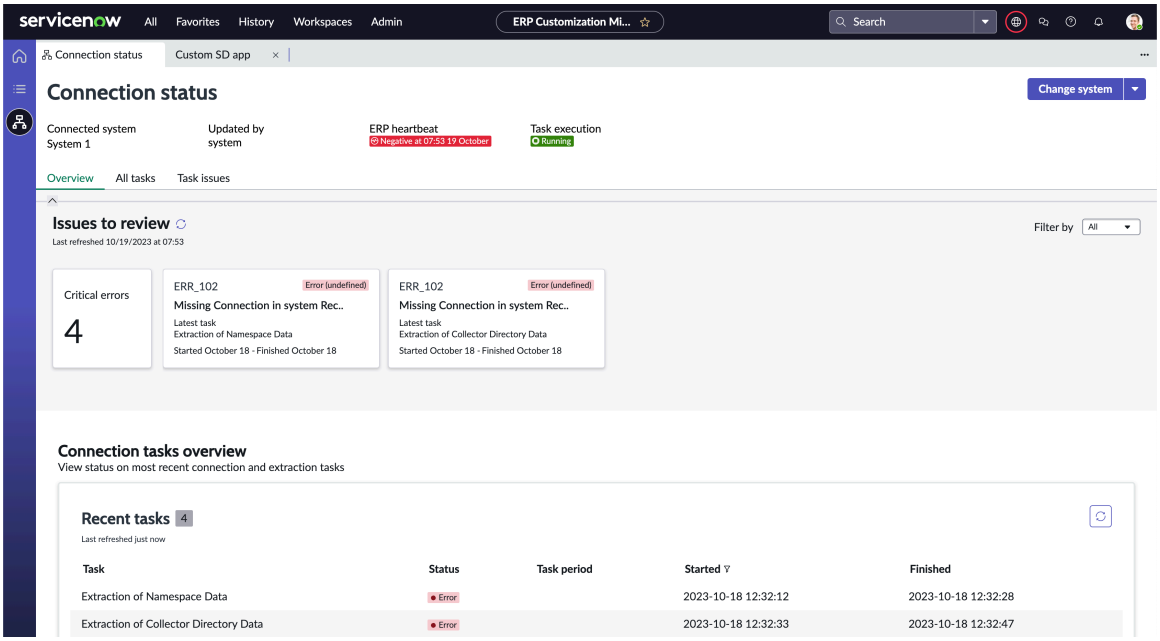
About this task

Warning:
Changing the system and credential alias deletes all existing data in the ERP-CM workspace and restarts the data integration process.

Procedure

1. Navigate to **All** > **ERP Foundation** > **ERP Customization Mining**.
2. Select the connection status icon ( ) in the side panel.
3. Select the **Change system** button.
4. In the **Change system & delete data** box, choose the system you configured in ERP Data Hub from the **Select system to change to** field.

5. Confirm your choice by selecting the **Yes, I am sure I want to change system and delete data** option.
6. Select the **Change and delete data** button.
   ERP-CM begins to delete current data and restarts the data integration process.
7. Refresh the Issues to review list and the Executed tasks list by selecting their respective refresh icons ( ).



What to do next

After the system is connected, you can check the connection status and investigate errors at any time on the Connection status page. For more information, see Check and troubleshoot the data refresh status for ERP Customization Mining.

Check and troubleshoot the data refresh status for ERP Customization Mining

Check the data refresh status to find out when ERP Customization Mining (ERP-CM) most recently loaded ERP (Enterprise Resource Planning) data from the system of record.

Before you begin

Role required: sn_erp_mining.erp_admin and sn_erp_mining.erp_user

About this task

To verify that ServiceNow AI Platform® is synchronized with the ERP system of record, ServiceNow AI Platform reloads data every 24 hours from the system of record.

You can receive email notifications for connection task success and failures. For more information, see Getting notifications for ERP Customization Mining connection updates.

Procedure

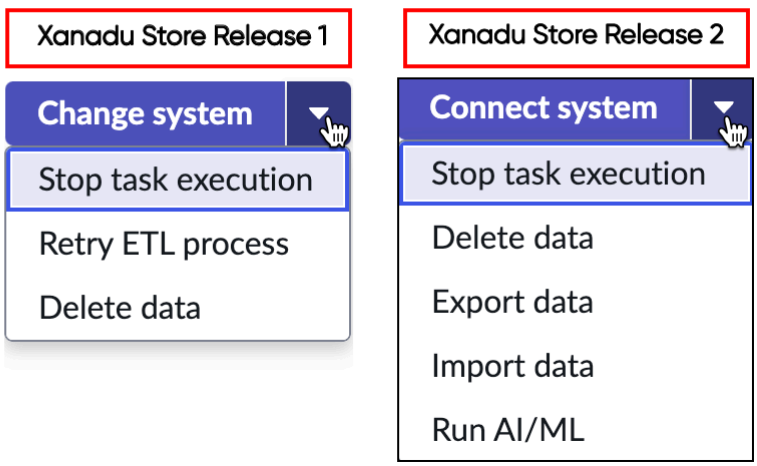
1. Navigate to **All** > **ERP Foundation** > **ERP Customization Mining**.
2. In the side panel, select the connection status icon ( ).
   The **Overview** tab displays a summary of connection issues to review, as well as a list of the most recent active connection tasks.
3. Check the most important connection details in the **Connection status** page header.

Connection status header details

Field	Definition
Credential alias	Alias of the connection credentials configured in ERP Data Hub.
Updated by	Name of the last account to update the connection credentials.
ERP heartbeat	Indicates whether a ping to the connection is currently successful.
Task execution	Indicates whether ServiceNow AI Platform® is currently attempting to connect to the instance.

4. **Optional:** View a refined subset of connection tasks by selecting one of the following tabs.

5. Troubleshoot any system connection issues using the **Change system** button (Xanadu Store Release 1) or **Connect system** button (Xanadu Store Release 2).



Trouble?

- Pause the task execution by selecting **Stop task execution**.
- Restart the ETL (extract, transform, and load) process by selecting **Retry ETL process**. (Xanadu Store Release 1)
- Delete all data in ERP-CM and start over by selecting **Delete data**. On the confirmation dialog, you must select the **Yes, I am sure I want to delete data** option and select the **Delete data** button.

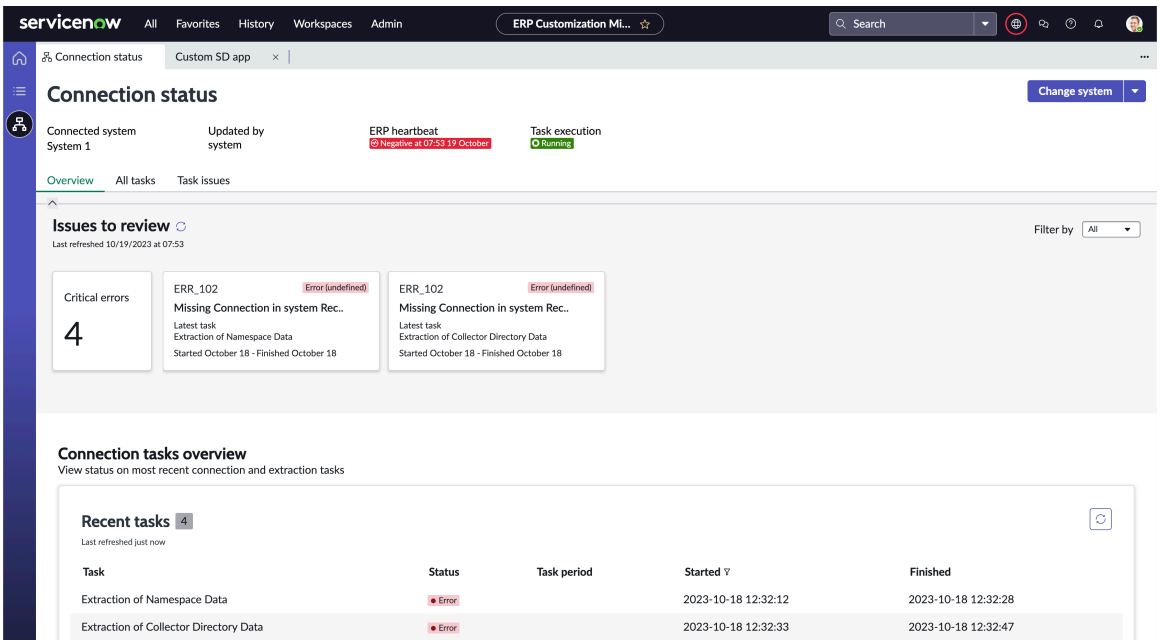
> ⚠ **Warning:**
> This action deletes all existing data in the ERP-CM workspace and restarts the data integration process.

- Share and back up data at any time by selecting **Export data**. A downloadable zip file is created.
- After exporting data, use the created zip file **Import data** for sharing and back up.
- Run AI/ML

6. View the information for each task and note any actions that you must take by scrolling to the task list.
   For a description of the field values, see ERP-CM task list field descriptions.

   For any column, you can select the more options icon ( ) to perform additional actions, such as **Show matching** and **Filter out**.

7. **Optional:** Update the status of any open task in error to indicate changes to its status.
   You can't resolve errors directly in ERP-CM, but you can mark them as resolved or irrelevant.
   a. Select the **Task** tab.
   b. On the **Task** tab, select the task that you want to update.
   c. Update the **Status** on the task record to **Resolved** or **Irrelevant**.
8. Refresh the Issues to review list and the Executed tasks list by selecting their respective refresh icons ( ).



Create a snapshot to share and save data in ERP Customization Mining

Export and import ERP Customization Mining base data to save and share.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **ERP Foundation** > **ERP Customization Mining**.
2. In the side panel, select the configuration icon ( ).
3. Select the **Connect system** button.

4. Select **Export data**.

   A check is performed automatically prior to exporting. For details about the process, see ERP Customization Mining snapshot prerequisite check.

   If another export is in progress, an export unavailable message is displayed. Select **OK** and view the **Snapshots** tab to monitor the progress.

   a. On the pop-up window, review the message and select **Export data**.

      An automatic export is only performed before an import because an import overwrites the existing data. An export saves the data for a later import. An automatic export saves the data as a backup.

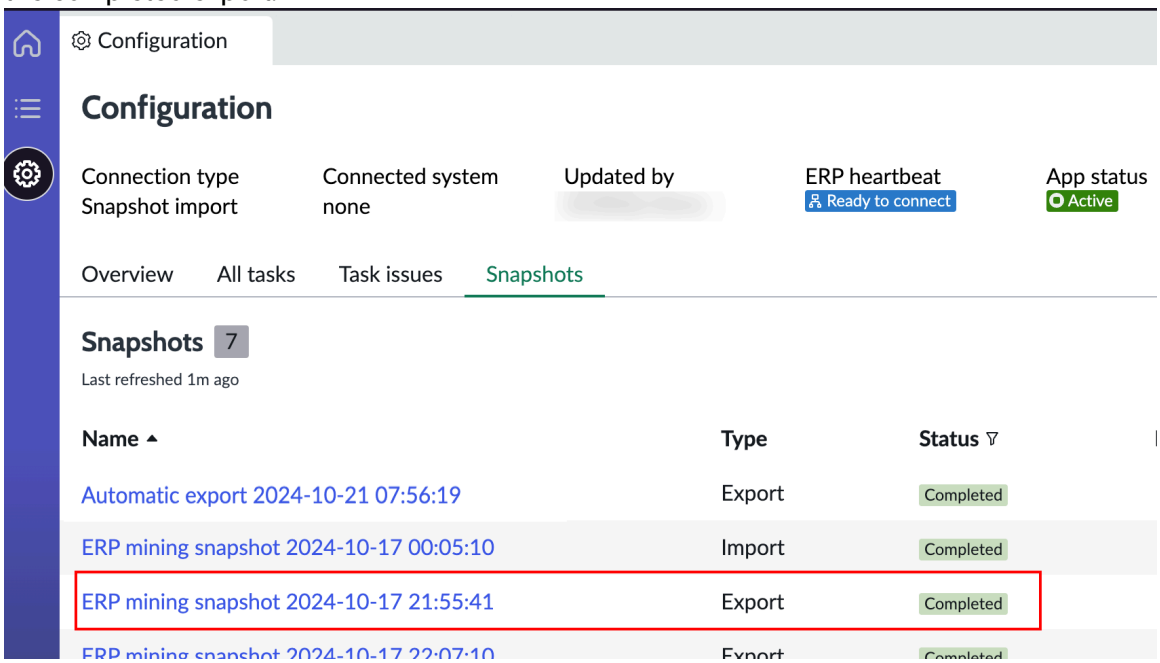
      In the **Snapshots** tab, the automatic export is **Pending**. Select the refresh icon to see the **Status** change to **In progress** and then **Complete**.

      You can also check the task status on the **All tasks** tab.

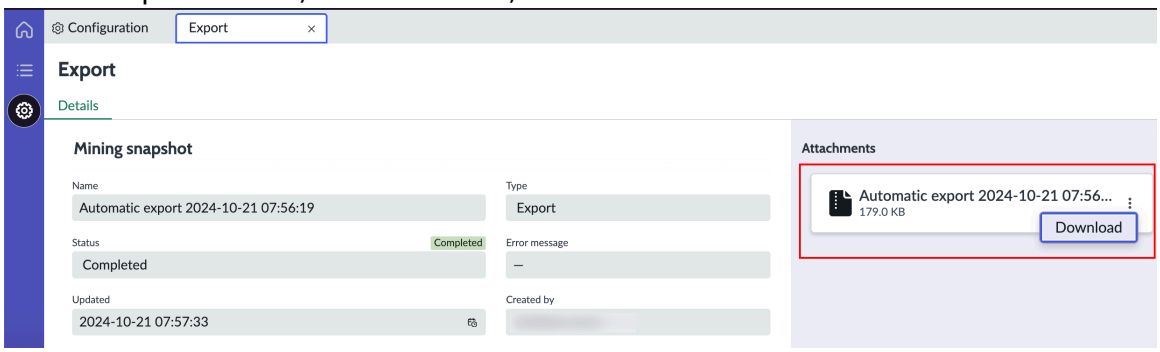
      For more execution details, open Workflow Studio, select **Operations**, and select **Flows**. The flow named **Export snapshot** calls the sub flow **Check set Snapshot to in progress**,

and then calls the sub flow **Create Snapshot**. For more information about viewing flows in Workflow Studio, see Workflow Studio.

b. When the export is finished, go to the **Snapshots** tab on the **Configuration** page and select the completed export.



c. On the snapshot record, in **Attachments**, select the actions icon and then select **Download**.



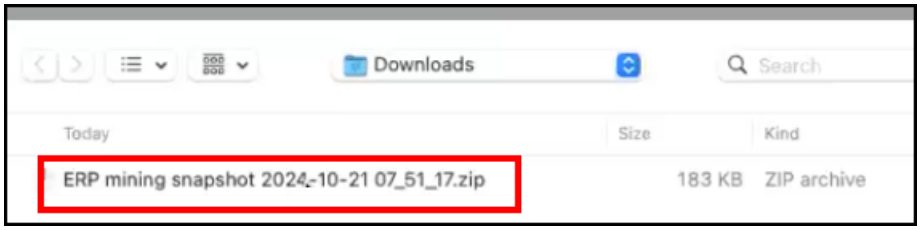
Next, import the data into another system.

5. Select the **Connect system** button, and then select **Import data**.

a. On the pop-up window, review the message and select the **I understand and want to import** option.

b. Select **+ Add file**.

c. Navigate to your downloads folder, select the ERP mining snapshot zip file, and select **Open**.



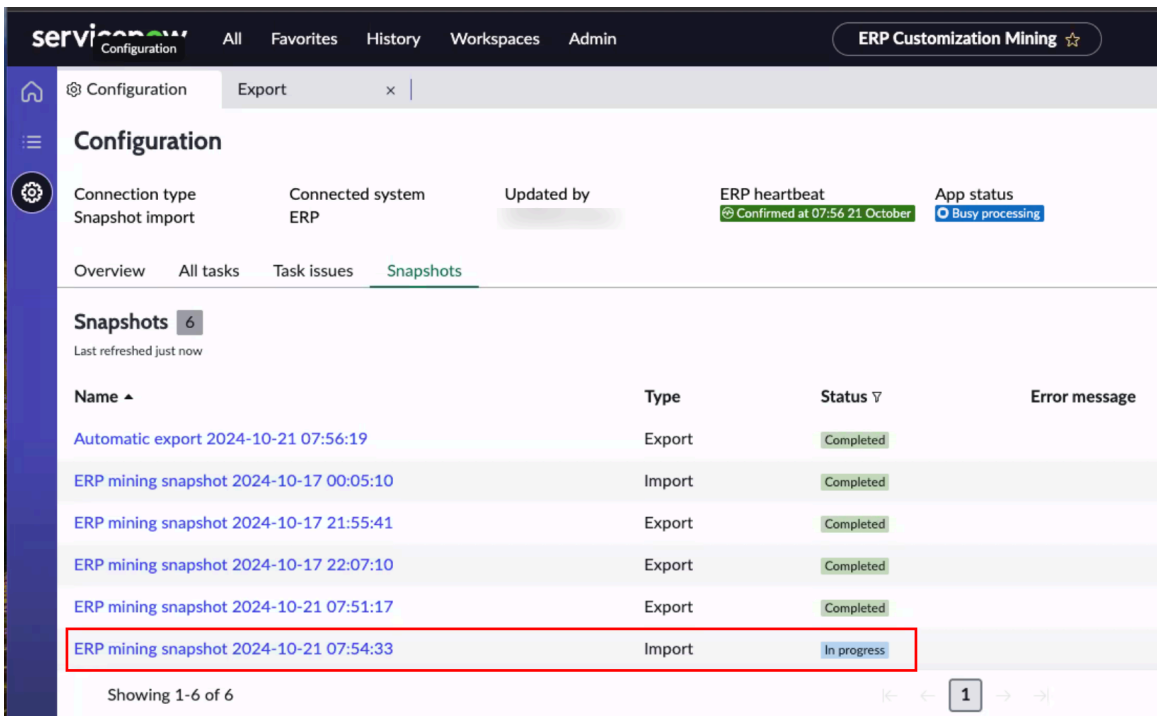
The zip process is done using the ServiceNow Integration Hub Professional Pack Installer plugin. If the plugin isn't installed, the process uses the existing zip functionality on the MID Server.

d. In the pop-up window, select **Upload**.

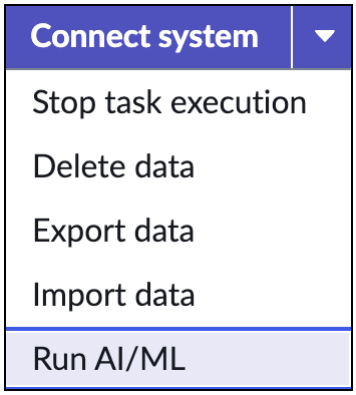
Validation is done automatically, for example, determining if there's an incomplete import job or an export job in progress.

e. When validation is complete, select **Import data**.

f. Check the status on the **Snapshots** tab.

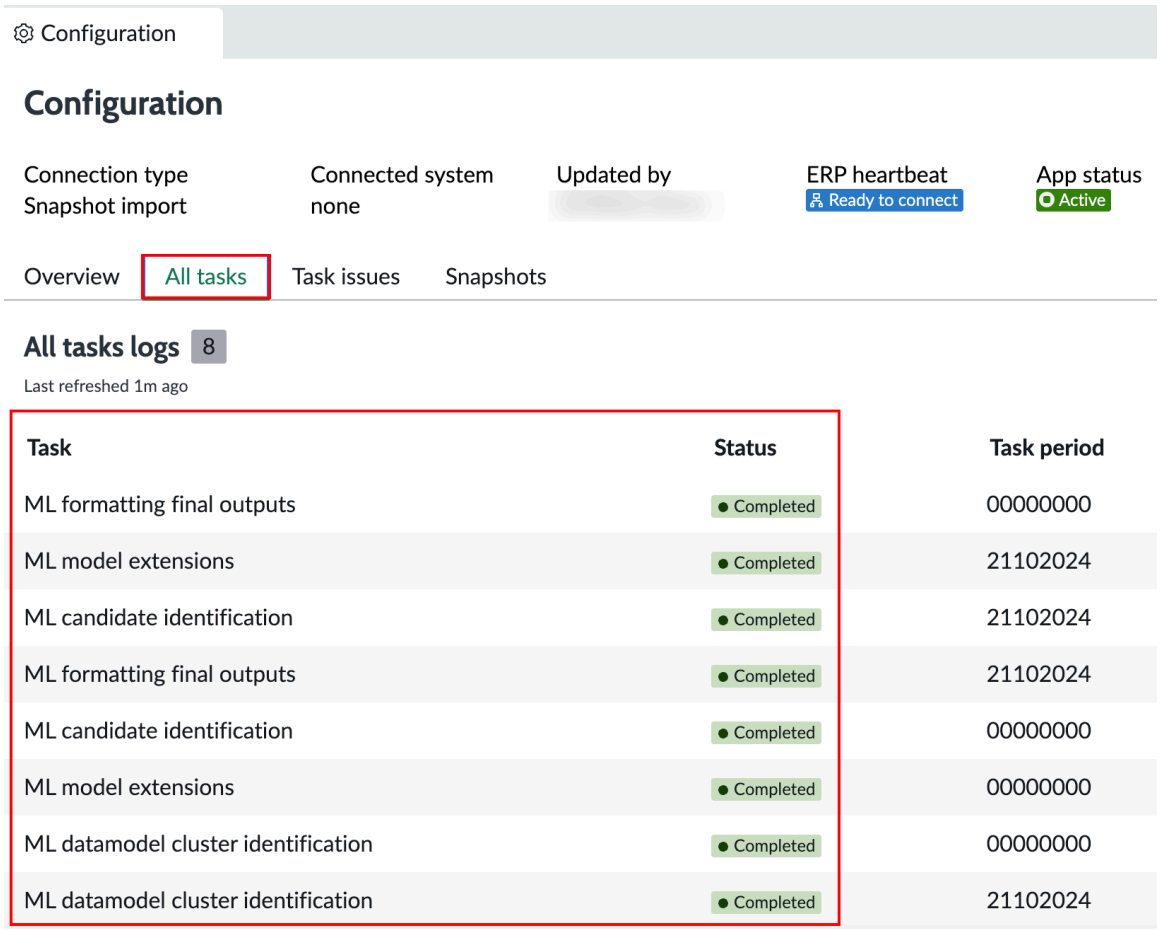


g. When the import is complete, manually run AI/ML to obtain candidates out of the new imported data by selecting the **Connect system** button and **Run AI/ML**.



AI/ML runs once according to day automatically, but you can initiate the process manually at any time using the **Run AI/ML** option. The manual and automatic process are the same and identify technical clusters, then candidate identification, and, lastly, model extensions.

View the **All tasks** tab to check the status.



Getting notifications for ERP Customization Mining connection updates

ERP Customization Mining (ERP-CM) can email you about the success and failures of ERP (Enterprise Resource Planning) system connections.

Notifications for success and failure

ERP-CM customization mining jobs run to find candidates for replatforming. With notifications, you can get an email when a customization mining task succeeds or fails.

- Success notifications indicate that all the customization mining tasks have finished running with no errors.
- Failure notifications indicate that one or more of the customization mining tasks are in error status.

The notification email you receive contains a link that takes you to the record for the customization mining job. You can view the progress of its tasks by selecting the **Show training progress** Related Link. The tasks there also appear in the Connection tasks overview list on the **Overview** tab of the Connection status page. You could then select to **Show matching** on a day's **Task period** value in the Connection tasks overview list to see the status of all tasks for that day.

Selecting your email notifications

Notification emails aren't enabled by default, and you must configure them for yourself in your ServiceNow AI Platform preferences. For details on configuring notifications, see Configure notifications for ERP-CM tasks.

Before you can set up notifications for yourself, your admin must add you to the ERP Customization Mining Notification group. For more information, see Add a user to a group.

Notifications also appear in the Notifications table

Notifications appear in the Notifications table, which you can access by navigating to **All** > **System Notification** > **Notifications**.

Flow that runs notifications

The ECM Statistical Data Extractor flow in Workflow Studio runs automatically to power notifications. You don't need to do anything to activate the flow, but you can customize it in Workflow Studio. For more information, see Edit a flow.

Configure notifications for ERP-CM tasks

Enable notifications to find out when ERP Customization Mining (ERP-CM) succeeds or fails in a mining job for the ERP (Enterprise Resource Planning) system of record.

Before you begin

Before you can set up notifications for yourself, your admin must add you to the ERP Customization Mining Notification group. For more information, see Add a user to a group.

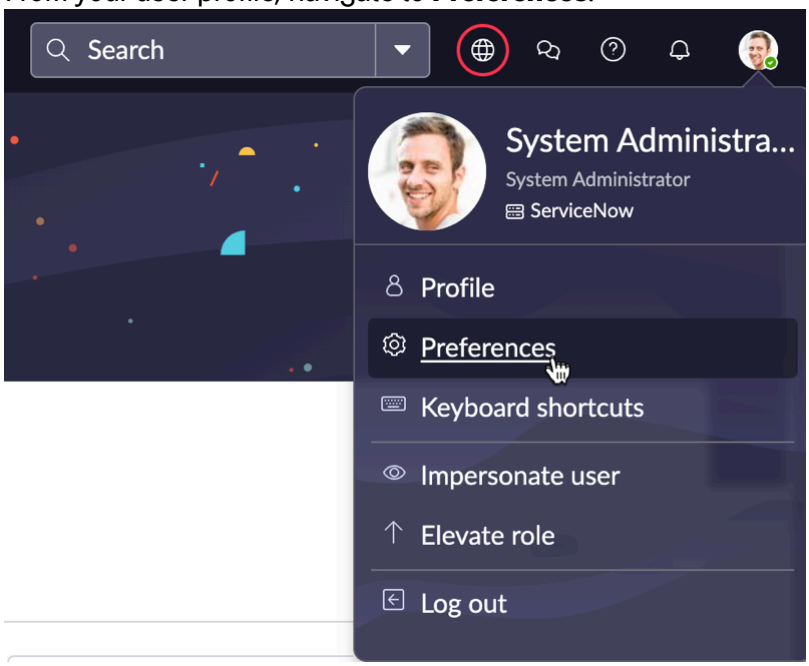
Role required: sn_erp_mining.erp_admin, sn_erp_mining.erp_user

About this task

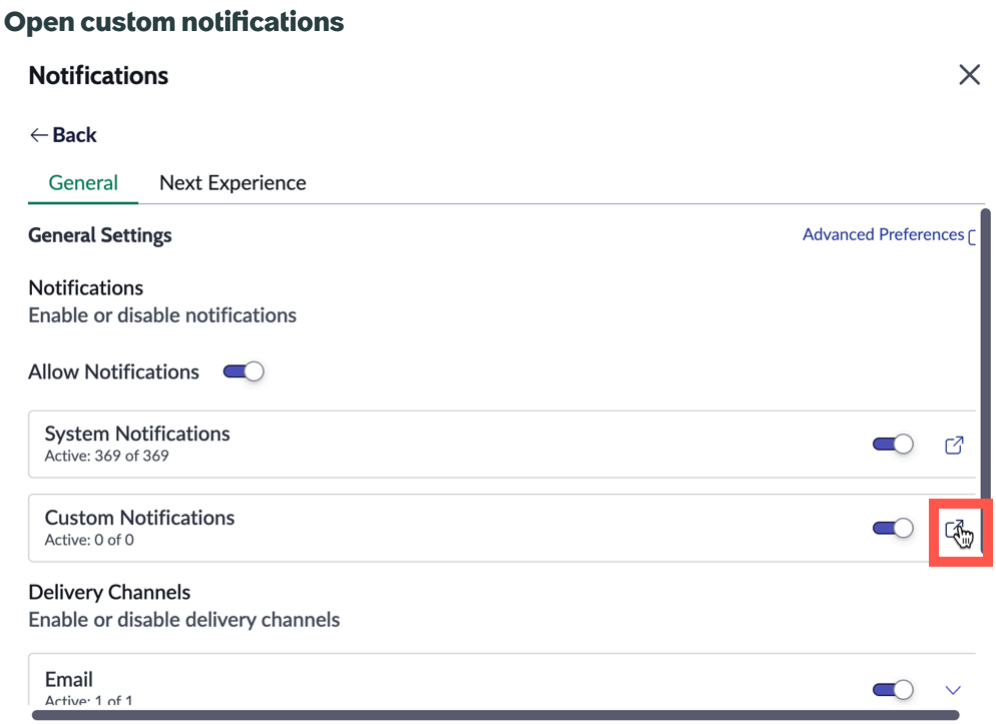
For general information on preferences, see System and custom notification and delivery channel preferences in Next Experience.

Procedure

1. From your user profile, navigate to **Preferences**.



2. Select the **Notifications** card.
3. Enable the toggle for **Custom Notifications** in **General Settings**.
4. Select the open in new tab icon for **Custom Notifications**.



5. Select the **Create notification** button.
6. Enter the basic details for the notification in the **Select notification** section of the **Create Notification** modal.

Basic notification fields

Field	Description
Personal notification name	Descriptive name for the notification you're setting up. For example, `Ann's ERP failure email notification`.
Notification	Select the notification that you want. The options are: ○ **ERP Extraction Completion Notification** ○ **ERP Extraction Failure Notification**

7. Select the **Next** button.
8. Select the delivery channel.
   a. Expand the method for how you want to be notified, such as **Email**.
   b. Enable the toggle for the email address that you want to receive the notification.
   Email addresses must already be associated with your ServiceNow AI Platform user account.
   c. Select the **Next** button.
9. Select the **Schedule** for your notification.
10. Finish setting up the notification by selecting the **Save** button.

Result

The notification email you receive contains a link that takes you to the record for the customization mining job. You can view the progress of its tasks by selecting the **Show training progress** Related Link. The tasks there also appear in the Connection tasks overview list on the **Overview** tab of the Connection status page. You could then select to **Show matching** on a day's **Task period** value in the Connection tasks overview list to see the status of all tasks for that day.

ERP Customization Mining roles

Administrators assign roles to give team members permission to configure or use ERP Customization Mining (ERP-CM).

Important:
When you assign ERP-CM roles to a user, you must include the scope. For example, assign the `sn_erp_mining.erp_admin` role, not just `erp_admin`.

For more on assigning roles, see Assign a role to a user.

To learn more about managing per-user subscriptions, see Managing per-user subscriptions in Subscription Management and contact your account representative.

ERP-CM roles

Role	Description	Additional access
sn_erp_mining.erp_admin	Grants the user access to updating application setup.	Contains sn_erp_mining.erp_user.
sn_erp_mining.erp_user	Grants the user read access on all tables needed for ERP Customization Mining, as well as some field-level write access in the sn_erp_mining_app_candidate table.	Contains the following roles: • sn_erp_integration.erp_data_pill • sn_erp_integration.erp_user

ERP-CM and security

In addition to role-based security and access control, ERP Customization Mining (ERP-CM) protects personally identifiable ERP (Enterprise Resource Planning) data in other ways.

Personally identifiable data is secured with ERP Data Hub and ERP-CM in several ways.

- You can customize ERP models and remote tables to exclude personal data in a specified field, such as email address.
- All remote tables are secured using access control rules (ACLs). If you have a remote table that contains sensitive data, use ACLs to restrict that table from ServiceNow users. For more information, see ServiceNow® access control.

Finding and working with candidates to replatform

Use ERP Customization Mining (ERP-CM) to identify potential ERP (Enterprise Resource Planning) app candidates for replatforming.

Replatforming is the process of scanning legacy ERP system code to find potential candidates to move onto your ServiceNow AI Platform instance as new apps. You can use data from the ERP system as a source for apps built on the ServiceNow AI Platform, improving performance, enhancing security, and reducing maintenance.

ERP Customization Mining evaluates application candidates and presents a numeric score. The higher the score, the better the candidate is for replatforming.

- A high potential indicates that ERP-CM can immediately use remote tables and extraction tables that match the ERP model for the application candidate without making additional changes.
- A low potential indicates that the application candidate matches few of the remote tables and extraction tables in the ERP models in ERP Data Hub.

Good candidates for replatforming tend to be smaller applications that use data from the system of record.

Note:

If you delete a candidate from ERP-CM, it automatically reappears the next time the ERP system is scanned. Instead of deleting candidates, use the **Save as potential candidate** feature to organize your candidates.

If ERP-CM shows that a candidate has a number of similar candidates, consider building one app that meets the needs of some or all similar candidates when you replatform.

Browse an overview of candidates in ERP-CM

View the ERP Customization Mining (ERP-CM) home page for a summary of ERP (Enterprise Resource Planning) app candidates to replatform onto the ServiceNow AI Platform.

Before you begin

Admins must first configure the connection to the ERP system in ERP Data Hub. For more information, see Working with ERP systems in ERP Data Hub.

Role required: sn_erp_mining.erp_user

Procedure

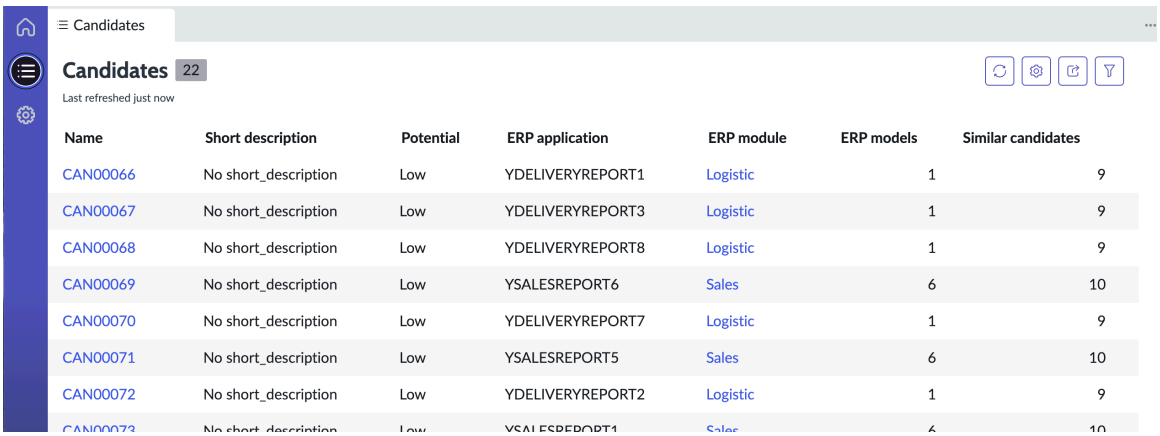
1. Navigate to **All** > **ERP Foundation** > **ERP Customization Mining**.
2. **Optional:** Filter potential candidates by selecting the card for the module in the **Candidates grouped per ERP module** section.
3. View the list of potential candidates.

   For a description of the field values, see ERP-CM candidate list field descriptions.

   Note:

   You can view the same list of candidates by selecting the candidates icon ( ) in the side panel.

   Candidate list in ERP-CM

Name	Short description	Potential	ERP application	ERP module	ERP models	Similar candidates
CAN00066	No short_description	Low	YDELIVERYREPORT1	Logistic	1	9
CAN00067	No short_description	Low	YDELIVERYREPORT3	Logistic	1	9
CAN00068	No short_description	Low	YDELIVERYREPORT8	Logistic	1	9
CAN00069	No short_description	Low	YSALESREPORT6	Sales	6	10
CAN00070	No short_description	Low	YDELIVERYREPORT7	Logistic	1	9
CAN00071	No short_description	Low	YSALESREPORT5	Sales	6	10
CAN00072	No short_description	Low	YDELIVERYREPORT2	Logistic	1	9
CAN00073	No short_description	Low	YSALESREPORT1	Sales	6	10

4. View and edit the details for a candidate by selecting the candidate.
   For more information, see Save potential candidates to replatform.

View and work with candidate details in ERP-CM

View and edit candidate details and recommended actions in ERP Customization Mining (ERP-CM). Analyze ERP (Enterprise Resource Planning) system scan results, linked ERP models, usage, and similar candidates.

Before you begin

Role required: sn_erp_mining.erp_user

Procedure

1. Navigate to **All** > **ERP Foundation** > **ERP Customization Mining**.
2. In the side panel, select the candidates icon ().
3. View and edit the basic details for a candidate in a new tab within ERP-CM by selecting the candidate **Name** in the candidates list.

   Alternatively, you can select a candidate directly on the ERP-CM home page. For more information, see Browse an overview of candidates in ERP-CM.

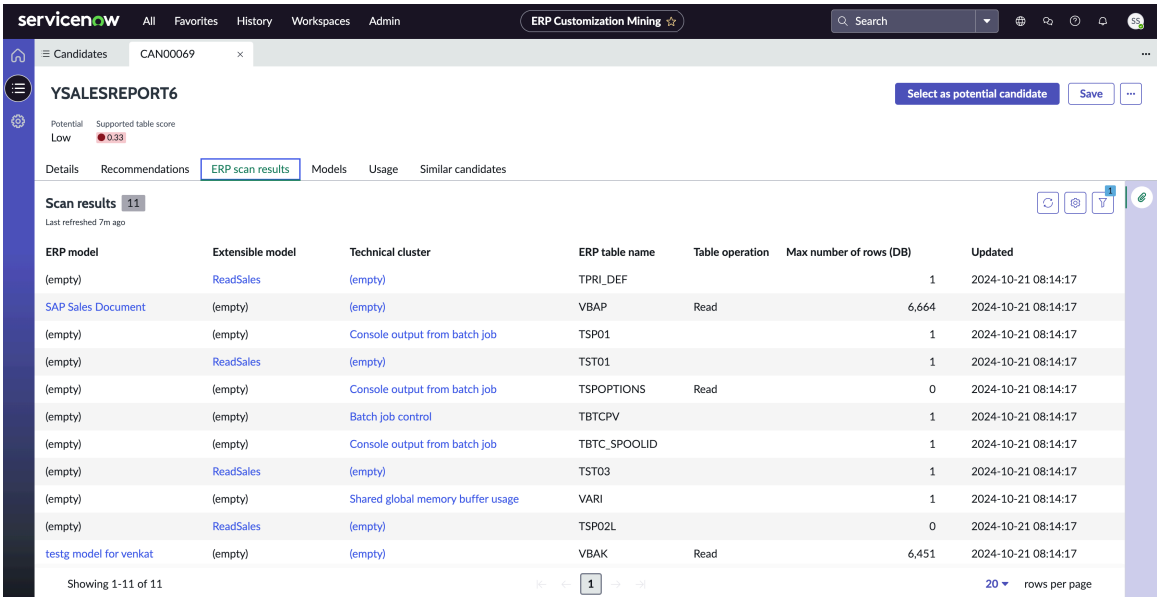
   The **Details** tab of the candidate is where you can review and update any basic details, as well as work with comments, attachments, and the Activity stream.

   #### Basic candidate details

Field	Description
Name	Record number of the potential candidate, which is automatically generated.
Status	Status of the candidate, either **Draft** or **Potential**. When you evaluate a draft candidate and decide the candidate is good to replatform, you can change the status from **Draft** to **Potential**.
ERP application	Name of the ERP application on the ERP system.
ERP module	Functional business area of the ERP system, such as **Sales**.
Short description	Brief description of the candidate, what the application does.
Long text	Additional information about the candidate.

4. Work with the next recommended steps by selecting the **Recommendations** tab.
   For more information, see Check candidate recommendations in ERP-CM.
5. View details on which tables were relevant to the candidate and the details of their scan on the ERP system by selecting the **ERP scan results** tab.
   For a description of the field values, see ERP-CM candidate scan results field descriptions.

Candidate scan results



6. Check and note which ERP models are ERP-CM identified as being related to the candidate by selecting the **Models** tab.

Models tab details

Field	Description
Model type	ERP model relevant to the candidate. This model can be a standard ERP model (which you work with in ERP Data Hub), a workflow, or a custom business area.
Relevant for implementation	Whether the ERP model is required for replatforming.
Module	ERP business area for the model on the system of record, such as **Sales**.
Table names	Names of the tables in the ERP model on the ERP system.
Updated	Date and time the list was most recently updated.

You can note which ERP models to work with in ERP Data Hub.

7. **Optional:** Check the number of system users that use the candidate application by selecting the **Usage** tab.
8. Research candidates related to the current candidate and their tables by selecting the **Similar candidates** tab.

   Similar candidates are helpful when planning how to best replatform a legacy app. When you replatform a custom app from the system of record, you don't have to replicate the old app exactly. Use the replatforming process to design a better app, perhaps one that addresses the needs of multiple similar candidates in a single, new app built using low-code tools on the ServiceNow AI Platform.

For a description of the field values, see ERP-CM similar candidates field descriptions.

9. Select the **Save** button and save any changes you made to the candidate details.

What to do next

After you work with the candidate details and identify similar candidates, you can:

- Check candidate recommendations in ERP-CM.
- Save potential candidates to replatform.
- Continue building remote table and extraction tables in the relevant ERP model in ERP Data Hub, making the data available on the ServiceNow AI Platform. For more information, see Using ERP models, extraction tables, and remote tables.

Note:

If you delete a candidate from ERP-CM, it automatically reappears the next time the ERP system is scanned. Instead of deleting candidates, use the **Save as potential candidate** feature to organize your candidates.

Check candidate recommendations in ERP-CM

Check the actions that ERP Customization Mining (ERP-CM) suggests to improve the ease of replatforming an ERP (Enterprise Resource Planning) candidate.

Before you begin

Role required: sn_erp_mining.erp_user

About this task

When you view a candidate, ERP-CM displays the number of recommended actions or next steps to take.

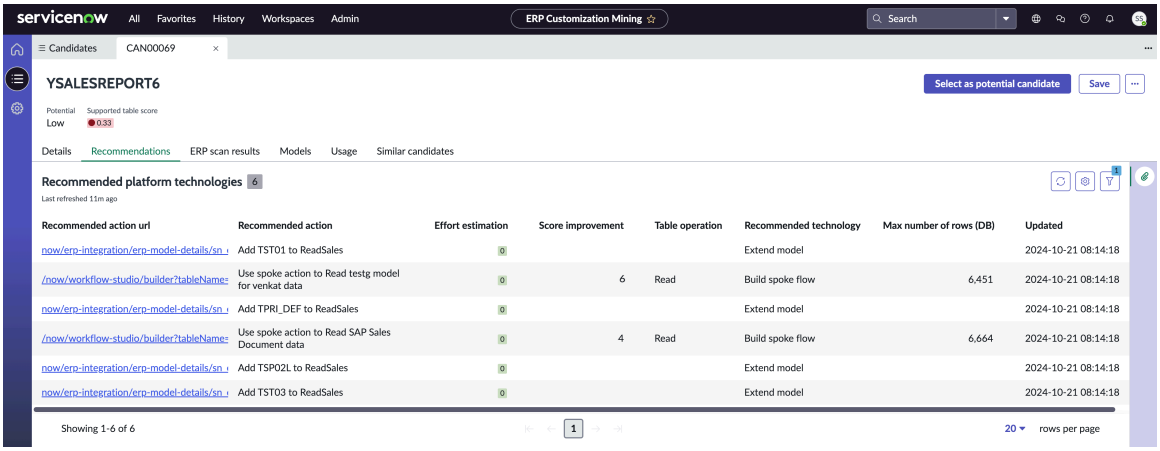
For example, you may need to create a workflow in Workflow Studio for one candidate, update an integration spoke for another, and read an extraction table or remote table for a third candidate.

Procedure

1. Navigate to **All** > **ERP Foundation** > **ERP Customization Mining**.
2. In the side panel, select the candidates icon ( ).
   Alternatively, you can select a candidate directly on the ERP-CM home page. For more information, see Browse an overview of candidates in ERP-CM.
3. Select the candidate that you want to view the recommended next actions for.
4. Select the **Recommendations** tab, which summarizes each suggested action.

   For a description of the field values, see ERP-CM candidate recommendations field descriptions.

Recommendations in ERP-CM



Note:
The score improvement feature is available starting with Xanadu Store Release 2.

5. Select a **Recommended action URL** to open the relevant destination on the ServiceNow AI Platform in a new browser tab.
   For example, if the recommendation is to read an extraction table, select the **Recommended action** link to open the ERP model in ERP Data Hub, where you can add the suggested table.

Save potential candidates to replatform

Use ERP Customization Mining (ERP-CM) to save ERP (Enterprise Resource Planning) app candidates to replatform.

Before you begin

Admins must first configure the connection to the ERP system in ERP Data Hub. For more information, see Working with ERP systems in ERP Data Hub.

Role required: sn_erp_mining.erp_user

About this task

Candidates are custom applications in your ERP system. ERP-CM scans your system of record to build a profile based on application logs and database activity logs. ERP-CM also scans for custom applications based on customized namespaces and other criteria. Replatformed apps use the ERP system of record as the live data source.

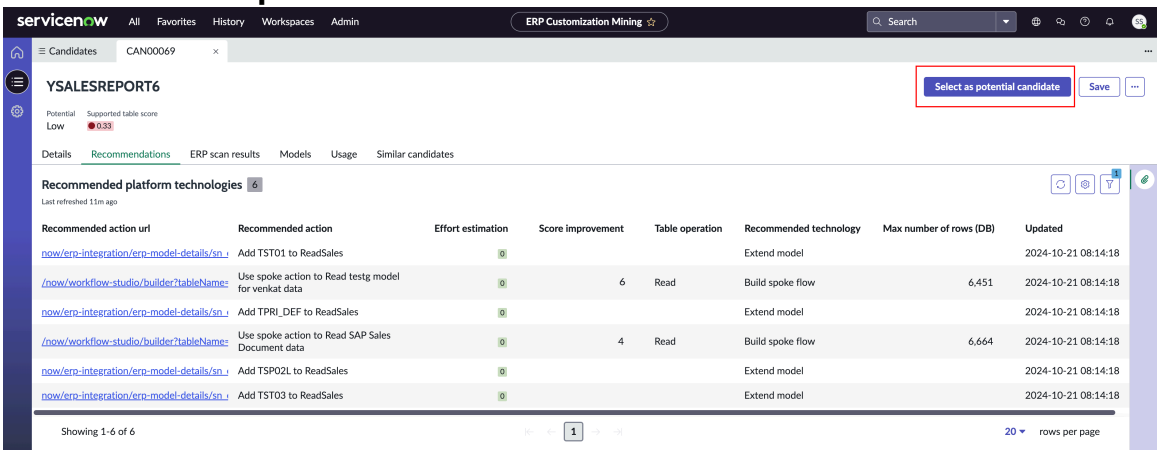
Note:

If you delete a candidate from ERP-CM, it automatically reappears the next time the ERP system is scanned. Instead of deleting candidates, use the **Save as potential candidate** feature to organize your candidates.

Procedure

1. Navigate to **All** > **ERP Foundation** > **ERP Customization Mining**.
   ERP-CM accesses the remote table that calls the system of record instance, and temporarily mirrors that data in the ServiceNow AI Platform.
2. Select the candidates icon ( ) in the side panel.
3. Select the candidate that you want to save as potential.
   Alternatively, you can select a candidate directly on the ERP-CM home page. For more information, see Browse an overview of candidates in ERP-CM.

4. Select the **Select as potential candidate** button.



If you change your mind and want to remove the candidate from the potential candidates list, select the **Change to draft candidate** button.

Note:
The score improvement feature is available starting with Xanadu Store Release 2.

Result

Selecting a candidate as a potential candidate changes the candidate status from Draft to Potential. The selected candidate is added to the Your selected potential candidates list on the home page.

What to do next

After you identify candidates, use ERP Data Hub to view custom fields in remote and extraction tables, and add them to your ERP model. For more information, see Building and managing ERP models to work with ERP data.

ERP-CM also recommends possible next steps for each candidate. For more information, see Check candidate recommendations in ERP-CM.

ERP Customization Mining reference

Find ERP (Enterprise Resource Planning) reference information for ERP Customization Mining (ERP-CM), including table details.

ERP Customization Mining and domain separation

Domain separation is unsupported for ERP Customization Mining (ERP-CM). Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

Domain separation for service providers

Sample Glide query for ERP data in ERP Customization Mining

Access data from the ERP (Enterprise Resource Planning) system of record through the Glide API.

The following is an example of a Glide query that fetches a customer name.

```
var sap_customer_gr = new
 GlideRecord('sn_erp_integration_st_sap_sales_customer');
sap_customer_gr.get('customer_number', '100032');
sap_customer_gr.getValue('name');
```

ERP-CM system connection tasks

ERP Customization Mining (ERP-CM) runs a number of tasks when connecting to the ERP (Enterprise Resource Planning) system.

- Aggregating daily extract of ERP activity
- Candidate identification
- Carveout Finalize import and prepare viewdata
- Extraction of Collector Directory Data
- Extraction of daily ERP Application activity
- Extraction of daily ERP Application SQL activity
- Extraction of daily ERP Module activity
- Extraction of Namespace Data
- Running ML similarity analysis

ERP Customization Mining snapshot prerequisite check

Before snapshot import and export in (ERP-CM), a check is performed automatically to confirm that other related processes aren't in progress.

Snapshot prerequisite checks

Prerequisite check	Description
System not connected	If you chose to import another snapshot, or attach a system, the 'table flush trigger' flow will immediately start to delete data. Once data is deleted, the selected snapshot will be imported, or the system will be attached.
System Connected and attach new system	The 'table flush trigger' flow will cancel Tasks that are currently executing. After tasks have been stopped' 'table flush trigger' flow will delete data, and attach the new system.
System Connected and import snapshot	The 'table flush trigger' flow will start by scheduling the creation of a snapshot. It will wait for the snapshot to be created. Snapshot is created when all tasks for all Collector entries are completed. Different flows execute subflow 'Check set Snapshot

Snapshot prerequisite checks (continued)

Prerequisite check	Description
	to in progress'. This subflow checks whether a record in the snapshot table should be completed with data. The 'table flush trigger' flow resumes and deletes all data. Subsequently, snapshot is imported.
System Connected and export snapshot triggered	Snapshot is created when all tasks for all Collector entries are completed. Different flows execute subflow 'Check set Snapshot to in progress'. This subflow checks whether a record in the snapshot table should be completed with data. If user wants to delete all data, or attach a new system, 'table flush trigger' flow will wait for the snapshot to be created.

ERP-CM standard tables and fields

Find details on standard ERP (Enterprise Resource Planning) remote tables, extraction tables, and fields in ERP Customization Mining (ERP-CM).

Standard remote tables for ERP-CM

ERP Customization Mining (ERP-CM) accesses several standard remote tables for ERP (Enterprise Resource Planning) data.

The following remote tables are available through ERP Data Hub and ERP-CM.

Remote tables for ERP Data Hub and ERP-CM

Label	Name	ERP module
SAP Company Code	sn_erp_integration_st_sap_company_code	Basis
SAP Country	sn_erp_integration_st_sap_country	Basis
SAP Currency	sn_erp_integration_st_sap_currency	Basis
SAP Language	sn_erp_integration_st_sap_language	Basis
SAP Material Stock	sn_erp_integration_st_sap_material_stock	Plant maintenance
SAP Purchase Document	sn_erp_integration_st_sap_purchase_document	Purchasing
SAP Purchasing Organization	sn_erp_integration_st_sap_purchasing_organization	Purchasing
SAP Customer Invoice	sn_erp_integration_st_sap_customer_invoice	Sales
SAP Distribution Channel	sn_erp_integration_st_sap_distribution_channel	Sales
SAP Division	sn_erp_integration_st_sap_division	Sales
SAP Sales Customer	sn_erp_integration_st_sap_sales_customer	Sales
SAP Sales Delivery	sn_erp_integration_st_sap_sales_delivery	Sales

Remote tables for ERP Data Hub and ERP-CM (continued)

Label	Name	ERP module
SAP Sales Document	sn_erp_integration_st_sap_sales_document	Sales
SAP Sales Organization	sn_erp_integration_st_sap_sales_organization	Sales
SAP Sales Revenue Recognition	sn_erp_integration_st_sap_sales_revenue_recognition	Sales
SAP Vendor	sn_erp_integration_st_sap_vendor	Sales
SAP Vendor Invoice	sn_erp_integration_st_sap_vendor_invoice	Sales
SAP Transport	sn_erp_integration_st_sap_transport	Transport

For more details on working with remote tables, see Remote tables.

You can use any of the standard remote tables as data sources when building apps in ServiceNow products, such as:

- App Engine Studio
- Flows in Workflow Studio
- Playbooks in Workflow Studio
- Table Builder
- UI Builder
- Workspace Builder

You can also access data from the system of record through the Glide API.

The following is an example of a Glide query that fetches a customer name.

```
var sap_customer_gr = new
 GlideRecord('sn_erp_integration_st_sap_sales_customer');
sap_customer_gr.get('customer_number', '100032');
sap_customer_gr.getValue('name');
```

Standard ERP-CM fields within remote tables

The standard ERP (Enterprise Resource Planning) remote tables available for use in ERP Customization Mining (ERP-CM) contain fields from additional SAP tables.

The standard remote tables contain the following additional fields. For details on the standard tables, see Standard remote tables for ERP-CM.

Standard ERP Data Hub and ERP-CM tables within remote tables

Remote table	Source table	ERP field name	Mapped field name
SAP Sales Document	VBAK	VBELN	document_number
SAP Sales Document	VBAK	ERDAT	date_of_document
SAP Sales Document	VBAK	ERZET	time_of_document
SAP Sales Document	VBAK	VKORG	sales_organization

Standard ERP Data Hub and ERP-CM tables within remote tables (continued)

Remote table	Source table	ERP field name	Mapped field name
SAP Sales Document	VBAK	VBTYP	document_category
SAP Sales Document	VBAK	AUART	document_type
SAP Sales Document	VBAK	AUGRU	order_reason
SAP Sales Document	VBAK	LIFSK	delivery_block
SAP Sales Document	VBAK	FAKSK	billing_block
SAP Sales Document	VBAK	KUNNR	customer_number

ERP-CM field descriptions

Some tables of field descriptions in ERP Customization Mining (ERP-CM) are too large to maintain in task topics. Find information on those large tables in this section.

ERP-CM task list field descriptions

The task list in ERP Customization Mining (ERP-CM) displays information on connection tasks for the ERP (Enterprise Resource Planning) system.

Task list details

Column	Definition
Task	Name of the task in the ServiceNow AI Platform, such as a background script for extraction, an ETL task, or an analysis training script.
Short description	Brief description of the connection task error. **Note:** This column appears on the **Task issues** tab only.
Code no.	Error code number for errors or warnings. **Note:** This column appears on the **Task issues** tab only.
Category	The type of issue, either **Error** or **Warning**.
Status	Status of the task, such as **New** or **Insufficient data**.
Current step	Step of the connection task that ServiceNow AI Platform is being performed.
Total steps	Number of total steps required to complete the connection task.
Task period	Date when the connection task was most recently updated.
Started	Date and time when the connection task started running.
Finished	Date and time when the connection task finished running.

ERP-CM candidate list field descriptions

The candidate list in ERP Customization Mining (ERP-CM) displays information on the basic details for each candidate.

Candidate list details

Column	Description
Name	Name of the application candidate, which is the record number on the ServiceNow AI Platform.
Short description	Brief information on what tables the candidates accesses.
Potential	Evaluation of how well a candidate is suited for replatforming.

Candidate list details (continued)

Column	Description
	The value represents how well the remote tables and extraction tables for the candidate match an application. • A high potential indicates that ERP-CM can immediately use remote tables and extraction tables that match the ERP model for the application candidate without making additional changes. • A low potential indicates that the application candidate matches few of the remote tables and extraction tables in the ERP models in ERP Data Hub. **Note:** This column is available only on the candidates list on the Candidates page, not on the home page.
ERP application	Record for the ERP application of the candidate.
ERP module	Name of the ERP functional area in the system of record. For example, logistics, procurement, or sales.
ERP models	Number of ERP models the candidates belongs to. ERP models are configured in ERP Data Hub. An ERP model functions as a staging area that contains all potential fields you can add to remote and extraction tables, and read and update operations. You can then use the tables and queried data as a data source on the ServiceNow AI Platform. For more information, see Building and managing ERP models to work with ERP data. **Note:** This column is available only on the candidates list on the Candidates page, not on the home page.
Similar candidates	Number of similar candidates. Similarity is based on the remote tables.

ERP-CM candidate scan results field descriptions

The candidate list in ERP Customization Mining (ERP-CM) displays information on the latest scan of the ERP (Enterprise Resource Planning) system.

ERP scan results tab details

Field	Description
ERP model	Relevant ERP model that the candidate uses, which is configured in ERP Data Hub. Select an ERP model to open the model in ERP Data Hub.
Closest ERP model/Extensible model	The suggested closest matching ERP model that you can add the table to in ERP Data Hub. This column is helpful for custom tables, which aren't part of a standard ERP model and therefore won't have a table listed in the **ERP model** column. Select an ERP model to open the model in ERP Data Hub.
Technical cluster	If the field is empty, the table is an ordinary, non-technical table. If the field contains a value, the table belongs to a technical group and is disregarded in the candidate identification analysis.
ERP table name	Name of the table on the ERP system.
Table operation	Action that ERP-CM took on the scanned table: Create, Read, Update, or Delete.
Max number of rows (DB)	Maximum number of rows on the scanned table, which is useful for knowing candidate limitations.
Updated	Date and time the table was most recently scanned.

ERP-CM candidate recommendations field descriptions

The candidate Recommendations list in ERP Customization Mining (ERP-CM) displays information on suggested next actions for replatforming ERP (Enterprise Resource Planning) candidates.

Recommendations list details

Field	Description
Recommended action URL	Link to the recommended action. Select the recommendation link to open the relevant destination on the ServiceNow AI Platform. For example, the **Build a workflow** recommended URL would link to the flow in Workflow Studio.
Recommended action	Brief description of the action that ERP-CM suggests you take on a candidate when replatforming.

Recommendations list details (continued)

Field	Description
Effort estimation	Numerical score for how much effort the recommended action should require. Each recommended action has an estimated effort, which is a numerical score that assesses how well the ServiceNow AI Platform has matching functionality. Green actions require little-to-no effort, while red actions are more difficult.
Score improvement (available in Xanadu Store Release 2)	The possible increase in the overall potential for a candidate if you implement the recommendation. Each time the AI/ML workflow is triggered, either automatically or manually, score improvements are calculated.
Table operation	The action you should take on the table, such as **Read** or **Update**.
Recommended technology	App or product on the ServiceNow AI Platform where you take the recommended action.
Max number of rows (DB)	The maximum number of database rows on the system of record that the recommended action allows.
Updated	Date and time the recommended action was most recently updated.

ERP-CM similar candidates field descriptions

The Similar candidates tab in ERP Customization Mining (ERP-CM) displays information on similar candidates for replatforming ERP (Enterprise Resource Planning) apps.

Similar candidates tab details

Field	Description
Candidate	Name of the application candidate, which is the record number on the ServiceNow AI Platform.
Similar candidate	Record number of the similar candidate, which is automatically generated by the ServiceNow AI Platform.
Short description	Brief description of the similar candidate. For example, the tables the similar candidate reads.
ERP application	Name of the ERP application on the ERP system.

Similar candidates tab details (continued)

Field	Description
ERP module	Functional business area of the ERP system, such as Sales.
Similarity	Numeric score representing how similar the candidates are, from 0 through 1. A higher score, for example 0.94, indicates very similar candidates. For more information, see Recommendations and similar candidates in ERP-CM.
Similar candidates	Number of similar candidates. Select the value in this column to view a list of the additional similar candidates.
Updated	Date and time the similar candidate details were most recently updated.

ERP Customization Mining snapshot field descriptions

The snapshot list in ERP Customization Mining (ERP-CM) displays information about import and export snapshots.

The snapshot features is available starting in Xanadu Store Release 2.

Snapshot list details

Column	Definition
Name	Unique, read-only name of snapshot. The name is created automatically.
Type	Classification of snapshot. The options are **Export** and **Import**.
Status	Current processing state. Options are **pending**, **in progress**, and **complete**.
Error message	If the import or export fails, an error message is displayed to explain the issue.
Created by	User that created the snapshot.
Updated	Date and time the snapshot was most recently updated.

ERP Data Hub and ERP-CM glossary

Learn about ERP (Enterprise Resource Planning) terminology and concepts that apply to ERP Data Hub and ERP Customization Mining (ERP-CM).

BAPI

A Business Application Programming Interface (BAPI) is a standard interface to the business object models in SAP products, similar to an API.

candidate

A candidate is a group of recommended remote tables that you can use to create an application based on a custom transaction (ERP root) in the system. Candidates can also be existing applications that sit on top of the legacy ERP system of record.

Good candidates for replatforming tend to be smaller applications that use data from the system of record.

candidate score

A metric for how well a custom application (ERP root) fits to a remote table in ERP Customization Mining.

connection and credential alias

The credential alias is the system connection access enabler that's maintained in the ServiceNow credential alias. The credential alias is used to access the ERP system of record.

custom fields

Custom fields are values added to a table by the customer.

entity

The table or Business Application Programming Interface (BAPI) function call that ERP Data Hub uses to read or update the system of record.

ERP application

The ERP (Enterprise Resource Planning) custom application that you choose to replatform using ERP Customization Mining is an ERP root in the ERP system.

ERP model

The ERP model represents a distinct set of features and functionalities tailored to address specific business processes or activities. An ERP model encompasses multiple tables from the system of record, as well as APIs and ETL processes, to create a holistic data set. For example, you can have one ERP model for sales orders and another for inventory.

ERP module

The functional business area on the ERP system. The ERP root can only have one selected business area.

ERP system

An ERP system represents a connection to a section of your ERP system of record. The system plays a crucial role in data synchronization, sharing, and collaboration, enabling seamless integration and operation between the ERP model and the connected ERP system.

ERP table

Individual tables (both custom and standard) in the ERP system are part of the remote tables. For example, in sales, ERP tables could include VBAK, VBAP, VBFA, VBPA, VBEP, MKPF, or MSEG.

extraction table

Extraction tables retrieve large amounts of data using a scheduled query, and use transform tables to process data for use on the ServiceNow AI Platform.

mapped value

Value of the field on the ERP system that's being mapped as an operation parameter in ERP Data Hub.

odata

In ERP Data Hub, create an OData connection to link to SAP via HTTP so data can be extracted for use in remote tables and extraction tables.

operation

Individual maintenance task performed to read or update the system of record.

remote table

A remote table is an aggregation of the system of record tables that provide value when gathered in one table. The remote table is the foundation of the ERP model. A candidate can consist of several remote tables.

system of record

The ERP system of record is where the data lives and is distributed from, for example, SAP.

Building applications with ServiceNow Studio

ServiceNow Studio provides a unified experience for all ServiceNow development activities, enabling admins and developers to extend base system solutions and create custom apps with ease. Use ServiceNow Studio to build apps and app files with integrated tools, access and edit app metadata in scoped and global apps, and package app changes for deployment, all in one powerful development tool.

Exploring ServiceNow Studio

ServiceNow Studio delivers a cohesive, efficient experience for mid-to-high-skilled developers to create, modify, and extend apps. ServiceNow Studio is a single place that you can go to do development work, delivering value to your business faster.

ServiceNow Studio overview

ServiceNow Studio enables you to be more efficient in your work by providing a cohesive and powerful app development experience from creation to deployment.

- Create, edit, maintain, and deploy custom and globally scoped apps and app files in a single, integrated development environment instead of having to switch back and forth between tools and builders. You can also edit base system apps and files and customize store apps.
- Search for and edit any type of metadata record using the Navigator file taxonomy.
- Package app changes for deployment using update sets, pipelines, or the Application Repository.

ServiceNow Studio features and benefits

ServiceNow Studio offers a unified app development experience that can accelerate your time to value in app creation and deployment.

ServiceNow Studio provides the following benefits for admins and delegated developers in a unified development experience.

- App and app file search: Search for any application or metadata record in your instance. For more information, see Find an app or app file using Search and Find an app or app file using the Navigator panel.
- Integrated tabs: Easily switch between apps and app files in different scopes without leaving ServiceNow Studio. For more information about working with different apps and app files, see Open apps and app files across scopes in ServiceNow Studio.
- Accelerated deployment: Create and package apps for deployment via update sets, pipelines, or the Application Repository without leaving ServiceNow Studio. For more information, see Working with update sets in ServiceNow Studio and Publish app changes to the Application Repository from ServiceNow Studio.
- Supercharged app development with Now Assist: Use the Now Assist capabilities to decrease the time it takes to create apps and app files. For more information, see Now Assist for app generation in ServiceNow Studio.

- File creation: Easily create any type of app file in any scope that you have access to edit, including the global scope. For more information, see Create an application in ServiceNow Studio and Create an app file in ServiceNow Studio.
- Taxonomy and collections: Use the ServiceNow Studio metadata taxonomy to easily find the type of files you're searching for. For more information, see ServiceNow Studio Navigator panel taxonomy.
- Integrated builders: Use many of the best low-code builders available in the ServiceNow AI Platform, such as Table Builder and flows in Workflow Studio, along with powerful app development tools. For more information, see Access integrated development tools and builders in ServiceNow Studio.

Use App Engine instead of customizations

App Engine development tools offer an excellent alternative to customizing existing ServiceNow AI Platform applications.

When your company needs to add new functionality to the ServiceNow AI Platform, you can customize existing applications, such as IT Service Management (ITSM), or create a new application using App Engine developer products, such as App Engine Studio, Creator Studio, or ServiceNow Studio. A simple guideline for which path to choose is:

- If the customization extends the intended purpose of the application, it works better to customize. For example, you can add IT functionality to ITSM.
- If the customization doesn’t extend the intended purpose of the application, it works better to create a new application using App Engine developer products. For example, do not repurpose the ITSM workflow to add a travel request workflow.

Examples of when to use App Engine

ServiceNow products work best when they’re used as they were intended. If you find yourself heavily customizing an application to repurpose it, a better plan is to create a new application using App Engine developer products.

The following scenarios demonstrate where creating a new application works better than heavily customizing an existing ServiceNow application:

- Your company has a business process that augments existing product functionality but doesn’t follow the same workflow exactly.
- You have a novel use case for an app that doesn’t align with any product workflow.
- You have a use case that could be built by heavily customizing an out-of-the-box application, but it doesn’t align with what the existing application was intended to do.

Let’s dive deeper into the last use case.

Issues with repurposing existing products

ServiceNow applications come with roles, processes, and flows that are specially tailored to their use case. For example, ITSM apps help with IT users, IT issues, IT reports, and IT cases.

You might have an idea for an app that’s similar to but doesn't exactly align with ITSM. Because ITSM gives you a starting point, you might be tempted to customize ITSM to add the new functionality. For example, ITSM tracks IT issues, and a travel app you want to create might track travel requests. While the workflows sound similar, in fact, they use very different data, different user interfaces, and the details of each workflow vary greatly. Rather than heavily customize ITSM to repurpose it, a better plan is to use App Engine developer products for the following reasons:

- Combining two workflows creates conflicts.
- Customizing applications has implications.

Combining two workflows creates conflicts

In the ITSM example, the repurposing of ITSM to include a travel workflow uses different data, different tables, different roles, and different workflows than ITSM. As ITSM, ITSM customizations, and the travel workflow grow over time:

- Their features will continue to diverge.
- Adding new functionality or fixing problems in one workflow might adversely impact the other.
- The performance of ITSM may suffer.
- The code base will grow and the two purposes of ITSM will make troubleshooting more difficult.
- Quality engineers will require two different testing frameworks.

All these issues may cause unnecessary complications, poorer performance, upgrade delays, and software problems.

Customizing applications has implications

The ServiceNow AI Platform is built to embrace customization and configuration. The ServiceNow AI Platform is flexible enough to fit your company's business needs. How you customize ServiceNow applications, however, can have significant impacts on ServiceNow support, upgrading to future ServiceNow AI Platform versions, and the functionality of the platform.

Let's start by differentiating customization and configuration:

- Customization is any change made to the code that is part of the baseline installation of a ServiceNow instance. You use code to customize applications.
- Configuration is any change you make to the behavior of a product that does not touch the code in the baseline installation of a ServiceNow instance. You can use system properties, ServiceNow products, or code to configure an application.

The following are some of the implications that result from customizing applications:

- If you add code to an application, you own it whether or not it modifies the code in the baseline installation on a ServiceNow instance.
- The platform marks all customizations and skips them when you update to a new version of the platform. That means you are responsible for manually updating the customizations. This can have a significant impact on the time and resources required to update to new platform versions.
- The ServiceNow AI Platform uses a framework that supports applications in how they process tasks, how forms are rendered in multiple browsers, and the overall user experience. Introducing customizations can have unintended consequences on this framework.
- You own the burden of testing custom code and determining if it impacts platform functionality.
- ServiceNow Customer Support cannot troubleshoot custom code or issues caused by custom code.

Customization is one of the key features of the ServiceNow AI Platform. However, over-customizing an application to repurpose it is likely to generate technical debt, lengthen your upgrade cycle, and complicate future platform upgrades because the custom code may not easily migrate to new platform versions.

Conclusion

Customization and configuration are hallmarks of the ServiceNow AI Platform that enable your company to customize workflows to fit its specific needs. Proceed with these tasks in the following order:

1. Configure ServiceNow applications as much as you can before customizing them.
2. Customize an application only when it extends the intent of the application.
3. Use App Engine developer products, such as App Engine Studio, Creator Studio, and ServiceNow Studio, to create new applications rather than customizing an application to create functionality that doesn't align with its original purpose.

For more information, see Customization vs configuration with ServiceNow Studio.

Customization vs configuration with ServiceNow Studio

There are important differences between customizing and configuring ServiceNow applications. The ServiceNow platform is built to embrace customization and configuration, but how you do so can have significant impacts on ServiceNow support, upgrading to future ServiceNow platform versions, and the functionality of the ServiceNow platform.

The general rules around customization are:

- Customize an application only if it extends the original intent of the application. For example, add IT functionality to ITSM but don't add a travel workflow. Instead of over-customizing an application, create a new application using App Engine products, such as Creator Studio or ServiceNow Studio.
- Configure as much as you can before customizing an application.
- If you add code or make other modifications to out-of-the-box functionality, you own them.

What is configuration

Configuration is the process of using ServiceNow built-in tools and features to modify an application's behavior without making changes to flows or the code that is part of the baseline installation on a ServiceNow instance.

Configuration can take the form of using ServiceNow built-in tools to add tables and more, setting instance-wide parameters, as well as using code to extend an application's functionality to meet business needs as long as the code does not modify the baseline code installation. The entire platform is designed for you to add configuration code.

If you add code, such as workflow scripts, you own it, even if it doesn't alter the baseline code installation. That includes owning the impact it has on the entire ServiceNow platform. Issues that arise from added code are beyond the scope of ServiceNow support to debug.

Reverting a configuration should not require any change to the baseline code.

Configuration examples include:

- Forms: Configure tables, fields, data types, default values, and field dependencies to configure the data you capture and display.
- UI elements: Modify layouts, add related lists, add buttons, and change field names.
- Service Catalog: Configure portals where your customers can request catalog items such as service and product offerings.
- ACLs: Restrict unauthorized users from accessing forms and data.
- System property values: Modify the application's experience for all users.

What is customization

Customization is any change made to the flows or the code that is part of the baseline installation on a ServiceNow instance. You use ServiceNow products or code to customize applications.

If you add code, you own it, even if it doesn't alter the baseline installation. That includes owning the impact it has on the entire ServiceNow platform.

Customization examples include:

- Scripting: Customize ServiceNow through scripting using JavaScript. This includes creating client scripts, server-side scripts, and business rules with intricate logic that modify the baseline code.
- Custom tables: Develop custom tables to accommodate specialized data that doesn't fit within standard tables.
- Integration: Customize integration with external systems, such as APIs and web services, for seamless data exchange.
- Widgets and portals: Create custom widgets and portals to provide unique features and user experiences.
- Workflows: Create and modify workflows using Workflow Studio. Create and manage playbooks, flows, actions, decision tables, and integrations from one design environment to automate tasks. Upgrading to a new version of a flow requires reapplying your customizations.

Tools for customization and configuration

ServiceNow offers many tools and features, such as business rules, to modify the out-of-the-box behavior of ServiceNow applications. Whether they customize or configure an application depends on how they're used. Using these tools to modify the installed code base constitutes customization. Using these tools to add code that does not modify the flows, or the installed code base constitutes configuration. In both cases, you own the code you add as well as the impact it has on the ServiceNow platform.

ServiceNow tools include:

- UI Policies: Dynamically modify the visibility of fields and attributes on a form according to user inputs.
- Business rules: Automatically trigger actions based on specified conditions.
- UI Actions: Extend and customize forms and lists by adding buttons, context menu items, or other UI elements that perform specific actions when clicked.
- Client-side scripts: Scripts that execute within the user's browser when certain actions occur on a form or a UI page.
- Server-side scripts: Scripts that execute on the ServiceNow server or database, for example, to update record fields when a database query runs.

What is personalization

Personalization is when users use out-of-the-box application tools to modify an application's look and feel only for themselves. Admins can change the look and feel for all users and that is considered configuration. Personalization examples include a user choosing to use dark mode or choosing which table columns to display.

Personalization does not change the baseline code installation on a ServiceNow instance. So, personalization does not impact customer support or interfere with upgrades to new ServiceNow versions.

Ramifications of customizing ServiceNow products

The ServiceNow platform is extremely flexible and built to embrace customization and configuration to fulfill a wide range of business requirements. How you customize ServiceNow applications, however, can have significant impacts on ServiceNow support, upgrading to future ServiceNow platform versions, and the functionality of the platform. Instead of customizing ServiceNow applications, consider using App Engine development products, such as Creator Studio and ServiceNow Studio to create new applications.

The ServiceNow platform uses a framework that supports applications in how they process tasks, how forms are rendered in multiple browsers, and the overall user experience. ServiceNow relies on the framework's integrity to develop and provide support in a consistent manner. Customizations can impair this framework, change platform functionality, and impair workflows and upgradeability.

Customizations trigger the platform to create sys_update_xml records, which are stored in the Customer Update table. The platform marks all customizations and skips the customized records when you update to a new version of the ServiceNow platform. That means you are responsible for manually updating the customizations. This can have a significant impact on the time and resources required to update to new platform versions.

Note:
The Customer Update table also contains modifications or additions to configuration metadata, for example, creating a new catalog item or a new workflow.

For more information, see the Customer Updates table. Note that the complexity of maintaining customizations dramatically increases as the number of customizations increases.

Customizing the installed code base can be costly, generate technical debt, lengthen your upgrade cycle, and complicate future platform upgrades because the custom code may not easily migrate to new platform versions. Custom code can change the standard functionality of the ServiceNow platform in unintended ways. Evaluate demands for customization carefully and only resort to customization where there is clear business value and no alternative. Wherever possible, avoid customization by using configuration instead.

If you customize a product:

- You are responsible for maintaining the customization going forward.
- Customer Service and Support will not support problems caused by custom code. If it is the cause of the problems, the support team will likely advise you to revert to the out-of-the-box code.

What is the Customer Service and Support stance on supporting customization

The ServiceNow Customer Service and Support stance on customization is if you add code, you own it and its consequences. Why? Customer Support is not privy to your custom business logic, doesn’t know what the expected behavior should be, is unable to reproduce the issue on an out-of-the-box instance, and customer support engineers are not certified implementation specialists, so they are not certified to review customized code logic.

Alternatives to customization

If you have requirements and ideas for enhancements, instead of customizing the installed code base, you can:

- Use configuration instead of customization.
- Submit an Enhancement Request to the ServiceNow development team. Each request is evaluated and, if approved, will be incorporated into a future release.
- Create an app using App Engine developer products to handle desired functionality.

When to use App Engine developer products instead of customizing

When your company needs to add new functionality to the ServiceNow platform, you can customize existing applications, such as ITSM, or create a new application using App Engine developer products, such as Creator Studio or ServiceNow Studio. A simple guideline for which path to choose is:

- If the customization extends the intended purpose of the application, it works better to customize. For example, you can add IT functionality to ITSM.
- If the customization doesn't extend the intended purpose of the application, it works better to create a new application using App Engine developer products. For example, do not repurpose the ITSM workflow to create a travel request workflow.

For example, ITSM is designed to handle IT issues. To customize it to handle travel requests goes beyond the original intention of ITSM. Because IT and travel requests have different workflows, it's better to create a travel request app using App Engine developer tools, such as Creator Studio and ServiceNow Studio, instead of customizing ITSM.

For more information, see Use App Engine instead of customizations.

Examples of when to use App Engine developer products

ServiceNow products work best when they're used as they were intended. If you find yourself heavily customizing an application to repurpose it, a better plan is to create a new application using App Engine developer products.

The following scenarios demonstrate where creating a new application works better than heavily customizing an existing ServiceNow application:

- You have a novel use case for an app that doesn't align with any product workflow.
- You have a use case that could be built by heavily customizing an out-of-the-box application, but it doesn't align with what the existing application was intended to do.
- Your company has a user group or business process that should be separate from the OOTB product workflow.

Guidelines for customizing ServiceNow products

If you must make a customization, consider the following suggestions:

- Maximize configuration options first.
- Avoid copying objects. Instead, update objects in place wherever possible, except for Service Portal widgets and other items designated to be reused.
- Default to "add before edit." This means that you should, for example, add fields to forms rather than change the type of an existing field. Avoid using the same names as out-of-the-box objects, methods, or classes when adding them.
- Minimize the number of fields you add to a form. The more fields you have on a form, the longer it may take to load.
- Export original records as backups before customizing them. Keep track of their out-of-the-box sys_id's in case you must restore them in the future.

- Use scoped applications as your default for any new custom development.
- Document all customizations. Add comments explaining why you customized (including business justification). Review all comments before upgrading to determine if you can revert to out-of-the-box code.
- Create tests for all customizations. Write Automated Test Framework (ATF) tests for all customizations where possible.
- Use HealthScan regularly to identify unnecessary customizations.
- Customizations should be made to baseline objects where necessary so that conflict resolution and decision-making can be appropriately recorded in the updates. Hidden customizations may cause administrators to overlook updates in future assessments in case reverts or merges are necessary.
- Test your customization for all use cases. Include performance testing and the introduction of unintended consequences.
- Administrators are responsible for verifying that their customizations work after a ServiceNow platform upgrade, and for keeping track of what customizations are made.

Handling customizations when you upgrade

Customizations trigger the platform to create sys_update_xml records, which are stored in the Customer Updates table. These records are not updated during platform version upgrades. ServiceNow marks them as skipped records in the ServiceNow Upgrade Monitor. To make sure they're successfully ported to the upgraded instance, you must manually process the skipped changes. For more information, see the Customer Updates table.

Assuming you've documented all your customizations—including the business justification—take your documented inventory and compare it with the skipped records identified in the Upgrade Monitor. After filtering out low-risk changes that have resulted in skipped records (for example, field labels or form layouts), you'll need to decide whether to:

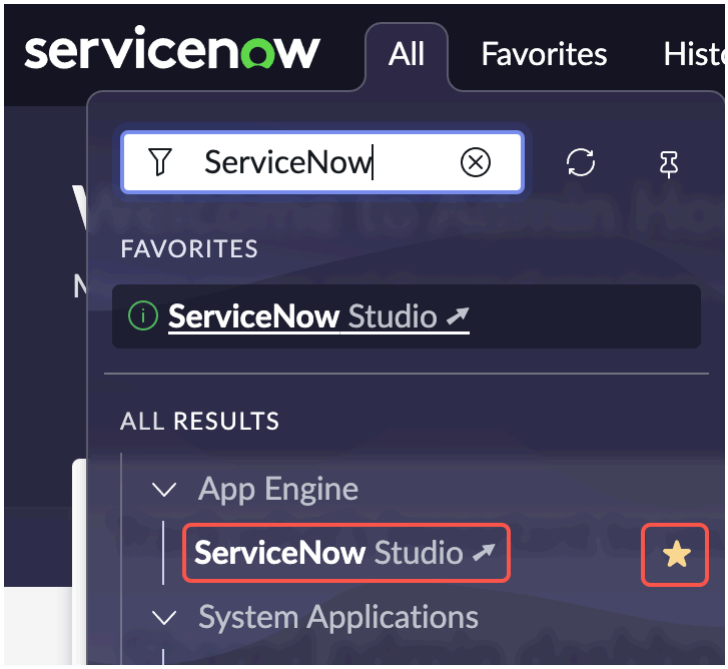
- Retain each customization
- Revert to out-of-the-box
- Merge your customization with the base system to resolve conflicts

Access ServiceNow Studio

Access ServiceNow Studio from the ServiceNow AI Platform All menu or from App Engine Studio.

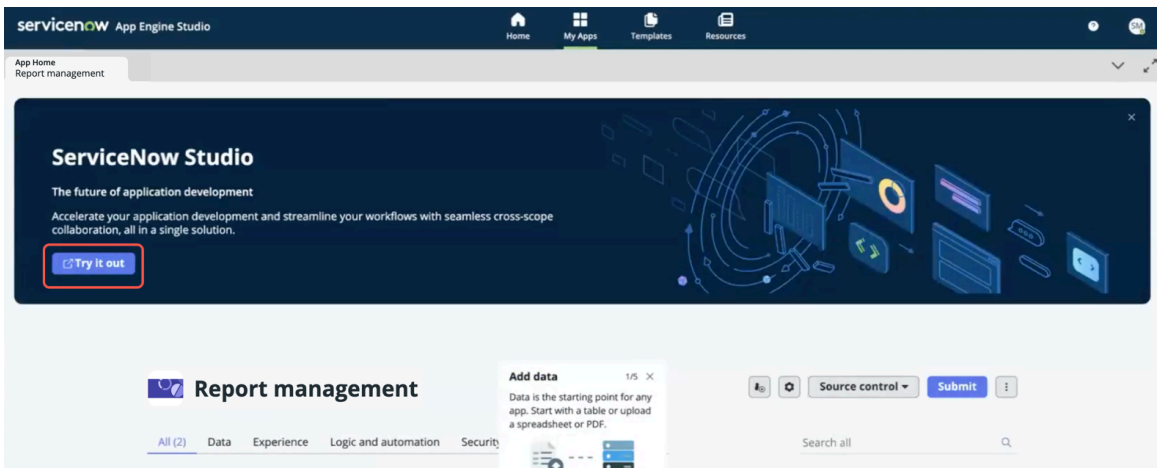
Open ServiceNow Studio through the All menu

On the platform, navigate to **All** > **App Engine** > **ServiceNow Studio** or search in the filter navigator for `ServiceNow Studio`. Open the application directly from the search results. You can also favorite ServiceNow Studio for quick access from the **Favorites** tab.



Open ServiceNow Studio from App Engine Studio

If you're creating apps in App Engine Studio (AES) and want a more advanced app development environment to work in, you can open your app in ServiceNow Studio. When you open your app in AES, a banner appears with information about ServiceNow Studio. Select **Try it out** to open your app in ServiceNow Studio.



ServiceNow Studio quick start

Familiarize yourself with ServiceNow Studio by completing several tasks. These tasks enable you to navigate around the interface and learn where to complete different types of activities.

Quick start tasks

Complete these tasks to familiarize yourself with ServiceNow Studio.

ServiceNow Studio quick start tasks

Task	Description
Find an app or app file using Search	Search from any page in ServiceNow Studio for quick access to your metadata.
Find an app or app file using the Navigator panel	Locate files or metadata items in the taxonomy.
Bookmark apps and files in ServiceNow Studio	Access frequently used apps or app files in one location.
Access recently opened apps and app files in ServiceNow Studio	View and open files or apps that you have been working on recently.
Navigate directly to a table in ServiceNow Studio	Open different table views directly by using shortcut commands like **.list**, **.do**, and **.config** after table names in the Search bar.
Open apps and app files across scopes in ServiceNow Studio	Access global and scoped apps and files in ServiceNow Studio. Scoped apps are color-coded by tab for quick reference.
Access integrated development tools and builders in ServiceNow Studio	Open any file type from the File Categories menu to access a suite of integrated development tools.
Create an update set in ServiceNow Studio	Package changes to your application for deployment.
Publish app changes to the Application Repository from ServiceNow Studio	Publish changes to the Application Repository. If your company has a deployment pipeline set up, you can also deploy through the pipeline in ServiceNow Studio.

Find an app or app file using Search

Search for and open an app or app file in ServiceNow Studio. You can also activate code search to search for snippets of code within select metadata types on your instance.

Before you begin

Role required: admin or delegated developer

Procedure

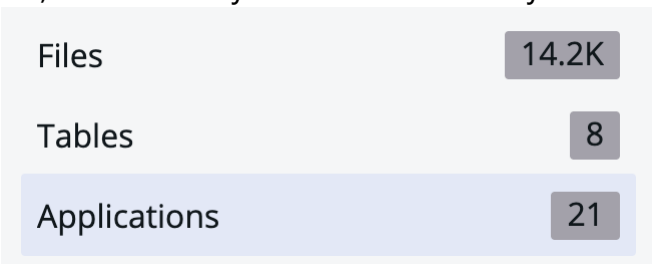
1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Choose from one of the following options to select the Search bar.
   - If you're on the ServiceNow Studio home page, select the Search icon ( ) in the Navigator panel, or select in the main Search bar.

   - If you're on any page other than the home page, such as Tools or Deployment, select the Search icon ( ) in the left side navigation.

3. **Optional:** Activate code search by selecting the switch next to **Activate code search**.

   Note:
   Code search enables you to search for snippets of code within specific application file types. For more information about using code search, see Find an app or app file using code search.

4. Enter your app or app file name.
   If you're familiar with the ServiceNow AI Platform search capabilities and want to navigate directly to a table, follow the instructions in Navigate directly to a table in ServiceNow Studio.
5. Select your app or file from the list that appears.
6. **Optional:** To expand and filter your search results, select **Enter** to open the **Search results** tab, then select any of the filters to narrow your list of search results.



Find an app or app file using the Navigator panel

Use the Navigator panel in ServiceNow Studio to find and open an app or app file.

Before you begin
Role required: admin or delegated developer

About this task
The Navigator panel in ServiceNow Studio is a powerful tool that you can use to find apps and app files. The Navigator panel is organized alphabetically and by metadata type. For example, if you want to find an audio app file, you can locate the file in the Navigator panel under **File Categories** > **Content** > **Audio**.

For more information about the types of files you can find in the Navigator panel, see ServiceNow Studio Navigator panel taxonomy.

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. On the left side of ServiceNow Studio, verify that the Navigator panel is open.
3. Select the icon that corresponds to the type of file that you want to find.
   - To find an app, select the Apps icon ( ).
   - To find an app file, select the File Categories icon ( ).
4. Choose from the following options to refine the list of apps or app files that appear.
5. **Optional:** Expand the list of apps or app files by selecting **Open list** link.
   Selecting **Open list** opens a new tab in ServiceNow Studio that displays a complete list of apps or app files.
6. Select the app or file to open it in a new tab in ServiceNow Studio.

Bookmark apps and files in ServiceNow Studio

Easily bookmark apps and app files from several locations for quick access in ServiceNow Studio.

Before you begin

Role required: admin or delegated developer

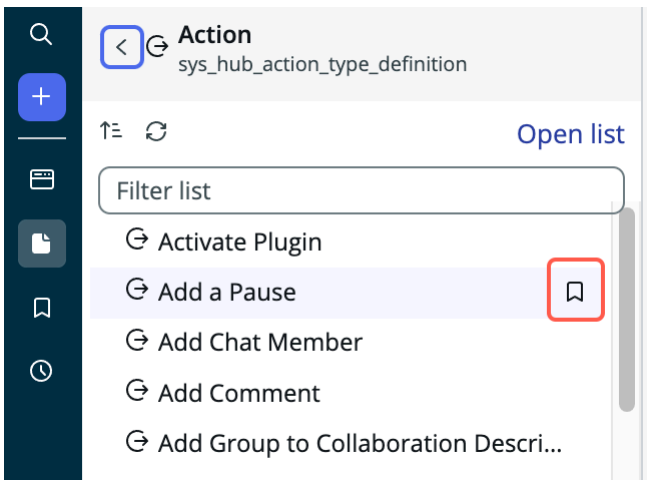
About this task

Note:
Bookmarks and favorites are distinct ServiceNow capabilities. Bookmarks exist only within ServiceNow Studio, while favorites are accessible throughout your instance. When you bookmark apps or files in ServiceNow Studio, your bookmarks do not automatically become favorites. Favorites also do not automatically become bookmarks.

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Bookmark your apps and files from different locations in ServiceNow Studio.
   - To bookmark an open app, select the Add to bookmarks icon ( ) next to the app name.

   - To bookmark an app or file in the Navigator panel, hover over it and select the Add to bookmarks icon ( ).



3. View bookmarked apps and files in the **Bookmarks** tab of the Navigator panel.

Access recently opened apps and app files in ServiceNow Studio

Access your recently opened apps and app files from several locations in ServiceNow Studio.

Before you begin
Role required: admin or delegated developer

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Access your recently opened apps and files from either the ServiceNow Studio home page or the Navigator panel.

Navigate directly to a table in ServiceNow Studio

Navigate directly to the list view of a table in ServiceNow Studio by using the **Open list** feature in the Navigator panel or search shortcuts in the main search.

Before you begin
Role required: admin or delegated developer

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Open a table directly in one of two ways.
   - In the Navigator panel, with any application or file category selected, select **Open list**.

     The list opens in a new integrated tab. In the example below, this is a list of all apps on the Custom Applications table [sys_app].

   - In the Search bar on the home page, enter one of the following inputs and press **Enter**.

> **Important:**
> The table name must match the name in the dictionary entry for the table. For more information about the primary table associated with each metadata type, see ServiceNow Studio Navigator panel taxonomy.

When you enter an input, the table view opens in a new integrated tab.

Table opening shortcuts

Input	Behavior
`<table name>.list`	Opens the list view of the table in the same window or tab.
`<table name>.form` or `<table name>.do`	Opens the form view of the table in the same window or tab.

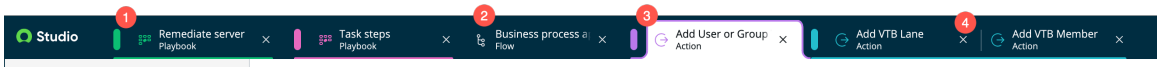
Input	Behavior
`<table name>.config`	Opens the configuration view [personalize_all.do] of the table in the same window or tab.
`<table name>.filter`	Opens an empty list view of the table in the same window or tab, so that you can apply filters without loading the list. This is helpful for large lists that take a long time to load.

For example, if you want to open the list of all users in your organization, you could search for the Users table [sys_user] using the search input `sys_user.list`. To add a new user quickly, search for `sys_user.do` to open a new form view of the Users table. To change the Users table configurations, search for `sys_user.config`. To open the Users table without loading any of the records, search for `sys_user.filter`.

Open apps and app files across scopes in ServiceNow Studio

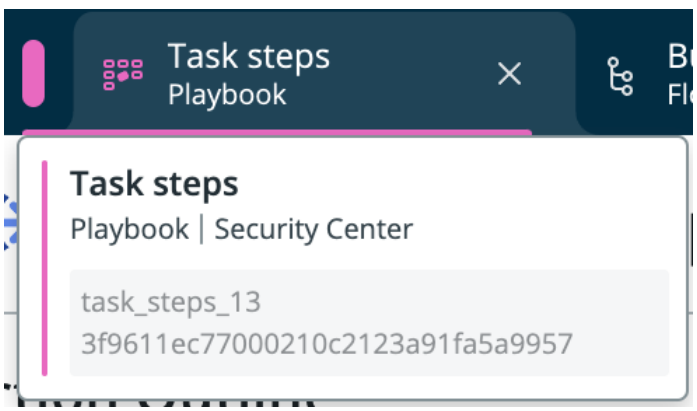
In ServiceNow Studio, you can open and edit apps and app files in any scope, global or custom. The scope that an app is associated with displays at the bottom of the screen and updates automatically when you switch to an app in a different scope.

When you open any app or file in ServiceNow Studio, it may open in an integrated tab. The following diagram and list outline key information about integrated tabs in ServiceNow Studio.

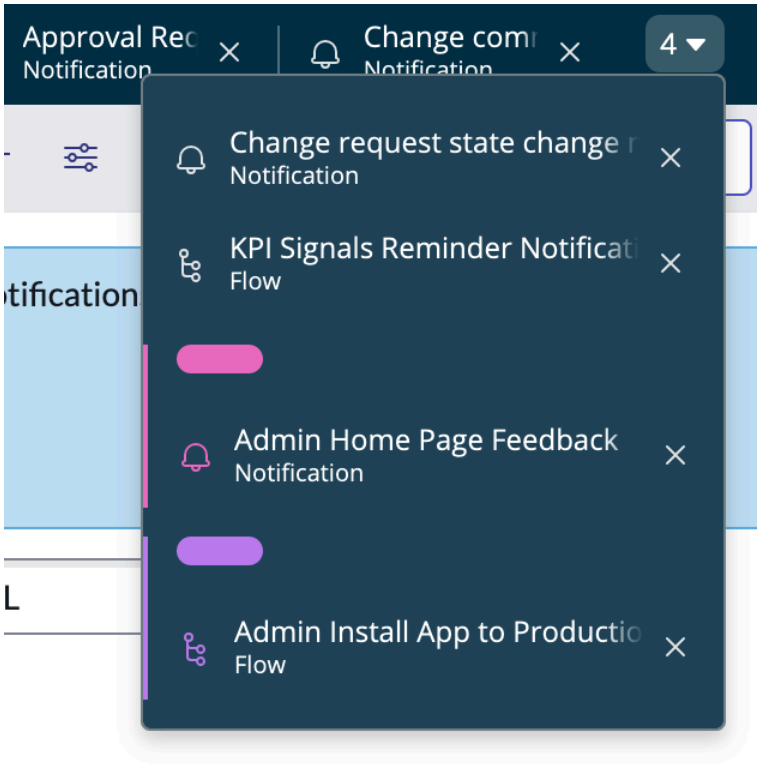


1. Any file in a scoped app opens in a color-coded tab with information about what kind of file it is. In this instance, the playbook opened in an integrated tab, where you can update it using the Workflow Studio interface.
2. Tabs without colors indicate that the file is in the global scope. You can edit global files in ServiceNow Studio.
3. Any tab that's actively open in the canvas shows a contrasting color to indicate the open state.
4. Tabs that are color-coded and grouped are in the same scope. In this example, both actions are in the same application, so they open in the same color tab.

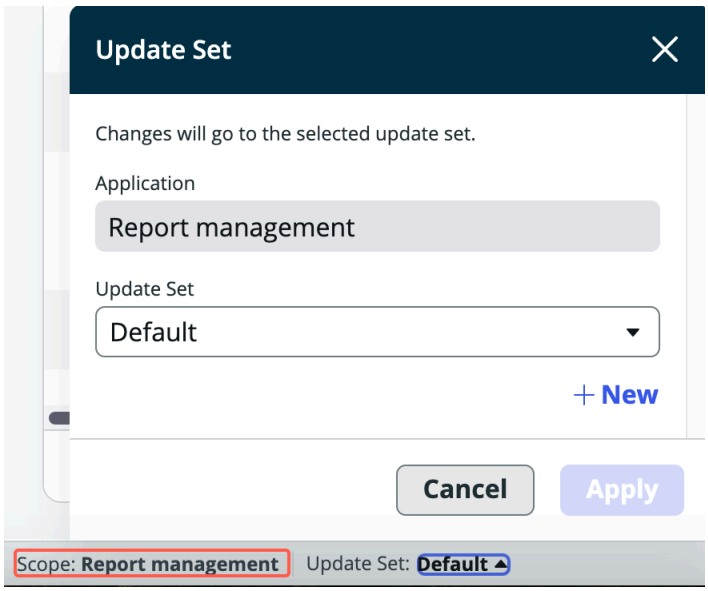
See what scope a file is in by hovering over the tab. In this image, the scope is **Security Center**.



Depending on the width of your browser screen, you may see an overflow tab appear for apps or files you've opened. The scopes for each file are grouped and color coded just like the open tabs. Select any file to open it in the canvas.

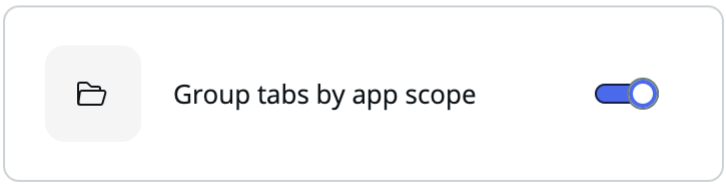


You can also see the scope and update set associated with each file at the bottom of the screen. You can switch update sets here or create one to package your changes.



If you want to ungroup the tabs, select your user preferences on the home page, and select **Studio settings**. Use the **Group tabs by app scope** toggle switch option to group or ungroup the tabs by scope.

Studio settings



Access integrated development tools and builders in ServiceNow Studio

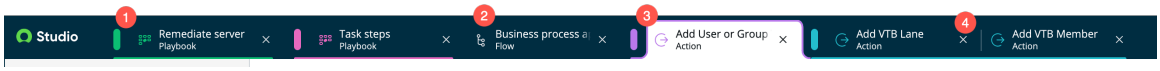
ServiceNow Studio contains several robust development tools and builders to help you expedite the app development process. Open and easily switch between tools and builders as you develop your applications.

Access integrated tools and builders through File Categories

Many of ServiceNow's tools and builders are integrated with ServiceNow Studio, so that all of your app development can happen in one interface.

Most integrated tools and builders, such as Table Builder, Workflow Studio, and flows in Workflow Studio, open in new tabs within ServiceNow Studio and are grouped if they're in the same scope. Some builders, such as Mobile App Builder, open in new browser tabs. Each file type in ServiceNow Studio has either a specified builder that it opens in, or the file opens in the classic UI16 form view. For more information on what tool each file type opens in, see ServiceNow Studio Navigator panel taxonomy.

To access these tools and builders, open ServiceNow Studio, and select the **File Categories** in the Navigator panel. Select the type of file that you'd like to open, and the file opens in either an integrated tab or a new browser tab. The following diagram and list outline key information about integrated tabs in ServiceNow Studio.



1. Any file in a scoped app opens in a color-coded tab with information about what kind of file it is. In this instance, the playbook opened in an integrated tab, where you can update it using the Workflow Studio interface.
2. Tabs without colors indicate that the file is in the global scope. You can edit global files in ServiceNow Studio.
3. Any tab that's actively open in the canvas shows a contrasting color to indicate the open state.
4. Tabs that are color-coded and grouped are in the same scope. In this example, both actions are in the same application, so they open in the same color tab.

For more information about the tools and builders you can use for app development, see Integrated development tools for ServiceNow Studio. For more information about what a builder is, see Builders in ServiceNow Studio.

Switching between tools and builders

During your app development, you may open one or many integrated development tools or builders. For example, you can build a flow or playbook and then use UI Builder to build a custom web experience for your users.

Because ServiceNow Studio seamlessly switches between tools and interfaces, you just have to open the file that you want to edit, and the correct integrated tool or builder opens your file.

Create an update set in ServiceNow Studio

Create an update set as you work in ServiceNow Studio.

Before you begin

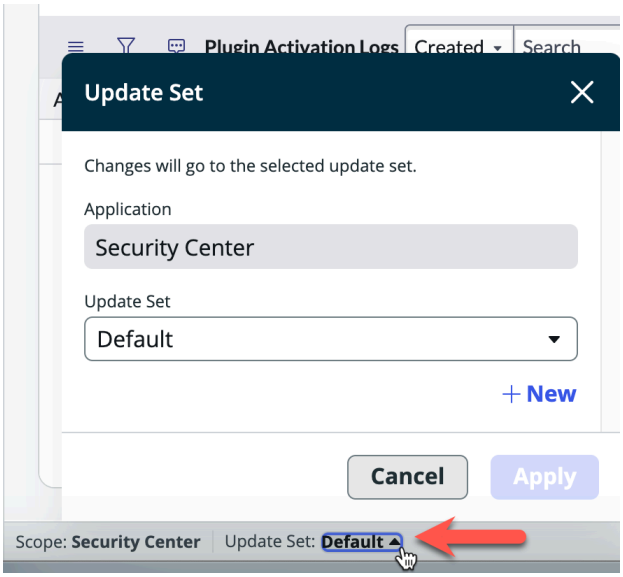
Role required: admin or delegated developer

About this task

Create an update set without having to leave ServiceNow Studio. For more information about creating an update set on the ServiceNow AI Platform, see Get started with update sets.

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Open the application that you have changes for that need a new update set.
3. At the bottom-left corner of the canvas, expand the update set dialog by selecting the current update set from the status bar.



4. Select **New**.
5. Enter a name for the new update set.
6. Select **Save**.
7. Select **Apply**.
   The changes you made in your app go to the new update set.

Publish app changes to the Application Repository from ServiceNow Studio

Publish changes that you have made to an app in ServiceNow Studio to the Application Repository (App Repo).

Before you begin

Role required: admin or delegated developer

About this task

The App Repo is one option ServiceNow offers for app deployment. You can also create update sets to publish changes, or if your company has a deployment pipeline set up, you can deploy

changes through the pipeline in ServiceNow Studio. For more information about the App Repo, see ServiceNow application repository.

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Open the **App details** page for the application that you want to update from either the ServiceNow Studio home page or the Navigator panel.
   - On the ServiceNow Studio home page, select the **Deployment** tab. Then select **Applications** and select your application from the **Name** column.
   - In the Navigator panel, select the Apps icon (). Then select your application and select **App details**.
3. On the App details page, select **Publish**.
4. In the **New version** field, enter a version number for the changes.
5. In the **Release notes** field, add notes about the changes that you're publishing.
6. Select **Publish**.
   You have submitted your changes for review and approval. Once your changes are approved, your updates are accessible to all instances of your application.

ServiceNow Studio user interface

Learn about the ServiceNow Studio user interface and how to customize it to your specifications.

ServiceNow Studio is an application that enables you to build, manage, and deploy applications all in one interface. You must be an admin or a delegated developer with access to an application to access ServiceNow Studio.

ServiceNow Studio home page

From the home page, you can access all of the tools and services in ServiceNow Studio.

- The Navigator panel enables you to see a quick view of all your apps, files, bookmarks, recents, and tools. You can filter or sort the lists, and you can open any list in the platform view by selecting **Open list**.

Navigator panel tools

Navigation item	Description
Menu ()	Option to expand or collapse the Navigator panel.
Search ()	Option to search for any file, app, metadata, or tool in any scope on the platform.
Create ()	Option to create a new app or file.
Apps ()	Option to view all apps.
File Categories ()	Option to view, sort, and filter all files and metadata.
Bookmarks ()	Access point for all your favorite files and apps.

Navigation item	Description
Recent ( )	Access point for all your most recently accessed files.

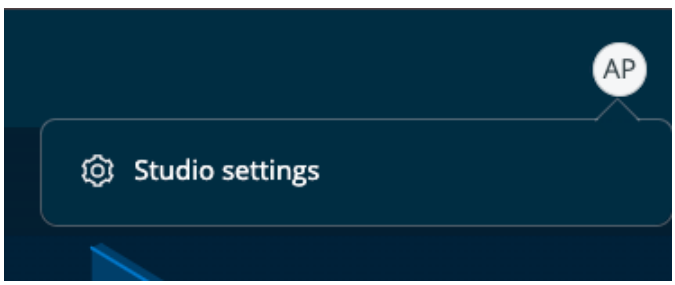
- You can show/hide and pin/unpin the Navigator panel in ServiceNow Studio by using the icons in the side panel. You might want to hide the panel for full-screen editing capabilities when you're working on an app.

- The toolbar provides another access point for the home page, Tools page, and Deployment.

Tool bar

Page	Description
Home	Main landing page for ServiceNow Studio. Access the Navigator panel, recently opened files and apps, and other tools and resources.
Tools	Access point for documentation related to the tools and builders integrated into ServiceNow Studio. For more information, see Integrated development tools for ServiceNow Studio.
Deployment	Landing page for viewing, managing, and deploying apps using update sets and accessing applications for deployment through pipelines or the Application Repository. If you create a new update set, you can see it on the **Deployment** page. Applications can also be deployed directly from the App details page for each app.

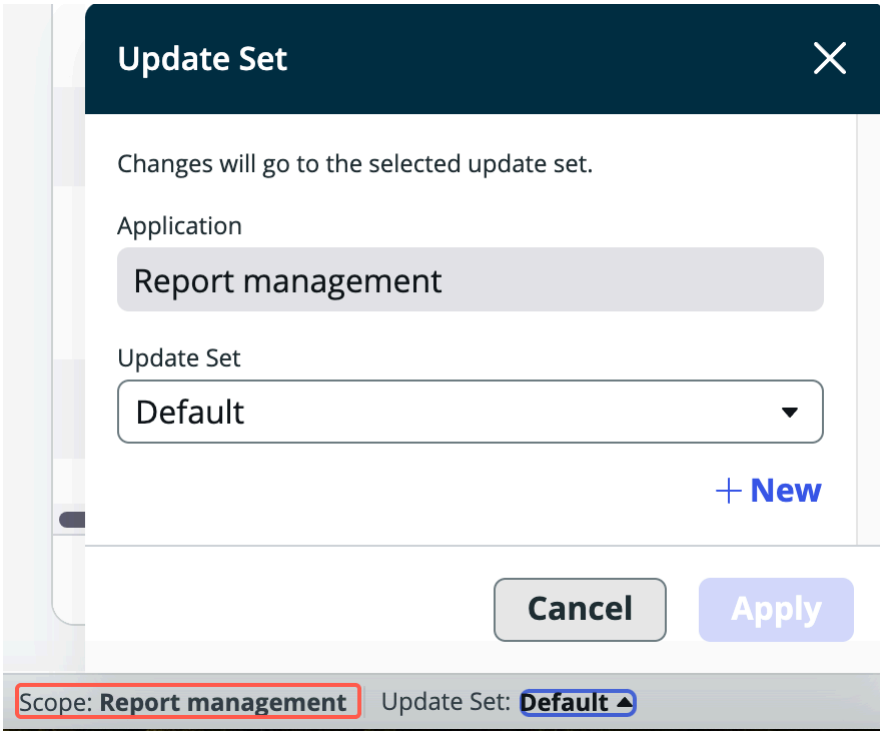
- The user preferences menu provides access to ServiceNow Studio settings.



- The Create button enables you to quickly create apps and app files.

See scope and update set

If you're in an app or file, you can see the scope of the file in the status bar. You can also see the update set associated with the application in the status bar. If you need to change the update set or create a new one, open the default update set and change your selection right within the app.



For more information, see Working with update sets in ServiceNow Studio.

Builders in ServiceNow Studio

Builders are specialized tools that provide an intuitive and efficient interface for editing metadata records primarily associated with tables extending sys_metadata. In ServiceNow Studio, you can use builders to create a variety of file types to support your app development.

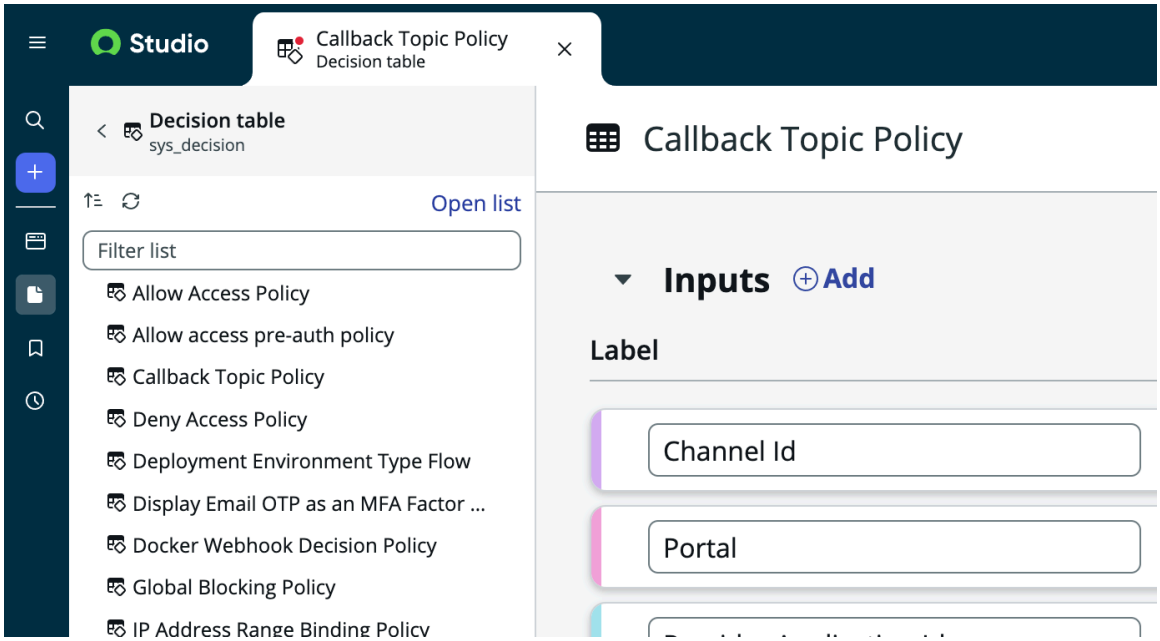
Builders focus on enhancing user experience by offering features such as inline editing, customizable views, and integrated collaboration. Each builder remains agnostic of design libraries or implementations, ensuring adaptability to evolving technologies and frameworks.

When you open files like decision tables, flows, or tables in ServiceNow Studio, the files open in an integrated tab in their designated builder tool. Some other file types like mobile app configurations open in a new browser tab. Note that you must create or open a file or application to access a builder. You cannot open builders on their own in ServiceNow Studio.

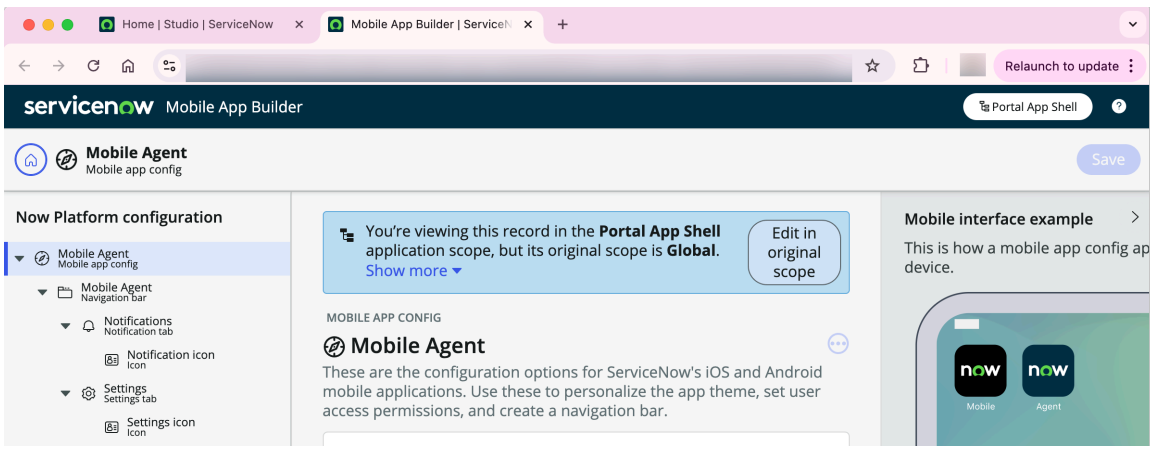
For a full list of the builders integrated in ServiceNow Studio, see Integrated development tools for ServiceNow Studio.

How builders open in ServiceNow Studio

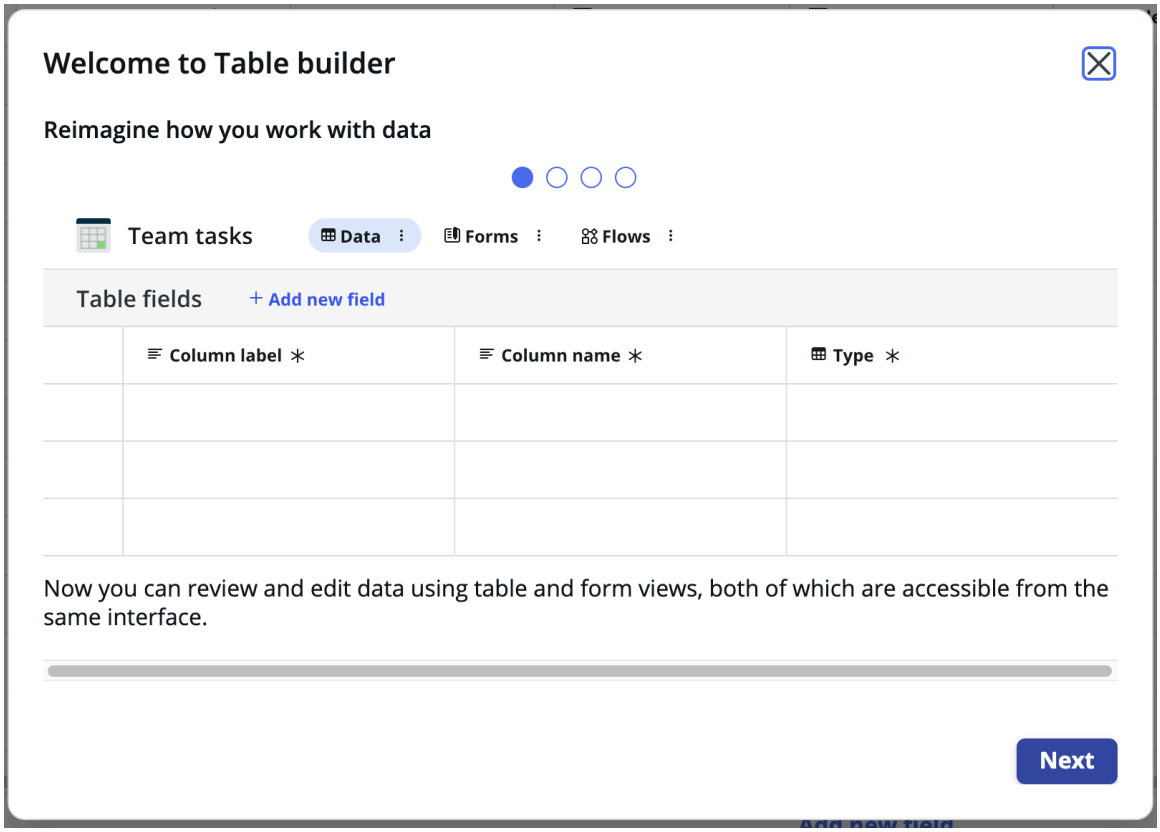
Decision tables and many other types of automations open in integrated tabs.



Mobile App Builder opens in a new tab.



When you open some tools like Table Builder, you may see a short tutorial to help you learn the tool.



Integrated development tools for ServiceNow Studio

ServiceNow Studio provides instant access to several tools available in the ServiceNow AI Platform development suite. As you create apps using ServiceNow Studio, you can extend their capabilities with these powerful development tools.

Development tools

Use the following integrated development tools to build apps, flows, processes, tables, and more in ServiceNow Studio.

While some tools have the word "Builder" attached to their name and others don't, all tools listed below enable you to build different parts of apps. Some builders are automation tools, while others enable you to build your user interface. For more information about builders, see Builders in ServiceNow Studio.

Automation

Builder	Description
Decision tables in Workflow Studio	Decision tables in Workflow Studio embed business logic into a series of if-then decision rules. Decision tables read data from inputs and evaluate the data according to specified conditions. When all the conditions for a decision rule are met, the decision table returns one or more results.
Flows, subflows, and actions in Workflow Studio	Flows, subflows, and actions enable process owners to automate work. Build multi-step

Builder	Description
	flows from reusable components without having to code.
Playbooks in Workflow Studio	Playbooks enable process owners to author cross-enterprise workflows and create a single, unified process. You can also use playbooks to provide end users with a simplified, task-oriented view of your process.

Data

Builder	Description
Form Builder	Customize any ServiceNow AI Platform record or form using Form Builder. Form Builder is accessed most often through Table Builder on the Forms tab.
Table Builder	Design tables, forms, and flows visually using a single user interface.

Integration

Builder	Description
Integration Hub Imports	Integration Hub - Import enables you to configure, run, and schedule your data imports all through a single simplified interface. It also consolidates multiple data integration capabilities into a single environment, eliminating the need to create and manage several forms throughout the platform. Its step-by-step experience guides you through the configuration of data sources, target tables, and data mapping. You can schedule your data imports or run them on demand.

Mobile builder

Builder	Description
Mobile App Builder	Configure how ServiceNow applications display on mobile devices.

User interface

Builder	Description
Catalog Builder	You can create or edit a catalog item (catalog item or record producer) using a visual and

Builder	Description
	guided experience along with specified restrictions. The catalog builder experience enables you to delegate the creation and maintenance of the catalog.
Service Portal	Create or update the portal page layout and add or remove widgets on the page.
Service Catalog	Create or edit a catalog item, which can be a record producer, an order guide, or a content item.
Survey designer	Create survey categories and questions, configure their details, and publish the survey to specific users or groups.
UI Builder	UI Builder is a web user interface builder. Use UI Builder to build pages for App Engine Studio generated workspaces or custom web experiences using Next Experience Components and custom web components.
Workspace Builder	Workspace Builder enables you to automate processes in a single design environment.

Other tools

Builder	Description
Script Debugger	The Script Debugger enables users with the script_debugger role to debug server-side JavaScript.

ServiceNow Studio and legacy products

ServiceNow Studio improves upon the functions of several other tools that you may have used to develop apps on the ServiceNow AI Platform. If you previously used Guided Application Creator or the legacy Studio product to create apps, try using ServiceNow Studio to continue your app development process.

Upgraded features

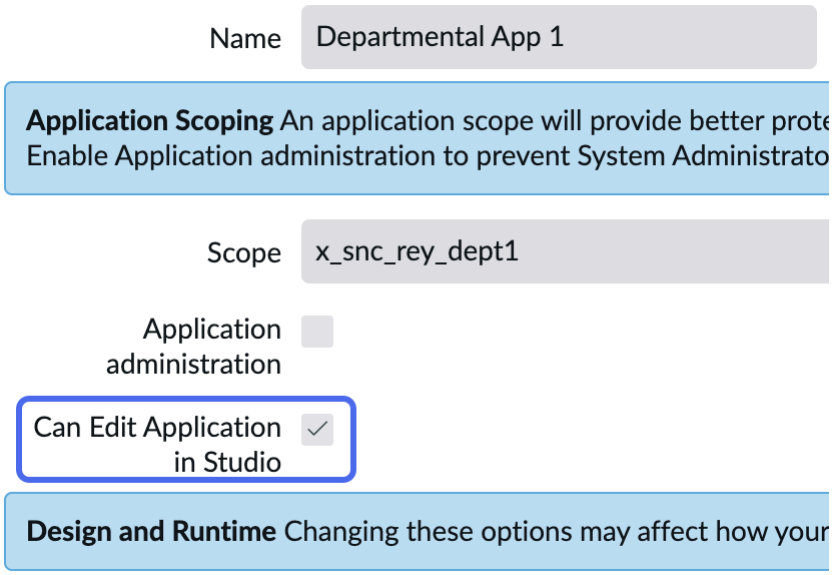
The intuitive navigation and taxonomy of ServiceNow Studio will help you efficiently find, organize, and edit your work. When it comes to creating or editing objects, every development capability you need is accessible in one place, enabling you to access, switch between, and leverage the right tool for the job every time. Once your app is ready to go live, you can effortlessly manage your deployments using any of the app life cycle options ServiceNow offers, such as pipelines or update sets. ServiceNow Studio also offers native support for Now Assist, giving you the ability to leverage the latest GenAI capabilities ServiceNow offers along with innovative low-code tools.

ServiceNow Studio and changed functionality

Some aspects of the upgraded ServiceNow Studio behave differently than legacy Studio. In the record for each app created on the ServiceNow AI Platform, there is an option to allow the app to be edited in legacy Studio. However, this option does not apply to the new ServiceNow Studio.

Any global, scoped, or custom app you have permission to edit can be edited in ServiceNow Studio.

The **Can Edit Application in Studio** option on each app record does not apply to the new ServiceNow Studio.



Using ServiceNow Studio with Guided Application Creator (GAC) roles

When you start using ServiceNow Studio, some features become available only after you create a scoped application. If you're new to using ServiceNow Studio, you may notice that the Search bar and **Create** > **App/File** aren't visible initially. This is expected behavior in ServiceNow Studio.

To get started, select **Create** and continue creating your scoped app. On the App details page for the new application, you can create metadata (or application files) by selecting **Create**. The Create file modal opens, and you can then create any file type you need and associate it to your app.

After you have created your application, return to the ServiceNow Studio home page, and refresh the browser window. You can now use the Search bar and **Create** > **App/File** features during your scoped application development. For more information about roles, see Assign a role to a user.

Configuring ServiceNow Studio

ServiceNow Studio is available from the ServiceNow Store. ServiceNow Studio leverages existing platform development tools. No additional configuration is required to use these tools in ServiceNow Studio.

Domain separation and ServiceNow Studio

Domain separation is not supported for ServiceNow Studio. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

Installing ServiceNow Studio

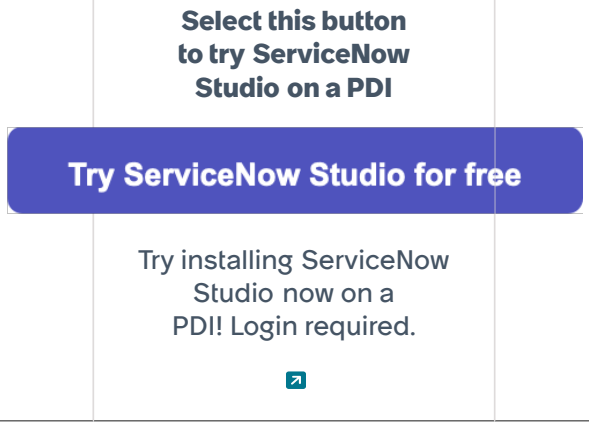
ServiceNow Studio is available for you to use on the ServiceNow AI Platform. You can also access premium features with an App Engine Enterprise license.

ServiceNow Studio is free to install and configure from the ServiceNow Store. If your company has an App Engine Enterprise license, you can install additional plug-ins to use in ServiceNow Studio. For instructions on installing ServiceNow Studio and other products from the ServiceNow Store, see Install a ServiceNow Store application.

After ServiceNow Studio is installed on an instance, no other configurations must happen.

Give ServiceNow Studio a try

Ready to give ServiceNow Studio a try? You can test it out using your own Personal Development Instance (PDI), which requires you signing in to the Developer Site. Find out more on PDIs in the Personal developer instance guide.



Premium features available with an App Engine Enterprise

If your company has an App Engine Enterprise license, you can access these additional premium features in ServiceNow Studio.

- Create a table from a spreadsheet. For more information, see Use a spreadsheet to add data.
- Create a table from a PDF. For more information, see Use a PDF to create data tables.
- Access the UI Template library.
- Access App Engine Studio Catalog templates. For more information, see Create your app using an application template.
- Access Workspace Builder. For more information, see Add a workspace.
- Access Workspace UI templates.
- Deploy scoped apps using the App Engine pipeline. For more information, see Managing app deployments using Pipelines and Deployments.

ServiceNow Studio instance strategy

You should install ServiceNow Studio on all ServiceNow instances where you develop applications.

You'll need to establish your company's instance strategy for ServiceNow Studio. Some of the decisions you need to make include:

- Whether you want to enable anyone within your company to have access to ServiceNow Studio to start building apps.
- Whether you want to grant access to a select group of people.
- Whether you want to grant access on a case-by-case basis by setting up a form where individuals can complete information about the app that they're looking to build. Your admin then decides whether to give those individuals access to build that app.

A non-production instance that is similarly configured to your production instance may be the best candidate for your test environment. You can then more accurately find issues that may arise if the application is deployed to production.

Note:
If you plan on cloning your production instance to one or more non-production instances, you should also install the ServiceNow Studio product on your production instance prior to cloning. For more information, see System clone.

After you have established your instance strategy, you must also complete the following tasks.

1. Establish and automate your approval or review process.
2. Decide which non-production environment ServiceNow Studio will run on. Because ServiceNow Studio is a product that runs on your non-production environment, you need to select one to run it on.
3. Determine which method to use for promoting apps from a particular non-production instance to your test instance, and then finally to production where the app will be running live. You can deploy apps using update sets, pipelines, or the Application Repository in ServiceNow Studio.

Components installed with ServiceNow Studio

When you activate the ServiceNow Studio plugin, various components like tables are automatically installed.

Tables and roles installed with ServiceNow Studio

One table is shipped directly with ServiceNow Studio: Resources [sn_sns_resources]. This table populates the Resources section at the bottom of the home page.

No specific roles are shipped with ServiceNow Studio, but Admin and Delegated Developer roles are used. For more information, see ServiceNow Studio personas and roles.

Plugin installed with ServiceNow Studio

The ServiceNow Studio [sn_sns] plugin is installed with several dependencies.

ServiceNow Studio plugin

Plugin [ID]	Description	Dependencies
ServiceNow Studio [sn_sns]	ServiceNow Studio provides a unified experience for all ServiceNow development activities.	• sn_udc • sn_studio_commons • sn_app_obj_wizards

ServiceNow Studio plugin (continued)

Plugin [ID]	Description	Dependencies
		• sn_deploy_pipeline • sn_workflow_studio

ServiceNow Studio personas and roles

Admins and delegated developers have access to work in ServiceNow Studio.

ServiceNow Studio personas

Admins and delegated developers have different capabilities in ServiceNow Studio. Admins can delegate people to work on certain apps and app files by providing delegated developer permissions.

Roles and capabilities

Role	Permissions	Capabilities
Delegated developer	Delegated developers have access to just the app or apps they're delegated to. These permissions may vary based on your configuration.	• Update apps that they are given delegated development permissions for. • Create an update set to package changes. • Create and update app files and other metadata records. • Submit an app for deployment through update sets, pipelines, or the Application Repository.
Admin	Admins can review and approve tasks related to custom application development.	• Create apps in ServiceNow Studio. • Edit existing apps and app files or delegate development to someone else. • Create, edit, and manage update sets. • Update existing metadata records.

Manage access to ServiceNow Studio

Admins and delegated developers have access to work in ServiceNow Studio. Manage access to develop apps and app files in ServiceNow Studio by assigning delegated development permissions.

Delegated development enables designated users without a system admin role to develop or deploy applications on the ServiceNow AI Platform. If you have the application-specific admin role or the system-level admin role, you can delegate application development to designated developers at the application level.

Note:
Currently, only admins can create apps in ServiceNow Studio, but delegated developers can work on existing apps and app files.

For more information about delegated development, see Delegated development and deployment. If you're an admin, you can also assign collaboration permissions to your development team. For more information, see Collaborating on apps using ServiceNow Studio.

Collaborating on apps using ServiceNow Studio

You can collaborate, or share app development in ServiceNow Studio with other people in your company.

Collaboration is delegated development

Collaboration, also referred to as delegated development, builds on the existing delegated development feature set in the ServiceNow AI Platform. It enables developers to invite other developers into apps so that they can co-create and develop the app together. Depending on your permissions, you can invite others to collaborate on an app with you, or request to join someone else's app. For more information on delegated development, see Delegated development and deployment.

There are two standard types of collaborators when you co-develop an app with other people: owners and editors. Admins can create a custom collaboration role by adjusting permissions.

Requirements for collaboration

ServiceNow Studio supports the collaboration plugin for properly licensed customers.

Note:

1. You must have an App Engine Enterprise license to take full advantage of collaboration.
2. If you already have the collaboration plugin installed, you can continue to use collaboration.
3. Customers that don't have Collaboration installed will not be able to manage delegated development permissions in ServiceNow Studio. Existing delegated development permissions will still be respected within ServiceNow Studio.

Apps that you can access

The two ServiceNow Studio roles that can access ServiceNow Studio, admin and delegated_developer, have different access to apps:

- Users with the admin role automatically have access to all apps in ServiceNow Studio.
- Users with the delegated_developer role have access to:
  - Apps they create
  - Apps they've been invited to edit (as an editor on the app)
  - All apps within the scope you have access to. For more information on scopes, see Application scope.

If you know of an app that you want to work on but don't see it in ServiceNow Studio, contact your admin and ask that they give you permission to work on the app using the Collaboration app. The ServiceNow AI Platform Collaboration app is automatically installed with ServiceNow Studio. For more information about the Collaboration app, see Application collaboration.

What app owners and editors can do

There are two default collaborator roles for working on apps with other developers: owner and editor.

- If you create an app, you're the owner of that app.
- If you see an app in ServiceNow Studio that you've been delegated to work on, you can open it and begin working on it with whatever collaboration role the owner assigned you. That role is usually editor.

Default collaboration descriptors

Descriptor	Description
Owner	Owner of the application. • If you created the app, you're automatically the owner. • Owners can manage other collaborators for the app. • Owners can delete apps because they have the delete app permission. • Owners automatically get the delegated_developer role for the app.
Editor	• Editors can invite collaborators. • Editors have a more limited ability to edit the app.

Note:
For the full list of default owner and editor collaborator collaboration type permissions, see Collaboration permissions for ServiceNow Studio.

Custom collaboration descriptors and permissions

The collaboration descriptor that someone is assigned determines if they can assign, manage, and monitor delegated development permissions. For example, people who are owners can do more than people with the editor collaboration descriptor.

If you want to create a customized collaboration role for help building your app, you can create a custom collaboration descriptor, which is a customized collaboration role. You then use collaboration permissions to control what developers (or users who deploy applications) can do in the app.

If needed, admins can define custom collaboration descriptors to select when managing collaborators using the Collaboration app. For more information on custom descriptors, see Create collaboration descriptors to assign permissions.

Managing collaboration permissions for other developers

If you invite someone to collaborate on an app and they don't have the Delegated developer (delegated_developer) role, an App Engine admin must approve the collaboration request. For more information, see Delegated development and deployment.

When you add a user or group to collaborate on an app, a collaboration task is generated behind the scenes, which initiates an approval flow. If you have App Engine Management Center (AEMC) installed, your admin can review and approve/deny these collaboration request tasks there. The collaboration task that goes to your admin provides information on which app a developer is being added to, and what permissions they get. Admins and approvers sometimes need to review these task records before they add developers to the application.

If you don't have AEMC installed, admins can navigate to **All** > **App Engine** > **Collaboration** > **Collaboration Tasks**.

View collaborators on an app in ServiceNow Studio

View the collaborators for an app to see who is co-developing the app in ServiceNow Studio.

Before you begin

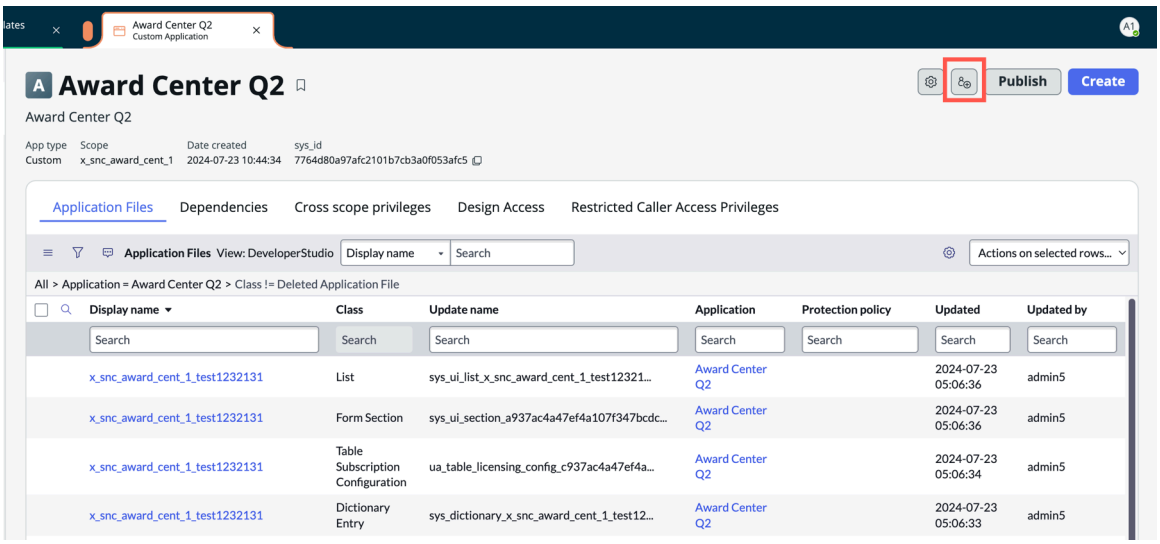
Customers that don't have Collaboration installed will not be able to manage delegated development permissions in ServiceNow Studio. Existing delegated development permissions will still be respected within ServiceNow Studio.

Role required: admin or delegated developer

Procedure

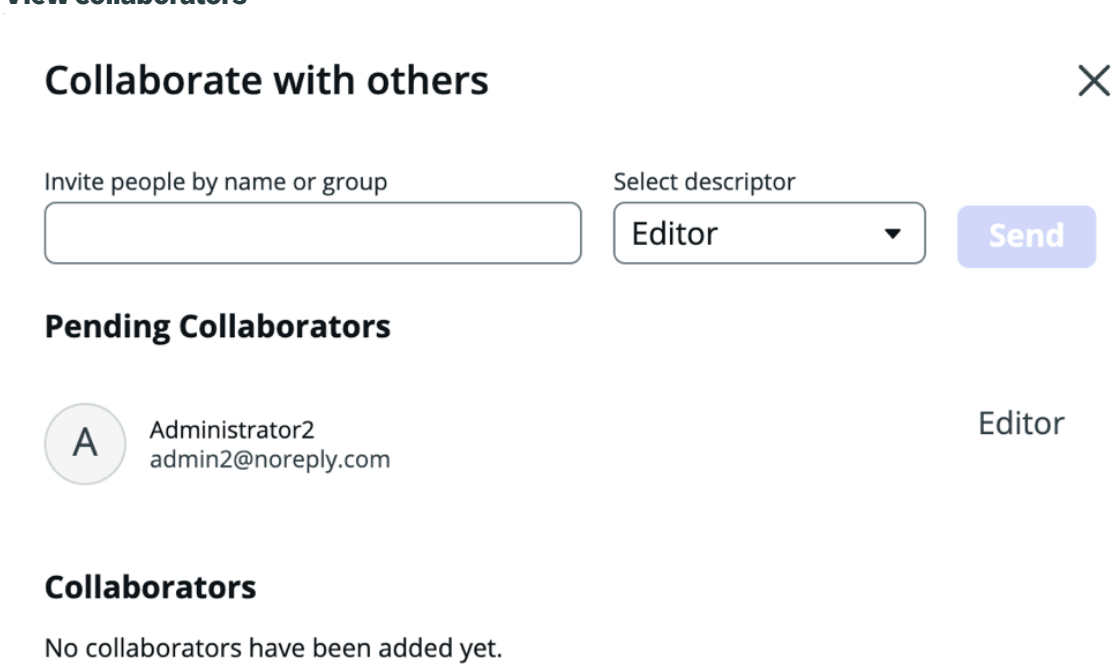
1. Navigate to **All** > *App Engine* > *ServiceNow Studio*.
2. Find and select the app that you want to view collaborators for.
3. Access collaboration settings by selecting the collaborators icon ( ).

Access collaboration in ServiceNow Studio



4. Review the collaborators' names, groups, and descriptors on the Collaborate with others modal.

View collaborators



Result
You can take additional actions when viewing collaborators. For more information, see the following topics:

- Add collaborators to an app in ServiceNow Studio
- Modify or customize collaboration permissions for a user or group in ServiceNow Studio
- Remove collaborators from an app in ServiceNow Studio

Add collaborators to an app in ServiceNow Studio

Invite other people to work on an app with you in ServiceNow Studio, collaborating as co-developers.

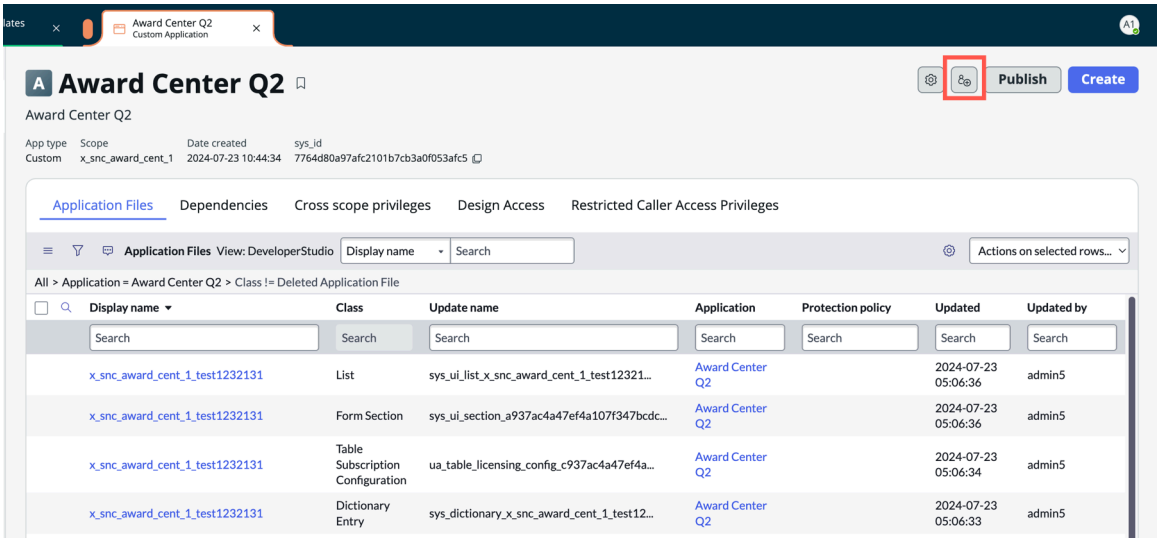
Before you begin
Customers that don't have Collaboration installed will not be able to manage delegated development permissions in ServiceNow Studio. Existing delegated development permissions will still be respected within ServiceNow Studio.

Role required: admin or delegated developer

Procedure

1. Navigate to **All** > *App Engine* > *ServiceNow Studio*.
2. Find and select the app you want to invite people to collaborate on.
3. Open collaboration settings for the app by selecting the collaborators icon ( ).

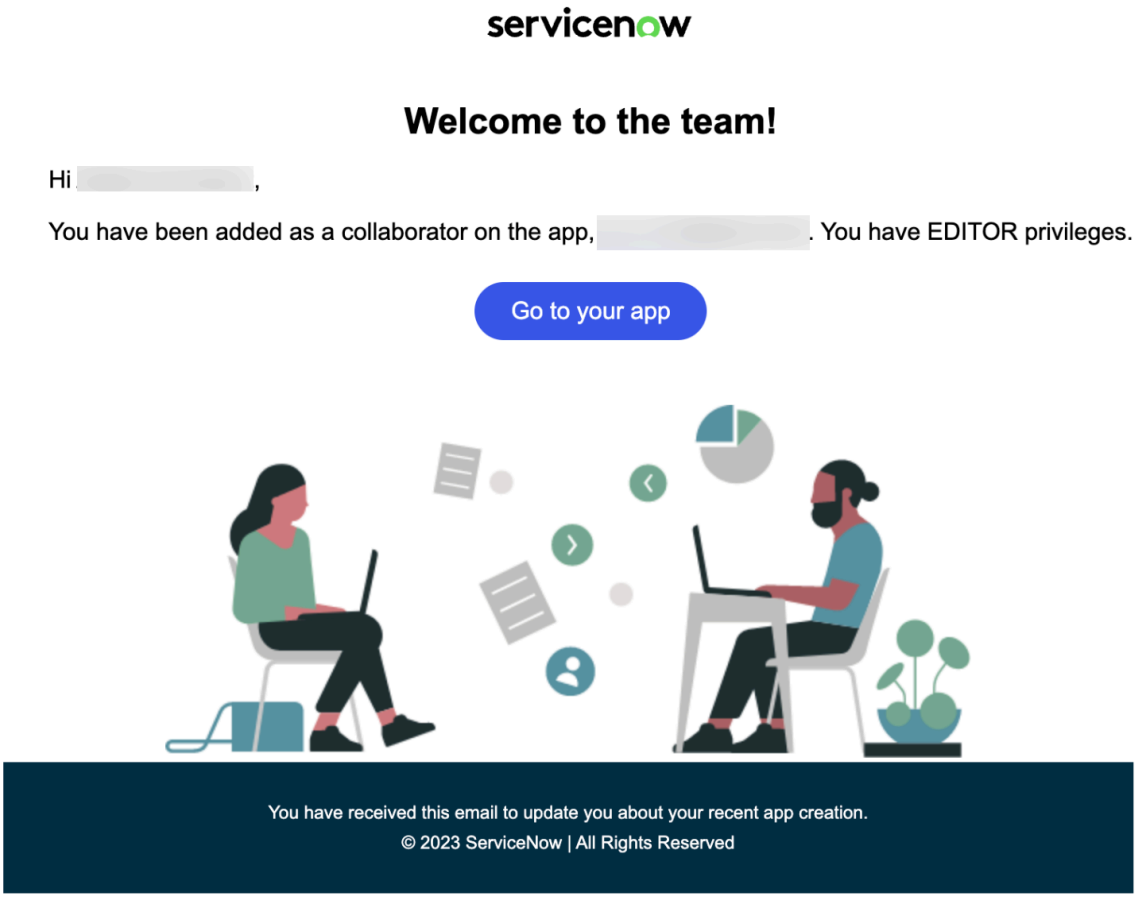
Access collaboration in ServiceNow Studio



4. Search for the user or group that you want to invite to work on the app by entering the name in the **Invite people by name or group** field.
   A drop-down list displays the matching people and groups. If a user or group appears in the drop-down list but you can't select it, it's already been added as a collaborator and can't be re-selected.
5. Select the collaboration role for the user or group that you're adding from the **Select descriptor** field.
   If you're an editor for the app, you can select only the editor descriptor.
   - For more information on collaboration descriptors, see Collaborating on apps using ServiceNow Studio.
   - For a list of all the collaboration permissions, see Collaboration permissions for ServiceNow Studio.
6. Finish inviting the collaborator by selecting **Send**.

Result

- If the user has ServiceNow Studio or delegated developer permissions and is new to the ServiceNow AI Platform, they must be approved by an admin. After the request is approved, both the requester and the user receive an email indicating that the user has been added to the application.



- If the user has ServiceNow Studio or delegated developer permissions and is not new to the ServiceNow AI Platform, the collaboration request is auto-approved. Both the requester and the user receive an email indicating that the user has been added to the application.

Modify or customize collaboration permissions for a user or group in ServiceNow Studio

Change the collaboration access that a user or group has to work on an app in ServiceNow Studio by modifying or customizing their collaboration descriptor.

Before you begin

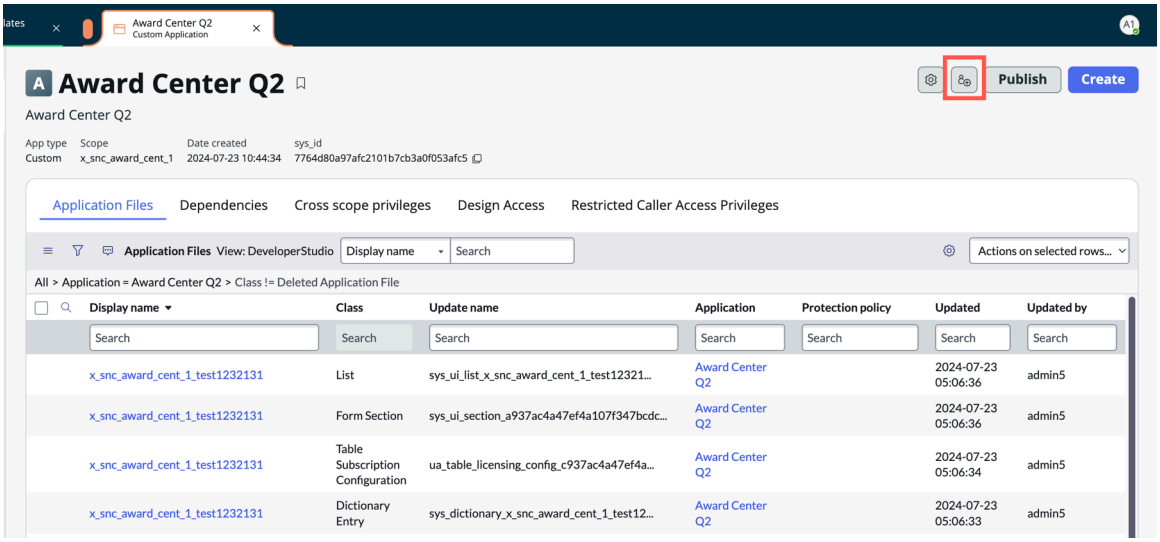
Customers that don't have Collaboration installed will not be able to manage delegated development permissions in ServiceNow Studio. Existing delegated development permissions will still be respected within ServiceNow Studio.

Role required: admin or delegated developer

Procedure

1. Navigate to **All** > *App Engine* > *ServiceNow Studio*.
2. Find and select the app where you want to modify permissions for collaborators.
3. Access collaboration settings by selecting the collaborators icon ( ).

Access collaboration in ServiceNow Studio



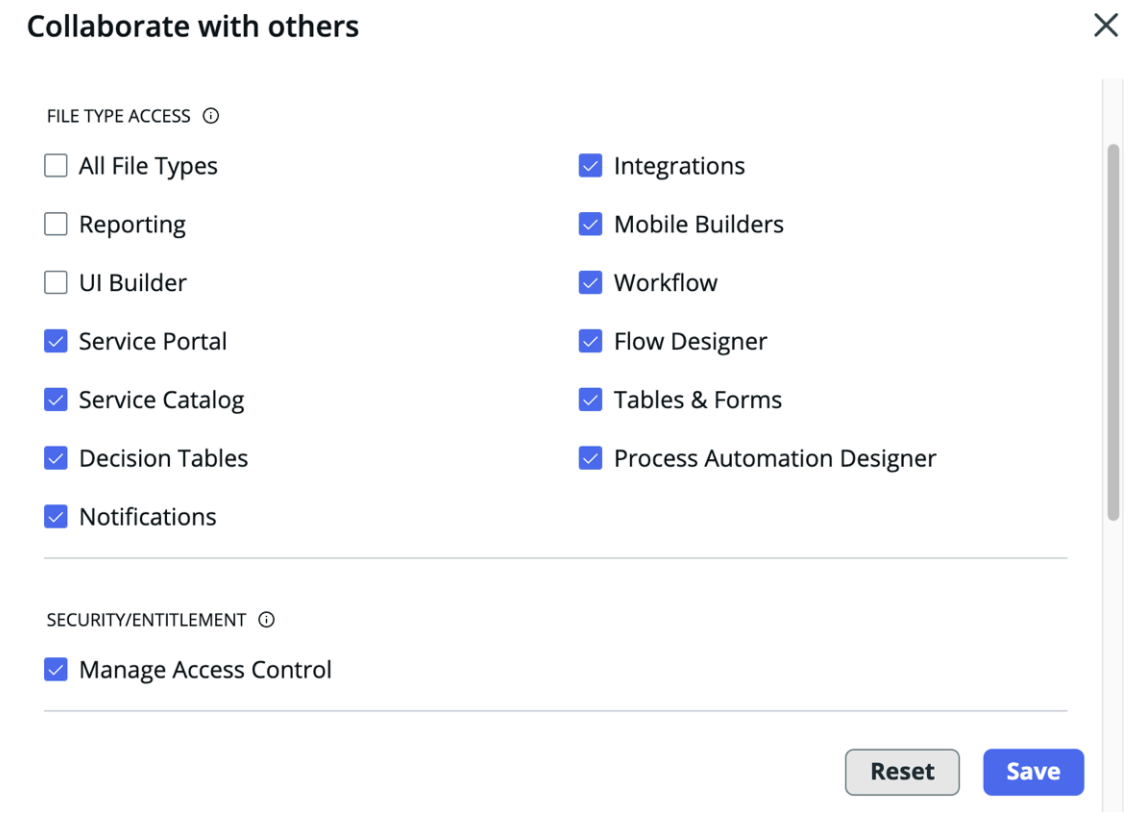
4. Choose the new permission level for the user or group in the Collaborators section of the modal.
5. **Optional:** Customize what the collaborator can do by creating custom permissions.

   a. Select **Customize permissions** for the user or group in the Collaborators section.

Customize collaboration permissions

   b. Choose the permissions you want the group or user to have.
   For more information on permissions and descriptions, see Collaboration permissions for ServiceNow Studio.

Customize collaboration permissions



c. Select **Save**.

Result
Your changes are automatically saved when you close the Collaborate with others modal.

What to do next
Your App Engine admin must then approve the changes to collaborators. For more information, admins should see Approve a collaboration request.

Remove collaborators from an app in ServiceNow Studio

Restrict a user or group from working on an app in ServiceNow Studio by removing them as a collaborator.

Before you begin
Customers that don't have Collaboration installed will not be able to manage delegated development permissions in ServiceNow Studio. Existing delegated development permissions will still be respected within ServiceNow Studio.

Role required: admin or delegated developer

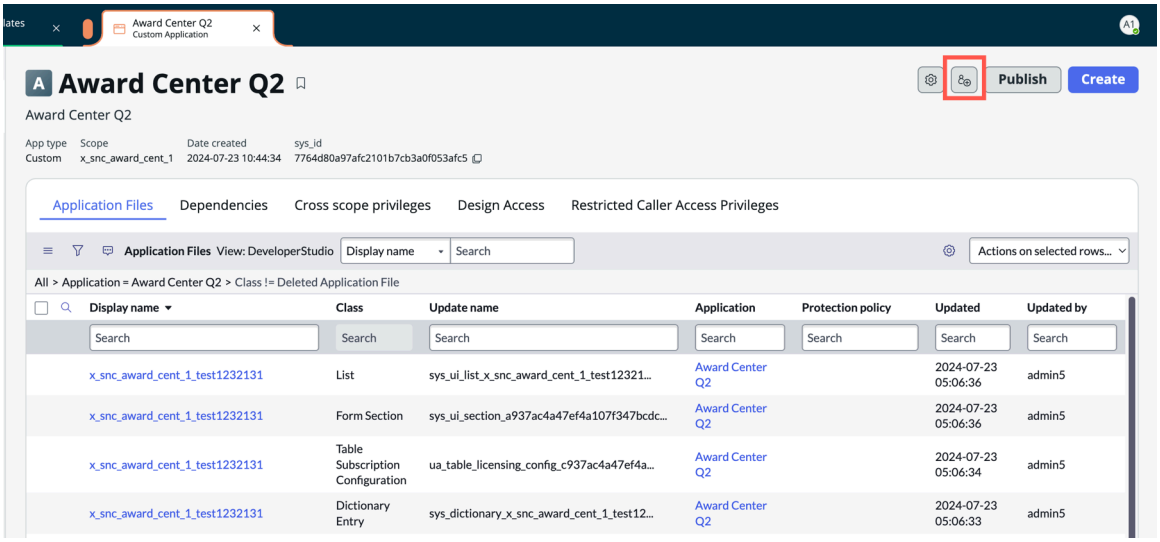
Procedure

1. Navigate to **All** > *App Engine* > *ServiceNow Studio*.

2. Find and select the app you want to remove collaborators from.

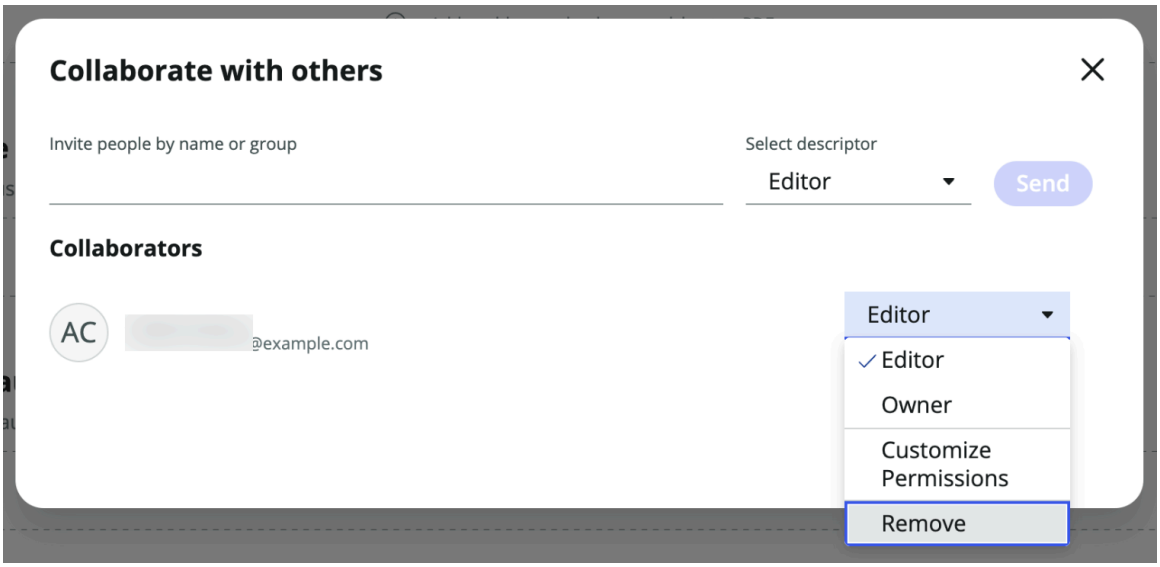
3. Access collaboration settings by selecting the collaborators icon ( ).

Access collaboration in ServiceNow Studio



4. Select **Remove** for the user or group in the Collaborators section of the modal.

Remove a collaborator



Result
Your changes are automatically saved when you close the Collaborate with others modal.

Using ServiceNow Studio

Accelerate your app development with ServiceNow Studio. Many ServiceNow AI Platform features are integrated with a suite of development tools and builders to provide an efficient and powerful app development and deployment experience.

Aims of ServiceNow Studio

ServiceNow Studio improves upon a lot of great features in the legacy Studio product, as well as integrates new features that can speed up your app development experience. ServiceNow Studio helps enable your app development experience by making it faster and easier to do the following:

- Access, switch between, and adopt the right tools you need for development.
- Find, organize, and edit your work in apps and metadata records.
- Track, package, and deploy your work in applications through update sets, pipelines, or the Application Repository.

Create an application in ServiceNow Studio

Create a custom application in ServiceNow Studio. After creating the foundations of your app, you can add data, automations, or many other types of app files using integrated development tools and builders in ServiceNow Studio.

Before you begin

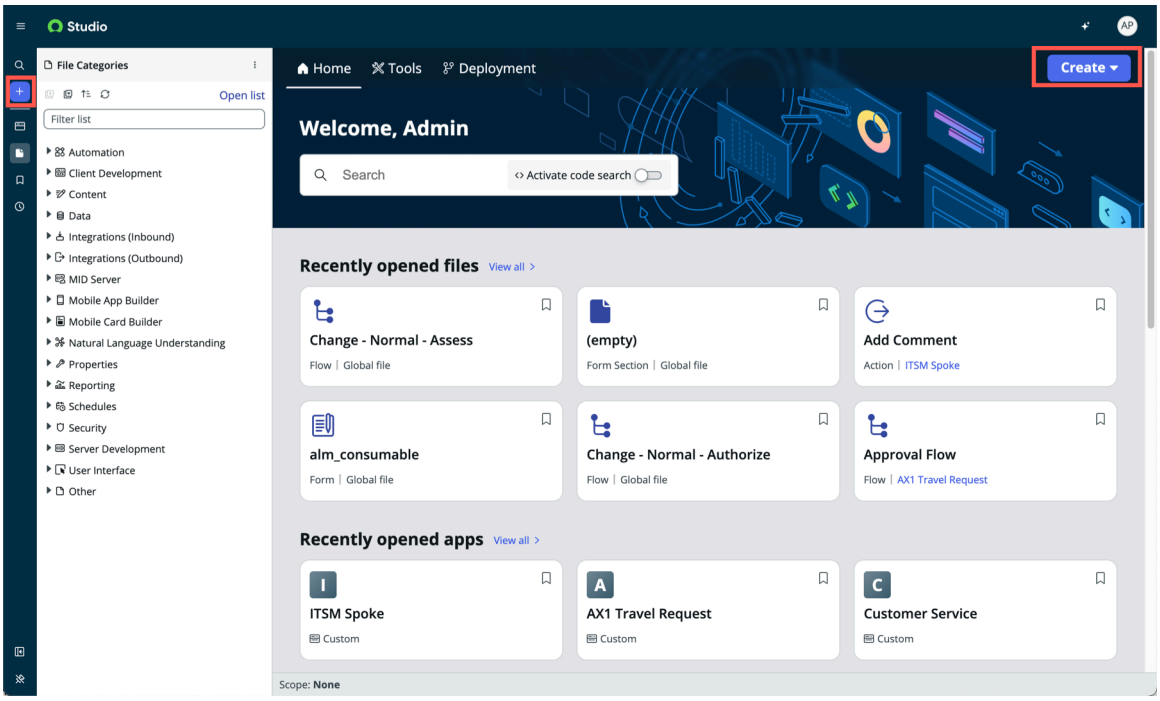
Only admins can create an app in ServiceNow Studio. If you need an app created for you, contact your admin.

Role required: admin

Procedure

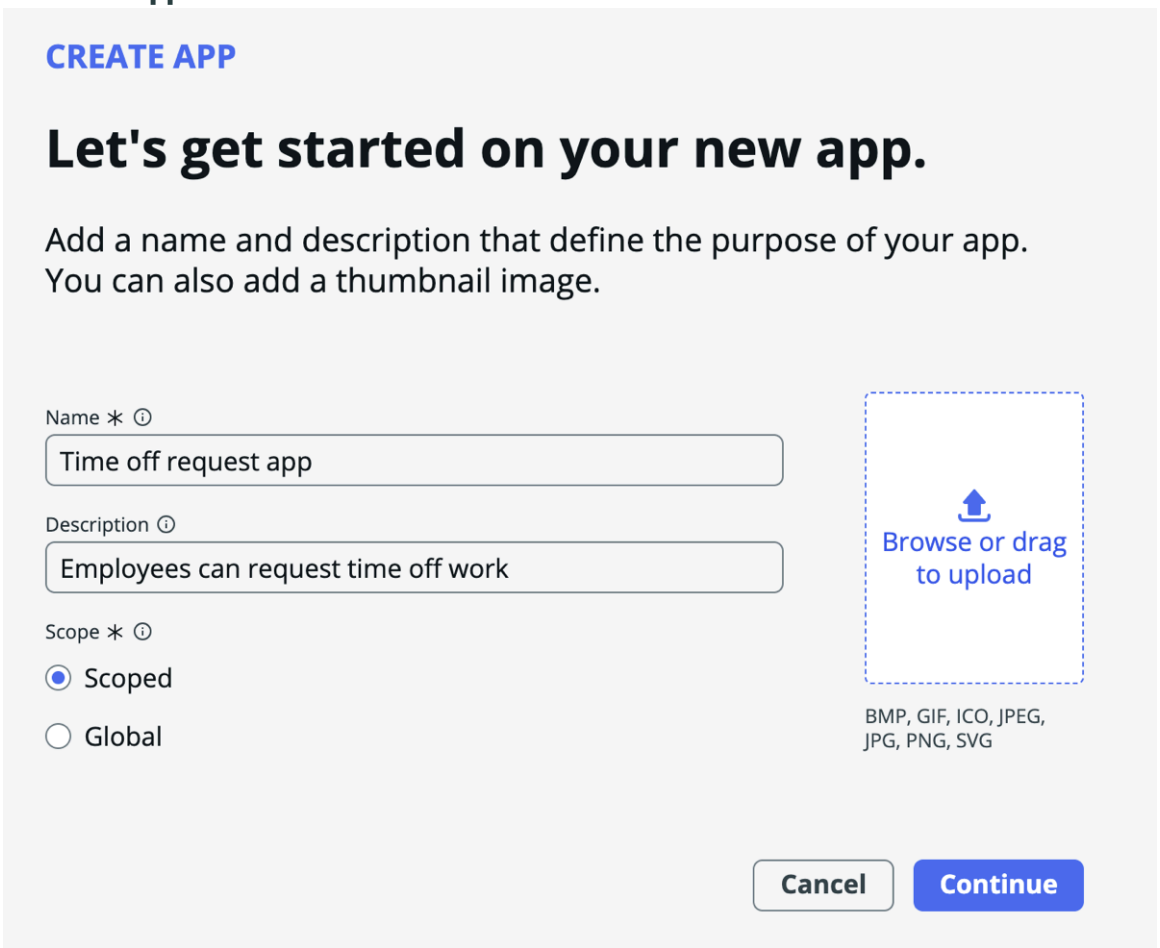
1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Select either the Create icon ( ) next to the Navigator panel or the **Create** button.

Select either Create button



3. Select **App** from the options that appear.
4. Enter the basic information for the app on the form.

Create an app basic details



a. Enter a **Name** and **Description** for your application.

b. **Optional:** Add a logo by either dragging the image to the **Browse or drag to upload** field or selecting the field, selecting the image from your file directory, and selecting **Open**.

c. Specify the **Scope**.

- **Scoped** means that the app doesn't interact with any other data on the instance. By default, the app can access and change its own tables and business logic, but other apps can't unless you give them explicit permission.
- **Global** means that all tables and business logic on the instance can interact with the app.

For more information about working with scopes, see Application scope.

d. Select **Continue**.

5. Define user access to the app by adding roles.
ServiceNow Studio automatically defines default admin and user roles. You can remove the pre-defined roles or add more roles. For more information about roles, see Managing roles.

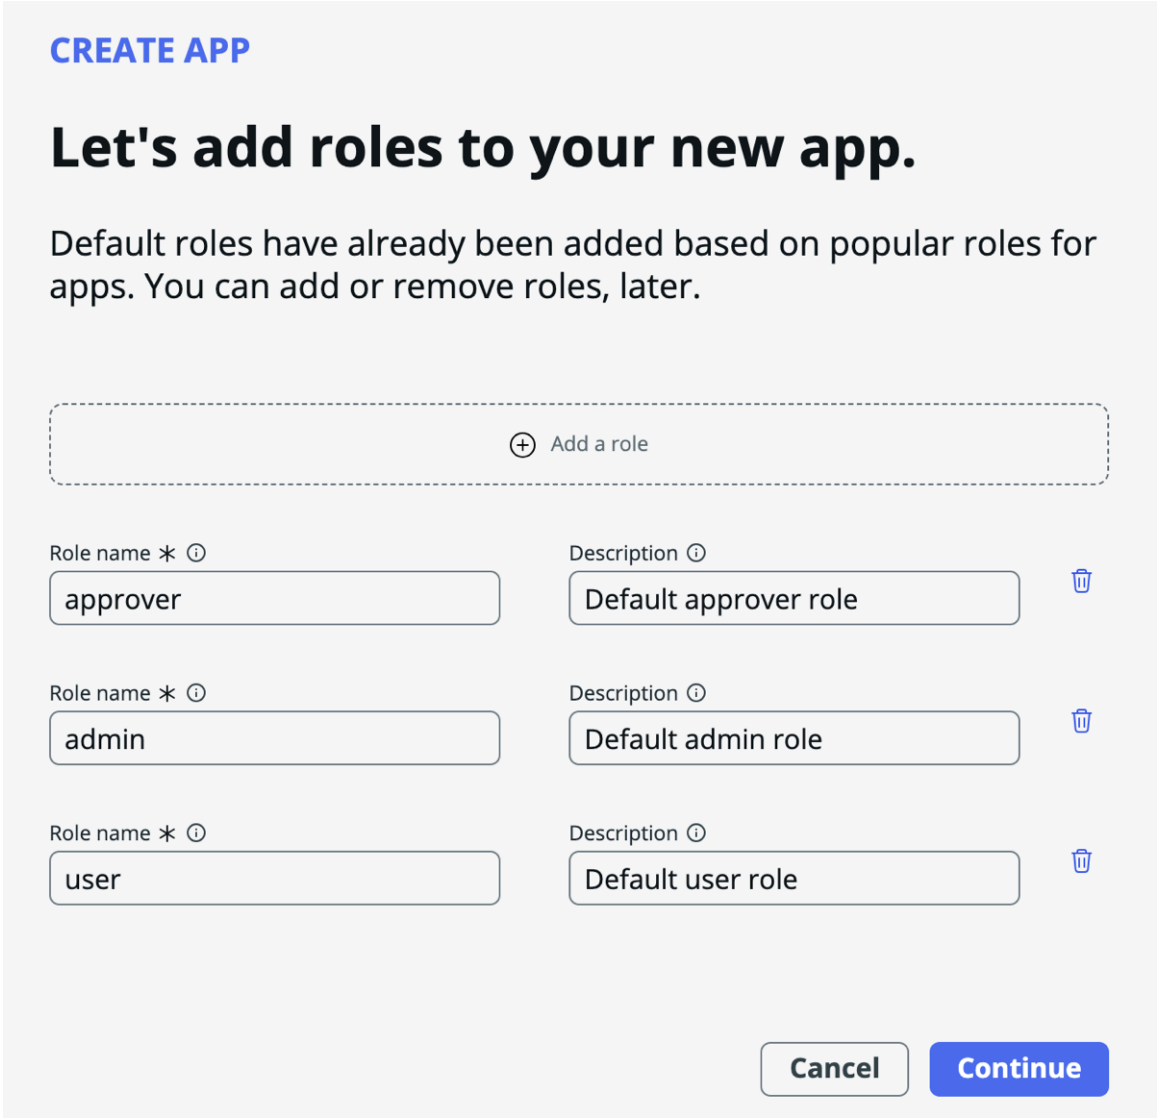
a. Select **Add a role**.

b. Enter the **Role name** and **Description**.

c. Repeat this process for as many roles that you need to add.

d. Select **Continue**.

Roles create user access to the app



6. Open the app dashboard when ServiceNow Studio is done creating the foundation of the app by selecting **Go to app dashboard**.

Result

The app dashboard opens within ServiceNow Studio. From there, you can add other content, such as application files, dependencies, and cross-scope privileges. For more information, see Create an app file in ServiceNow Studio, Working with metadata app file categories in the ServiceNow Studio Navigator, and Access integrated development tools and builders in ServiceNow Studio.

Create an app file in ServiceNow Studio

Create an app file to define an aspect of how an application functions. For example, you could add a security file using ServiceNow Studio to define which users can access the app.

Before you begin

Role required: admin or delegated developer

About this task

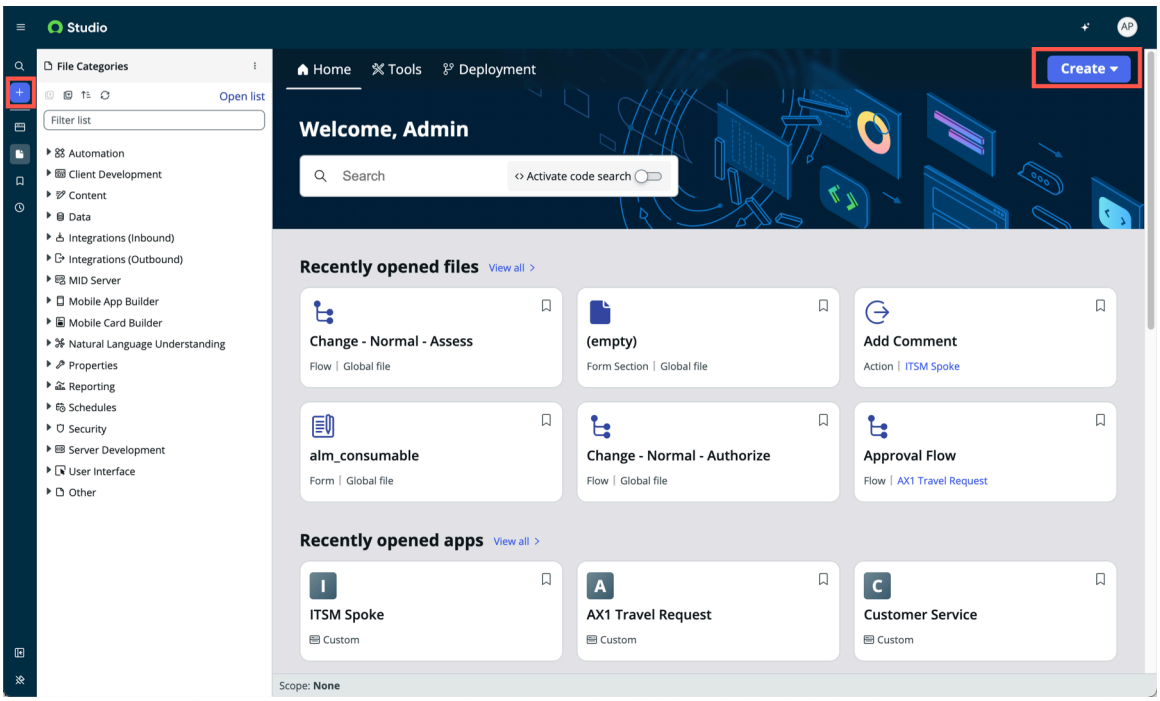
Application files are essentially metadata records for application logic such as business rules, workflows, and script includes. For more information on app files, see Application files and Working with metadata app file categories in the ServiceNow Studio Navigator.

Delegated developers have access to create app files for apps they have access to. If you need an app created, contact your admin.

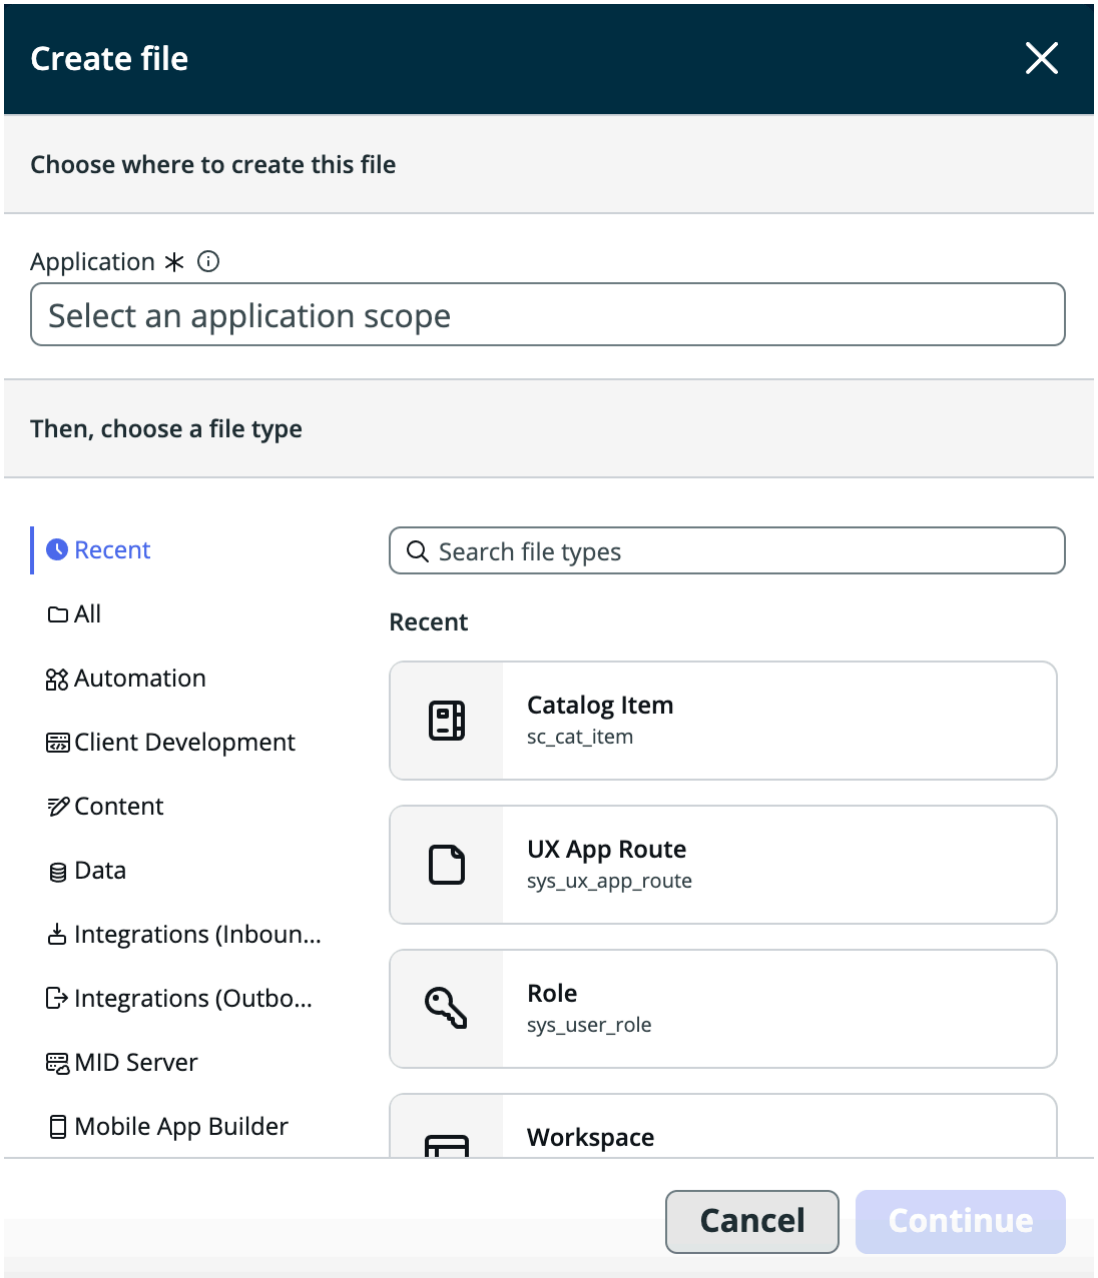
Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Select either the Create icon ( ) next to the Navigator panel or the **Create** button.

Select either Create button



3. Select **File** from the options that appear.



4. Specify which app the file belongs to by entering it in the **Application** field.
   If you want the app file to be available to all apps, select the **Global** scope.
5. Select the card for the type of file you want to create.
   You can find the file type in several ways:
   - Filter the available types by selecting one of the metadata taxonomies in the left of the modal.
   - Enter the type of file you're looking for in the search bar.
   - Choose from the list of Recent file types.

   For a list of all types of metadata that you can use to create app files, see ServiceNow Studio Navigator panel taxonomy. For more information about each file type, see Working with metadata app file categories in the ServiceNow Studio Navigator.
6. Select **Continue**.
   The record for the app file appears in a new browser tab in ServiceNow Studio.
7. Fill in the form with the details for the new app file.

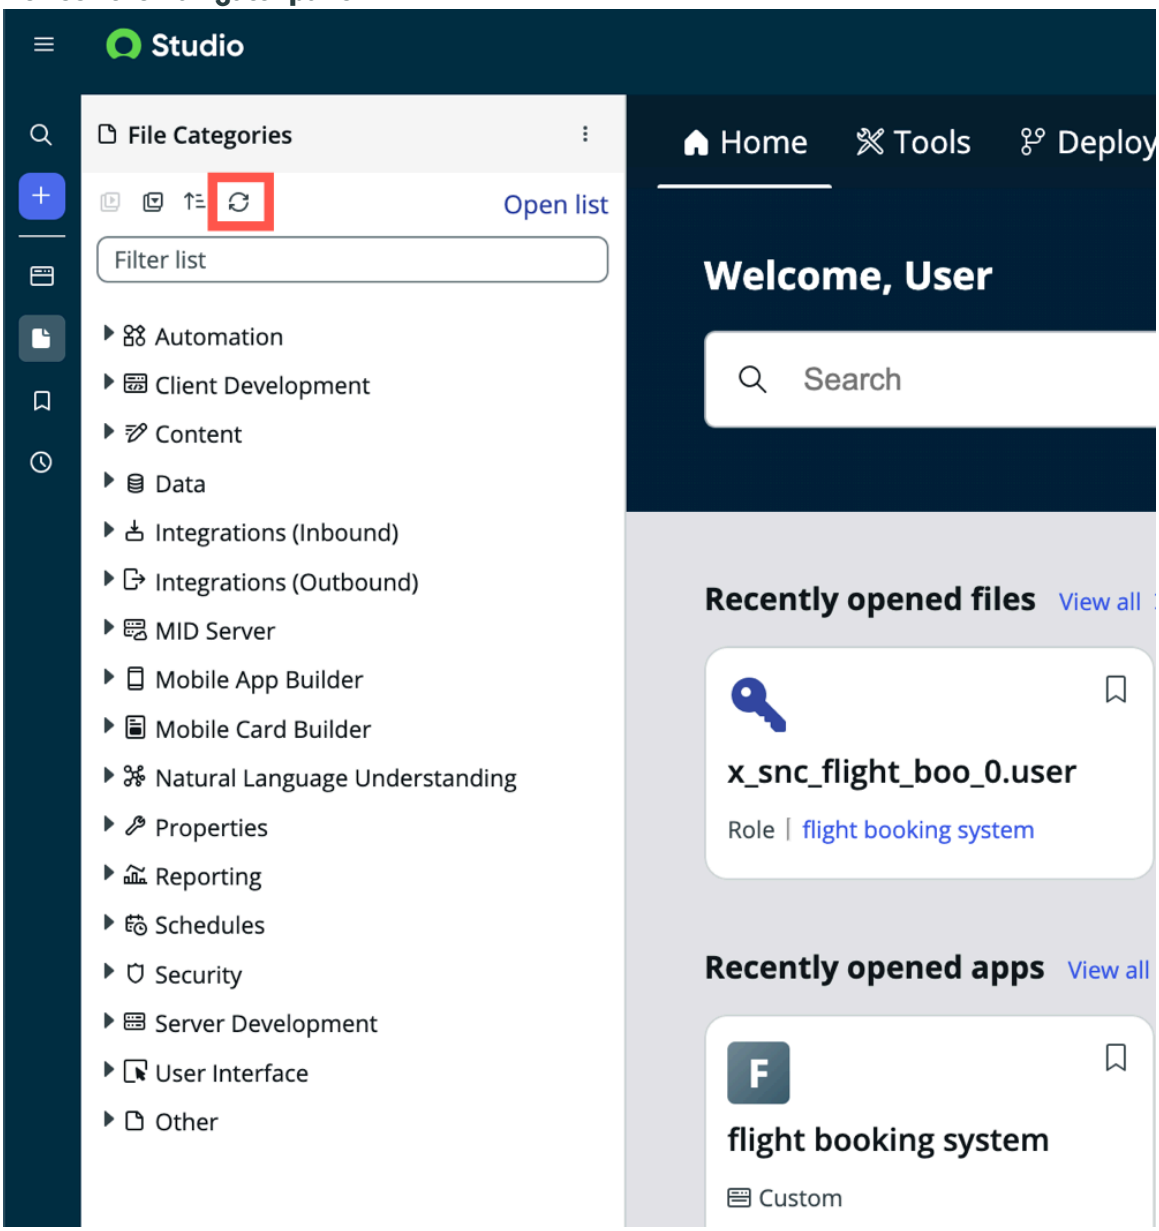
The form fields vary depending on the type of file you created.

8. Select **Submit**.

What to do next

After you finish creating the app file, you must select the refresh icon in the Navigator panel for it to appear in the list of app files.

Refresh the Navigator panel



Now Assist for app generation in ServiceNow Studio

Use the ServiceNow® Now Assist for Creator application to use generative AI for simplifying app creation. After having a conversation about the app that you want to create, Now Assist for Creator generates the app that you can then modify in ServiceNow Studio (Xanadu Store release 2).

Get started

Explore  Learn how to create apps through conversation	Configure  Set up app generation
Generate  Build apps through conversation	Reference  Get details about properties, roles, and more

Important:

- Not all model providers are available for customers with in-country SKUs, and some Now Assist products/features are currently unavailable for in-country customers. For more information, see the KB1584492 article in the Now Support Knowledge Base. Be sure to check for model provider availability updates in future releases.
- Some Now Assist products/features are currently unavailable for customers in the FedRAMP, NSC DOD IL5, or Australia IRAP-Protected data centers, self-hosted customers, or in other restricted environments. For more information, see the KB0743854 article in the Now Support Knowledge Base . Be sure to check for availability updates in future releases.
- Some Now Assist products/features are currently available only for customers in some regions. Be sure to check for availability updates in future releases.
- Some AI products and skills are not available in Regulated Markets. For more information, see KB2593939: Regulated Markets AI Products/Skills Not Available. Be sure to check for availability updates in future releases.

Troubleshoot and get help

AI limitations

This application uses artificial intelligence (AI) and machine learning, which are rapidly evolving fields of study that generate predictions based on patterns in data. As a result, this application may not always produce accurate, complete, or appropriate information. Further, there is no guarantee that this application has been fully trained or tested for your use case. To mitigate these issues, it is your responsibility to test and evaluate your use of this application for accuracy, harm, and appropriateness for your use case, employ human oversight of output, and refrain from relying solely on AI-generated outputs for decision-making purposes. This is especially important if you choose to deploy this application in areas with consequential impacts such as healthcare, finance, legal, employment, security, or infrastructure. You agree to abide by ServiceNow's AI Acceptable Use Policy, which may be updated by ServiceNow.

Data processing

This application requires data to be transferred from ServiceNow customers' individual instances to a centralized ServiceNow environment, which may be located in a different data center region from the one where your instance is, and potentially to a third-party cloud provider, such as Microsoft Azure. This data is handled per ServiceNow's internal policies and procedures, including our policies available through our CORE Compliance Portal.

Data collection

ServiceNow collects and uses the inputs, outputs, and edits to outputs of this application to develop and improve ServiceNow technologies including ServiceNow models and AI products. In addition, this application will collect information about applications (and associated application files) in which App generation was utilized. Customers can opt out of future data collection at any time, as described in the Now Assist Opt-Out page.

Exploring app generation in ServiceNow Studio

App generation overview

Administrators and developers must be assigned the admin and now.assist.creator roles to create and edit apps using app generation. In Xanadu Store Release 2 there is a second option to assign users the delegated developer, now_assist_panel_user, and now.assist.creator roles to edit apps (not create) using app generation. For more information about using app generation, see Generate apps with Now Assist for Creator for ServiceNow Studio

Conversation

Chat with Now Assist for Creator to specify the business processes you want in the application including the details on the objectives, users, workflows, and experiences.

Refinement in Xanadu Store Release 2

Now Assist for Creator provides a summary of the application requirements based on the information collected during the conversation. Preview the application and check that it's accurate. If you want to make changes, stay in the conversation and keep editing. Now Assist continues to update the preview tab based on your comments and provides summaries until you choose to proceed with generating the application.

Generation

Now Assist for Creator generates the application and associated components, including the tables, roles, access control lists (ACLs), and record producers.

Open and verify everything that is generated. In Xanadu Store Release 2, verify in ServiceNow Studio. Modify the app to make it suit your organization's needs. For example, the app's functionality can be extended by adding flows and automation, script includes, business rules, and other features.

General guidelines for using app generation in ServiceNow Studio

Learn about general guidelines for using app generation.

Configuring app generation in ServiceNow Studio

Install Now Assist for app generation in ServiceNow Studio

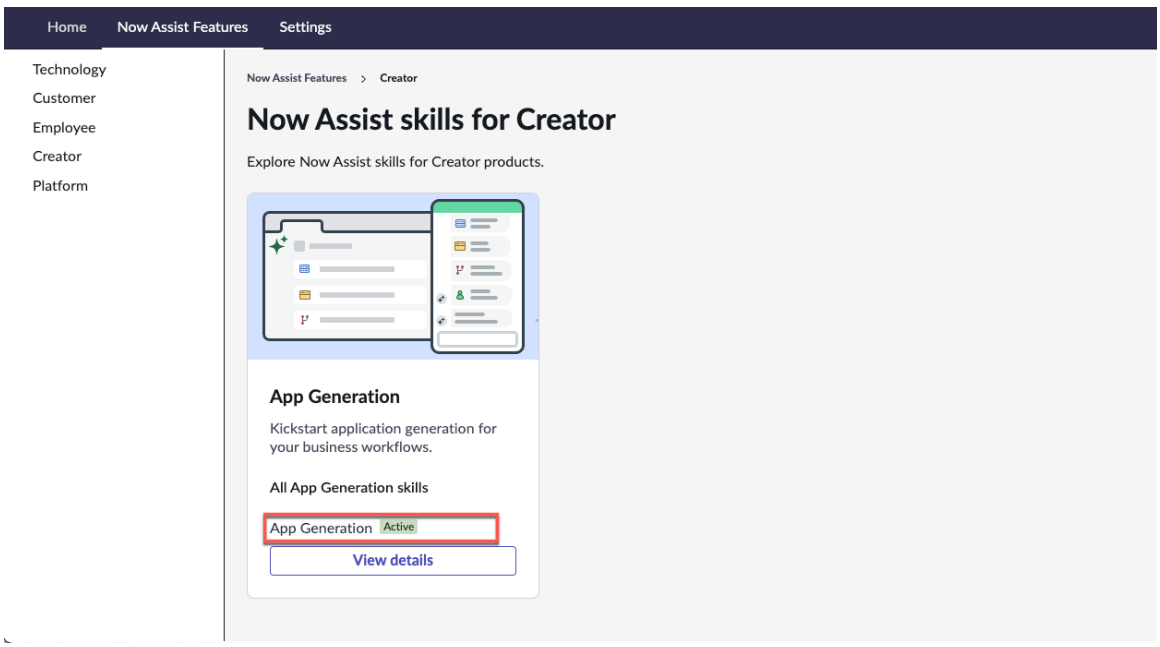
Before you begin

Review the Now Assist for Creator application listing in the ServiceNow Store to learn about dependencies, licensing, and subscription requirements, and release compatibility. Now Assist for Creator installs the Now Assist for app generation application.

Role required: admin

Procedure

1. Navigate to the Now Assist for Creator application on the ServiceNow Store .
2. On the Now Assist for Creator application page, select **Request App**.
3. After your request is approved, navigate to **All** > **System Applications** > **All Available Applications** > **All**.
4. Find the Now Assist for Creator application (sn_now_creator) by using the filter criteria and search bar.
5. Select **Install**.
6. Verify that Now Assist for Creator is installed.
   a. Navigate to **All** > *Now Assist Admin* > **Features**.
   b. In the workflow list, select **Creator**.
   c. On the App Generation card, verify that the app generation skill is active.



For more information about using the Now Assist Admin console to access information about setting up, configuring, and monitoring Now Assist applications, see Now Assist Admin console .

What to do next

Grant the admin and now.assist.creator roles to each user that you want to create and edit applications using app generation.

As of Xanadu Store Release 2, users that only need to edit (not create) applications using app generation can be granted the delegated_developer, now_assist_panel_user, and now.assist.creator roles. For more information, see Delegated development and deployment.

To begin generating applications, see Generate apps with Now Assist for Creator for ServiceNow Studio.

Have a conversation with the Now Assist for Creator application to start building applications.

This video shows you how to perform the following procedure.

https://player.vimeo.com/video/1040832044?h=b2b8dc6b7c&badge=0&autopause=0&player_id=0&app_id=58479

Before you begin

To use app generation, you must activate the skill in Now Assist for Creator. For more information, see Install Now Assist for app generation in ServiceNow Studio.

Role required: admin and now.assist.creator

Note:
As of Xanadu Store Release 2, if you have users that only need to edit (not create) apps, they can be assigned the delegated_developer, now_assist_panel_user, and now.assist.creator roles.

About this task

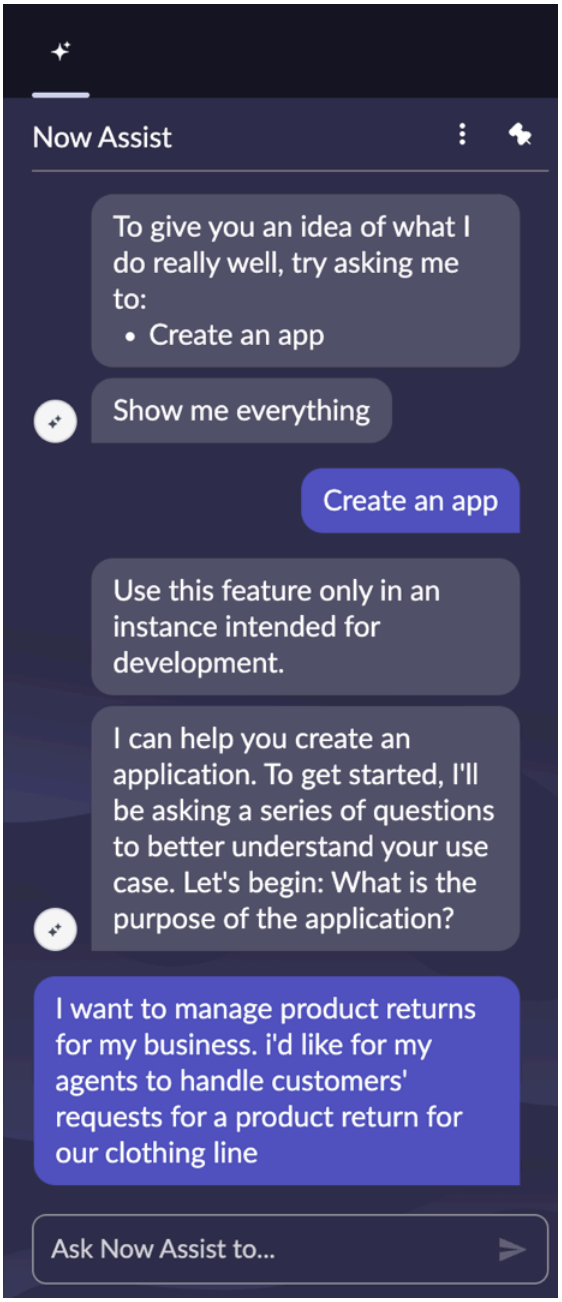
When app generation is enabled on an instance, the Now Assist icon (✨) appears on the home page banner.

Procedure

1. Open the Now Assist panel by navigating to **App Engine** > **ServiceNow Studio** and selecting the Now Assist icon.

2. In the Now Assist panel, select **Create an app**.
   Now Assist asks you to describe your application.
3. Summarize your current business process.

   Describe your application's use case so Now Assist understands the purpose of your application. You can be highly detailed if you have a clear idea of what you want. If you don't, start with a broad description. Now Assist narrows down your app's requirements.



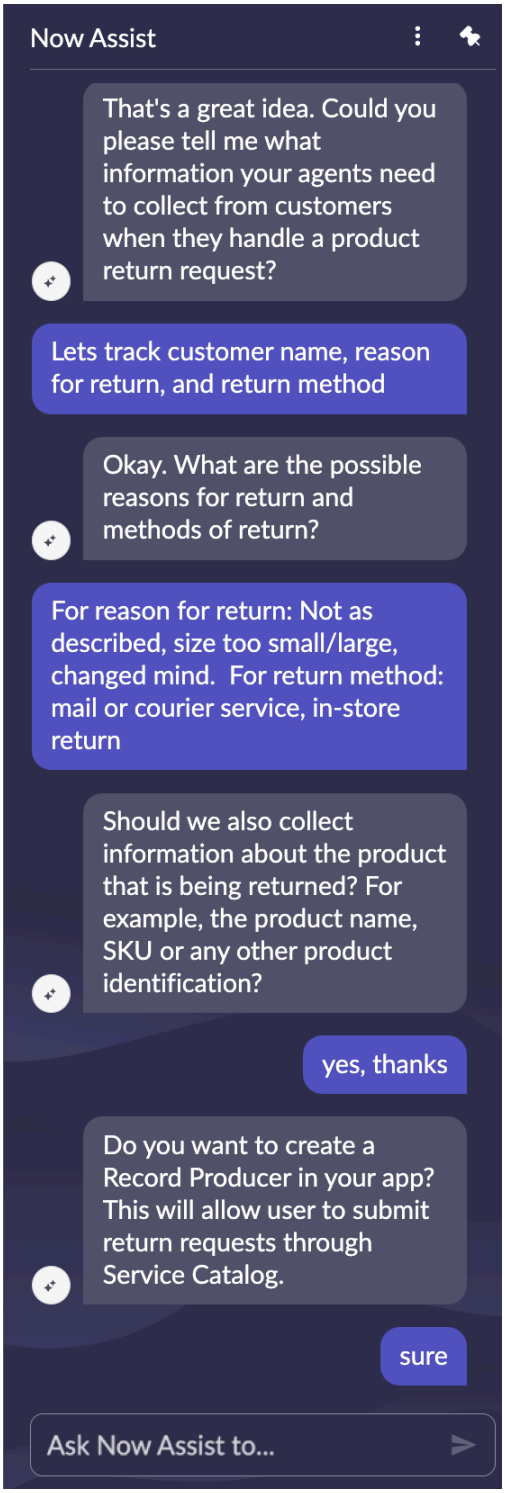
4. Continue the conversation with Now Assist by providing details about how you want the app to work.

   Example

   Now Assist asks you questions to understand the data to be collected, the users involved and their permissions, and the desired interface. Your answers help Now Assist create the correct tables, roles, access control lists (ACLs), forms, and record producers for your application.

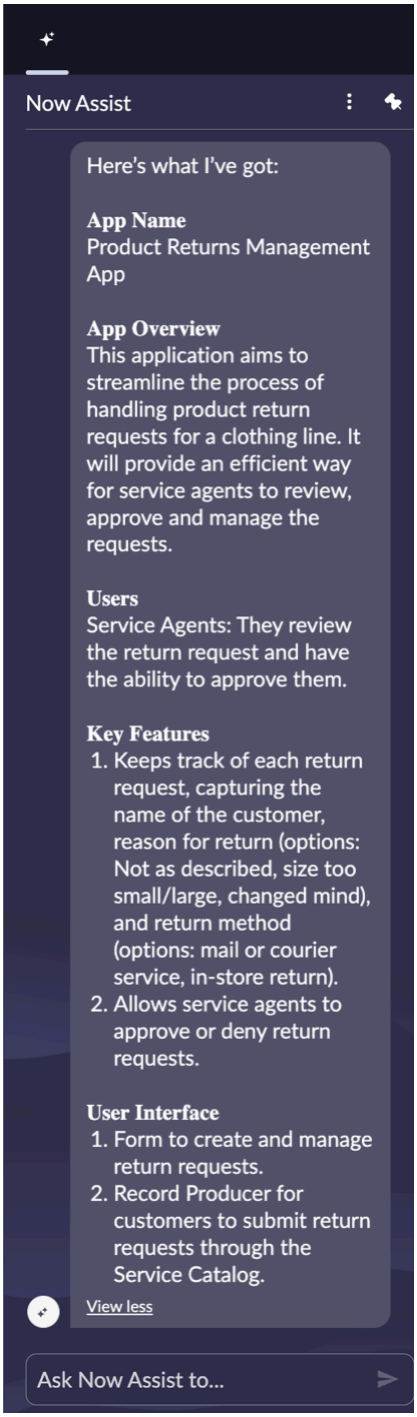
   If you know exactly how you want your app to work, be specific about its functionality. If you don't, interact with Now Assist to determine the correct application requirements. For more information, see General guidelines for using app generation in ServiceNow Studio.

   When Now Assist collects enough information, it provides a detailed summary of the application requirements.



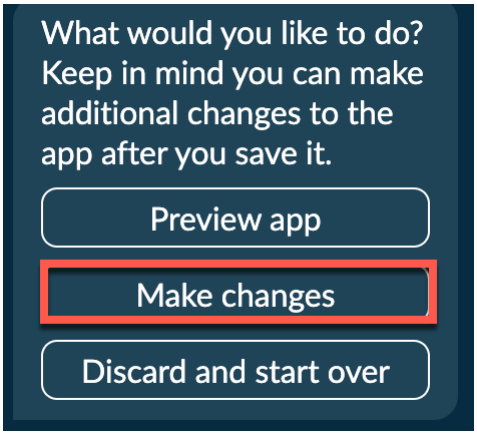
5. Review the summary of your application requirements.

Note:
Because the information is generated by AI, review the text to make sure it's accurate.



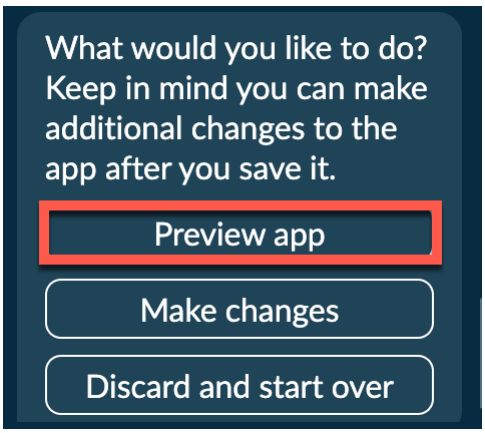
6. In Xanadu Store Release 2, preview, finalize, and then generate the app.

a. If necessary, select **Make changes** to continue editing.



Continue to interact with Now Assist until the summary it produces matches your app's requirements.

b. After you're satisfied with the application requirements, select **Preview app**.



The preview opens and displays a list of app files. Select any of the app files to view details. For example, select a role to see if it grants users create, read, write, or delete permissions. If your app contains a record producer, select it to see what the form and fields look like.

Note:

If the Now Assist panel is covering information, select the Now Assist icon to close the panel. Select the icon again to open the panel and continue the conversation.

When you are finished previewing, select an option:

- **Save and open app** generates the app and opens it in ServiceNow Studio for you to review and edit as needed.
- **Make changes** enables you to continue the conversation with Now Assist to refine and edit the app. After Now Assist makes any changes you request, the app preview is also updated.
- **Discard and start over** deletes the current app and resets the conversation in the Now Assist panel.

For more information about ServiceNow Studio, see Building applications with ServiceNow Studio.

Result
In Xanadu Store Release 2, use the tools in ServiceNow Studio to add more features and enhance your app further.

Review the apps generated by Now Assist for Creator in ServiceNow Studio

In Xanadu Store Release 2, use the ServiceNow Studio development environment to verify and modify the application that you created with Now Assist for Creator.

This video shows you how to perform the following procedure.

https://player.vimeo.com/video/1040832738?h=0b12434687&badge=0&autopause=0&player_id=0&app_id=58479

Before you begin
You must have created an application using Now Assist for Creator.

Role required: admin and now.assist.creator, or sn_g_app_creator.app_creator and now.assist.creator (If you have users that only need to edit, not create, apps, they can be assigned the delegated_developer, now_assist_panel_user, and now.assist.creator roles.)

About this task
The application generated by Now Assist for Creator provides a starting point for further development. Examine the contents of the application and confirm that they align with your business process. Enhance the application by adding functionality as needed.

Procedure
1. If the application isn't already open, navigate to App Engine > ServiceNow Studio and select the application tile.

   Notice the AI indicator AI at the top showing that the application was generated with Now Assist for Creator.

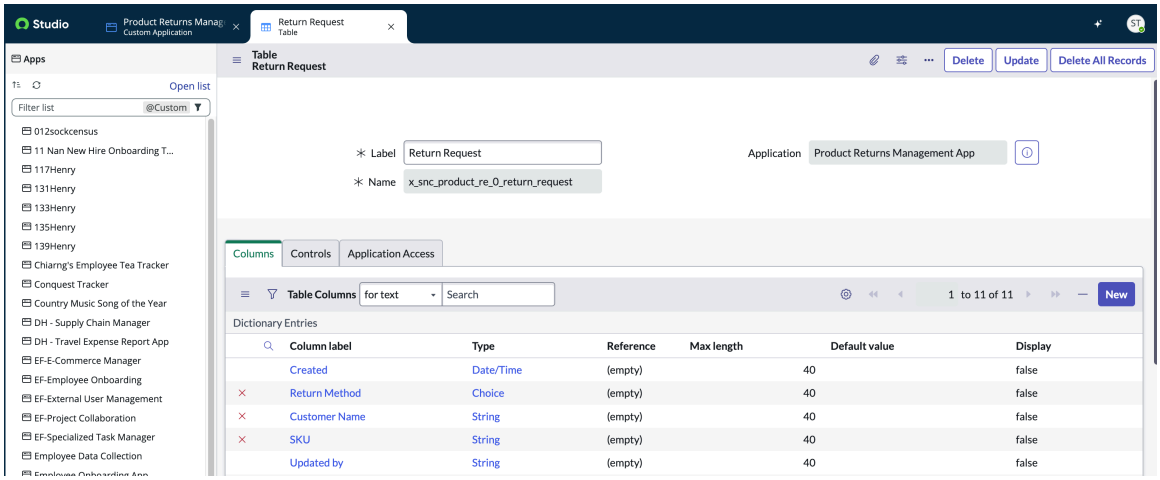
   To learn more about the ServiceNow Studio home page, see Building applications with ServiceNow Studio.

2. Review the generated tables.

   a. On the **Application Files** tab, in the **Display name** column, select an existing table in your application.
   The table record opens in a new tab.

   Note:

   If the Now Assist panel is covering information, select the Now Assist icon to close the panel. Select the icon again to open the panel and continue the conversation.



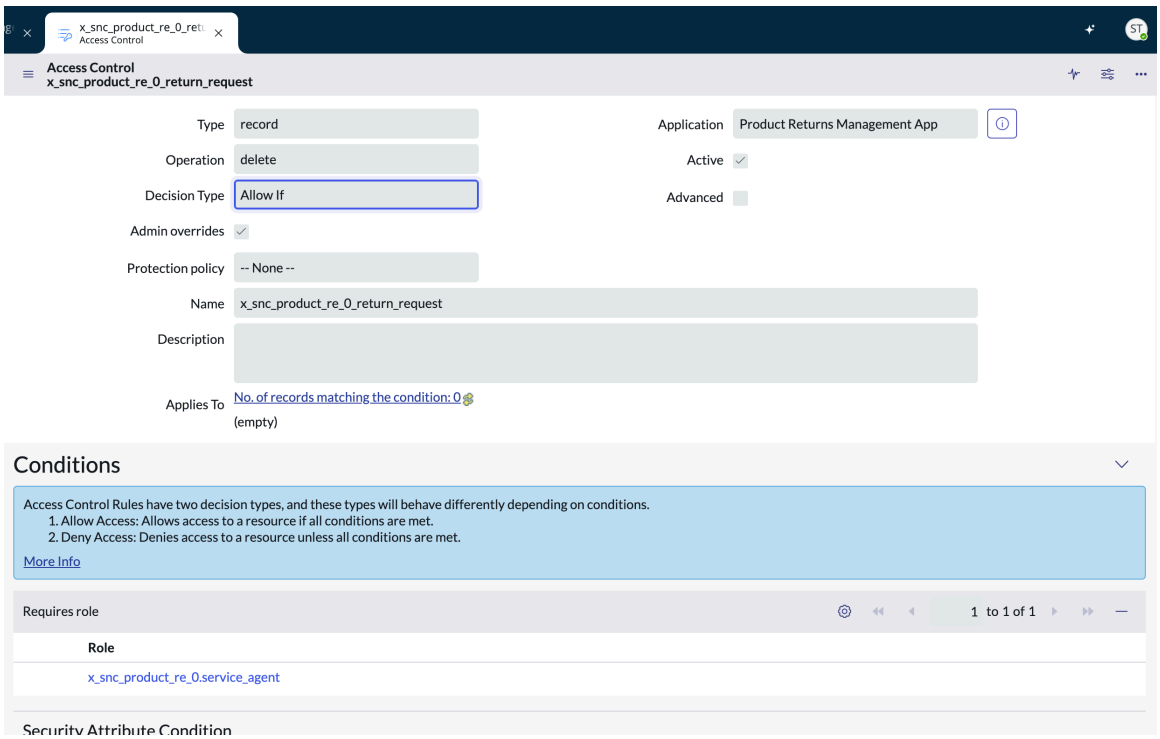
b. Now Assist created the table based on your instructions; confirm that the table is accurate and captures the correct data.

- Manage table fields.
- Edit the table and field column properties.
- Verify that the generated choices are implemented correctly.

3. Close the table tab.

4. Review the generated access control lists (ACLs).

a. On the **Application Files** tab, in the **Display name** column, select an existing access control in your application.
The access control record opens in a new tab.



b. Verify that the created ACL is accurate and requires the correct role or roles.

5. Close the access control tab.
6. Review the generated roles.

   a. On the **Application Files** tab, in the **Display name** column, select an existing role in your application.
   The role record opens in a new tab.

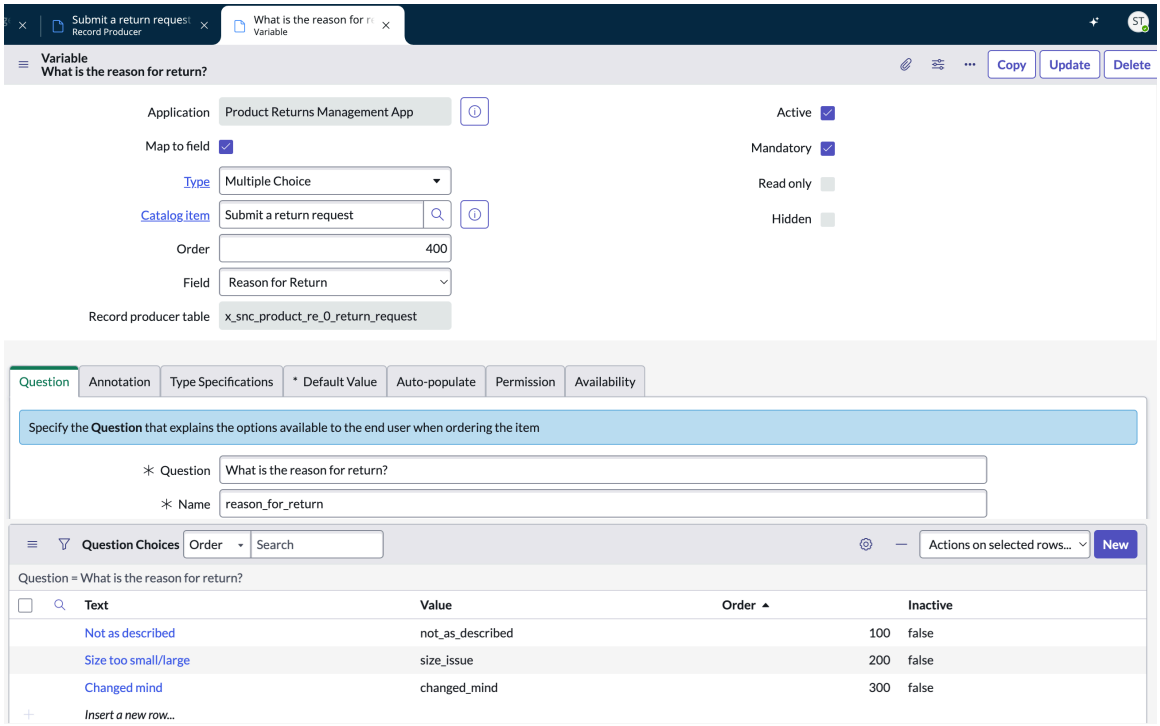
   b. Verify that the created role and its assigned permissions accurately represent the users of your application.

7. Close the role tab.
8. Review the generated record producers.

   a. On the **Application Files** tab, in the **Display name** column, select an existing record producer in your application.
   The record producer record opens in a new tab.

   b. Review and modify the record producer if necessary.

   For example, select the **Variables** tab and then select a **Question** to confirm that the question options are correct.



For more information about record producers, see Record Producer.

9. Close the record producer tab.

What to do next

Continue opening, verifying, and modifying items in the application list as needed. For more information, see Building applications with ServiceNow Studio.

Edit applications in Now Assist for App generation with ServiceNow Studio

In Xanadu Store Release 2, use the generative AI capabilities in Now Assist for Creator to edit applications.

Before you begin

You have created an application using Now Assist for Creator.

Role required: admin and now.assist.creator (as of Xanadu Store Release 2, if you have users that only need to edit, not create, apps, they can be assigned the delegated_developer, now_assist_panel_user, and now.assist.creator roles)

Procedure

1. Open the Now Assist panel by navigating to App Engine > ServiceNow Studio and selecting the Now Assist icon.

2. In the Now Assist panel, select **Update an app**.
3. Select the app to edit.

   The apps that appear in the Now Assist panel for editing are custom applications you have created or to which you have access.

Users with the admin and now.assist.creator roles can create and edit applications. Users with the delegated_developer, now_assist_panel_user, and now.assist.creator roles can edit applications.

If you have the delegated_developer, now_assist_panel_user, and now.assist.creator roles, but do not see the app that you need, contact your App Engine admin. Ask them to add you to the app as a delegated developer. For more information, see Delegated development and deployment.

To edit with Now Assist, ensure that your scope is set to the same scope as the app. If you aren't in the correct scope, return to the browser tab you used to launch ServiceNow Studio and use the scope picker to change the scope. (For more information, see Application picker.) When you're finished, select the tab with ServiceNow Studio open and select **Done**.

4. Interact with Now Assist to edit the app.

   For example, request new metadata such as a form or request a new table that is extended from an existing table.

   Note:
   Now Assist may encounter issues while updating a large app. Consider updating the app manually in ServiceNow Studio instead.

What to do next

Continue interacting with Now Assist to edit and refine the app. For more information, see General guidelines for using app generation in ServiceNow Studio.

App generation in ServiceNow Studio reference

Reference topics provide additional information about configuration properties, roles, and more.

App generation roles for ServiceNow Studio

The following roles are installed for use with the Now Assist for Creator app generation skill.

As of Xanadu Store Release 2, users that only need to edit (not create) applications using app generation can be granted the delegated_developer, now_assist_panel_user, and now.assist.creator roles. For more information, see Delegated development and deployment.

Administrator [admin] role for Now Assist with ServiceNow Studio

Access all system features, functions, and data, regardless of security constraints.

Now Assist Creator [now.assist.creator] role for Now Assist with ServiceNow Studio

Create applications through a conversation with generative AI.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

None.

Bookmark apps and app files in ServiceNow Studio

Easily bookmark apps and app files from several locations for quick access in ServiceNow Studio.

Before you begin
Role required: admin or delegated developer

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Bookmark your apps and files from different locations in ServiceNow Studio.
3. **Optional:** To view your bookmarked apps and files, ensure that the Navigator panel is open and select the bookmarks icon ().
   Your bookmarked apps and files appear in the bookmarks tab under the appropriate file type.

Find an app or app file using code search

Find an app or app file using code search in ServiceNow Studio. Code search enables you to search through all applications and tables on your instance to find what you're looking for.

About this task
You can use code search for troubleshooting issues on your instance. For example, if a client script automatically updates a record incorrectly and displays an error message, you can perform a code search for the error message to find out where it's being generated. For a detailed example of using code search to troubleshoot, see the Community article on Using Code Search to make developing on the platform easier.

Before you begin
Role required: admin or delegated developer

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. In the search bar, select the **Activate code search** toggle.
3. Enter the code snippet you're looking for in the search bar.
4. Specify whether to search all apps or a specific app.
   - Choose **Select all** to search all apps on the instance for the code snippet.
   - Choose **Select specific app** and then enter the name of the app in the search bar that appears.
5. **Optional:** Limit the search to a table by entering the name of the table in the **File types / tables** field.
   Only tables in the same scope are available. For a list of supported file types, see ServiceNow Studio supported file types using code search.
6. Run the search by selecting **View results**.
   The results open in a new **Code search** tab inside ServiceNow Studio.
7. Expand the type of script that you want to review for the code snippet.

For example, you can expand the **Notification** section to view all code search results in notification scripts, or the **Access control** section to view all instances of code related to roles and security.

For a list of types of scripts, see Available script types.

8. View the code you searched for and its corresponding line number by expanding the name of the individual script within the section you're viewing.
   Each script that contains the code snippet appears in an expandable section that displays the number of times the code appears in the script.
9. **Optional:** View the whole script that contains the code by selecting **open file**.
   The complete script appears in a new tab in ServiceNow Studio.

Debug a script in ServiceNow Studio

Use the Script Debugger in ServiceNow Studio to debug business rules and other synchronous server-side scripts. Access the Script Debugger during the course of your app development in ServiceNow Studio.

Before you begin

Role required: admin or delegated developer

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. On the home page, scroll down to the bottom of the screen, and select *`Script Debugger`* from the **Resources** section.
3. Use the Script Debugger features you use in the normal course of your app development work.
   The Script Debugger opens in a new tab outside of ServiceNow Studio. Some tabs and features are role-dependent. For more information about using Script Debugger, see Script Debugger and Session Log.

Modify an app's settings in ServiceNow Studio

Adjust an app's settings in ServiceNow Studio to meet your needs. Change the name, description, or image associated with the app, or delete the app if it's no longer needed.

Before you begin

Role required: admin or delegated developer

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. In the Navigator panel, select the **Apps** icon ( ).
3. Select the app that you want to open.
4. Select **App details** to open the app in the canvas.
5. In the top-right corner, select the App settings icon ( ).
6. Edit the app's settings.
7. Select **Save**.

Working with metadata app file categories in the ServiceNow Studio Navigator

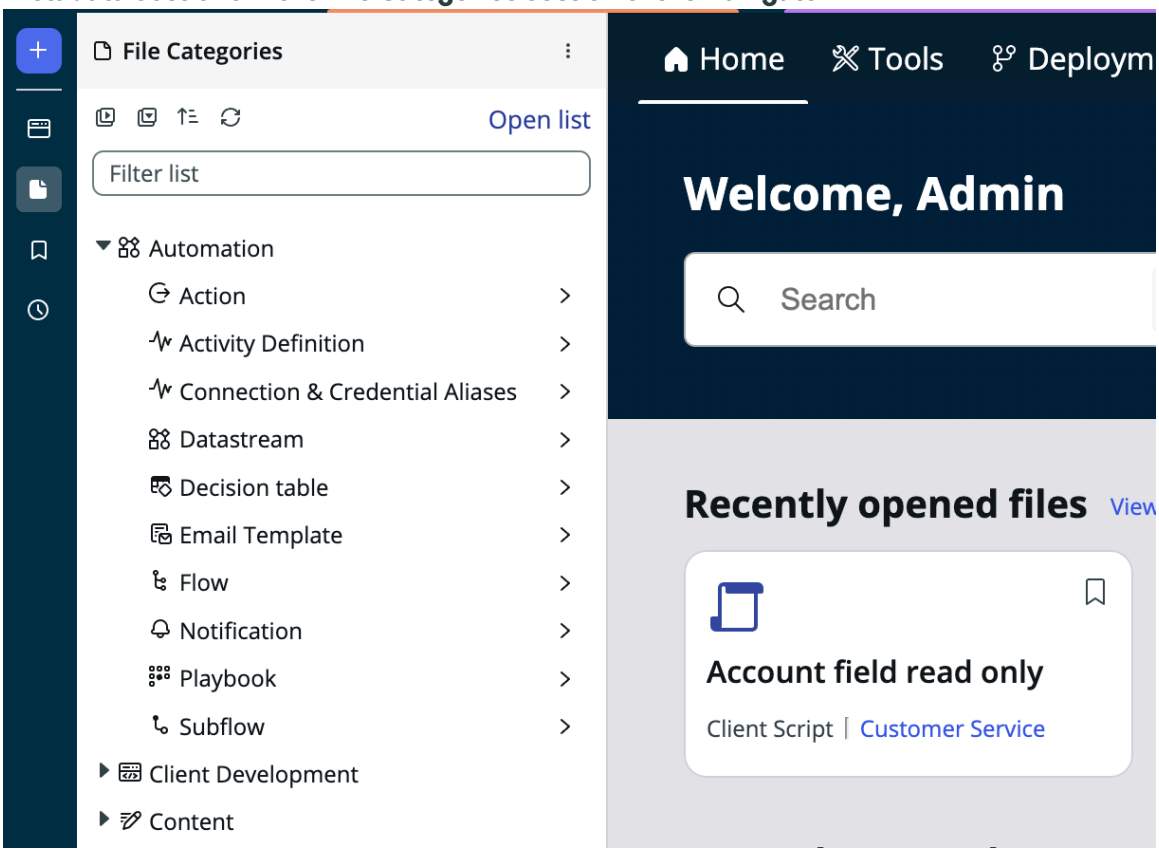
ServiceNow Studio enables you to work with all types of metadata that the ServiceNow AI Platform supports, from automations and integrations to user interface files.

Accessing metadata for your ServiceNow Studio apps

The **File Categories** section of the Navigator panel enables you to quickly view all types of metadata that you have access to, arranged by taxonomy category. Expanding each metadata file category shows its subcategories. For example, expanding the **Automation** category provides access to view all of the sub-types of automation metadata, such as actions, flows, and playbooks.

Note:
To see a complete list of each category's file types and information about each file, see ServiceNow Studio Navigator panel taxonomy.

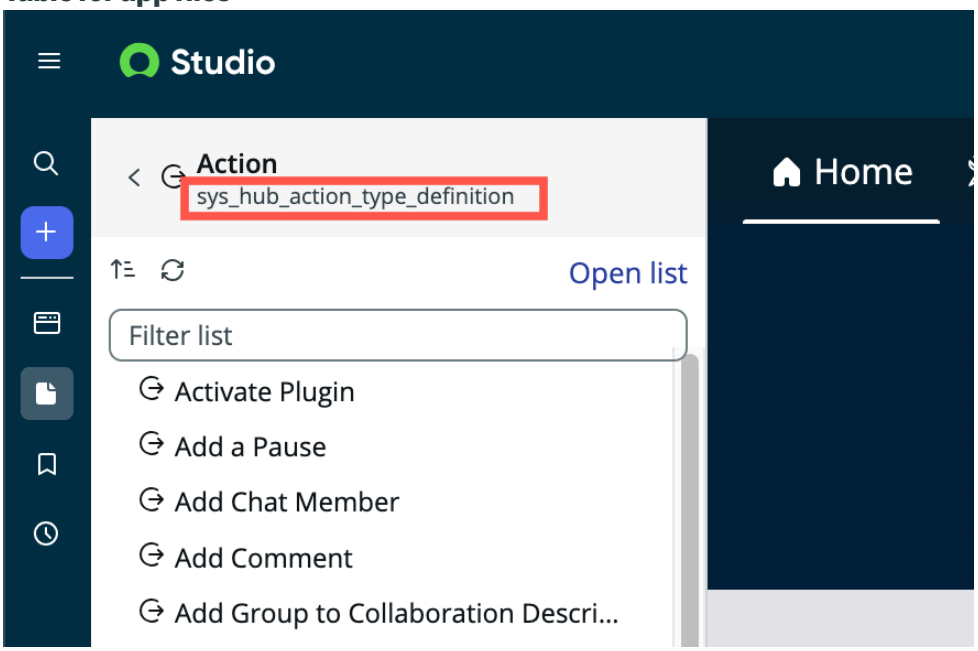
Metadata sections in the File Categories section of the Navigator



When you select a sub-type of an expanded file category, ServiceNow Studio displays all of the metadata of that type, which you can select to view. For example, selecting **Flow** under the **Automation** file category displays a list of all flows that you have access to. Select one to open it in Workflow Studio within a tab in ServiceNow Studio.

Note:
The source table for each sub-category of metadata file type appears when you select the category. Select **Open list** to see a complete list of all the files of that type.

Table for app files



For more information on using the Navigator panel to find app files by their metadata category, see Find an app or app file using the Navigator panel.

Metadata table and its extended tables

Metadata lives as application files in their corresponding tables on the ServiceNow AI Platform. The main metadata table is sys_metadata, but specific types of metadata extend the sys_metadata table. For example, flows and sub-flows use the extended sys_hub_flow table.

See ServiceNow Studio Navigator panel taxonomy for a list of available metadata and corresponding tables that extend sys_metadata.

Metadata by category

Each file category has different types of metadata available for automations, data, integration, mobile app builder, UI, and other categories. For a list of each type of file, its primary table, primary builder experience, and more, see ServiceNow Studio Navigator panel taxonomy.

Categories of metadata

Category	Metadata sections
Automation	• Automation • Schedules
Data	• Client development • Data • MID Server • Server development

Categories of metadata (continued)

Category	Metadata sections
Integrations	• Inbound integration • Outbound integration • Properties
Mobile	• Mobile App Builder • Mobile Card Builder
UI	• Content • User interface
Other	• Natural Language Understanding (NLU) • Reporting • Security

Working with update sets in ServiceNow Studio

An update set is a group of configuration changes that can be moved from one instance to another. This feature allows administrators to group a series of changes into a named set and then move them as a unit to other systems for testing or deployment.

If you're an admin, you might work with update sets in ServiceNow Studio to move changes through your instances. Access update sets from within an individual application or from the **Deployment** tab. Most of the ways you can interact with update sets in ServiceNow Studio are very similar to how you would use them on the ServiceNow AI Platform. For more information about tasks you can accomplish with update sets, see System update sets.

Administrators have the following options with update sets.

- Create an update set to store local changes.
- Select the current update set to store local changes.
- Commit an update set to prepare it for distribution.
- Report on the contents of update sets.
- Compare update sets to determine what differences they contain.
- Merge separate update sets into a single update set.
- Create an external file from an update set.
- Retrieve update sets from remote instances.
- Apply retrieved update sets.
- Back out changes applied from an update set.
- Set system properties related to update sets.

Delegated developers have the following options with update sets in ServiceNow Studio.

- Create an update set to store local changes.
- Switch between update sets easily using the update set picker.
- Package changes for deployment using the **Publish** button in any app.

Create an update set

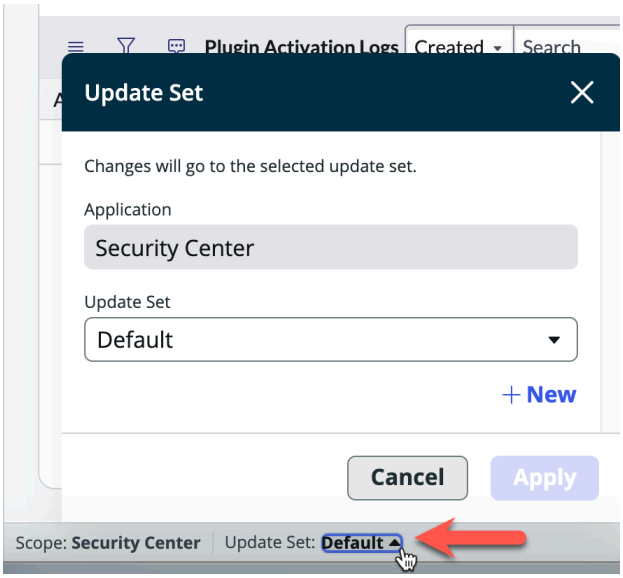
Create an update set to package app changes for deployment in ServiceNow Studio.

Before you begin

Role required: admin or delegated developer

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Open the application that you have changes for that need a new update set.
3. At the bottom-left corner of the canvas, expand the update set dialog by selecting the current update set from the status bar.



4. Select **New**.
5. Enter a name for the new update set.
6. Select **Save**.
7. Select **Apply**.
   The changes you made in your app go to the new update set.

Mark an update set complete in ServiceNow Studio

Mark an update set as **Complete** in ServiceNow Studio to enable your changes to be retrieved by other instances.

Before you begin

Role required: admin or delegated developer

About this task

Only mark an update set as **Complete** when it's ready to migrate. Once an update set is **Complete**, don't change it back to **In progress**. Instead, create another update set for the rest of the changes.

Procedure

1. Navigate to **All** > **App Engine** > **ServiceNow Studio**.
2. Select the **Deployment** tab.
3. Open the update set record you want to change.
4. Change the **State** of the update set from **In progress** to **Complete**.

Working with pipelines in ServiceNow Studio

Pipelines enable you to automate the propagation and installation of your applications from one instance to another. As an admin, you can manage app deployment requests coming from ServiceNow Studio in the App Engine Management Center (AEMC).

Pipelines are powered by the ServiceNow CICD spoke, which enables you to automate processes such as publishing applications to the Application Repository, installing them on target instances, running ATF tests, and running instance scans.

If you're an admin, you might work with pipelines to move changes to your apps through your instances. For more information about configuring pipelines, see Configure Pipelines and Deployments.

If you have the App Engine Management Center (AEMC) installed, you can manage deployment requests that are created when a developer selects **Deploy** in ServiceNow Studio. For more information, see Managing app deployments using Pipelines and Deployments.

Working with the Application Repository in ServiceNow Studio

After you develop and test a custom application in ServiceNow Studio, you can make the application available to company instances by publishing it to the ServiceNow Application Repository. The Application Repository is a central repository for all scoped applications that are published by all ServiceNow customers.

The Application Repository enables you to upload and distribute applications between your instances. When you access the Application Repository, you can see and manage only the applications that are published by your own organization. You can't see or manage applications that are published by other organizations.

After you have developed your app using ServiceNow Studio, successfully tested your app, and selected **Deploy**, you can publish your application to the Application Repository to share it to other instances in your company. For more information about the publishing process, see Publish app changes to the Application Repository from ServiceNow Studio.

For more information, see ServiceNow application repository.

ServiceNow Studio reference

Reference topics provide additional information about the Navigator panel taxonomy, supported file types, properties, and collaboration permissions for ServiceNow Studio.

ServiceNow Studio Navigator panel taxonomy

Learn more about each metadata file type and its corresponding primary table in the File categories tab of the ServiceNow Studio Navigator panel.

Note:
Any additional extensions of the sys_metadata table are automatically included in the Navigator panel in the appropriate section.

For each file category, see the file types that you can create and their corresponding primary table. For more information about navigating to a file's primary table, see Navigate directly to a table in ServiceNow Studio.

Automation files

Automations provide ways to manage recurring tasks efficiently, with fewer steps, reducing human input and effort. For example, you can configure an email notification to be sent automatically when a record is approved. Create automations to streamline and simplify how you work by adding automations to an app, such as actions, flows, and other automatic tasks.

Automation file types

File type	Description	Primary table	Primary editing experience
Action	Actions automate a repeatable task or operation within a flow as a sequence of related steps. Actions run a sequence of steps to complete the task, and pass data to the flow as outputs. For more information, see Exploring actions.	sys_hub_action_type_definition	Workflow Studio
Activity definition	Activity definitions describe how the activities in your playbook get the data that they need when your playbook runs. Each activity definition contains some basic configuration details, as well as an automation plan and activity experience. For more information, see Activity definitions.	sys_pd_activity_definition	UI16
Connection & Credential Aliases	A Connection and Credential alias defines an alias that labels a credential or connection record, enabling an app to connect to another system or component.	sys_alias	UI16

Automation file types (continued)

File type	Description	Primary table	Primary editing experience
	For more information, see Connections and Credentials.		
Datastream	A datastream is a reusable action that processes a stream of response data within a flow. For example, you can create a data stream action to import a large quantity of employee data from a third-party HR site. For more information, see Data Stream actions and pagination.	sys_hub_action_type_definition	Workflow Studio
Decision table	Decision tables decouple decision logic from your code by creating and maintaining decision rules. Decision tables provide a single point where you can create, view, and modify decisions. For more information, see Exploring decision tables.	sys_decision	Workflow Studio
Email Template	Email templates enable administrators to create reusable content for the subject line and message body of email notifications. Admins can add rich text and other items, such as images, to email templates. For more information, see Email templates.	sysevent_email_template	UI16

Automation file types (continued)

File type	Description	Primary table	Primary editing experience
Flow	Flows are automated processes that consist of a trigger and a sequence of reusable actions and flow logic. The trigger specifies when to run the flow. The actions perform a sequence of operations on your data. For example, the Visual Task Boards (VTB) Sample Flow creates and assigns a VTB card whenever a priority 1 incident is created. For more information, see Exploring flows.	sys_hub_flow	Workflow Studio
Notification	Notifications alert users when a record changes. For example, you could get a push notification when a request is rejected. For more information, see System notifications.	sysevent_email_action	UI16
Playbook	Playbooks are sets of automated activities that occur based on a trigger. For example, you can create a playbook for your app to send an email when a request is approved. For more information, see Getting started with Playbooks.	sys_pd_process_definition	Workflow Studio
Subflow	Subflows are processes that consist of a sequence of reusable actions	sys_hub_flow	Workflow Studio

Automation file types (continued)

File type	Description	Primary table	Primary editing experience
	and flow logic, data inputs, and outputs. In contrast to flows, subflows don't have a trigger but instead run when called from a playbook, flow, another subflow, or a script. For more information, see Exploring subflows.		

Client development files

Client development files define operations that occur based on actions you can take when working with an app built in ServiceNow Studio.

Client development file types

File type	Description	Primary table	Primary editing experience
Assignment Data Lookup	Use assignment data lookups to assign a record automatically using Data Lookup and Record Matching. For example, you can automatically set a value in the assigned_to and assignment_group fields for a record when a set of conditions occurs, such as assigning approvals to a group of managers for users below a certain level. For more information, see Defining assignment rules.	dl_u_assignment	UI16
Client Extension Instance	Use a client extension integration to a registered instance of a client extension	sys_client_extension_instance	UI16

Client development file types (continued)

File type	Description	Primary table	Primary editing experience
	point that links a UI script with a client extension point. The UI script is included on pages that invoke the client extension point. For more information, see Using extension points to extend application functionality.		
Client Extension Point	Client extension points extend the functionality of an application without altering the original application code. Extension points can help prevent your custom code interactions from breaking, which often occurs after an upgrade if you directly embed the custom code into the application code. For more information, see Using extension points to extend application functionality.	sys_client_extension_point	UI16
Client Script	Client scripts enable apps on the ServiceNow AI Platform to run JavaScript on the client (web browser) when client-based events occur. For example, it could run when a form loads, after form submission, or when a field changes value.	sys_script_client	UI16

Client development file types (continued)

File type	Description	Primary table	Primary editing experience
	For more information, see Client scripts.		
Data Lookup Definitions	Data lookup definitions are no-code solutions that enable you get attributes from a record on the same table. For example, you can create a data lookup definition to populate an email field automatically when you enter your name. For more information, see Create a catalog lookup definition.	dl_definition	UI16
Priority Data Lookup	Priority data lookups enable you to define the impact and urgency of an incident to calculate how it should be prioritized. For more information, see Define priority lookup rules.	dl_u_priority	UI16
UI Extension Instance	Use a UI extension instance to create a registered instance of a UI extension point that links a UI macro with a UI extension point. The macro can be called whenever the UI extension point is invoked. For more information, see Creating and adding a UI extension point.	sys_ui_extension_instance	UI16

Client development file types (continued)

File type	Description	Primary table	Primary editing experience
UI Extension Point	UI extension points enable you to add custom content to a UI page without having to modify the page directly. You must first create the UI extension points, and then add them to the UI macros in the base application code. For more information, see Using UI extension points in server-side UI macros.	sys_ui_extension_point	UI16
UI Policy	UI policies dynamically change the behavior of information on a form and control custom process flows for tasks. For example, you can use UI policies to make the number field on a form read only, make the short description field required, and hide other fields. For more information, see UI policies.	sys_ui_policy	UI16
UI Script	UI scripts provide a way to package client-side JavaScript into a reusable form, similar to how script includes store server-side JavaScript. For more information, see UI scripts.	sys_ui_script	UI16

Content files

Content files define ways to provide users and systems with information by referring to knowledge articles and other forms of communication. For example, content files can reference knowledge articles, static blocks of text, or external web-based content. Use content files to provide information to apps you're building in ServiceNow Studio.

Content file types

File type	Description	Primary table	Primary editing experience
Audio	Use audio files to upload sounds and recordings that your app can use on the ServiceNow AI Platform. For more information, see Manage audio files.	db_audio	UI16
Detailed content	Use a detailed content block to display the content of an existing document, such as an incident, knowledge article, or service management request. For more information, see Configure a detailed content block.	content_block_detail	UI16
Dynamic content	Dynamic content uses scripting or pulls information from the ServiceNow AI Platform into an app. For example, use dynamic content to create a job posting, where the postings are stored in knowledge articles and displayed in the app with a dynamic block. For more information, see Configure dynamic blocks.	content_block_programmatic	UI16

Content file types (continued)

File type	Description	Primary table	Primary editing experience
iFrames	Use iFrames to embed a URL on a page within a frame. You can embed external pages or render ServiceNow content. For more information, see Configure iFrames.	content_block_iframe	UI16
Images	Upload and store images on the ServiceNow AI Platform to be used in apps and forms. You can then reference images from HTML fields by appending the name of the image to the URL of the instance. For more information, see Storing images in the database.	db_image	UI16
Static content	Use static blocks for text that doesn't change. For example, use a static block for a site footer with only the company or organization name. For more information, see Configure a static HTML block.	content_block_static	UI16

Data files

Data files enable you to use information stored in or referenced by an application in apps built in ServiceNow Studio. Data is the foundation of any app. You can start with a table, or upload spreadsheets and PDFs to get data into the ServiceNow AI Platform for apps to consume.

Data file types

File type	Description	Primary table	Primary editing experience
Form	A form is a content page that displays fields and values for a single record from a database table. For more information, see Forms in Table Builder.	sys_ui_form	Form Builder
Form section	Use sections to design the layout of a form. For example, you can have one column or two. For more information, see Customize your form layout in Table Builder.	sys_ui_section	Form Builder
Many to Many Definition	Use a many to many task to define relationships between different tasks. You can implement one-to-one, one-to-many, and many-to-many relationships. For example, users and roles are a many-to-many relationship because a user can have multiple roles, and multiple users can have any given role. For more information, see Creating many-to-many task relations.	sys_m2m	UI16
Relationship	Use relationships to define how tables interact with each other. You can create relationships between tables by extending tables, referencing	sys_relationship	UI16

Data file types (continued)

File type	Description	Primary table	Primary editing experience
	records in another table, creating many-to-many relationships, and joining tables in a database view. For more information, see Table relationships.		
Table	Tables are the foundation of how the ServiceNow AI Platform stores data. When you view a table as a list, each row is a record, and each column is a field from the record. For example, the Incident table has a record for every customer interaction, or incident. For more information, see ServiceNow AI Platform tables and data and Table Builder.	sys_db_object	Table Builder
Table Column	A table column represents a field from a record. For example, a user record might have a column for first name and a separate column for family name. For more information, see Table properties in Table Builder.	sys_dictionary	UI16

Inbound integration files

Inbound integrations enable you to get information and data onto the ServiceNow AI Platform from another system or source. Inbound integrations enable seamless data flow into ServiceNow from external systems, facilitating efficient communication and integration between systems.

Inbound integration file types

File type	Description	Primary table	Primary editing experience
Data Import	Use data imports to view the all the records that are being processed for an import job and also the import jobs that are awaiting approvals. For more information, see Importing data using import sets and Integration Hub - Import.	sn_ihub_integration_instance	Integration Hub
Data Source	A data source specifies how and where to get the data you want to import. For more information, see Data sources and Configure a data source.	sys_data_source	UI16
Scheduled Data Import	Scheduled data imports specify to import data from data sources using import sets. Transform maps are applied to the imported data before writing the data to the target table. For more information, see Run or schedule a data import.	scheduled_import_set	UI16
Scheduled Data Import	Scheduled data imports specify to import data from data sources. Transform maps are applied to the imported data before writing the data to the target table.	scheduled_data_import	UI16

Inbound integration file types (continued)

File type	Description	Primary table	Primary editing experience
	For more information, see Run or schedule a data import.		
Scripted REST API	Use scripted REST APIs to build custom web service APIs for your application. You can define service endpoints, query parameters, and headers for a scripted REST API, as well as scripts to manage the request and response. For more information, see Scripted REST APIs.	sys_ws_definition	UI16
Scripted Web Service	Scripted web services enable developers to create their own APIs on the ServiceNow AI Platform. Third-party applications use scripted web services to access records in ServiceNow tables. For more information, see Web services.	sys_web_service	UI16
Table Transform Map	Transform maps contain a set of field maps that determine the relationships between fields in an import set and fields in an existing ServiceNow table, such as Incident [incident] or User [sys_user]. After creating a transform map, you can reuse it to map data from another import set to the same table.	sys_transform_map	UI16

Inbound integration file types (continued)

File type	Description	Primary table	Primary editing experience
	For more information, see Transform maps.		

Outbound integration files

Outbound integrations enable you to work with data that comes from the ServiceNow AI Platform and is sent to an external system or source.

Outbound integration file types

File type	Description	Primary table	Primary editing experience
Export Definition	Export definitions determine the data to include in an export set. For more information, see Create an export definition.	sys_export_definition	UI16
Export Set	Export sets define the data to export, as well as the export target to use when exporting data. For example, you can push data from an instance to an external file. For more information, see Create an export set.	sys_export_set	UI16
Export Target	Export targets specify the target file on a MID Server to which the export set data will be written. For more information, see Create an export target.	sys_export_target	UI16
REST Message	A REST message is a record that stores details on how to	sys_rest_message	UI16

Outbound integration file types (continued)

File type	Description	Primary table	Primary editing experience
	interact with an external web service through REST. Use REST messages to send requests to a REST web service endpoint by creating a REST message record. For more information, see Create a REST message.		
Scheduled Data Export	Scheduled data exports specify a schedule when export sets will be run. A single export can be scheduled or regular intervals can be scheduled with support for including only delta records. For more information, see Schedule an export.	scheduled_data_export	UI16
SOAP Message	A SOAP message is a record that stores details on how to interact with an external web service through SOAP. SOAP messages define the remote endpoint, web services description language (WSDL), and authentication settings. For more information, see SOAP message.	sys_soap_message	UI16

MID Server files

Work with management, instrumentation, and discovery (MID) Server files to facilitate communication and data movement between a single ServiceNow instance and external applications, data sources, and services.

MID Server file types

File type	Description	Primary table	Primary editing experience
MID Server Application	The ServiceNow MID Server is a Java application that runs as a Windows service or UNIX daemon on a server in your local network. For more information, see MID Server.	ecc_agent_application	UI16
MID Server Capability Value Test	MID Server capabilities define the specific functions of a MID Server within an IP address range. The capability value can be empty, a single value, or a * (wildcard). You can use value tests to create capabilities that find devices using values without requiring exact string matching. For more information, see MID Server capabilities.	ecc_agent_capability_value_test	UI16
MID Server IP Range	Use MID Server to specify an IP range or the specific IP address of a target. For more information, see Configure an IP address range for the MID Server.	ecc_agent_ip_range	UI16
MID Server Property	Use MID Server properties to define the behavior of one or more MID Servers.	ecc_agent_property	UI16

MID Server file types (continued)

File type	Description	Primary table	Primary editing experience
	For more information, see MID Server properties.		
MID Server File	Use a MID Server script file to synchronize to a connected MID Server. For more information, see Attach a script file to a file synchronized MID Server.	ecc_agent_script_file	UI16
MID Server Script Include	Use MID Server script includes to make REST calls to cloud providers. For more information, see CAPI classes in MID Server script includes.	ecc_agent_script_include	UI16

Mobile App Builder files

Mobile App Builder is a configuration tool to build and manage screens and records that make up workflows within ServiceNow mobile apps. The organizational layout and navigation options in the Mobile App Builder facilitate a faster and more intuitive creation of ServiceNow mobile applications.

Mobile App Builder file types

File type	Description	Primary table	Primary editing experience
Analytics preview	Analytics previews display previews of data visualization charts and single score reports in your launcher screen's analytics section. Analytics previews enable you to verify that your data is tailored for mobile use and communicates	sys_sg_chart	Mobile App Builder

Mobile App Builder file types (continued)

File type	Description	Primary table	Primary editing experience
	the appropriate information for users. For more information, see Create a mobile analytics preview.		
Calendar screen	Calendar screens display a calendar interface and records associated with the selected date. You can use a calendar screen to display dates that are relevant to application records. For example, you can display when tasks are due or when important events take place. For more information, see Calendar screen.	sys_sg_calendar_screen	Mobile App Builder
Chart screen	Chart screens display data visualizations created in the Analytics Center and are displayed in the analytics section of your launcher screen. Adding data visualizations helps you identify trends and turning points through indicator scores and visual representation. For more information, see Chart screen.	sys_sg_chart_screen	Mobile App Builder
Custom map screen	Custom map screens enable you to create maps that display content for specific records.	sys_sg_custom_map_screen	Mobile App Builder

Mobile App Builder file types (continued)

File type	Description	Primary table	Primary editing experience
	For more information, see Configure a map screen.		
Function	Functions determine what actions users can perform in your mobile application. For example, you can create a navigation function that enables users to open a record from a list, or move from an employee user profile screen to a manager user profile screen. For more information, see Mobile functions.	sys_sg_button	Mobile App Builder
Input form screen	Input form screens provide interfaces for users to enter information in mobile applications. For example, you can use input form screens to create or edit records, complete surveys, or any other situation where your users must enter information. For more information, see Input form screen.	sys_sg_parameter_screen	Mobile App Builder
Launcher screen	Launcher screens serve as landing pages or home pages. Using a launcher screen, you can access screens in various formats, search, perform quick actions, and find user information.	sys_sg_applet_launcher	Mobile App Builder

Mobile App Builder file types (continued)

File type	Description	Primary table	Primary editing experience
	For more information, see Launcher screens.		
List screen	List screens display a list of records. Records in list screens appear in a card format, showing a limited selection of the information for the record. For more information, see List screen.	sys_sg_list_screen	Mobile App Builder
Map screen	Map screens display a map with locations that are associated with the records in a data item. For example, map screens can show your users where their assets are located, or which job locations they must travel to. For more information, see Map screen.	sys_sg_map_screen	Mobile App Builder
Mobile App config	Mobile app configs enable you to create customized mobile experiences for the Now Mobile app and Mobile Agent app. For more information, see Configuring the Mobile Platform.	sys_sg_native_client	Mobile App Builder
Mobile web screen	Mobile web screens open an external URL or a relative URL within your instance.	sys_sg_browser_screen	Mobile App Builder

Mobile App Builder file types (continued)

File type	Description	Primary table	Primary editing experience
	For more information, see Mobile web screen.		
Record screen	Record screens display content for a specific single record. You can configure functions on record screens to enable users to make edits and perform actions. For more information, see Record screen.	sys_sg_form_screen	Mobile App Builder

Mobile Card Builder files

Mobile Card Builder files enable you to edit the cards and templates used in applications for iOS and Android.

Mobile Card Builder file types

File type	Description	Primary table	Primary editing experience
Card	Cards are predetermined layouts that can show visuals, text, and data in mobile applications. You can define card elements and specify how elements are arranged within a card. For more information, see Cards and icons.	sys_sg_view_config	Mobile Card Builder
Card template	Card templates are preconfigured layouts or frameworks that determine how information is displayed in mobile application cards. You can use the existing	sys_sg_view_template	Mobile Card Builder

Mobile Card Builder file types (continued)

File type	Description	Primary table	Primary editing experience
	Mobile Card Builder card templates or create your own templates. For more information, see Create a card template with Mobile Card Builder.		

Natural Language Understanding (NLU) files

Natural Language Understanding (NLU) is a model that enables a computer to interpret, analyze, and derive meaning from human language. By creating NLU files, you build and train your application's NLU model to help it recognize user input, or utterances, and determine the corresponding user or system actions.

NLU file types

File type	Description	Primary table	Primary editing experience
NLU Model	A Natural Language Understanding (NLU) model is the collection of utterance examples and their associated intents and entities that an application uses as a reference to infer intents and entities in a new utterance. For more information, see Natural Language Understanding.	sys_nlu_model	UI16

Properties files

Properties files are configurable parameters that enable you to change the behavior of an application without hard-coding the values directly into scripts.

Properties file types

File type	Description	Primary table	Primary editing experience
Message	Messages are the text values used in informational messages, confirmation messages, error messages, and other types of system messages in your application. For more information, see Message table.	sys_ui_message	UI16
System Property	A system property is a way to store important values for an application, like settings or configurations, that you might need in different scripts. Instead of writing these values directly into the script (hard-coding), you can store them as system properties. Creating system properties enables you to update and edit properties in one place, without having to change each script that references the values manually. For more information, see What are application properties? and Available system properties.	sys_properties	UI16
System Property Category	A system property category creates the page layout for an application's system properties.	sys_properties_category	UI16

Properties file types (continued)

File type	Description	Primary table	Primary editing experience
	The system property category page contains all the application properties in a single location. For more information, see Create a system property category.		

Reporting files

Reporting files enable you to create and distribute reports that show the current state of instance data, such as the number of open incidents of each priority.

Reporting file types

File type	Description	Primary table	Primary editing experience
Chart Colors	Chart colors assign a consistent color to a grouping or stacking value in reports and dashboards. The color stays the same across reports regardless of the order of the values. For more information, see Chart colors.	sys_report_chart_color	UI16
Color Definition	Color definitions enable you to maintain consistency in the platform's look and feel by applying defined colors to various UI components, such as buttons, backgrounds, text, and other elements. For more information, see Define system colors for analytics.	sys_report_color	UI16

Reporting file types (continued)

File type	Description	Primary table	Primary editing experience
Dashboard	Dashboards enable you to display performance analytics, reporting, and other widgets on a single screen. You can use dashboards to create a story with data that you can share with other users. For more information, see Create and use dashboards.	pa_dashboards	Dashboard Builder
Metric Definition	A metric measures and evaluates the effectiveness of an application process. For example, a metric could measure the effectiveness of the incident resolution process by calculating how long it takes to resolve an incident. You can define metrics and create reports and dashboards using your metrics definitions. For more information, see Metrics and Define a metric.	metric_definition	UI16
Range	Ranges are defined data intervals that are used in bar and pie charts to segment the data into logical groups. For example, you might create a range to see how many tasks were completed well within the service level	sys_report_range	UI16

Reporting file types (continued)

File type	Description	Primary table	Primary editing experience
	agreement (SLA) and how many tasks elapsed during the SLA. For more information, see Report ranges.		
Report	Reports are tools used to display data visually, enabling you to gain insights, track performance, and make data-driven decisions. For example, you can create and distribute reports that show the current state of instance data, such as the number of open incidents of each priority. For more information, see Exploring reporting.	sys_report	UI16
Scheduled Email of Report	Scheduled emails of reports enable you to generate and distribute scheduled reports via email. For more information, see Schedule emails of reports.	sysauto_report	UI16

Schedules files

Schedules can help you manage the entire life cycle of your application, from setting up maintenance schedules to defining durations and risks for operations.

Schedules file types

File type	Description	Primary table	Primary editing experience
Blackout Schedule	A blackout schedule is a time during which certain activities, such as changes or updates, are restricted to avoid disruptions. You can set up blackout schedules to confirm that critical business operations remain unaffected during high-impact or sensitive times, such as holidays, end-of-quarter financial processing, or other key business events. For more information, see Create blackout and maintenance schedules in Change Management.	cmn_schedule_blackout	UI16
Maintenance Schedule	A maintenance schedule is a time during which planned maintenance activities, such as changes and updates, should take place. Maintenance schedules usually occur during low-impact times to minimize disruptions to business operations. For more information, see Create blackout and maintenance schedules in Change Management.	cmn_schedule_maintenance	UI16
Relative Duration	Relative durations are a duration type available in ServiceNow Studio	cmn_relative_duration	UI16

Schedules file types (continued)

File type	Description	Primary table	Primary editing experience
	that you can select when defining service level agreements (SLAs). Relative durations enable you to calculate how much time you have to work on an SLA by defining the amount of time to wait. For example, you can define a relative duration as three business days by 4pm. For more information, see Define a relative duration and Use a relative duration.		
Risk Conditions	A risk condition is a set of rules or criteria that evaluate the potential risks associated with scheduling activities, such as changes, updates, or maintenance tasks. You can define risk conditions and run risk calculations using The Best Practice - Change Risk Calculator. For more information, see Add or modify risk and impact conditions and Risk conditions and calculation.	risk_conditions	UI16
Schedule	Schedules are rules that include or exclude time for various actions or tasks.	cmn_schedule	UI16

Schedules file types (continued)

File type	Description	Primary table	Primary editing experience
	For more information, see Schedules and Define a schedule.		

Security files

Security files enable you to control who has access to application data and help prevent accidental modification or deletion of data.

Security file types

File type	Description	Primary table	Primary editing experience
Access Control	Access control, or access control lists (ACLs), restrict access to data by requiring users to pass a set of requirements before they can interact with application content. For more information, see Exploring Access Control Lists.	sys_security_acl	UI16
Public Pages	Public pages enable users to see the application content without logging in. For more information, see Make UI pages public or private.	sys_public	UI16
Role	Roles determine what application access is granted to which users. For more information, see Managing roles and Determine What Roles to Create.	sys_user_role	UI16

Server development files

Server development files manage back-end processes in ServiceNow Studio to verify that data is handled appropriately and securely.

Server development file types

File type	Description	Primary table	Primary editing experience
Business Rule	A business rule is a server-side script that runs when a record is displayed, inserted, updated, or deleted, or when a table is queried. You can establish server-side conditions to determine when a business rule script should run and what record operations the business rule applies to. For more information, see Classic Business rules.	sys_script	UI16
Data Policy	Data policies enable you to enforce data consistency by setting mandatory and read-only states for fields. Data policies are similar to UI policies, but UI policies only apply to data entered on a form through the standard browser. Data policies can apply rules to all data entered into the system, including data brought in through import sets or web services and data entered through the mobile UI. For more information, see Data policy.	sys_data_policy2	UI16

Server development file types (continued)

File type	Description	Primary table	Primary editing experience
Event Registration	Events are special records that the system uses to log when certain conditions occur and to take some kind of action in response to the conditions. By registering an event, you can define properties about the event and associate the event with the business rule that fires the event. For more information, see Register an event.	sysevent_register	UI16
Extension Instance	An extension instance is a registered instance of a scripted extension point that links a script include with a scripted extension point. When you want to define custom logic or methods without affecting your original code, you may consider using an extension instance. An extension instance enables you to encapsulate specific logic and functions, making it easier for you to manage, update, and debug your code. For more information, see Using extension points to extend application functionality.	sys_extension_instance	UI16

Server development file types (continued)

File type	Description	Primary table	Primary editing experience
Extension Point	An extension point designates where custom script logic can be incorporated into your code, so that you can integrate customizations and new features without altering the existing code for your application. Data or objects returned by an extension point must conform to requirements that are specified by the application creator. For more information, see Using extension points to extend application functionality.	sys_extension_point	UI16
Fix Script	Fix scripts are server-side JavaScript that run after a custom application is installed or upgraded. You can include fix scripts to make changes that are necessary for the data integrity or product stability of an application. For more information, see Fix scripts and Create a fix script.	sys_script_fix	UI16
Scheduled Script Execution	Scheduled script executions, also known as scheduled jobs, are automated, server-side script logic that execute at a specific time or on a recurring basis. Use scheduled script executions when	sysauto_script	UI16

Server development file types (continued)

File type	Description	Primary table	Primary editing experience
	application processes require script logic to be executed based on a time schedule. For more information, see What is a Scheduled Script Execution? and Creating a Scheduled Script Execution.		
Script Action	A script action is server-side JavaScript that is executed when a particular event is generated. For more information, see Script actions	sysevent_script_action	UI16
Script Include	Script includes are reusable, server-side JavaScript that define a function or class and execute only when explicitly called. For more information, see Script includes and Script Includes.	sys_script_include	UI16
UI Action	UI actions are configurations that define the behavior of buttons, links, or context menu items in your application, specifying how they interact with the server-side database. For more information, see UI actions and Create a UI action.	sys_ui_action	UI16

User interface files

User interface files define layouts for pages, modules, and tools that users interact with. Some examples of user interface files include catalog items, guided tours, and themes.

User interface file types

File type	Description	Primary table	Primary editing experience
Application Menu	An application menu is a grouping of modules as they appear in the application navigator (UI16) or **All** menu (Next Experience). You can refer to an Application menu as simply an application. For more information, see Enable or disable an application menu or module.	sys_app_application	UI16
Assessment Metric	In the Assessments application, a metric is a trait or value used to evaluate assessable records. For more information, see Assessment metrics.	asmt_metric	Survey Designer
Catalog	A catalog is a section of the Service Catalog where users can order items and services. A catalog is like a portal where your users can request catalog items such as service and product offerings. For example, a hardware catalog may have items to request a new keyboard or a new mouse device. For more information, see Exploring Service Catalog.	sc_catalog	Catalog Builder

User interface file types (continued)

File type	Description	Primary table	Primary editing experience
Catalog Item	A catalog item is essentially a form that describes a good or service you can order in the service catalog. For example, if you're requesting time off using a catalog item, you may enter your name and requested dates off on the form. For more information, see Service Catalog items.	sc_cat_item	UI16
Context Menu	The context menu for a form provides controls for a list or form based on the table and user access rights. For more information, see Form context menu.	sys_ui_context_menu	UI16
Embedded Help	Embedded Help provides targeted help content to a user in a UI page, based on their role. Some embedded help content comes with the base instance. Your organization can add or replace embedded help content. For more information, see Embedded Help.	sys_embedded_help_content	UI16
Embedded Help Qualifier	An Embedded Help qualifier is an identifier that helps a ServiceNow instance identify the correct	sys_embedded_help_qualifier	UI16

User interface file types (continued)

File type	Description	Primary table	Primary editing experience
	Embedded Help topic when there could be more than one topic for a UI page. For more information, see Use qualifiers in Embedded Help.		
Guided Tour	Guided Tours contain a series of interactive steps that help users complete online tasks within their browser window to help train and onboard users working in a ServiceNow app. For more information, see Guided tours.	sys_embedded_tour_guide	UI16
List	Lists display a set of records from a table, and can be filtered to refine the contents. For example, you can filter the Task list to show only Unassigned tasks. Each row in a list is a record, and each column is a field from the record. For more information, see Lists in the classic environment and List administration.	sys_ui_list	UI16
List Control	List controls are settings that specify which features are available on a list, such as the **New** and **Edit** buttons. For more information, see Configure list controls.	sys_ui_list_control	UI16

User interface file types (continued)

File type	Description	Primary table	Primary editing experience
Map Page	Map pages display ServiceNow data graphically on a Google map page based on location data that you provide. For more information, see Map pages.	cmn_map_page	UI16
Module	A module is any link in the application navigator (UI16) or **All** menu (Next Experience) that opens a page in the content frame or in a separate tab or window. For more information, see Modules on the Developer Site.	sys_app_module	UI16
Page Collection	Page Collections are groups of pages that can be reused across multiple experiences. For more information, see Page collections.	sys_ux_extension_point	UI Builder
Portal	Portals provide users with access to the services, information, and resources they need to get their work done quickly and efficiently. Work with portals in UI Builder. For more information, see Configure UI Builder portal experiences.	sys_ux_page_registry	UI Builder
Record Producer	Record producers are catalog items that	sc_cat_item_producer	Catalog Builder - Record producer

User interface file types (continued)

File type	Description	Primary table	Primary editing experience
	enable users to create task-based records, such as incident records, from the service catalog. For more information, see Record Producer.		
Related List	Related lists appear on forms and show records in tables that have relationships to the current record. For more information, see Related lists.	sys_ui_related_list	UI16
Schedule Page	A schedule page is a record that contains a collection of scripts that enable custom generation of a calendar or timeline display. For more information, see Schedule Pages.	cmn_schedule_page	UI16
Service Portal	Service Portal enables you to build a mobile-friendly self-service portal experience for your employees or customers. For more information, see Service Portal.	sp_portal	Service Portal
Style	Styles define properties such as font size, border, and alignment for text that appears in your app. For more information, see Create a Next Experience style	sys_ui_style	UI16

User interface file types (continued)

File type	Description	Primary table	Primary editing experience
	and Style - Scoped, Global.		
Template	Templates enable administrators to create reusable content. For example, an email template could have a reusable subject line and message body for email notifications. Form templates simplify the process of submitting new records by populating fields automatically. For more information, see Email templates, Form templates, and Page templates.	sys_template	UI16
Theme	Themes enable you to tailor the visual experience for your users, helping to update the look and feel to be more like your brand. For more information, see Working with themes in Next Experience.	sys_ui_theme	UI16
Timeline Page	Use timeline pages to track any activity bounded by two dates, such as change request start and end dates, or incident open and close dates. For more information, see Timeline pages.	cmn_timeline_page	UI16
UX App Configuration	UX app configuration files store	sys_ux_app_config	UI16

User interface file types (continued)

File type	Description	Primary table	Primary editing experience
	configuration settings for specific applications built with UI Builder. For more information, see UI Builder.		
UX Application	Use UX application files to register and manage pages in UI Builder. For more information, see UI Builder.	sys_ux_page_registry	UI16
View Rule	Use view rules to force a specified view when users access a page or application. For more information, see Create a view rule.	sysrule_view	UI16
Workspace	Workspaces are spaces that provide agents and managers with tools to help answer customer questions and resolve customer problems. Workspaces are primarily used for request and fulfillment processes, such as a service desk to manage tickets. For more information, see Configurable Workspace UI and Add a workspace.	sys_ux_page_registry	Workspace Builder

ServiceNow Studio properties

System properties control system behavior. The properties in this section are specific to the ServiceNow Studio application and delegated development deployment. You can access system properties for ServiceNow Studio by navigating to **All** > **sys_properties.list**.

System properties

System property	Description
com.snc.dd.manage_update_set_enabled	Enables or disables display of the **Manage Update Set** permission. • Type: true | false • Default value: false • To enable the display of this permission, set this value to **true**. Delegated developers cannot see the update sets list unless granted permissions via the system property shown.
com.snc.dd.publish_to_app_repo_enabled	Enables or disables display of the **Publish To App Repo** permission. • Type: true | false • Default value: true • To disable display of this permission, set this value to **false**.
com.snc.dd.publish_to_app_store_enabled	Enables or disables display of the **Publish To App Store** permission. • Type: true | false • Default value: true • To disable display of this permission, set this value to **false**.
com.snc.dd.publish_to_update_set_enabled	Enables or disables display of the **Publish To Update Set** permission. • Type: true | false • Default value: false, which disables display of this permission. • To enable the display of this permission, set this value to **true**.
com.snc.dd.upgrade_app_enabled	Enables or disables display of the **Upgrade App** permission. • Type: true | false • Default value: true • To disable display of this permission, set this value to **false**.
sn_devstudio.servicenow_studio_banner.enable	Shows the banner for navigating to ServiceNow Studio from App Engine Studio or

System properties (continued)

System property	Description
	legacy Studio. Change this property to false to hide the banner. • Type: true | false • Default value: true • Location: System Properties [sys_properties] table

ServiceNow Studio supported file types using code search

ServiceNow Studio supports the following file types when using code search.

When using code search in ServiceNow Studio, the application uses the default code search group. The following table outlines the file types that are supported when using the default ServiceNow Studio code search.

Tip:
If your company wants to expand the list of supported file types used in code search, an administrator can create a new code search group that includes additional file types. For more information about expanding code search, see Expand code search tables.

Supported file types for code search

File type	Code search table name	Description
Access control	sys_security_acl	Determines whether access is granted for a specified operation to a specific entity, such as: • Type of entity being secured • Operation being secured • Unique identifier describing the object
Business rules	sys_script	Customize system behavior. • Business Rules run when a database action occurs (query, insert, update, or delete). • The script can run: ○ before or after the database action is performed (runs as part of the database operation).

Supported file types for code search (continued)

File type	Code search table name	Description
		○ asynchronously (at some point after the database operation). ○ on display (when displaying the data in a form).
Client scripts	sys_script_client	Used for changing the appearance of forms, displaying different fields based on values that are entered or other custom display options. • onLoad means that the Client Script runs when the form or page is loaded • onChange means that the Client Script runs when something specific gets changed AND also when the form or page loads • onSubmit means that the Client Script runs when the form is submitted Client Scripts can also be called by other scripts or modules, including UI policies.
Email templates	sysevent_email_template	Enable administrators to create reusable content for the subject line and message body of email notifications.
Inbound email actions	sysevent_in_email_action	Script how the system responds to inbound emails.
Map pages	cmn_map_page	Display ServiceNow data graphically on a Google map page based on location data that you provide.
Map transforms	sys_transform_map	Used for importing data. Transform maps:

Supported file types for code search (continued)

File type	Code search table name	Description
		• Define mapping relationships between tables. • Can use business rules, other scripts, or other options to import data.
Notifications	sysevent_email_action	Determine how an application communicates with users and alerts them about important application-related events.
Processors	sys_processor	Provide customizable URL endpoints that can execute arbitrary server-side JavaScript code and produce output such as TEXT or JSON.
Relationships	sys_relationship	Used to extend tables, reference records in another table, create many-to-many relationships, and join tables in a database view.
Scheduled script executions	sysauto_script	Define automated, server-side script logic that executes at a specific time or on a recurring basis. Scheduled script executions are also referred to as scheduled jobs.
Script actions	sysevent_script_action	Contain scripts that run when an event occurs, for example: • Approval is canceled • Change is approved • Problem is assigned
Script includes	sys_script_include	Contain scripts that can be functions or classes. These scripts run only when called by other scripts, often business rules. Any server script that is complicated or reusable should be a Script Include, especially complicated business rules.
Schedule items	sys_trigger	Contain the back-end data for the System scheduler, where scheduled jobs are created,

Supported file types for code search (continued)

File type	Code search table name	Description
		queued up, and executed. Schedule items can execute scheduled jobs, business rules, inactivity monitors, service level agreement (SLA) calculations, metric events, upgrades, and more. You can access schedule item records to troubleshoot scheduling.
UI actions	sys_ui_action	Include the buttons, links, and context menu items on forms and lists. Configure UI actions to make the UI more interactive, customized, and specific to user activities.
UI macros	sys_ui_macro	Contain discrete scripted components that administrators can add to the user interface. UI macros are typically controls that provide inputs or information that is not provided by existing field types. By default, the system provides UI macros for a variety of user interface elements.
UI pages	sys_ui_page	Used to create and display forms, dialogs, lists, and other UI components.
UI policies	sys_ui_policy	Define the behavior and visibility of fields on a form. Fields can be one of the following: • Mandatory • Visible • Read only The following apply to usage: • UI policies are always attached to one table. • UI policies often have a condition that must be true for them to run.

Supported file types for code search (continued)

File type	Code search table name	Description
UI scripts	sys_ui_script	Contains client scripts stored for reuse. Only used when called from other scripts.
UI style	sys_ui_style	Enables you to declare individual CSS styles for a field in a list or form.
Widgets	sp_widget	Describe objects that contain content and can be added to or embedded in portal pages. You can use the base system widgets provided with the Service Portal, clone and modify widgets, or develop custom widgets to fit your own needs.

Collaboration permissions for ServiceNow Studio

Collaboration permissions determine what delegated developers can do when working on an app in ServiceNow Studio. They can be set by an admin or the app owner.

For more information, see Collaborating on apps using ServiceNow Studio.

File types custom collaboration permissions

File type collaboration permissions

Permission	Description	Owner default setting	Editor default setting
All File Types	Grants access to work with all types of files, including additional file types not granted by the other options.	Yes	Yes
Integrations	Grants access to web service APIs, REST APIs, data sources, and Integration Hub - Import.	Yes	Yes
Reporting	Grants access to reports and scheduled reports.	Yes	Yes
Mobile builders	Grants access to build mobile experiences, such as with Mobile App Builder.	Yes	Yes
UI Builder	Grants access to work with UI Builder to build	Yes	Yes

File type collaboration permissions (continued)

Permission	Description	Owner default setting	Editor default setting
	out more complex interfaces.		
Workflow	Grants access to Workflow Editor and Activity Creator.	Yes	Yes
Service Portal	Grants access to work with Service Portal editors and tools.	Yes	Yes
Workflow Studio	Grants access to the Workflow Studio design environment to create flows and actions.	Yes	Yes
Service Catalog	Grants access to work with catalog-related file types such as catalog items, record producers, and variables to add catalog items to apps.	Yes	Yes
Tables & forms	Grants access to model and layout-related file types such as table columns, form layout, and list layout.	Yes	Yes
Decision Tables	Grants access to work with decision tables to create decision logic based on multiple if-else rules.	Yes	Yes
Playbooks	Grants access to work with the Playbooks design environment to create processes. Editing activity subflows or actions requires the **Flow Designer** permission.	Yes	Yes
Notifications	Grants access to create automatic email notifications and work with email templates.	Yes	Yes

Security/Entitlement custom collaboration permissions

Manage access control grants access to security management files, such as Access Control Lists and roles.

The default setting for both owners and editors is selected.

Programming tools custom collaboration permissions

Allow scripting grants access to script fields, such as those in Business Rule, UI Action, and Client Script.

The default setting for both owners and editors is de-selected.

Application management custom collaboration permissions

Application management collaboration permissions

Permission	Description	Owner default setting	Editor default setting
Delete application	Grants access to delete the app.	Yes	No
Manage collaborators	Grants access to change the developers and their permissions to collaborate on an app.	Yes	No
Source control	Grants access to work with source control tool integrations.	No	No
Invite collaborators	Grants access to invite developers to collaborate on an app.	Yes	Yes

Deployment custom collaboration permissions

Deployment collaboration permissions

Permission	Description	Owner default setting	Editor default setting
Upgrade app	Grants access to upgrade applications.	No	No
Submit for deployment	Grants access to request deployment for an app.	Yes	No
Publish app to repo	Grants access to publish the app to your repo.	No	No
Publish to app store	Grants access to publish the app to your app store.	No	No

Building pro-code applications

Create and manage custom applications from scratch using classic pro-code tools.

ServiceNow Studio

Use ServiceNow Studio to build apps and app files with integrated tools, access and edit metadata in scoped and global apps, and package app changes for deployment, all in one powerful development tool.

ServiceNow IDE

ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform. With the ServiceNow IDE, you can create and develop scoped applications in source code, create JavaScript modules, and use third-party libraries.

ServiceNow SDK

ServiceNow SDK enables developers to create scoped applications in source code locally in Visual Studio Code Desktop and upload changes to a ServiceNow instance. You can also use the ServiceNow SDK to create JavaScript modules and use third-party libraries.

ServiceNow Extensions for Visual Studio Code

The ServiceNow extensions for VS Code editor enables you to edit applications offline and within ServiceNow instances.

Which builder should I use to create an app?

Types of builders

Want to build an app easily, without code?

Creator Studio specializes in helping you craft request-fulfillment applications without writing code. For example, an application to request office supplies by filling out a form, and someone approves or denies your request. For more information, see Exploring Creator Studio.

Need a more general app but still want low-code options?

App Engine Studio lets you build a broader range of apps than Creator Studio without being a programming pro. For more information, see Exploring App Engine Studio.

Are you a developer who wants more control in a centralized user interface?

Build apps smarter and deliver them faster with the new ServiceNow Studio. ServiceNow Studio empowers platform developers with a modern, unified environment for building on the ServiceNow AI Platform. ServiceNow Studio features streamlined navigation to applications and metadata, integrated low-code tools, efficient tracking and packaging of development work that accelerates development processes and enhances productivity. For more information, see Exploring ServiceNow Studio.

Are you a developer who wants to use industry-standard development tools and processes?

The ServiceNow IDE and ServiceNow SDK support developing applications in source code with ServiceNow Fluent, creating JavaScript modules, and using third-party libraries. ServiceNow Fluent is a domain-specific programming language for creating application metadata in code.

The ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform. The ServiceNow SDK uses Visual Studio Code Desktop locally. For more information, see Building applications in source code.

Scripting

Action Designer

Use Workflow Studio to automate a repeatable task within a flow as a sequence of related steps. Enable flow authors to add actions to multiple flows with minimal configuration.

Client-side scripting

Client scripts enable the system to run JavaScript on the client (web browser) when client-based events occur, such as when a form loads, after form submission, or when a field changes value.

Now Assist for code generation

Now Assist for code generation allows developers to write scripts quickly with AI-generated code suggestions based on text or code prompts.

Now Code Editor

Now Code Editor provides a rich-text editor interface that supports Cascading Style Sheets (CSS), Hypertext Markup Language (HTML), JavaScript, Extensible Markup Language (XML), and JavaScript Object Notation (JSON). Use Now Code Editor to modify UI configuration, data resource configuration, styles, events, client-side and server-side scripts in Next Experience UI Builder components.

Server-side scripting

Server scripts run on the server or database. They can change the appearance or behavior of the ServiceNow AI Platform or run as business rules when records and tables are accessed or modified.

Core functionality

Groups

Simplify user administration by assigning roles to groups. Any business rules, assignment rules, system roles, or attributes that refer to the group apply to all group members automatically.

Notifications

Use ServiceNow Notifications to manage system email, create system notifications, and configure how your system responds to inbound email.

Roles

Roles control access to features and capabilities in applications and modules. The admin role provides access to all features and capabilities.

ServiceNow plugins

Plugins are software components that provide specific features and functionalities within a ServiceNow instance.

UI policies

UI policies dynamically change the behavior of information on a form and control custom process flows for tasks.

Users

User records establish a relationship between an individual and your ServiceNow instance. User records consist of a user name, a password, and information relating to the individual, such as contact information, location, and job title.

Related applications and features

JavaScript APIs

Use JavaScript APIs in scripts that you write to change the functionality of applications, or when you create new applications.

UI Builder

Use UI Builder to build web user interfaces for CSM Configurable Workspace, App Engine Studio generated workspaces and portals, or custom web experiences using Next Experience Components and custom web components.

Building applications in source code

Create and develop custom applications in source code using familiar development tools and processes.

Overview of development in source code

You can create scoped applications in code using the ServiceNow IDE on the ServiceNow AI Platform or locally in Visual Studio Code Desktop with the ServiceNow SDK.

In either development environment, you use ServiceNow Fluent, a domain-specific programming language, to define the metadata that makes up applications. ServiceNow Fluent includes APIs for defining the different types of metadata.

With the ServiceNow IDE or ServiceNow SDK, you can also create JavaScript modules and use third-party libraries in your application to optimize code reuse in scripts within a scoped application.

Developing and maintaining applications in source code enables you to work in familiar development environments, create and modify complex applications, manage code in source control more easily, and catch errors at build time.

Note:
The ServiceNow IDE and ServiceNow SDK don't support the Global scope or global applications in the Xanadu release.

ServiceNow IDE

Develop applications in code in an IDE on the ServiceNow AI Platform.

ServiceNow SDK

Develop applications in code locally and upload changes to an instance.

Comparison of the ServiceNow IDE and the ServiceNow SDK

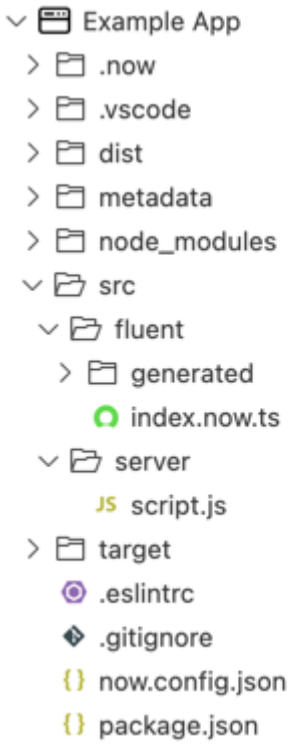
Feature	ServiceNow IDE	ServiceNow SDK
Development environment	Online ServiceNow instance	Local development and the ability to work offline
User interface	IDE based on Visual Studio Code for the Web	Visual Studio Code Desktop
Collaboration	View any user's changes in real time in code or embedded ServiceNow AI Platform user interfaces from the Metadata Explorer. Collaborate with other developers on applications in source control.	Download changes from an instance and install local changes to an instance using the ServiceNow SDK CLI to collaborate with other users. Collaborate with other developers on applications in source control.
Source control	Supports the most common Git functionality and integrating with a Git provider of your choice. One concurrent branch per repository per instance (or developer sandbox).	Full support
Application conversion	Support for converting existing scoped applications not created with the ServiceNow IDE or ServiceNow SDK.	Support for converting existing scoped applications not created with the ServiceNow IDE or ServiceNow SDK.
ServiceNow Fluent	Full support The ServiceNow Fluent Language server is included with the ServiceNow IDE.	Full support The ServiceNow Fluent Language server can be installed from the Visual Studio Code Extension Marketplace.

Feature	ServiceNow IDE	ServiceNow SDK
JavaScript modules and third-party libraries	Full support	Full support
Now Assist for Code	Code auto-complete support for scripts. For information about activation, see Now Assist for code generation.	Not supported

Application structure

Custom scoped applications created with the ServiceNow IDE or ServiceNow SDK include source code files and metadata XML files. The `package.json` and `now.config.json` files define the application structure, which is similar to that of Node.js applications or Node Package Manager (npm) packages.

Default structure of an application created in the ServiceNow IDE



By default, applications include the following directories and files. You can modify certain aspects of the application structure to suit your needs in the `now.config.json` file.

.vscode

Directory containing recommended Visual Studio Code extensions.

dist

Directory containing the build artifacts for packaging. This directory includes the following subdirectories:

- `app`: Directory containing the built metadata XML files.
- `static`: Directory containing the built static asset files.

metadata

Directory containing the application metadata (XML) of the application, such as table schemas and business rules, organized in the same directory structure as existing ServiceNow applications.

> **Note:**
> Application metadata shouldn't be edited from the XML files. Edit application metadata in the source code or on the ServiceNow AI Platform.

node_modules

Directory containing the third-party Node.js modules on which your application depends.

src

Directory containing the source code of your application. This directory includes the following subdirectories:

- `client`: Directory containing the client-side files for developing user interfaces.
- `fluent`: Directory containing ServiceNow Fluent code in `.now.ts` files. The `generated` subdirectory contains the application files converted to ServiceNow Fluent.
- `server`: Directory containing JavaScript module code in `.js` or `.ts` files.

target

Directory containing an installable package (`.zip` file) to upload to an instance.

.eslintrc.json

File containing the ESLint configuration. ESLint helps identify and fix issues in the application code.

.gitignore

File containing a list of directories or files for Git to ignore. These files aren't tracked in source control.

now.config.json

File containing the ServiceNow application configuration. The `now.config.json` file must be in the base directory for an application.

You can configure the directory structure for an application by adding the following parameters. For example:

```
{
   "scope" :  "x_snc_example_app",
   "scopeId" :  "2f8400eb07426110f736e28f69d3017a",
   "name" :  "ExampleApp",
   "dependencies": {
  "global": {
   "tables": ["incident"],
   "roles": ["admin"],
  },
  "x_custom": {
   "tables": ["custom_table"]
  }
 },
   "metadataDir" :  "metadata",
   "fluentDir" :  "src/fluent",
   "generatedDir" :  "generated",
   "serverModulesDir" :  "src/server",
```

```
  "clientDir": "src/client",
  "appOutputDir": "dist/app",
  "staticContentDir": "dist/static",
  "packOutputDir": "target",
  "modulePaths": {
        "src/server/*.ts": "dist/server/*.js",
    },
  "staticContentPaths": {
        "src/client/*.html": "dist/static/*.html",
    },
  "ignoreTransformTableList":
 ["ua_table_licensing_config", "sys_embedded_help_role"],
  "taxonomy":{
   "mapping":{
     "sys_script": "scripts/server/rules",
     "custom_table": "my-custom-folder/my-nested-folder"
   },
   "fallbackFolderName": "unclassified"
  }
}
```

Supported now.config.json parameters

Parameter	Description
dependencies	The items in another application scope on which your application depends. You must specify the application scope and the dependency type and names or sys_ids. `"dependencies": { "<scope>": { "<type>": ["<sys_id or name>"], ... }, ... }` For more information, see Download ServiceNow Fluent application dependencies.
metadataDir	Directory containing the application's metadata as XML files. Default: `metadata`
fluentDir	Directory containing ServiceNow Fluent files (`.now.ts`) that define application metadata in source code. Default: `src/fluent`
generatedDir	Directory containing generated ServiceNow Fluent files, including existing application metadata converted into ServiceNow Fluent code. This directory is relative to the directory defined with the *`fluentDir`* parameter. Default: `generated`
serverModulesDir	Directory containing the JavaScript or TypeScript files to be built into JavaScript modules for use in server-side scripts.

Supported now.config.json parameters (continued)

Parameter	Description
	Default: `src/server`
clientDir	Directory containing the client-side files for developing user interfaces with React. Default: `src/client`
appOutputDir	Directory to output the build artifacts to for packaging. The pack and install commands refer to this directory package the artifacts. Default: `dist/app`
staticContentDir	Directory to output the static asset files used for developing user interfaces. Default: `dist/static`
packOutputDir	Directory to output the installable package (`.zip` file) when building the application. The install command refers to this directory to install the package. Default: `target`
serverModulesIncludePatterns	A list of file patterns to include when building JavaScript modules. Default: `[ "**/*.ts", "**/*.tsx", "**/*.js", "**/*.jsx", "**/*.cts", "**/*.cjs", "**/*.mts", "**/*.mjs", "**/*.json" ]`
serverModulesExcludePatterns	A list of file patterns to exclude when building JavaScript modules. Default: `[ "**/*.test.ts", "**/*.test.js", "**/*.d.ts" ]`

Supported now.config.json parameters (continued)

Parameter	Description
trustedModules	A list of npm packages to identify as trusted (or internal). Trusted modules have access to ServiceNow APIs. For example: `"trustedModules": [ "<package-name>", // Specific package "@servicenow/*" // All packages from an organization ]` In the EcmaScript Module [sys_module] table, the **External source** field is set to false for trusted modules. **⚠ Warning:** Only add dependencies that you trust completely as trusted modules. Valid patterns: • Fully qualified package names, such as `'@servicenow/sdk'`. • Organization prefixes with a wildcard, such as `'@servicenow/*'` or `'@mycompany/*'`.
modulePaths	A map of the module source files to their equivalent output files for if you use a custom transpilation step before building the application. For more information, see Using TypeScript in JavaScript modules with the ServiceNow SDK. **⚠ Warning:** You can't use this parameter and the `tsconfigPath` parameter. Configuring both results in an error.
staticContentPaths	A map of the client-side source files to the output paths for static asset files.
tsconfigPath	A path to a `tsconfig.json` file with custom options for transpiling TypeScript into JavaScript during the build process. Specifying a `tsconfigPath` generates diagnostic results from TypeScript using the `tsconfig.json` file. **⚠ Warning:** You can't use this parameter and the `modulePaths` parameter. Configuring both results in an error. Default: .
ignoreTransformTableList	A list of tables to ignore when transforming application metadata into source code.
tableDefaultLanguage	The BCP 47 code of a default language for field labels [sys_documentation] in a table or column. Th default language is used to resolve field labels with multiple languages.

Supported now.config.json parameters (continued)

Parameter	Description
	Default: en
tableOutputFormat	The type of build artifacts for table metadata XML generated from ServiceNow Fluent code. Valid values: • bootstrap: The build process outputs a bootstrap XML file with the `<database>` root element for the table, field label XML files [sys_documentation], licensing configuration XML files [ua_table_licensing_config], and auto-numbering XML files [sys_number]. • component: The build process outputs XML files for each component of the Table API. Default: `bootstrap`
taxonomy	A configuration for organizing generated ServiceNow Fluent files, which maps table names to directories and defines a fallback directory. The default taxonomy configuration uses ServiceNow standard table classifications to add generated ServiceNow Fluent files in a logical directory structure within the `fluent/generated` directory when metadata is initially transformed into ServiceNow Fluent code. For example: • Business rules [sys_script] are added to the `fluent/generated/server-development/business-rule` directory. • Script includes [sys_script_include] are added to the `fluent/generated/server-development/script-include` directory. You can override the default mappings or configure additional ones. In the following example, the configuration overrides the default directory for business rules [sys_script] and the fallback folder and configures an additional mapping for metadata from a custom table. `"taxonomy": { "mapping": { "sys_script": "scripts/server/rules", "custom_table": "my-custom-folder/my-nested-folder" }, "fallbackFolderName": "unclassified" }` • mapping: An object that maps table names to directories. Directory paths are relative to the directory configured with the *`generatedDir`* parameter and must include only lowercase letters, numbers, hyphens, underscores, and slashes to separate subdirectories.

Supported now.config.json parameters (continued)

Parameter	Description
	• fallbackFolderName: A name for a directory to use for tables that don't have a default or a custom mapping configured. Within this directory, ServiceNow Fluent files are added to subdirectories named after the table, such as `src/fluent/generated/other/x-unmapped-table/`. Default: Default taxonomy mappings are defined for all standard ServiceNow tables and are automatically applied when no custom configuration is defined in the `now.config.json` for an application. The default value of *`fallbackFolderName`* is `other`.

now.prebuild.mjs

Auto-updated file containing complete information about dependencies and their versions. This file is only available with the ServiceNow SDK.

package-lock.json

Auto-updated file containing complete information about dependencies and their versions. This file is only available with the ServiceNow SDK.

package.json

File containing information about your application and custom or third-party module dependencies. The `package.json` file must be in the base directory for an application. On an instance, the `package.json` path is specified in the **Package JSON** field of the custom application record [sys_app] in the format `<scope>/<package-name>/<version>/package.json`.

Related applications and features

JavaScript APIs

Use JavaScript APIs in scripts that you write to change the functionality of applications or when you create applications.

Related topics

ServiceNow Fluent

JavaScript modules and third-party libraries

User interface development with React

ServiceNow Fluent

Define application metadata in source code using the ServiceNow Fluent domain-specific programming language.

Overview of ServiceNow Fluent

ServiceNow Fluent is a domain-specific language (DSL) based on TypeScript for defining the metadata files [sys_metadata] that make up applications and includes APIs for the different types of metadata, such as tables, roles, ACLs, business rules, and Automated Test Framework tests.

Developers define this metadata in a few lines of code instead of through a form or builder tool user interface. Applications created or converted with the ServiceNow IDE or ServiceNow SDK support development in ServiceNow Fluent.

ServiceNow Fluent supports two-way synchronization, which allows changes to metadata to be synced from other ServiceNow AI Platform user interfaces into source code and changes to source code to be synced back to metadata across the instance.

To get started using the ServiceNow IDE or ServiceNow SDK, see the ServiceNow IDE or ServiceNow SDK documentation.

ServiceNow Fluent APIs

ServiceNow Fluent includes APIs for the following types of metadata. You can use the Record API to define application metadata that doesn't have a dedicated API.

For details about the APIs and examples, see ServiceNow Fluent API reference and the ServiceNow SDK examples GitHub repository.

- Access control lists (ACLs)
- Application menus
- Automated Test Framework tests
- Business rules
- Client scripts
- Cross-scope privileges
- Dashboards
- Email notifications
- Flows
- Import sets
- Lists
- Properties
- Records
- Roles
- Script actions
- Script includes
- Scripted REST APIs
- Service level agreements (SLAs)
- Service portal widgets
- Tables
- UI actions
- UI pages
- UI policies
- Workspaces

Note:
A limited number of metadata types, such as Metadata Snapshots [sys_metadata_link] and UX Assets [sys_ux_lib_asset], can't be represented as ServiceNow Fluent code and aren't transformed. These metadata types remain as metadata XML files in the `metadata` directory of your application.

ServiceNow Fluent usage

In files with the `.now.ts` extension, use objects in the ServiceNow Fluent APIs to define metadata in the application. You must also include the required imports for the APIs from `@servicenow/sdk/core`. For objects with server-side scripts, such as the *`BusinessRule`* object, you can import and use code from JavaScript modules.

The following example includes the definitions of a table, client script, and business rule in the application. The client script uses a script from the `client-script.js` file. The business rule uses a function from the `script.js` JavaScript module.

```
import '@servicenow/sdk/global'
import { BusinessRule, ClientScript, DateColumn, StringColumn,
 Table } from '@servicenow/sdk/core'
import { showStateUpdate } from '../server/script.js'

//creates todo table, with three columns (deadline, status and task)
export const x_snc_example_to_do = Table({
    name: 'x_snc_example_to_do',
    schema: {
        deadline: DateColumn({ label: 'Deadline' }),
        state: StringColumn({
            label: 'State',
            choices: {
                ready: { label: 'Ready' },
                completed: { label: 'Completed' },
                inProgress: { label: 'In Progress' },
            },
        }),
        task: StringColumn({ label: 'Task', maxLength: 120 }),
    },
})

//creates a client script that pops up 'Table loaded successfully!!' message everytime todo
 record is loaded
ClientScript({
    $id: Now.ID['cs0'],
    name: 'my_client_script',
    table: 'x_snc_example_to_do',
    active: true,
    appliesExtended: false,
    global: true,
    uiType: 'all',
    description: 'Custom client script generated by Now SDK',
    isolateScript: false,
    type: 'onLoad',
    script: Now.include('../client/client-script.js'),
})

//creates a business rule that pops up state change message whenever a todo record is
 updated
```

```
BusinessRule({
    $id: Now.ID['br0'],
    action: ['update'],
    table: 'x_snc_example_to_do',
    script: showStateUpdate,
    name: 'LogStateChange',
    order: 100,
    when: 'after',
    active: true,
})
```

The client script referenced from the *ClientScript* object:

```
function onLoad() {
    g_form.addInfoMessage("Table loaded successfully!!")
}
```

The JavaScript module referenced from the *BusinessRule* object:

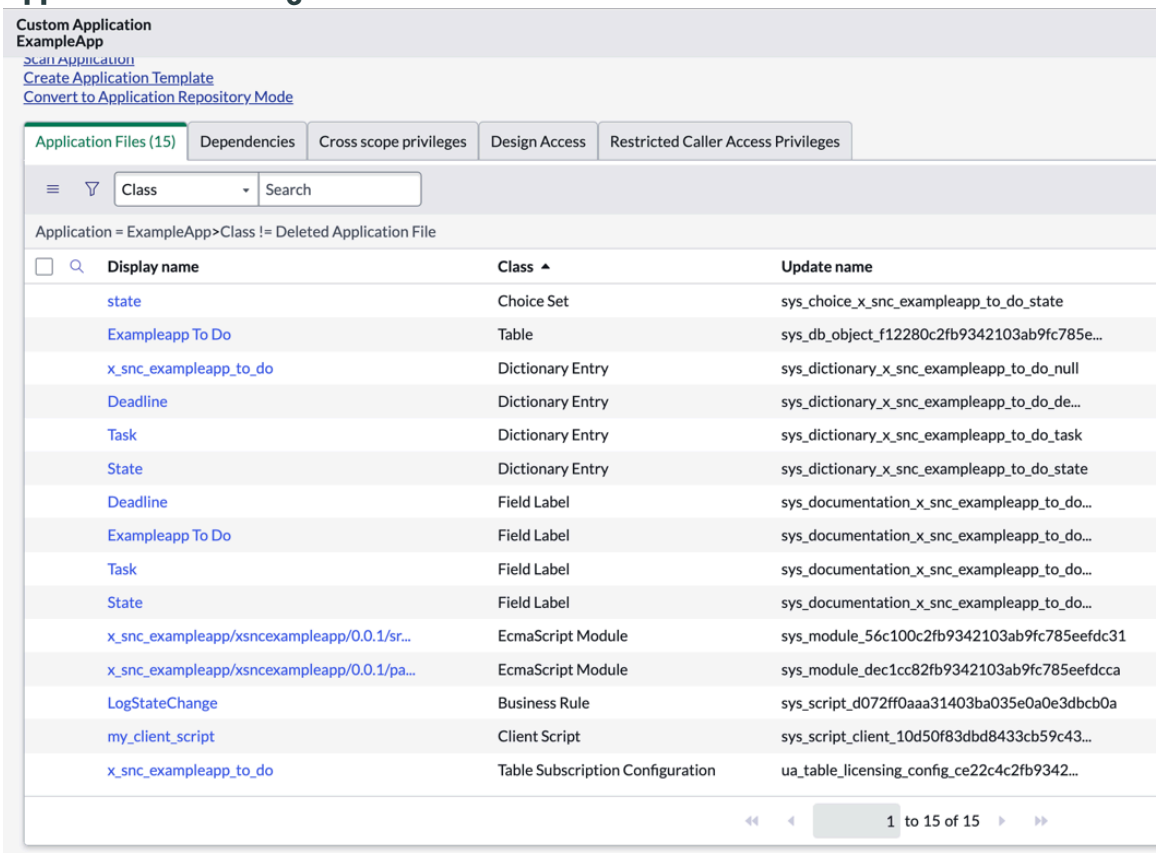
```
import { gs } from '@servicenow/glide'

export function showStateUpdate(current, previous) {
    const currentState = current.getValue('state')
    const previousState = previous.getValue('state')

    gs.addInfoMessage(`state updated from "${previousState}"
 to "${currentState}"`)
}
```

After building the application, this source code generates the following application metadata files on the instance.

Application metadata generated from ServiceNow Fluent code



Tip:
You can use the following directives in a code comment to help manage your code:

- `@fluent-ignore`: Suppresses ServiceNow Fluent diagnostic warnings and errors in the following line of code.
- `@fluent-disable-sync`: Turns off syncing changes to a ServiceNow Fluent object. Use before a call expression (for example, `Record({ ... })`) to turn off syncing for that object and its child objects. Only use this directive if you want to ignore changes made outside of the source code to the object and never update it when syncing.
- `@fluent-disable-sync-for-file`: Turns off syncing changes to a ServiceNow Fluent file (`.now.ts`). Use in the first line of the file to turn off syncing for all code in the file. Only use this directive if you want to ignore changes made outside of the source code to the file and never update it when syncing.

Define application metadata in code with ServiceNow Fluent and the ServiceNow SDK

JavaScript modules and third-party libraries

Optimize your code base using JavaScript modules to group related code or add third-party libraries and reuse their code within applications.

Overview of using JavaScript modules

A module is a JavaScript file that contains related code that's shared and reused within applications on an instance. You can add JavaScript modules and third-party libraries in scoped

applications that are created or converted with the ServiceNow IDE or ServiceNow SDK. You can also use TypeScript to create modules and compile them to JavaScript before building your application. After installing an application on an instance, JavaScript modules are stored in the EcmaScript Module [sys_module] table.

In a module, you identify code for reuse with `export` statements. Then, use `import` or `require` statements to reuse the code elsewhere in your applications. You must add third-party Node Package Manager (npm) libraries to applications as dependencies to use their module code. For general information about the syntax used to create JavaScript modules, see the JavaScript modules page on the MDN Web Docs website.

Note:
To use global Glide Server APIs in modules, they must be imported from the `@servicenow/glide` package. For more information, see Importing server APIs.

Limitations

- Global applications and application customizations aren't supported with instances on the Xanadu release.
- Modules can be used only within the application scope in which they're added. They can't be used across application scopes.
- A subset of ECMAScript features are supported in modules in accordance with the JavaScript engine feature support.
- Node.js APIs aren’t supported in modules. The ServiceNow SDK build process polyfills any Node.js built-in modules while packaging modules, otherwise modules are resolved from the `node_modules` directory.
- Global variables related to web APIs aren’t supported.
- CommonJS modules from third-party libraries aren't supported unless they define exports. Subpath imports aren't supported with CommonJS modules. ECMAScript modules from third-party libraries are supported.
- `import` and `export` statements are only supported in modules. To import module code in scripts, such as business rules or script includes, use `require` statements.
- JavaScript modules [sys_module] can be modified only in the ServiceNow IDE or in Visual Studio Code with the ServiceNow SDK.

Important:
You can't use third-party libraries that rely on unsupported functionality, such as unsupported APIs or ECMAScript features.

Exporting modules

In a module, identify code for reuse with `export` statements. You can use named exports or default exports. Named exports can be for variables, constants, functions, or classes whereas default exports can be for functions or classes only. The following example is one way of adding a named export for multiple features (a function and a variable) in a module:

```
export { myFunction, myVariable };
```

Importing modules

To import the module code you want to reuse, use `import` statements in other modules or `require` statements in server-side scripts.

The following example is one way that you could import an exported feature in a module:

```
import { feature } from 'path/to/module';
```

The following example is one way that you could import an exported feature in a script:

```
const { feature } = require('path/to/module');
```

Note:
To import code from one TypeScript file to another TypeScript file, you must include the `.ts` file extension. For example, `import { feature } from './module.ts'`.

To use shorthand to import module code, you can use subpaths in the *`imports`* field of the application's `package.json` file. For example:

```
{
 "name": "math",
 "version": "1.0.0",
 "exports": {
  "./functions/*.js": "./src/functions/*.js",
  "./functions/private-functions/*": null
 },
 "imports": {
  "#calc": "calculus",
  "#derivative": "calculus/derivative"
 },
 "dependencies": {
  "calculus": "1.0.0"
 }
}
```

Based on that example, instead of writing out the relative path to `derivative.js` every time you want to import it in the `math` application, you can use the `#derivative` shorthand instead. Subpaths can also be used in the *`imports`* field to use shorthand for dependencies, such as `#calc`.

```
import { derivative } from '#derivative';
import * as calculus from '#calc';
```

Adding third-party libraries

Applications must declare dependencies on third-party libraries to use their module code. In an application's `package.json` file, include the package name and version for any dependencies. For example, to use modules from the "math" library in the "test" application, add the "math" package as a dependency:

```
{
 "name": "test",
 "version": "1.0.0",
 "dependencies": {
  "math": "1.0.0"
 }
}
```

Importing server APIs

To import server APIs and use them in a module, use *`import`* statements. Glide APIs can be imported from the `@servicenow/glide` package or their namespace in the package.

For example:

```
import { API } from '@servicenow/glide';
import { API } from '@servicenow/glide/<namespace>';
```

In the following example, the *gs* (GlideSystem) and *GlideRecord* APIs are imported in a module:

```
import { gs } from '@servicenow/glide';
import { GlideRecord } from '@servicenow/glide';
```

In the following example, the *RESTAPIRequest* and *RESTAPIResponse* APIs are imported from the `sn_ws_int` namespace in a module because they run in that namespace:

```
import { RESTAPIRequest, RESTAPIResponse }
 from '@servicenow/glide/sn_ws_int';
```

To access server APIs in a third-party library module, you must add the module as a trusted module with the *trustedModules* parameter in your application's `now.config.json` file. For more information, see Supported now.config.json parameters.

For more information about available server APIs, see Server API reference.

Importing script includes

To import script includes and use them in a module, use *import* statements. Script includes can be imported from their application scope or the global scope in the `@servicenow/glide` package.

For example:

```
import { global } from '@servicenow/glide/global';
import { ScriptInclude } from '@servicenow/glide/<scope>';
```

For more information about script includes, see Script includes.

User interface development with React

Develop a user interface (UI) with the React library to build a full-stack application in source code.

Overview of UI development with React

React is an industry-standard web framework for building UI components that you use to develop and render custom user interfaces. A React component is a self-contained, reusable JavaScript function, such as a button, and supports JavaScript (JS/JSX) and TypeScript (TS/TSX) syntax. For general information about React, see the React documentation on the react.dev website.

With the ServiceNow IDE or ServiceNow SDK, you can use React in your scoped application to create a UI page in ServiceNow Fluent code. The ServiceNow Fluent UI Page API refers to an HTML entry point (`index.html`) that loads the page at the endpoint provided. After building and installing the application on an instance, the static assets are stored in the appropriate tables. For an example of a React application in source code, see the ServiceNow SDK examples GitHub repository. To get started using React, select one of the React templates when creating an application with the ServiceNow IDE or ServiceNow SDK.

Note:
You can use some Next Experience Components in a React application with the React Wrapper Component Library Node Package Manager (npm) package on the public npm registry. To use the React Wrapper Component Library in an application, you can use Build Agent or you must install it from the ServiceNow IDE or ServiceNow SDK. For more information, see Use third-party libraries with the ServiceNow IDE or Use third-party libraries with the ServiceNow SDK.

UI development process

The following list is a high-level overview of the process to develop a React application with the ServiceNow IDE or ServiceNow SDK:

1. Create an application and select one of the React templates.

   The application includes the files and directories required for React development.

2. In the `src/client` directory, add client assets for a user interface, such as an HTML entry point (`index.html`), client scripts, and style sheets. The `index.html` file must contain the `<script>` tag as the JavaScript entry point.
3. Define a UI page [sys_ui_page] in code with the ServiceNow Fluent UI Page API. In the `now.ts` file that contains the UI page definition, you import the HTML and refer to it from the *`html`* property of the *`UiPage`* object.
4. Build the application to execute a pre-build Rollup script that bundles dependencies and packages the client assets in the `src/client` directory before executing the rest of the build process. The standard Rollup build process and plugins are used as the default JavaScript bundler.

   Static assets are output to the `dist/static` directory.

5. Install the application to add the static assets to the application files [sys_metadata] in the appropriate tables: UX Asset [sys_ux_lib_asset], Images [db_image], and UX Theme Asset [sys_ux_theme_asset] tables. These tables support adding files as attachments.

Important:
UI development with React is an experimental feature due to how content is served from an instance and the content types and tables that are currently supported.

Limitations

- The UI page HTML should be modified only in source code. Changes to the HTML of a UI page [sys_ui_page] on an instance aren't synchronized into source code and are likely to result in unintended behavior.
- Audio, video, and WASM content types aren't supported.
- The maximum file size of uploaded attachments is limited by the size configured with *`com.glide.attachment.max_size`* system property. For more information, see Maximum allowed attachment size [Updated in Security Center 1.3].
- Output paths must be deterministic.
- Pre-loading content linked from HTML isn't supported (`rel="preload"`).
- Relative style sheets linked from HTML aren't supported (`rel="stylesheet"`). Import style sheets into code instead (`@import 'path/to/style-sheet'`).
- Relative imports in CSS aren't supported.
- CSS modules aren't supported.

- Only hash routing is supported by UI pages.
- Server-side rendering and React server components aren't supported.

Example: UI page development with React

In a `.now.ts` file in the `src/fluent` directory, a UI page is defined in ServiceNow Fluent code. The HTML of the page is imported from the `index.html` file in the `src/client` directory.

```
//incident-manager.now.ts
import '@servicenow/sdk/global'
import { UiPage } from '@servicenow/sdk/core'
import incidentPage from '../../client/index.html'

UiPage({
    $id: Now.ID['incident-manager-page'],
    endpoint: '<scope>_incident_manager.do',
    description: 'Incident Response Manager UI Page',
    category: 'general',
    html: incidentPage,
    direct: true,
})
```

In the `index.html` file, the `<script>` tag refers to the `main.jsx` file in the `src/client` directory.

```
//index.html
<html>
<head>
  <title>Incident Response Manager</title>

  <!-- Initialize globals and Include ServiceNow's required scripts -->
  <sdk:now-ux-globals></sdk:now-ux-globals>

  <!-- Include your React entry point -->
  <script src="./main.jsx" type="module"></script>
</head>
<body>
  <div id="root"></div>
</body>
</html>
```

In the `main.jsx` file, the imports required for rendering the page and the main application component are included and the entry point of the React application is defined.

```
//main.jsx
import React from 'react'
import ReactDOM from 'react-dom/client'
import App from './app'

const rootElement = document.getElementById('root')
if (rootElement) {
    ReactDOM.createRoot(rootElement).render(
        <React.StrictMode>
            <App />
        </React.StrictMode>
```

```
        )
}
```

After building and installing the application, you can open the page from the endpoint provided in the *UiPage* object (`https://<instance>/<scope>_incident_manager.do`), which displays an interface for creating and managing incidents.

Example of a UI page created with React

Which builder should I use to create an app?

Are you a developer who wants to use industry-standard development tools and processes?

The ServiceNow IDE and ServiceNow SDK support developing applications in source code with ServiceNow Fluent, creating JavaScript modules, and using third-party libraries. ServiceNow Fluent is a domain-specific programming language for creating application metadata in code.

The ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform. The ServiceNow SDK uses Visual Studio Code Desktop locally. For more information, see Building applications in source code.

Are you a developer who wants more control in a centralized user interface?

Build apps smarter and deliver them faster with the new ServiceNow Studio. ServiceNow Studio empowers platform developers with a modern, unified environment for building on the ServiceNow AI Platform. ServiceNow Studio features streamlined navigation to applications and metadata, integrated low-code tools, efficient tracking and packaging of development work that accelerates development processes and enhances productivity. For more information, see Exploring ServiceNow Studio.

Need a more general app but still want low-code options?

App Engine Studio lets you build a broader range of apps than Creator Studio without being a programming pro. For more information, see Exploring App Engine Studio.

Want to build an app easily, without code?

Creator Studio specializes in helping you craft request-fulfillment applications without writing code. For example, an application to request office supplies by filling out a form, and someone approves or denies your request. For more information, see Exploring Creator Studio.

ServiceNow Fluent

JavaScript modules and third-party libraries

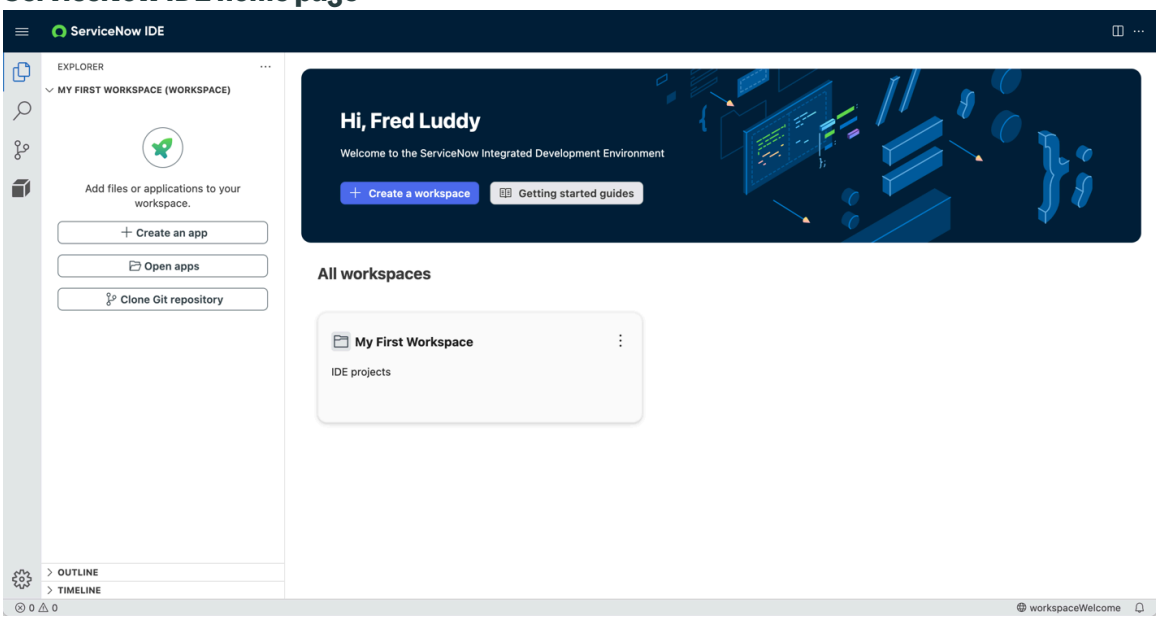
Exploring the ServiceNow IDE

Learn about developing scoped applications in source code in the ServiceNow IDE.

ServiceNow IDE overview

The ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform. With the ServiceNow IDE, you can get started building scoped applications quickly using familiar tools and industry-standard development practices. The ServiceNow IDE has many of the same features as Visual Studio Code, including type safety, IntelliSense, dependency enforcement, code search, and source control integration.

ServiceNow IDE home page



In the ServiceNow IDE, you can create scoped applications in source code using ServiceNow Fluent to define application metadata [sys_metadata]. To see a side-by-side visual representation of your changes in real time, you can open the application metadata in other ServiceNow AI Platform user interfaces embedded within the ServiceNow IDE.

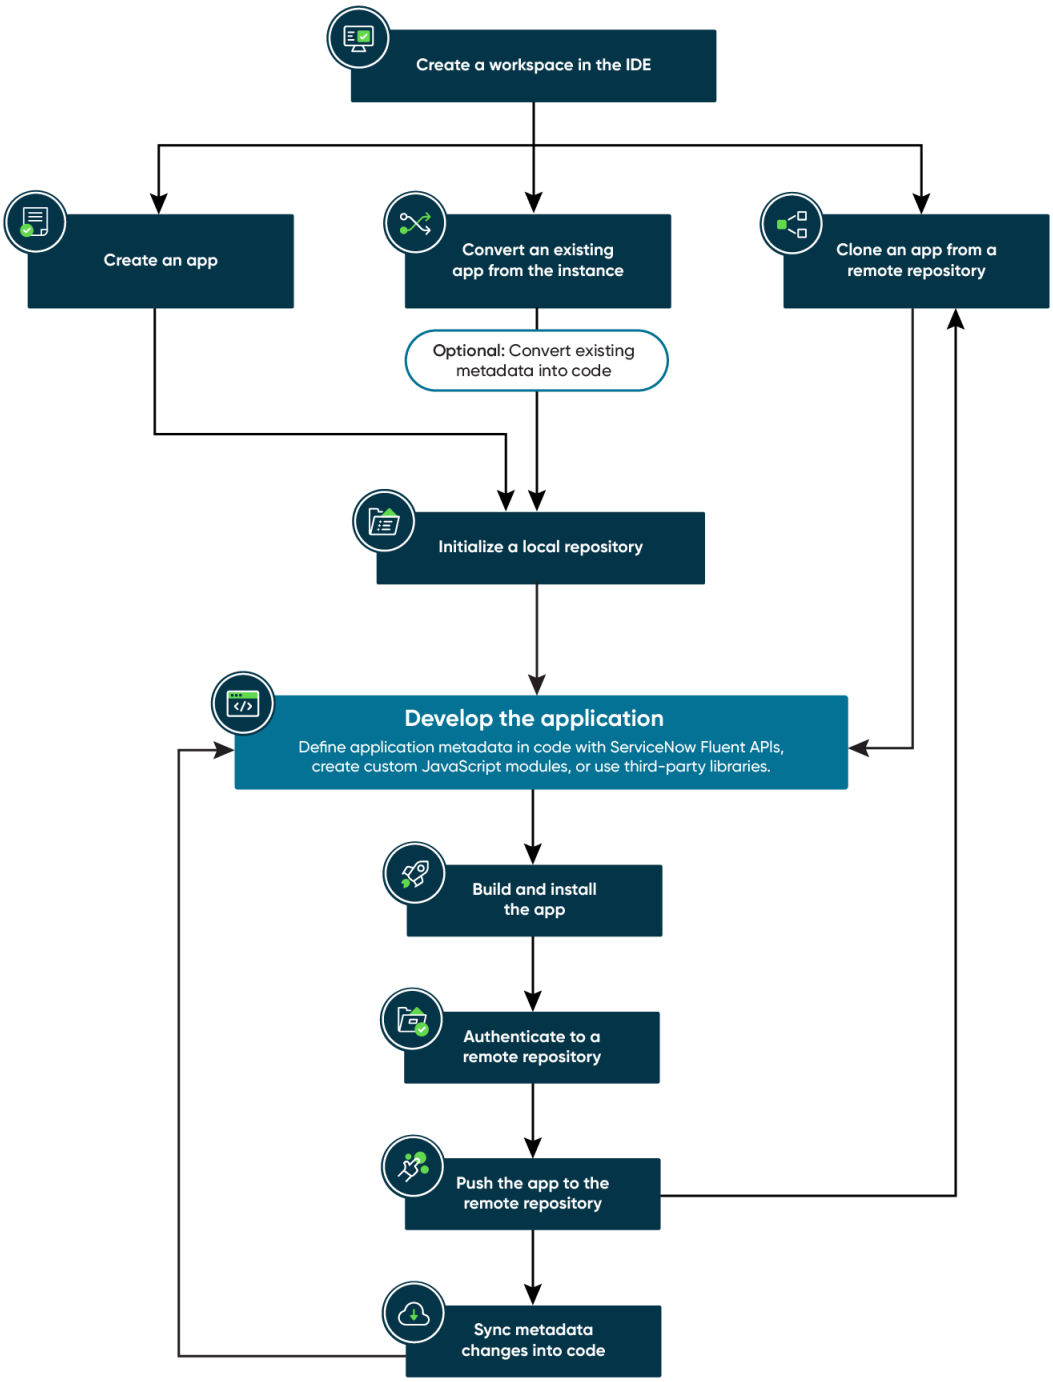
Optionally, you can create JavaScript modules and use third-party libraries to organize and reuse code within scoped applications.

In the background, this functionality is enabled by the ServiceNow SDK application packaging service, which builds applications in the ServiceNow IDE.

ServiceNow IDE workflow

The following infographic shows the workflow for developers to get started developing applications with the ServiceNow IDE.

Developing applications with the ServiceNow IDE



1. From the ServiceNow Store, an administrator installs the ServiceNow IDE application on a non-production instance.
2. Depending on the authentication method, an administrator or developer configures the credentials needed to connect to their Git provider.

- To use OAuth 2.0 authentication, an administrator configures an OAuth 2.0 application registry in their Git provider and on the instance.
- To use basic authentication, a developer generates a personal access token from their Git provider.

3. From their Git provider, a developer creates a dedicated Git repository for an application.
4. From the ServiceNow IDE, the developer configures their Git credentials.
5. The developer creates a ServiceNow IDE workspace to organize applications.
6. The developer creates a scoped application or converts an existing scoped application from the ServiceNow IDE.
7. The developer initializes a local Git repository for the application and pushes it to the remote repository they created to manage the application in source control.
8. The developer can define application metadata in source code using ServiceNow Fluent, create custom JavaScript modules, or use third-party libraries.
9. When metadata changes are detected, the developer synchronizes the application to download and transform changes to metadata from other interfaces into source code.
10. After saving their changes, they build the application, which compiles the source code and transforms it into application metadata.
11. When the build is complete, the developer can view their changes reflected in other embedded ServiceNow AI Platform user interfaces without leaving the ServiceNow IDE.
12. The developer stages, commits, and pushes their changes to the Git repository.
13. From the ServiceNow IDE, other developers can clone the repository, create branches, and begin collaborating on the application.

Other users can modify the application metadata at the same time as developers modify the source code. Developers can reuse module code in other modules or scripts within the application.

ServiceNow IDE benefits

Benefit	Feature	Users
Develop applications in an IDE based on Visual Studio Code on the ServiceNow AI Platform	ServiceNow IDE user interface	Developers
Write source code to define the metadata that makes up ServiceNow applications	ServiceNow Fluent Define application metadata in code with ServiceNow Fluent in the ServiceNow IDE	Developers
Organize and reuse code within scoped applications with custom JavaScript modules and third-party JavaScript utilities	JavaScript modules and third-party libraries Create and use JavaScript modules in applications in the ServiceNow IDE	Developers

Benefit	Feature	Users
	Use third-party libraries in applications in the ServiceNow IDE	
Collaborate on applications with users of different skill sets	Build and install an application in the ServiceNow IDE	Developers
Integrate source control with your Git provider of choice	Integrating source control with the ServiceNow IDE	Developers, Administrators

ServiceNow IDE user interface

The ServiceNow IDE user interface contains many of the same features as Visual Studio Code for the Web and some unique functionality for creating ServiceNow applications.

Overview of the ServiceNow IDE user interface

The ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform, which includes the following features:

- Basic editing and keyboard shortcuts
- IntelliSense
- Code navigation
- Code and file search
- Command palette
- Source control integration

Visual Studio Code for the Web is similar to Visual Studio Code Desktop but doesn't support all of the features that are available in the desktop interface. For information about browser-based implementations of Visual Studio Code, see Visual Studio Code for the Web. The following Visual Studio Code features aren't supported in the ServiceNow IDE:

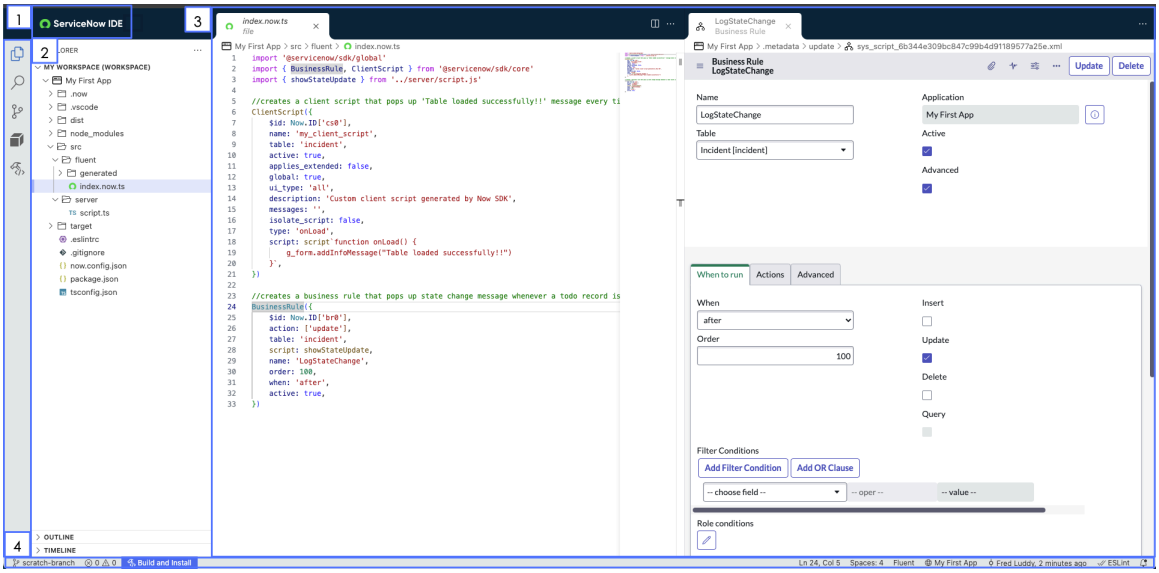
- Integrated terminal
- Debugger
- Marketplace extensions
- Integrated unit testing
- Remote development

For general information about common features in Visual Studio Code and the ServiceNow IDE, see the Visual Studio Code documentation website.

Features in the ServiceNow IDE

Learn about features of the ServiceNow IDE user interface.

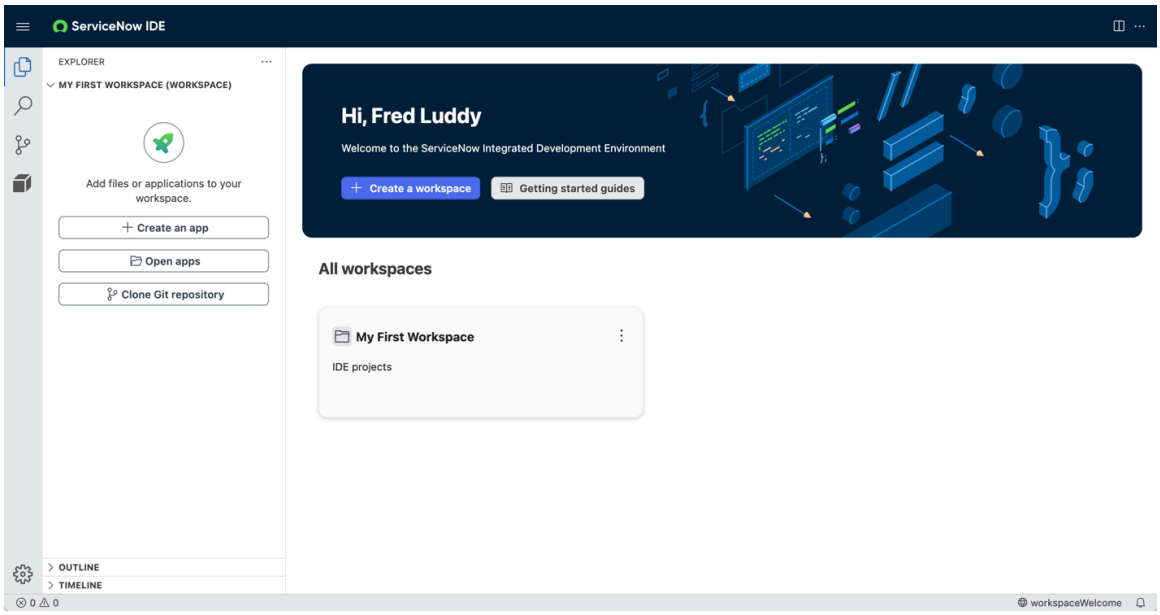
ServiceNow IDE user interface



1. ServiceNow IDE home page: Get started creating workspaces and applications and view existing workspaces.
2. Activity Bar
   - File Explorer view: Navigate through applications in your workspace and their code.
   - Search view: Find content within files.
   - Source Control view: Integrate with a Git repository for version control of your code.
   - Metadata Explorer view: Create, update, and view application metadata.
   - Now SDK view: Synchronize changes to application metadata or build and install applications.
   - Manage menu: Access and configure various aspects of the user interface.
3. Editor: Write source code and view application metadata through embedded ServiceNow AI Platform user interfaces.
4. Status bar: View status information about your applications and files and build applications.

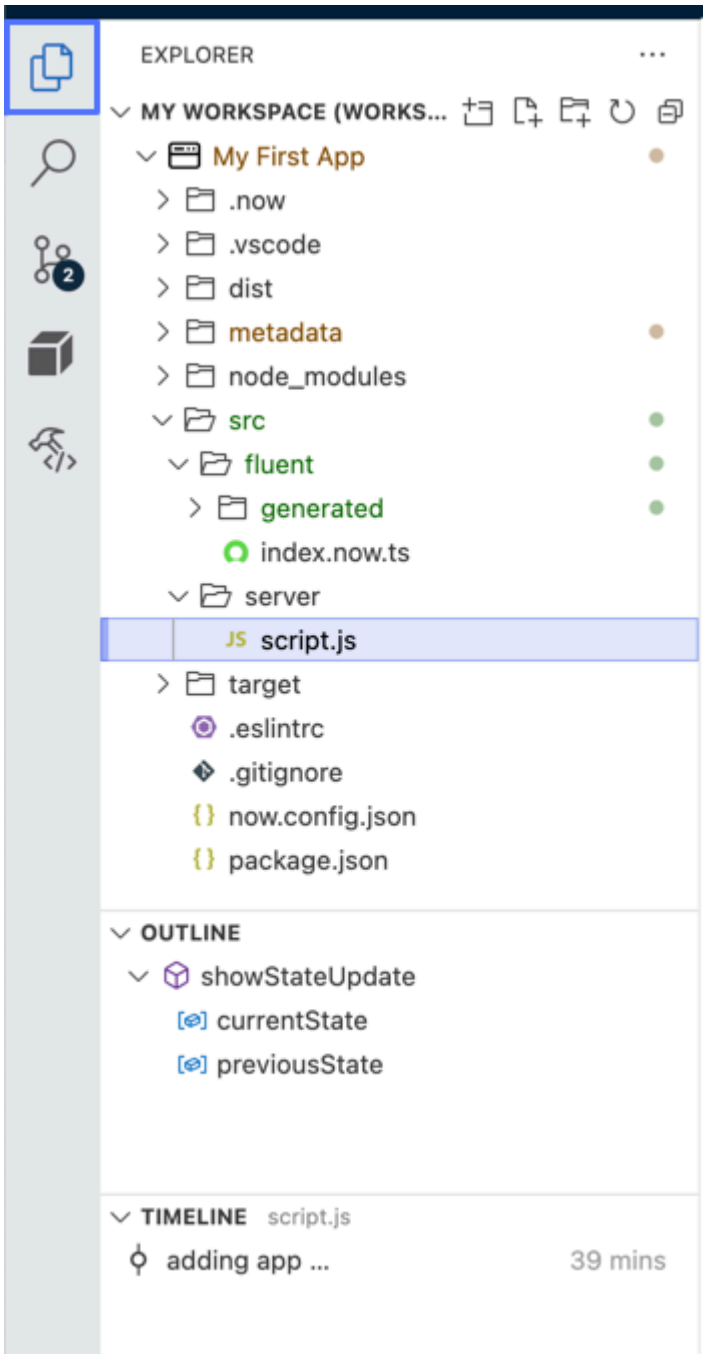
In addition to these features, you can open the command palette to run a variety of commands to develop applications, manage files, use source control, and more. For more information, see Command palette.

ServiceNow IDE home page



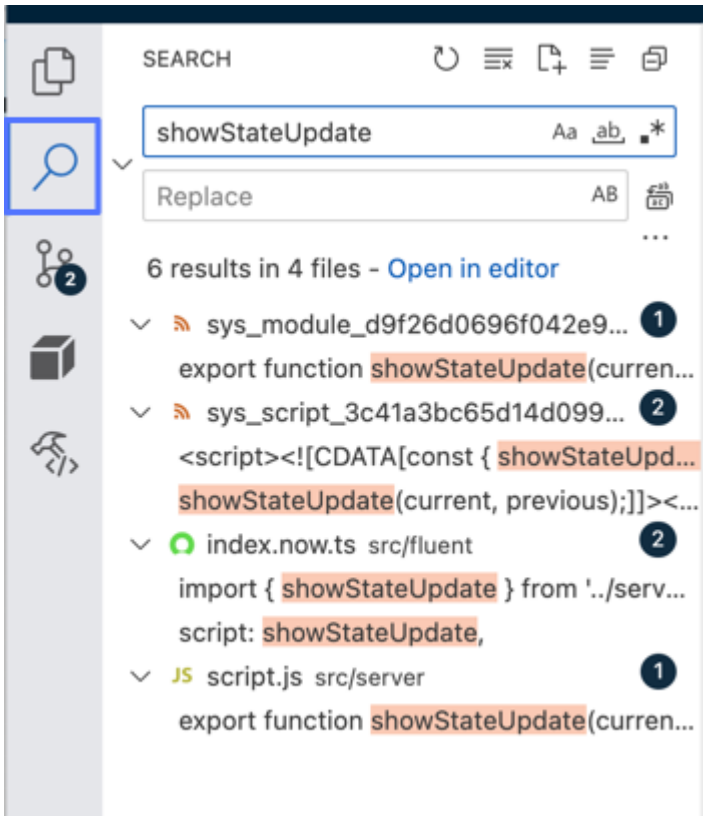
Create workspaces, access existing workspaces, and create or open applications. Clone a Git repository to add an existing application from a remote repository. To get started creating workspaces and applications, see Developing applications with the ServiceNow IDE. To clone a Git repository, see Clone a Git repository with the ServiceNow IDE.

File Explorer view



Navigate through applications in a workspace and add files or folders. In the Outline section, view the outline of the active file in the editor. In the Timeline section, view a history of changes to the active file. For information about the default application file structure, see the Application structure section of the Building applications in source code topic.

Search view

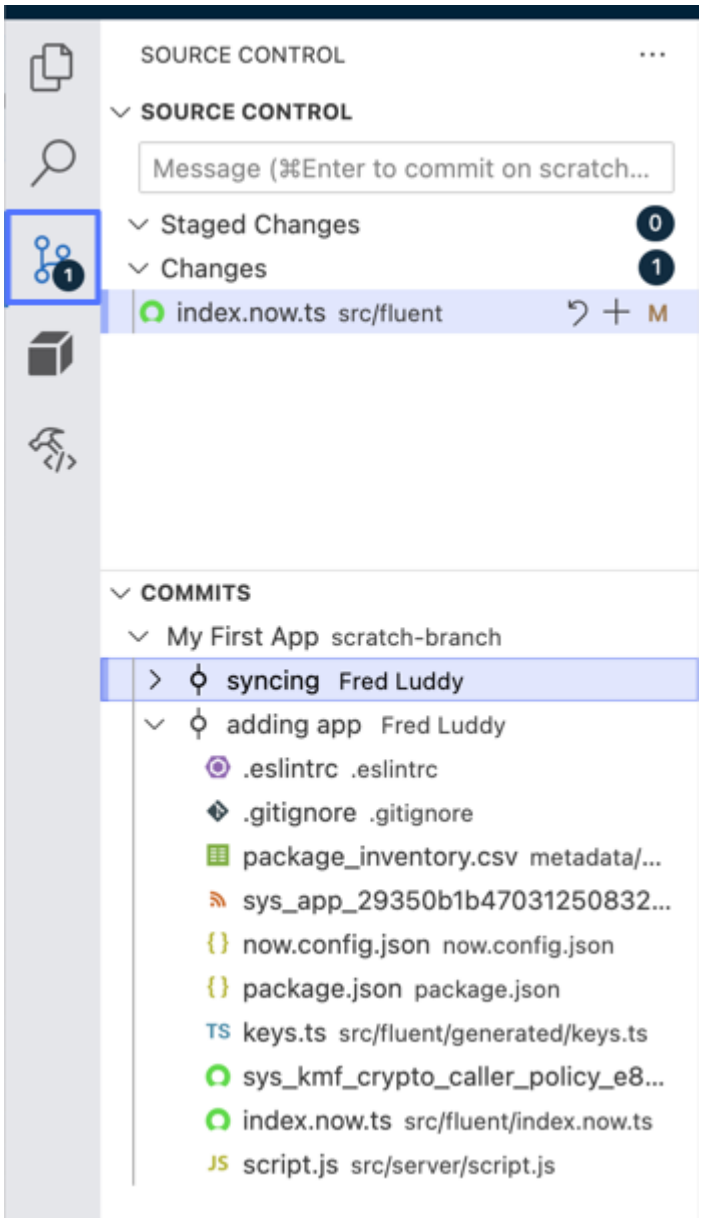


Search across files in the active workspace. The Search view supports using regular expressions, find and replace, and advanced search options.

To search for files by name, open the search box with the following keyboard shortcuts:

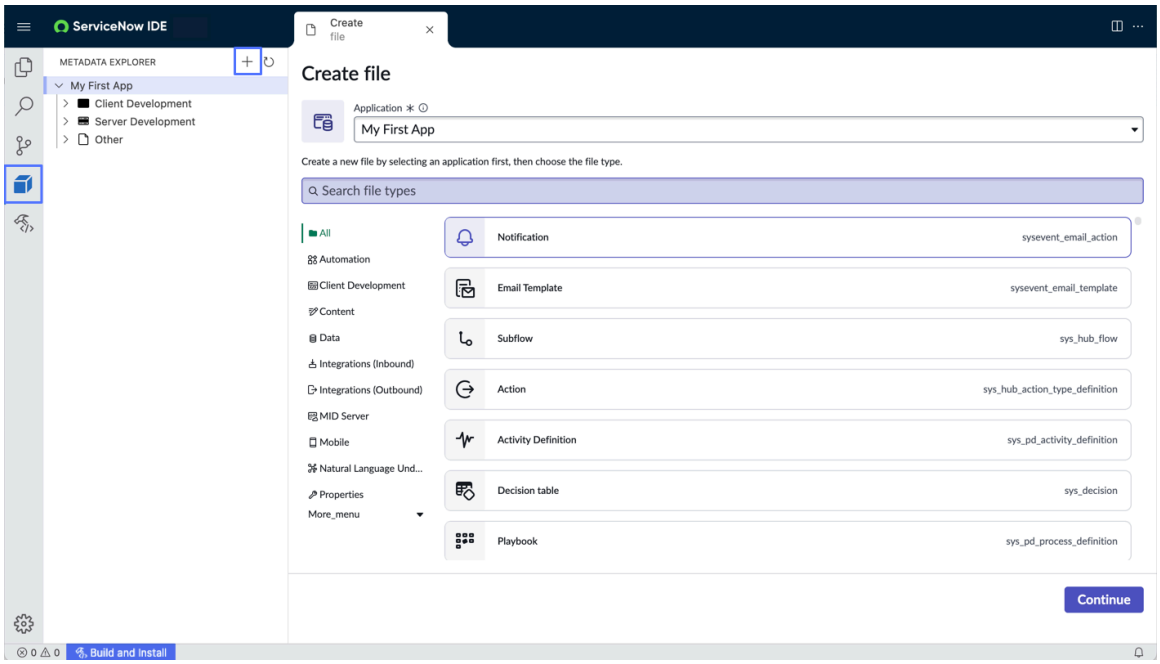
- Windows: Ctrl-P
- Mac: Cmd-P

Source Control view



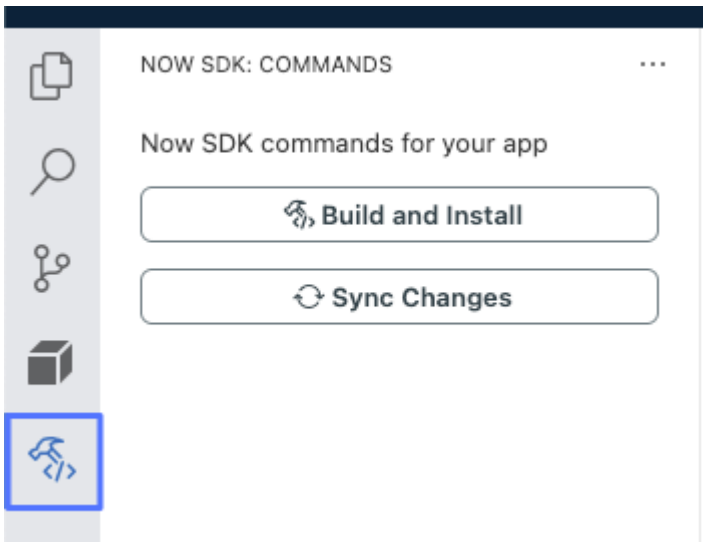
See changes to files grouped by application and the type of change. Stage, commit, and push changes to a remote repository and pull changes into your local repository. Create and checkout branches for your applications. In the Commits section, see the commit history for branches in the repository. To get started integrating with source control providers, see Integrating source control with the ServiceNow IDE.

Metadata Explorer view



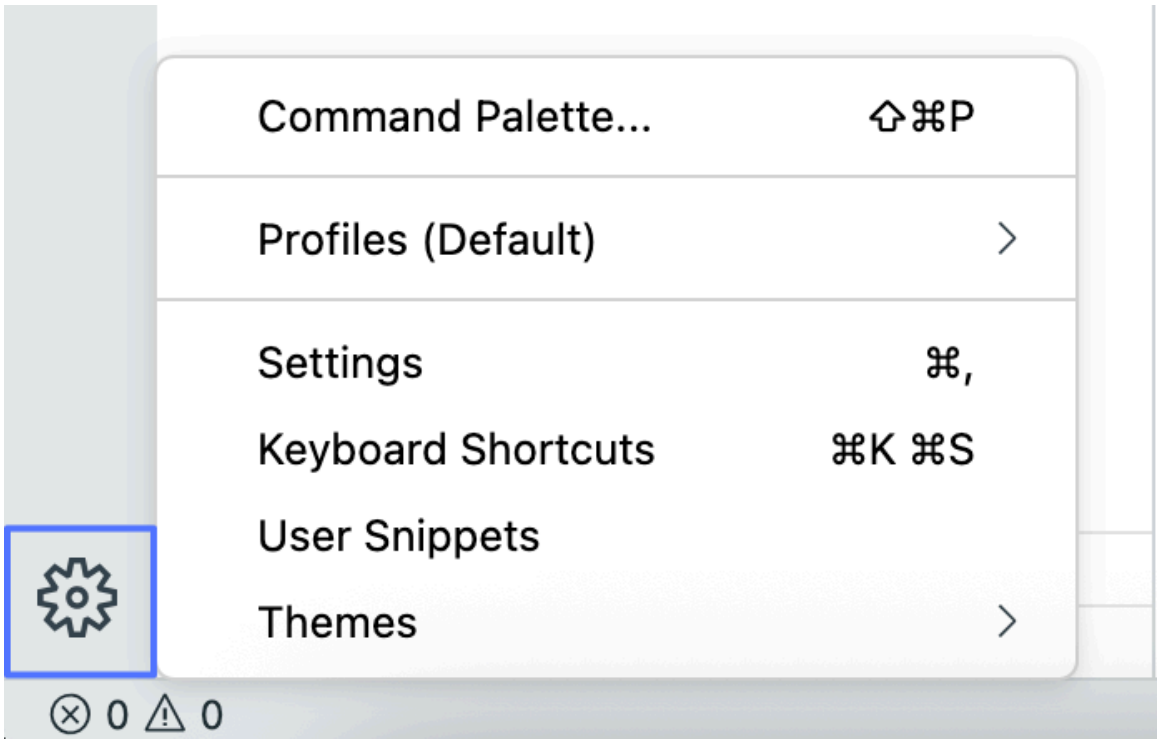
Create, update, and view application metadata in the most applicable embedded ServiceNow AI Platform user interface in the editor. If you need to create some application metadata outside of source code, you can create application files from the Metadata Explorer. For more information, see Create an application file from the Metadata Explorer.

Now SDK view



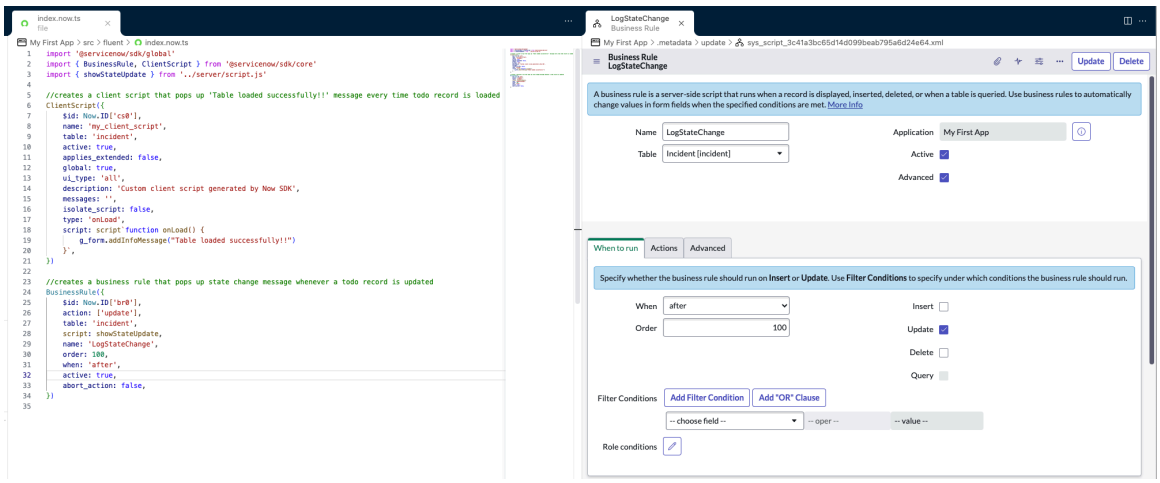
Run commands from the ServiceNow SDK application packaging service to synchronize changes to application metadata or build and install an application. For more information, see Synchronizing applications in the ServiceNow IDE and Build and install an application in the ServiceNow IDE.

Manage menu



Access and configure various aspects of the ServiceNow IDE user interface from the Manage menu. You can manage your settings, select a theme preference, view or edit keyboard shortcuts, and more.

Editor



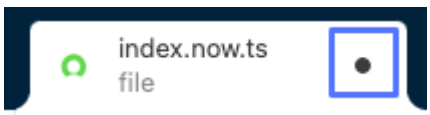
Write and edit code using IntelliSense, custom language processing and validation for ServiceNow Fluent, side-by-side editing, and more.

After building an application, review changes to ServiceNow Fluent source code as application metadata in embedded ServiceNow AI Platform user interfaces without leaving the ServiceNow IDE. Application metadata opens in the most applicable embedded ServiceNow AI Platform user interface. From links in the editor, you can open the Metadata Explorer view for metadata defined with a dedicated ServiceNow Fluent API.

```
import '@servicenow/sdk/global'
import { DateColumn, StringColumn, Table } from '@servicenow/sdk/core'

//creates todo table, with three columns (deadline, status and task)
Open Table
export const x_snc_hello_world_to_do = Table({
    name: 'x_snc_hello_world_to_do',
    schema: {
        deadline: DateColumn({ label: 'Deadline' }),
        state: StringColumn({
            label: 'State',
            choices: {
                ready: { label: 'Ready' },
                completed: { label: 'Completed' },
                inProgress: { label: 'In Progress' },
            },
        }),
        task: StringColumn({ label: 'Task', maxLength: 120 }),
    },
})
```

Switch between tabs and split the editor into groups. If a file has unsaved changes, the file tab includes a dot icon.

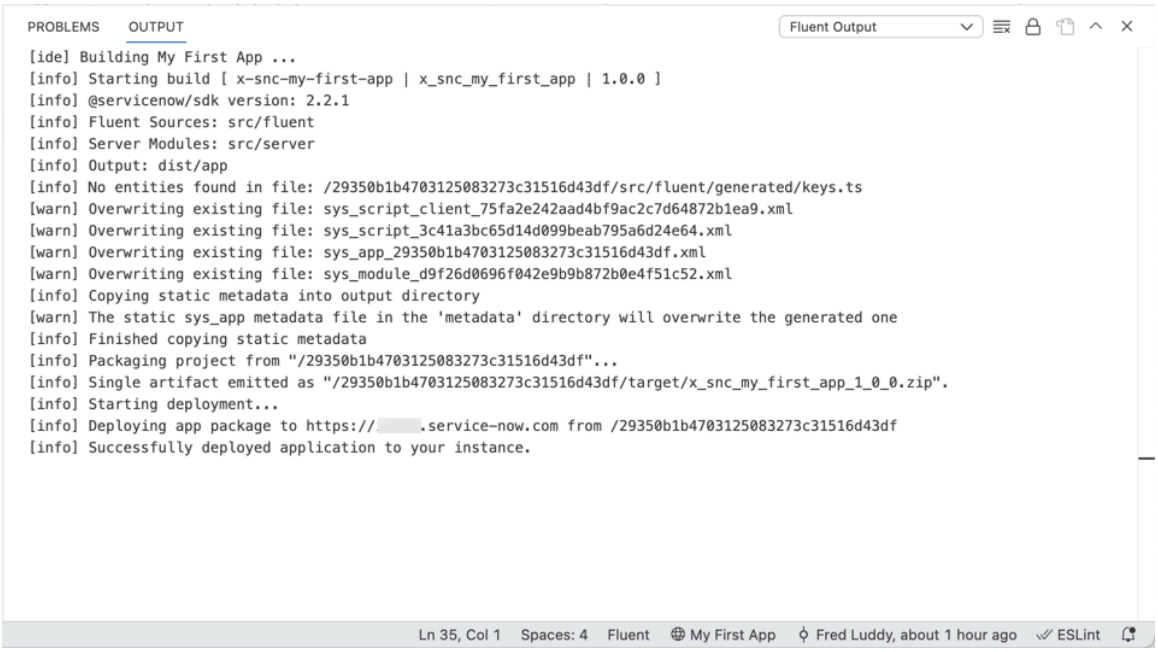


To get started developing applications in source code, see Developing applications with the ServiceNow IDE.

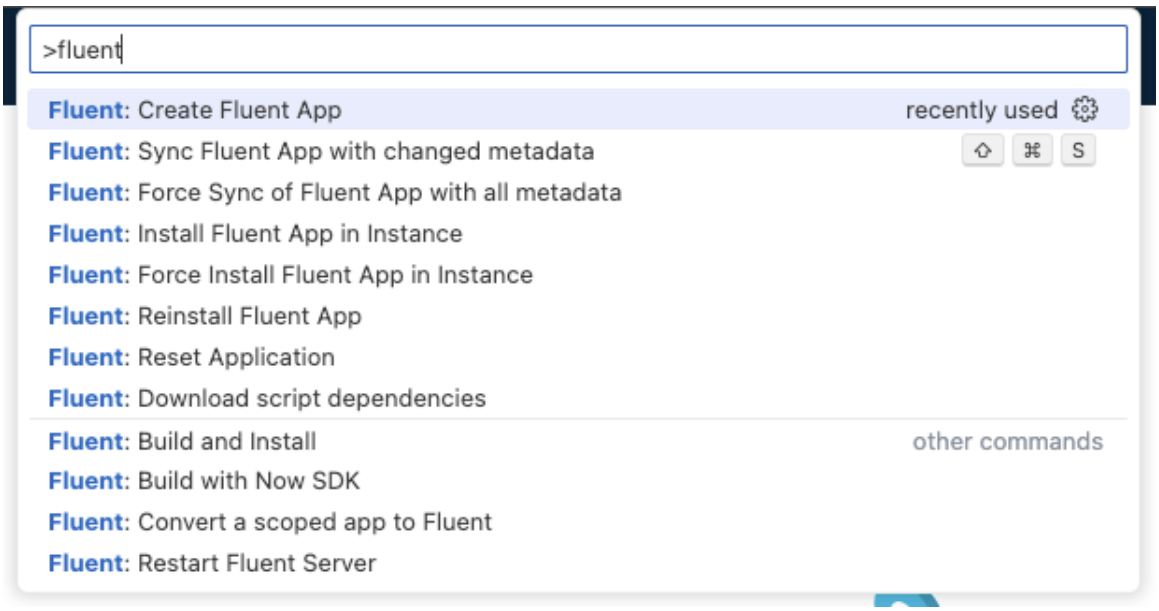
Status bar

Get information about the state of your application and build applications. View the progress when creating, building, and syncing applications. In addition, the status bar displays the active branch, problems in your code, the active application scope, the active update set, and more.

From the status bar, the panel opens and displays more information about problems in your code and logging related to creating, building, and syncing applications.



Command palette



Run commands to configure the user interface, develop applications, manage files, use source control, access a list of keyboard shortcuts, and more. The command palette includes commands unique to the ServiceNow IDE and Visual Studio Code commands. For a list of commands specific to the ServiceNow IDE, see ServiceNow IDE commands.

To open the command palette, use one of the following keyboard shortcuts:

- Windows: Ctrl-Shift-P
- Mac: Cmd-Shift-P

To close the command palette, press the Escape key.

Getting started: Create your first application in the ServiceNow IDE

Get started in the ServiceNow IDE by creating an application that you can develop in source code, pushing it to a remote repository, and cloning it on another instance.

The ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform. With the ServiceNow IDE, you can get started building scoped applications quickly using familiar tools and industry-standard development practices. For an overview of the ServiceNow IDE user interface, see ServiceNow IDE user interface.

Tutorial overview

In this tutorial, you complete the following tasks to familiarize yourself with developing a new application in source code from the ServiceNow IDE:

- Create an application that supports development in source code.
- Configure basic authentication and connect your application in the ServiceNow IDE to a remote Git repository and then push your application to the repository.
- Create a simple table for a to-do list using ServiceNow Fluent APIs.
- Install a third-party library and use its code in a JavaScript module.
- Clone the application from the remote Git repository onto another instance.

Afterward, you should be ready to take the basic application you create and continue learning to develop it into a more complex application that meets your requirements.

Before you begin

You should have access to the following items to complete this tutorial:

- A non-production instance on the Xanadu release or later with ServiceNow IDE version 2.0.4 or later installed. To complete the last part of the tutorial by cloning the application to another instance, you need access to a second non-production instance. Personal developer instances (PDIs) are supported and can be obtained from developer.servicenow.com. For more information, see Install or update the ServiceNow IDE.
- A user with the admin role on both instances.
- A Git provider such as GitHub, GitLab, Bitbucket, or Azure Repos. This tutorial demonstrates using GitHub.

Tutorial part 1: Create an application in the ServiceNow IDE

Create an application that you can develop in source code in the ServiceNow IDE.

Before you begin

Role required: admin

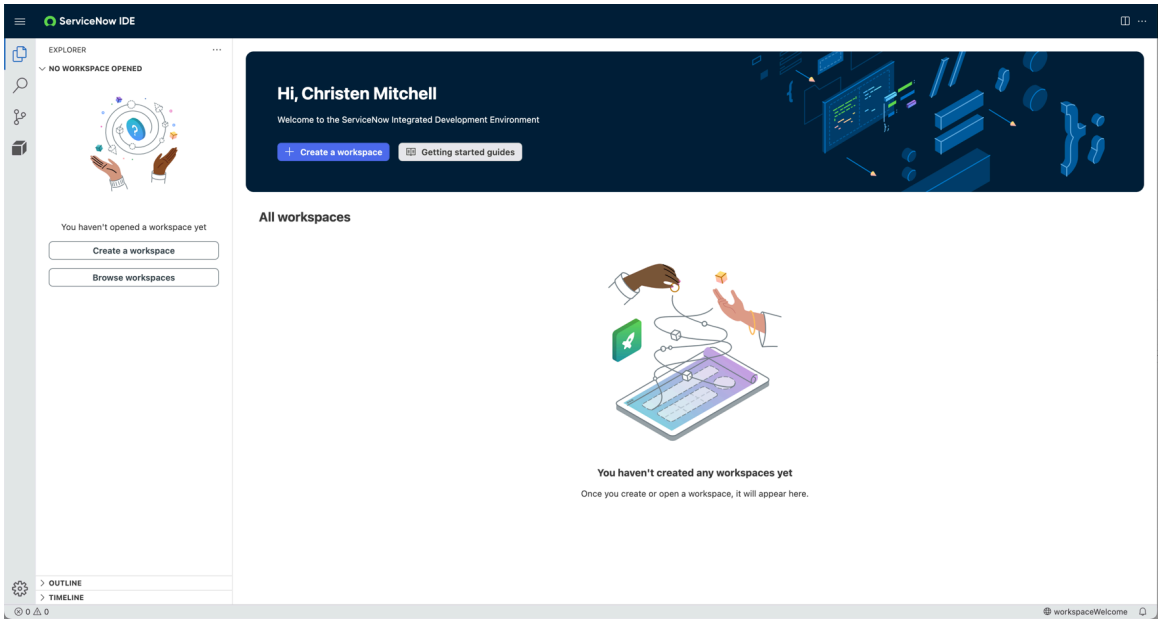
About this task

In the ServiceNow IDE, you can develop scoped applications in source code using ServiceNow Fluent to define application metadata [sys_metadata]. You can also create JavaScript modules and use third-party libraries to organize and reuse code within scoped applications. For an application to support development in source code, you must create a scoped application or convert an existing scoped application using the ServiceNow IDE or ServiceNow SDK. In this tutorial, you create a scoped application from the ServiceNow IDE.

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.

   Before you can create an application, you must create a workspace in which you can add applications and navigate through them from one place.



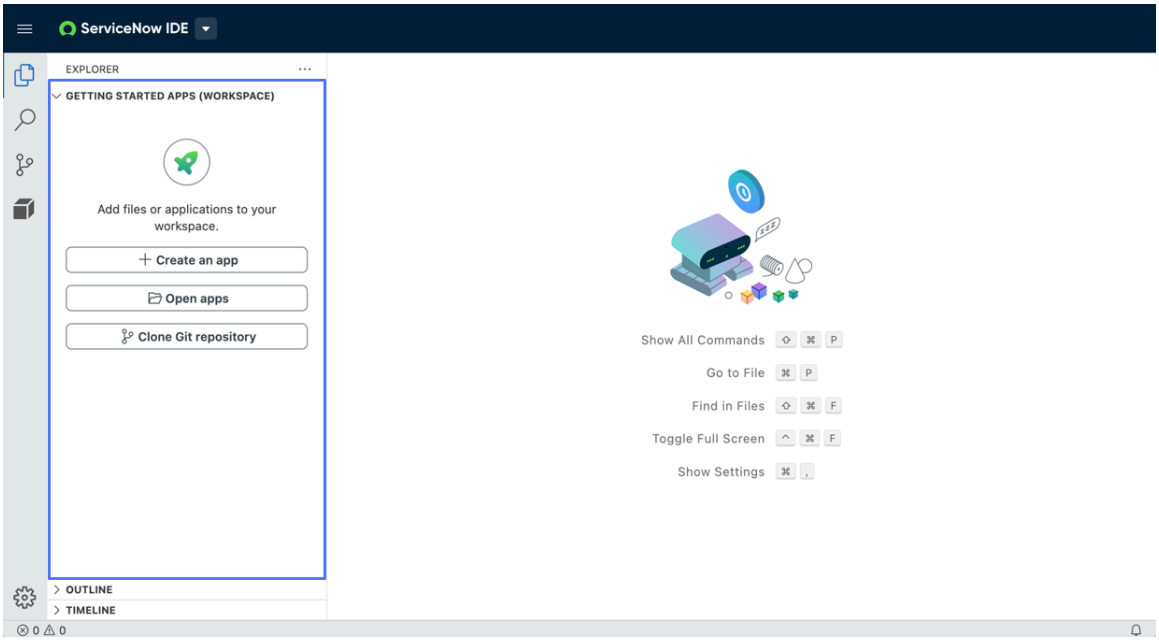
Workspaces are specific to a user, and you can create multiple workspaces to group different sets of applications. Applications can be added or removed from a workspace at any time. Workspaces in the ServiceNow IDE are based on workspaces in Visual Studio Code.

2. Create a workspace.

   a. Select **Create a workspace**.

   b. Enter a name for the workspace and press Enter.

   c. Enter a description for the workspace and press Enter.
   The workspace becomes the active workspace but doesn't contain any applications yet.



Tip:
To switch the active workspace, you can browse and select other workspaces from the ServiceNow IDE home page or from the command palette with the `Workspaces: Browse Workspaces` command.

3. Create an application in the workspace.

   a. Select **Create an app**.

   b. Enter a name, such as `Hello World`, and press Enter.

   c. Enter a description for the application and press Enter.

   d. Enter a scope, such as `x_snc_hello_world`, and press Enter.

   Important:
   The scope name must be unique on the instance, begin with x_<prefix>, and be 18 characters or fewer. For more information, see Namespace identifier.

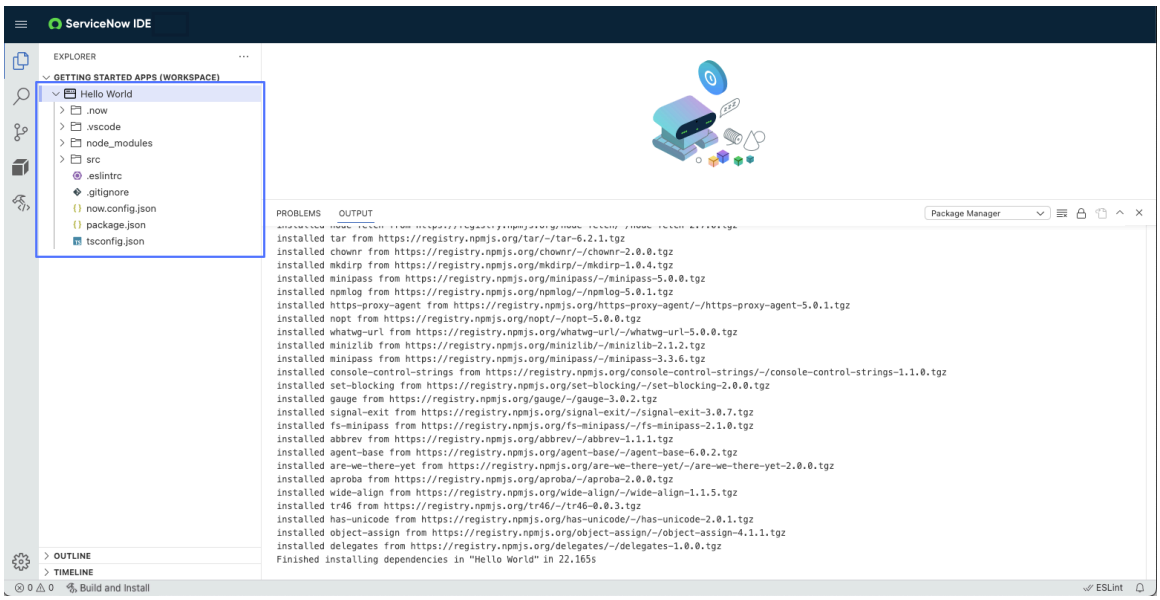
   e. Enter a package name, such as `x-snc-hello-world`, and press Enter.
   The package name must adhere to Node Package Manager (npm) package naming standards.

   f. Select the **A basic application using NowSDK and TypeScript** template to use TypeScript to create JavaScript modules.

   The application templates define the default application structure.

   Note:
   TypeScript uses static typing and type annotations to support developers catching errors earlier while writing code. If you'd prefer to get started with JavaScript instead, select **JavaScript**.

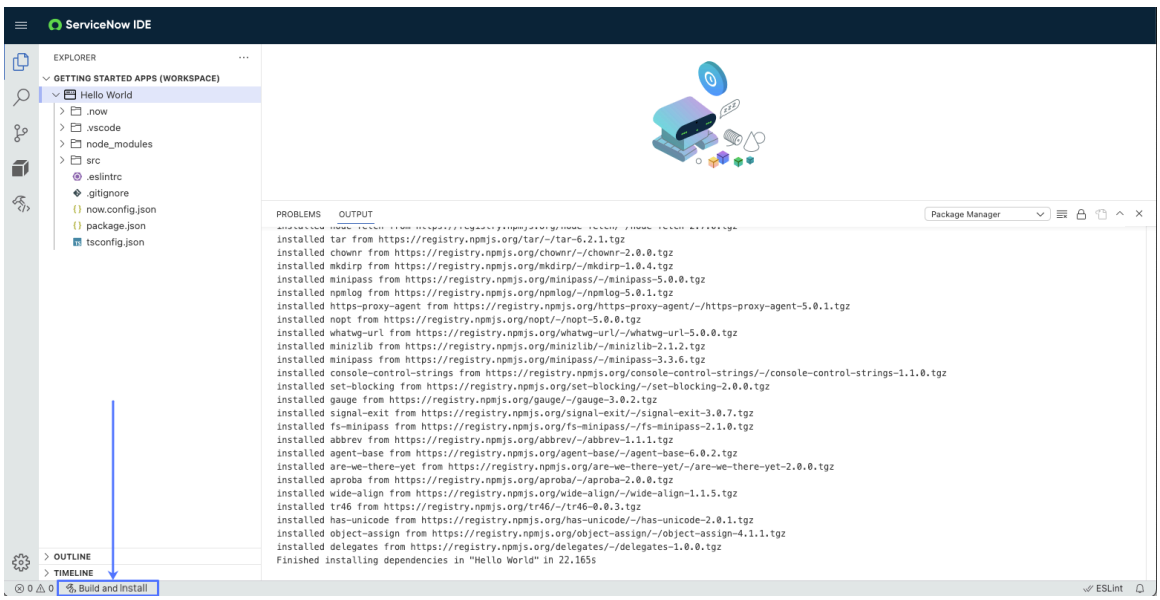
Your application is added to your workspace. From the File Explorer view ( ), you can navigate through the application files.



The `package.json` and `now.config.json` files define the application structure, which is similar to that of Node.js applications or Node Package Manager (npm) packages. A sample ServiceNow Fluent file (`index.now.ts`) and JavaScript module (`script.js` or `script.ts`) were created in the `src` directory, and dependencies were installed into the `node_modules` directory. The application is also added to the Custom Application [sys_app] table.

Next, build and install the application to make it available for development across the instance.

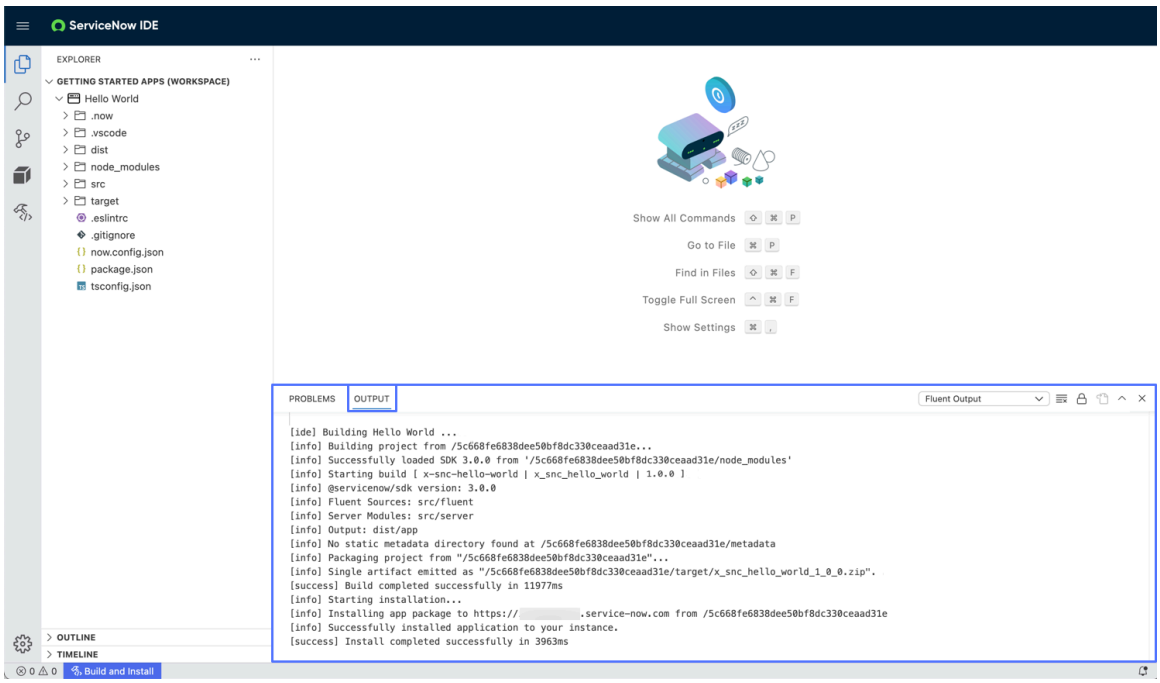
g. From the Status Bar at the bottom of the ServiceNow IDE, select **Build and Install**.



Building and installing the application compiles its ServiceNow Fluent code and JavaScript or TypeScript module code into Application Files [sys_metadata] and EcmaScript Modules

[sys_module] on the instance, respectively. Build artifacts in the `dist/app` directory are packaged into an installable `.zip` file in the `target` directory.

Logs in the Output panel indicate the status of the build and if the application is installed successfully. If either process fails, review the logs to identify any issues.



For information about the application structure, see the Application structure section of the Building applications in source code topic.

What to do next

Continue to Tutorial part 2: Initialize a repository for your application.

Tutorial part 2: Initialize a repository for your application

Initialize a local Git repository for an application in the ServiceNow IDE and push it to a remote Git repository in GitHub to manage the application in source control.

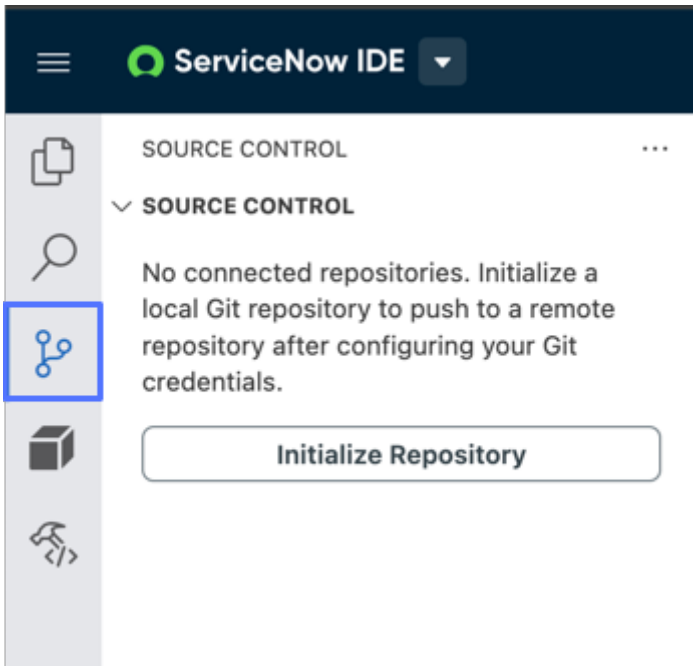
Before you begin

Complete Tutorial part 1: Create an application in the ServiceNow IDE.

Role required: admin

Procedure

1. From the Activity Bar, select the Source Control view ( ).



2. Initialize a Git repository that's local to the ServiceNow IDE.
   a. Select **Initialize Repository**.
   b. Press Enter to use **main** as the default branch name.

   A local repository is initialized for your application, and the application files that are tracked in source control are in the Untracked Changes list. Application files and directories specified in the `.gitignore` file aren't tracked in source control.

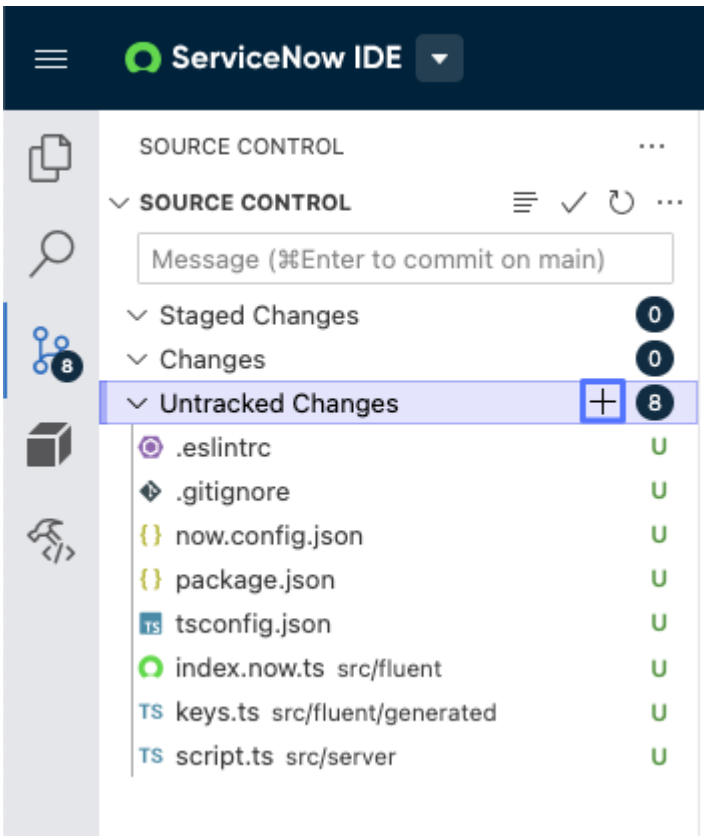
   Tip:
   If you select a file in the list, you can view a comparison of the current and previous version of the file in the Diff editor.

   Before you can push your application to a remote Git repository, you must stage and commit your changes in the local Git repository.

3. Stage and commit your changes.

a. From the Untracked Changes list, select the Stage All Untracked Changes icon (+).

Example

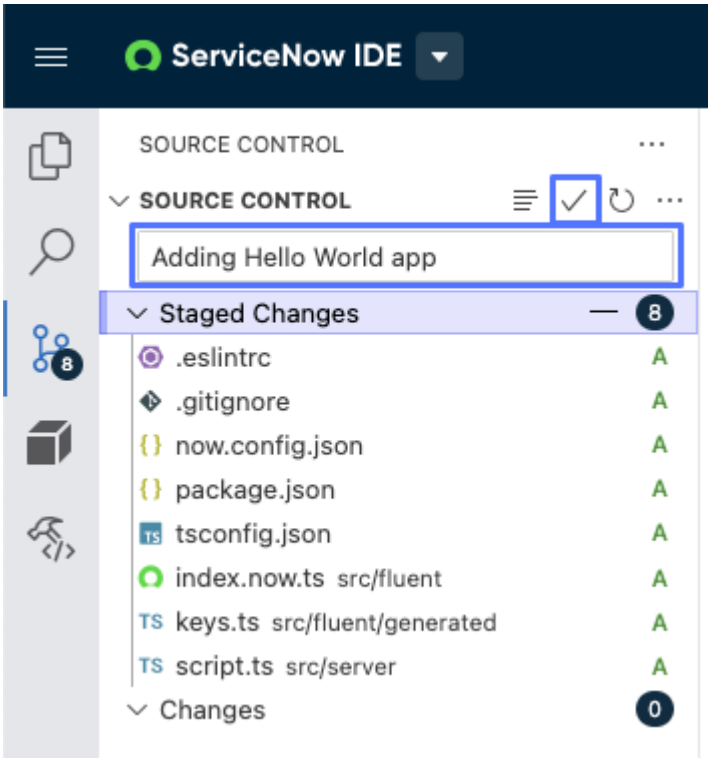


Your changes move to the Staged Changes list.

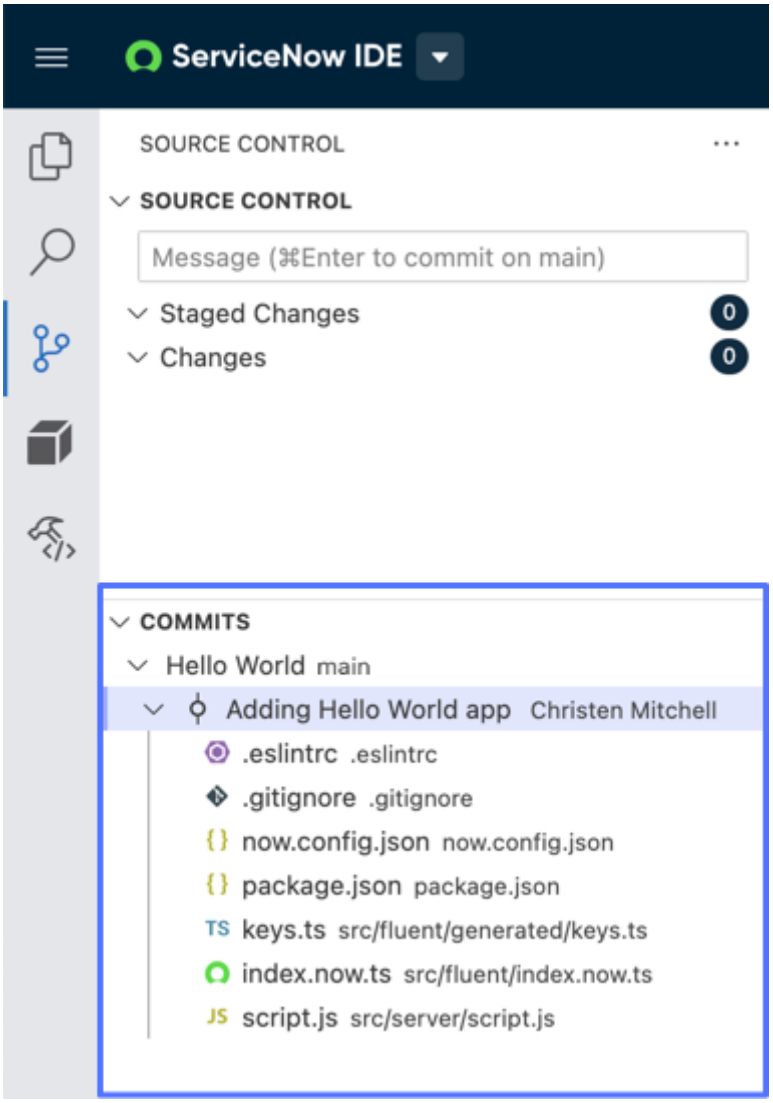
b. In the message box, enter a commit message.

c. Select the Commit icon ( ).

Example



Now that you have committed changes, you can expand the Commits section to see your commit history and details about each commit.



To push your changes to a remote repository that other developers can access, you need to create a repository with a Git provider like GitHub and generate a personal access token.

Note:
The following steps demonstrate using GitHub and basic authentication as an example, but you could use another Git provider of your choosing or OAuth 2.0 authentication. For more information, see Integrating source control with the ServiceNow IDE.

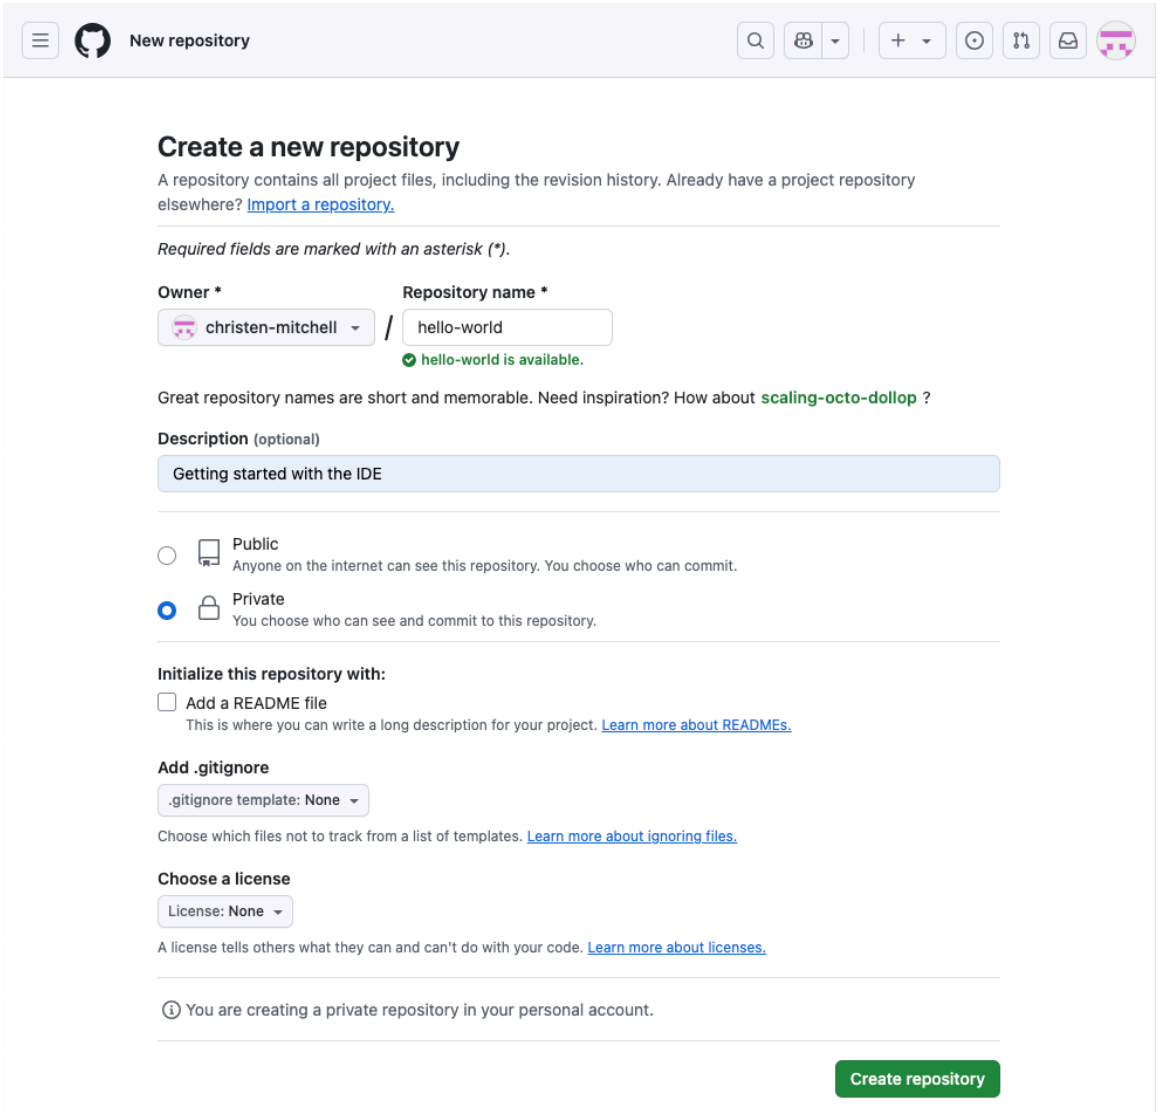
4. Create a remote repository.

   a. Log in to your GitHub account.

   b. Select the Create new menu (+) and select **New repository**.

   c. On the New repository form, fill in the fields.

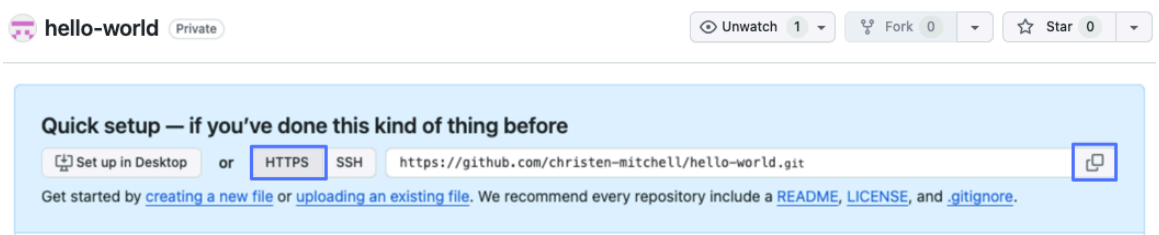
Example



d. Select **Create repository**.

e. From your repository, copy the HTTPS URL and paste it somewhere that you can easily access it again for use in the following steps.

Example



5. Create a personal access token.

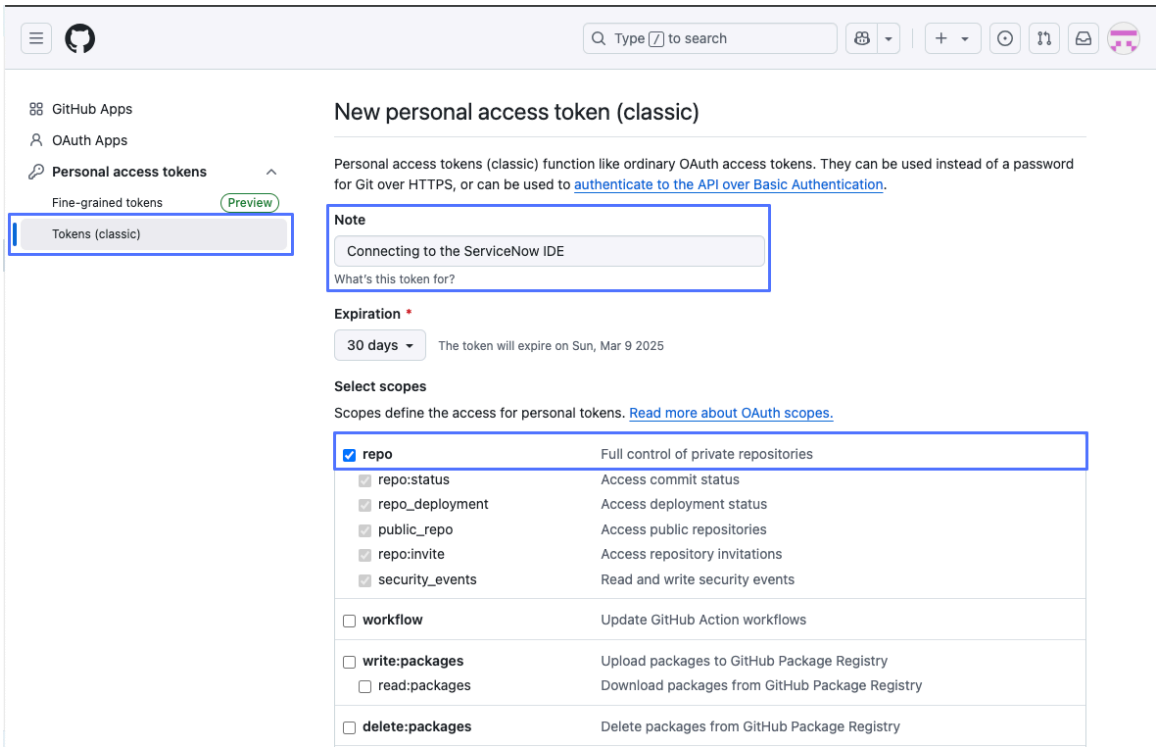
a. From your user profile in GitHub, select **Settings**.

b. From the settings categories, select **Developer Settings**.

c. From the Personal access tokens menu, select **Tokens (classic)**.

d. From the Generate new token menu, select **Generate new token (classic)**.

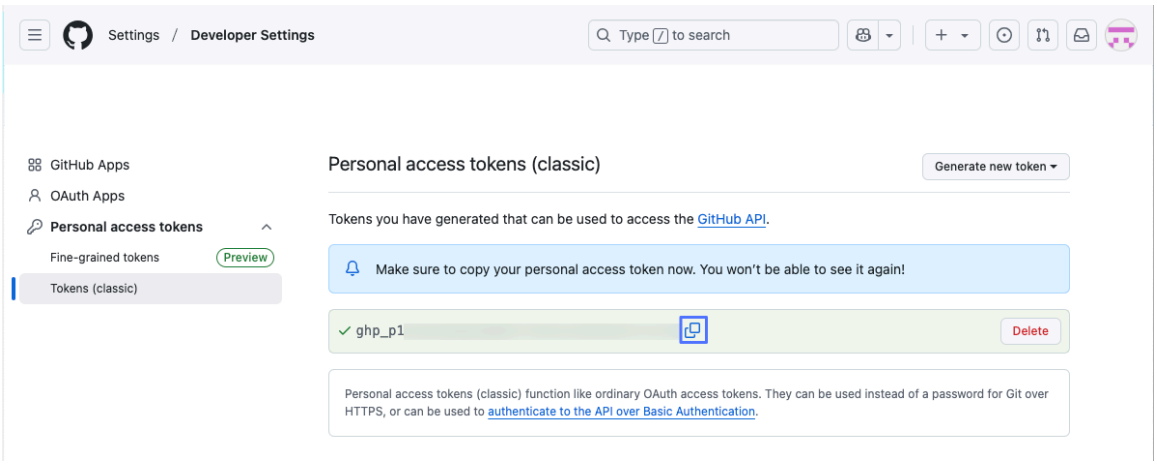
e. On the New personal access token (classic) form, select the **repo** scope and fill in the remaining required fields.
The **repo** scope is required to connect to the ServiceNow IDE.



f. Select **Generate token**.

g. Copy the token and paste it somewhere that you can easily access it again for use in the following steps so you don't need to regenerate it.

Example



6. Configure basic authentication in the ServiceNow IDE to connect to the remote repository.

a. Navigate to the ServiceNow IDE.

b. Use one of the following keyboard shortcuts to open the command palette:

- Windows: Ctrl-Shift-P
- Mac: Cmd-Shift-P

c. Enter `Git: Set IDE Git credentials` and press Enter.

d. From the New Git credential form, select **Basic auth**.

e. On the form, fill in the fields.

New Git credential form

Field	Description
Git repository URL	The HTTPS URL of the Git repository you created in GitHub. For example: `https://github.com/<owner>/hello-world.git`.
Git username	Your GitHub user name.
Personal access token	The personal access token that you generated from GitHub.

f. Select **Submit**.

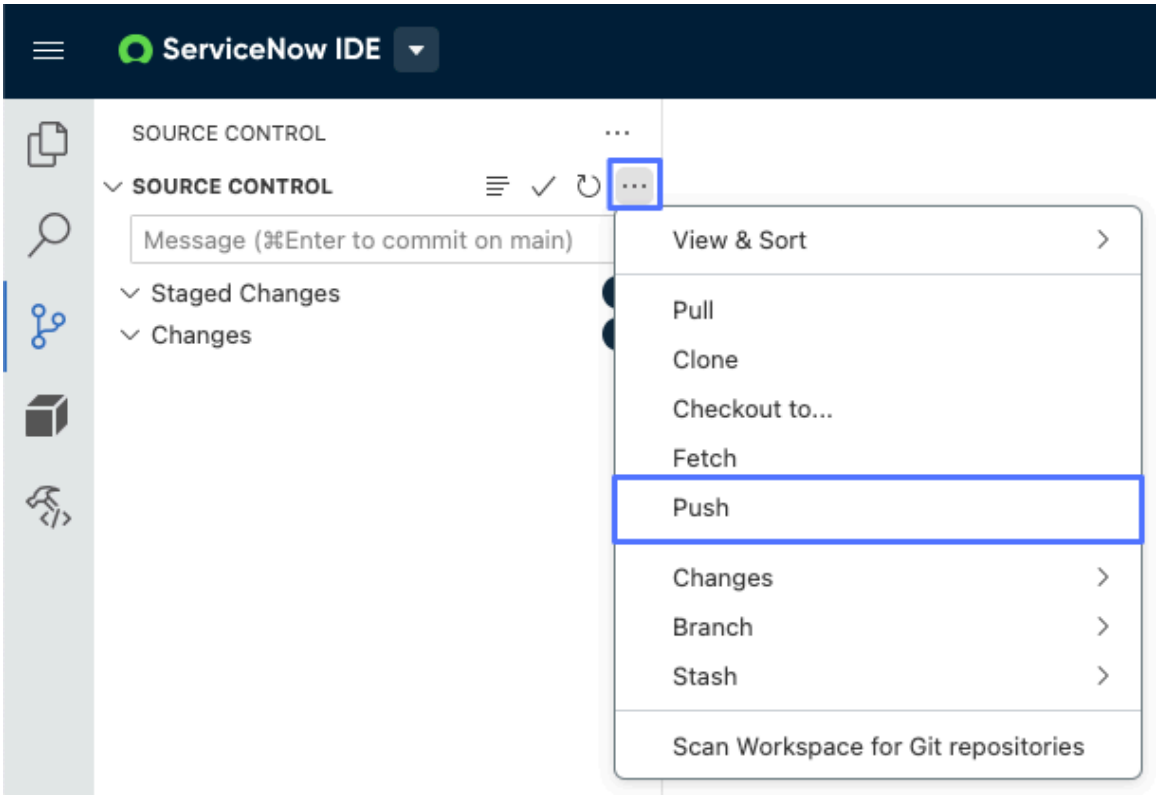
Now that your authentication credentials are configured, you can push your application to the remote repository.

Tip:
If you need to manage existing Git credentials, use the `Git: Manage Git credentials` command from the command palette.

7. Push your changes to the remote repository.

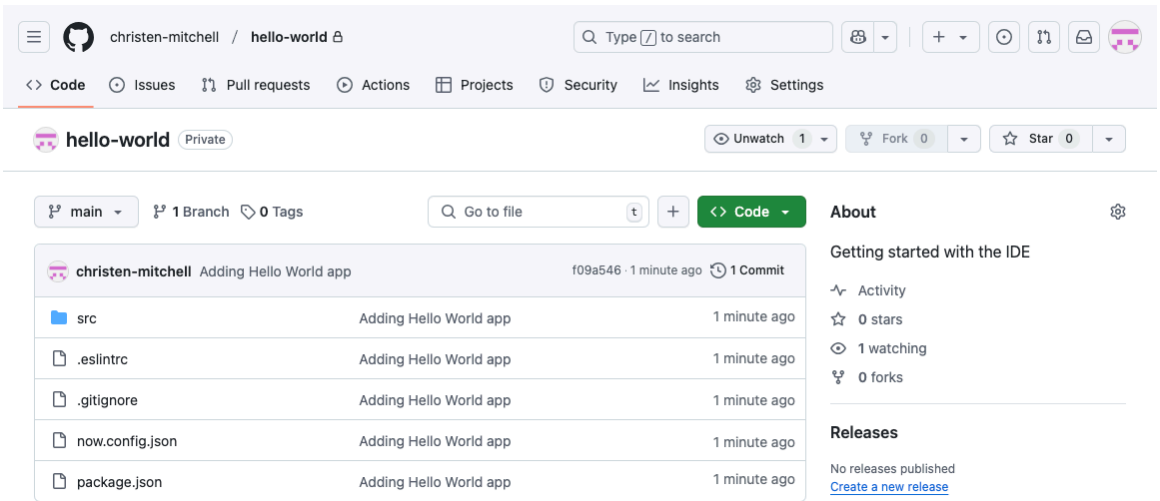
a. Select the More actions menu icon (···) and select **Push**.

Example



b. Enter the HTTPS URL of the remote Git repository and press Enter.

The application is added to the remote repository in GitHub, and changes to the application across users are tracked remotely.



Result

You can check out or create branches in the repository and push changes to the remote repository. For more information, see Using source control in the ServiceNow IDE.

Note:
An application on an instance can be connected to only one repository at a time. To update the remote repository an application is connected to, you can use the `Git: Update remote origin` command from the command palette and enter a different remote repository URL.

What to do next
Continue to Tutorial part 3: Define a table in ServiceNow Fluent code.

Tutorial part 3: Define a table in ServiceNow Fluent code

Create a table and reference it in sample script definitions using the ServiceNow Fluent APIs.

Before you begin
Complete Tutorial part 2: Initialize a repository for your application.

Role required: admin

About this task
ServiceNow Fluent is a domain-specific language (DSL) based on TypeScript for defining the metadata files [sys_metadata] that make up applications and includes APIs for the different types of metadata, such as tables, roles, ACLs, business rules, and Automated Test Framework tests. You use objects in the ServiceNow Fluent APIs to define metadata in files with the `.now.ts` extension. The ServiceNow IDE has language processing and validation for ServiceNow Fluent APIs and applications by default. For more information about ServiceNow Fluent, see ServiceNow Fluent.

In this example, you create a simple table for a to-do list using objects in the ServiceNow Fluent Table API. Then, you update the sample code for business rule and client script definitions to reference the new table. Lastly, you review your changes from the Metadata Explorer. For more information about the Table API, see Table API - ServiceNow Fluent.

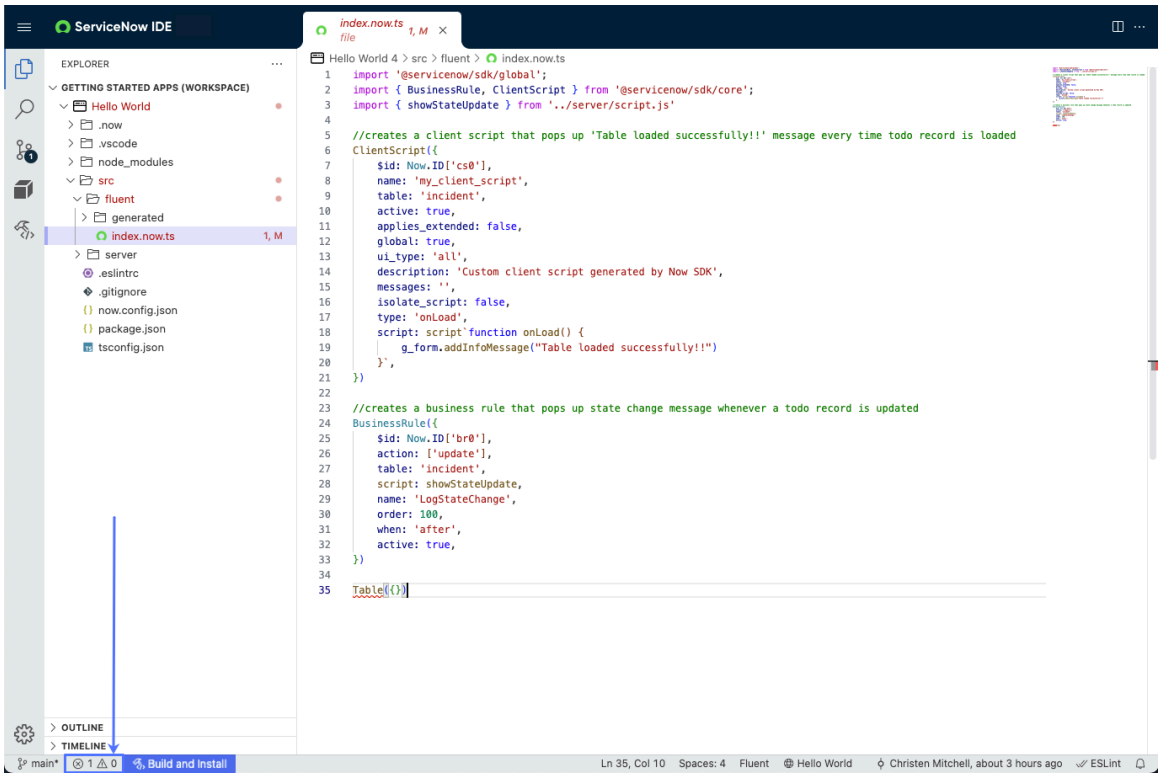
Procedure

1. From the Activity Bar, select the File Explorer view ( ).
2. Navigate to the `src/fluent` directory in your application.
3. Open the `index.now.ts` sample file.

   Tip:
   You can write ServiceNow Fluent code in a single file or as many `.now.ts` files as you want and organize files in directories within the `fluent` directory.

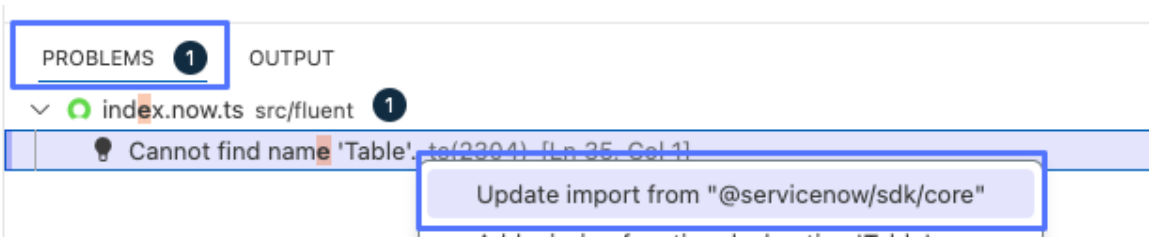
4. On a new line at the end of the file, enter `Table({})` to add the Table object.
5. From the Status Bar, select the diagnostics icon (⊗ 1 ⚠ 0) to open the Problems panel and check for issues in the code.

Example



6. Right-click the error that appears and select the **Update import from "@servicenow/sdk/core"** quick fix.

Example



In line 2, the *Table* object is added to the list of imports from `@servicenow/sdk/core`:

```
import { BusinessRule, ClientScript, Table }
 from '@servicenow/sdk/core'
```

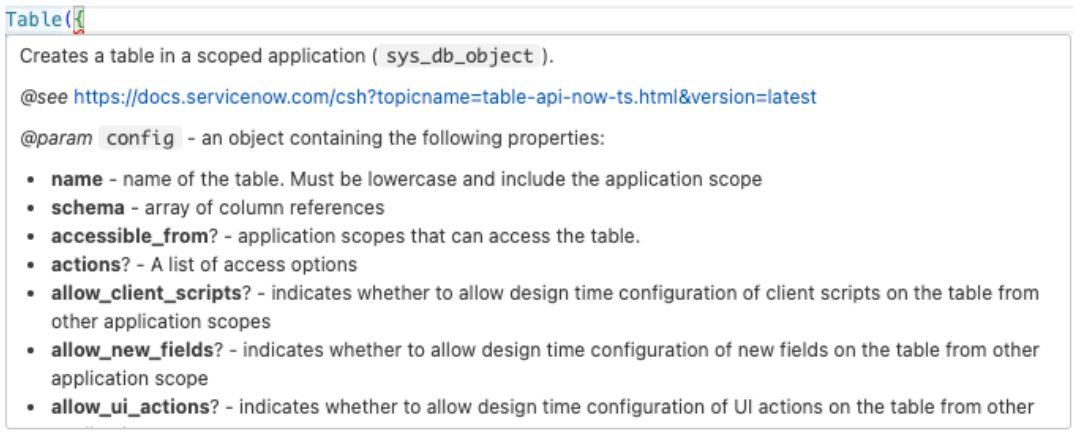
Tip:
After fixing this issue, you can close the Problems panel while you proceed through the following steps. In a later step, you return to it if any issues remain.

7. In the *Table* object, add the following properties.

   - name: The table name must begin with the application scope and use all lowercase letters in the following format: `<scope>_<name>`. You can find the scope in the `now.config.json` file for the application.
   - label: The label should be unique and appears for the table in list and form views.
   - extends: The name of another table on which the table is based.

```
Table({
    name: 'x_snc_hello_world_to_do', //ensure that the name begins with the correct scope (<scope>_<name>)
    label: 'To-do Items',
    extends: 'task',
})
```

Tip:
Hover over an object to see its in-product documentation.



8. For type-ahead support when defining columns in the table, before the *Table* object, add an exported variable with the same name as the *name* property.

```
export const x_snc_hello_world_to_do = Table({
    name: 'x_snc_hello_world_to_do',
    label: 'To-do Items',
    extends: 'task',
})
```

9. In the *Table* object, add the *schema* property to define columns in the table.

```
export const x_snc_hello_world_to_do = Table({
    name: 'x_snc_hello_world_to_do',
    label: 'To-do Items',
    extends: 'task',
    schema: {
        //define columns here
    }
})
```

The schema property is an array of *Column* objects. There are many types of columns based on the field type. Column objects use the format *<Type>Column* where *<Type>* is the field type.

Use the following details to define three columns in the table: Deadline, Matrix, and Task. Refer to the Column object documentation to help you configure each column.

Column name	Details
deadline	○ Label: Deadline ○ Type: Date/Time

Column name	Details
matrix	○ Label: Matrix ○ Type: String ○ Choices: ▪ Label: Urgent and Important ▪ Label: Important but Not Urgent ▪ Label: Urgent but Not Important ▪ Label: Neither Urgent nor Important
task	○ Label: Task ○ Type: String ○ Max length: 120

Example
With these details, the *schema* property should look similar to this example. The keys that you use for the choices can be any string.

```
export const x_snc_hello_world_to_do = Table({
    name: 'x_snc_hello_world_to_do',
    label: 'To-do Items',
    extends: 'task',
    schema: {
        deadline: DateColumn({ label: 'Deadline' }),
        matrix: StringColumn({
            label: 'Matrix',
            choices: {
                do: { label: 'Urgent and Important' },
                decide: { label: 'Important but Not Urgent' },
                delegate: { label: 'Urgent but Not Important' },
                delete: { label: 'Neither Urgent nor Important' },
            },
        }),
        task: StringColumn({ label: 'Task', maxLength: 120 }),
    },
})
```

10. In line 2, add imports for the *DateColumn* and *StringColumn* objects.

```
import { BusinessRule, ClientScript, Table, DateColumn,
 StringColumn } from '@servicenow/sdk/core'
```

11. Update the existing business rule and client script definitions to reference the table you created.
    a. In the *ClientScript* object, change the value of the *table* property to the table name (`x_snc_hello_world_to_do`).
    b. Repeat the previous step for the *BusinessRule* object.
12. If the diagnostics icon (⊗ 1 ⚠ 0) shows any errors or warnings, select it to open the Problems panel and review the diagnostic messages and quick fixes to resolve them.
13. Save your changes using one of the following keyboard shortcuts.

- Windows: Ctrl-S
- Mac: Cmd-S

Note:
If you have unsaved changes in a file, a dot icon appears on the file tab.

14. From the Status Bar, select **Build and Install**.

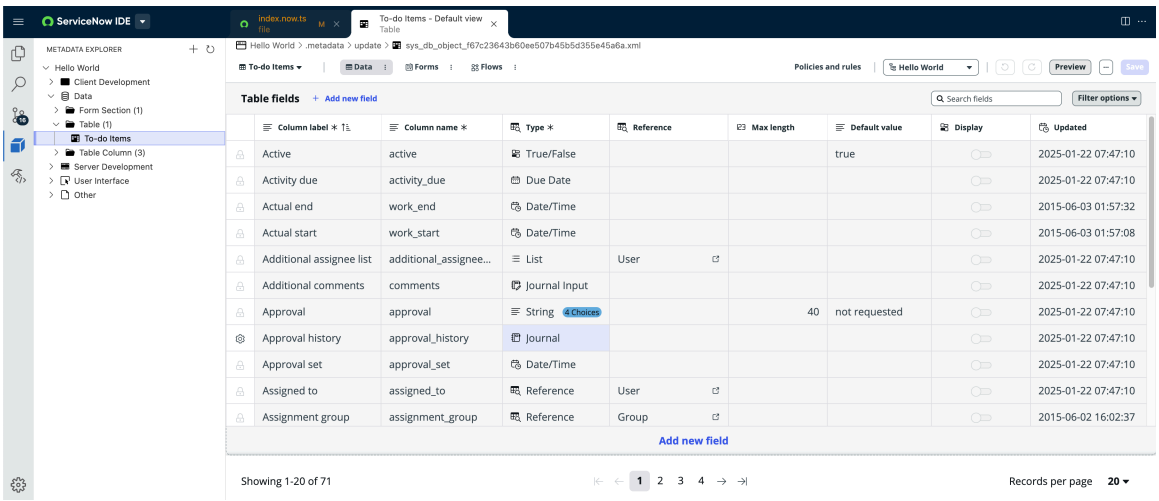
    If the installation completes successfully, the updated ServiceNow Fluent source code is compiled into Application Files [sys_metadata] on the instance.

15. Review your changes as metadata.

    a. From the Activity Bar, select the Metadata Explorer view ( ).

    b. Select your application to expand it.

    c. Navigate to **Data** > **Table** and select **To-do Items**.
    The table opens in Table Builder.



16. **Optional:** Edit the metadata and synchronize your changes into the source code.
    From the Metadata Explorer, you can simulate another user editing the metadata outside of the source code to see changes transformed back into the code you added.

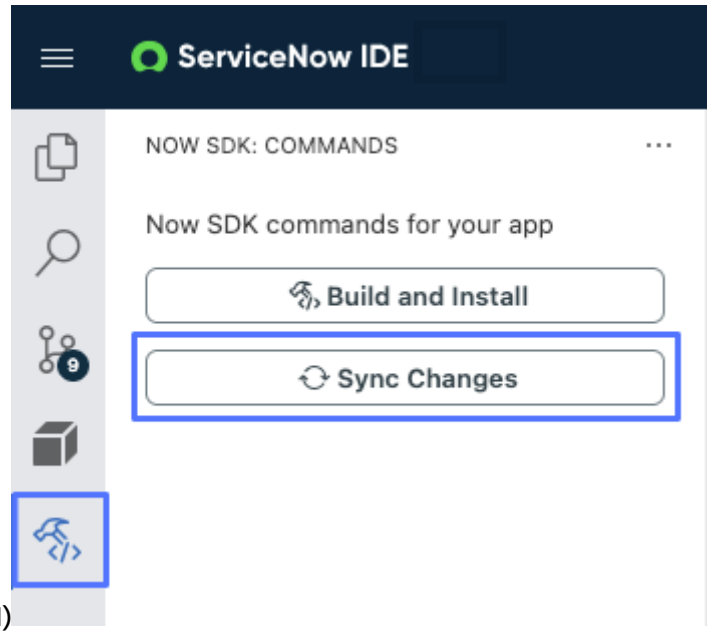
    a. In Table Builder, search for the Task field and change the Column label from "Task" to "To Do".

    b. Select **Save**.

    c. From the Activity Bar, select the Now SDK view ( ).

    d. Select **Sync Changes**.

Example



(Optional)

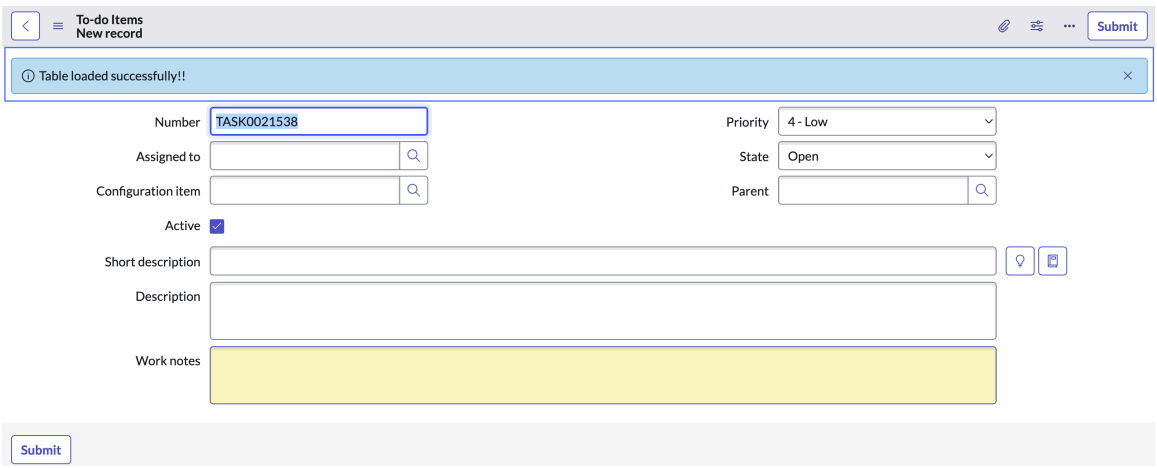
In the `index.now.ts` file, you should see the *`label`* property of the task column changed to `'To Do'`.

```
task: StringColumn({ label: 'To Do', maxLength: 120 }),
```

Result

You have created your first application metadata using ServiceNow Fluent APIs. The To-do Items [x_snc_hello_world_to_do] table can be modified in source code by other ServiceNow IDE users or from other ServiceNow AI Platform user interfaces.

From the ServiceNow AI Platform, you can navigate to the list view of the table by entering `x_snc_hello_world_to_do.list` in the navigation filter. Because you updated the client script definition to run on the To-do Items [x_snc_hello_world_to_do] table, if you select **New** to add a record to the table, the message from the client script appears when the record loads.



What to do next

Continue to Tutorial part 4: Install and use a third-party library.

Tutorial part 4: Install and use a third-party library

Install a third-party library from Node Package Manager (npm) and use it in a JavaScript module.

Before you begin

Complete Tutorial part 3: Define a table in ServiceNow Fluent code.

Role required: admin

About this task

Installing third-party libraries allows you to use existing open-source functionality in JavaScript modules to accelerate application development. Then you can refer to JavaScript modules that call third-party code from server-side script definitions in your source code, such as the business rule in the `index.now.ts` file.

In this example, you install a Lodash library to get common JavaScript utilities and methods. You use one of these methods, *`snakeCase`*, in the *`showStateUpdate`* function in a sample JavaScript module to display a message string in snake case, which separates words with underscores instead of spaces. In the `index.now.ts` file, the sample business rule is configured to use the *`showStateUpdate`* function for its script and to run after a record is updated in the To-do Items [x_snc_hello_world_to_do] table.

Procedure

1. Install the *`snakeCase`* method from the Lodash library in your application.

   a. From the Activity Bar, select the File Explorer view ( ).

   b. Open the `package.json` file for the application.

   c. After the `devDependencies` field, add the `dependencies` field with the package name and version of the library.

   Example

   ```
   },
        "dependencies": {
             "lodash.snakecase": "4.1.1"
        }
   }
   ```

   d. For applications that use TypeScript in JavaScript modules, add the lodash.snakecase types to the `devDependencies` field to get the type annotations for the library.

   ```
   "devDependencies": {
             "@types/lodash.snakecase": "4.1.1",
             "typescript": "5.5.4",
             "@servicenow/sdk": "2.2.4",
             "@servicenow/glide": "26.0.1",
             "eslint": "8.50.0",
             "@servicenow/eslint-plugin-sdk-app-plugin": "2.2.4"
        }
   ```

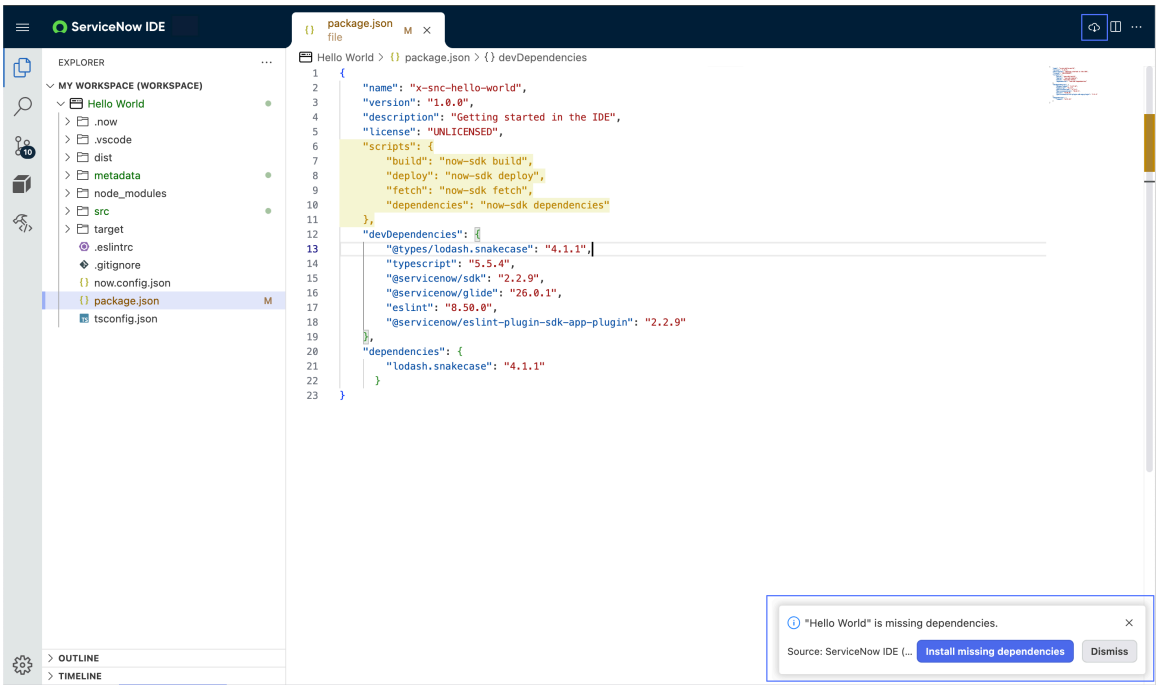
   e. Save your changes.

   f. When prompted, select **Install missing dependencies**.

   Tip:

   You can also select the Install Dependencies icon ( ) or use the `Package Manager: Install Dependencies` command from the command palette.

Example



Libraries are installed as modules in the `node_modules` directory.

2. Use code from the Lodash library in a JavaScript module in your application.

   a. Navigate to the `src/server` directory in your application.

   b. Open the `script.ts` sample module.

   c. In the *`addInfoMessage`* method, wrap the message string in the *`snakeCase`* method from Lodash to convert it to snake case.

```
gs.addInfoMessage(snakeCase(`state updated from "${previousState}"
 to "${currentState}"`))
```

   d. In line 2, add an import for the *`snakeCase`* method in the *`lodash`* module.

Example

```
import snakeCase from 'lodash.snakecase'
```

> **Note:**
> The global Glide APIs are also imported so that you can use methods like *`addInfoMessage`* in your module code.
>
> ```
> import { gs } from '@servicenow/glide'
> ```

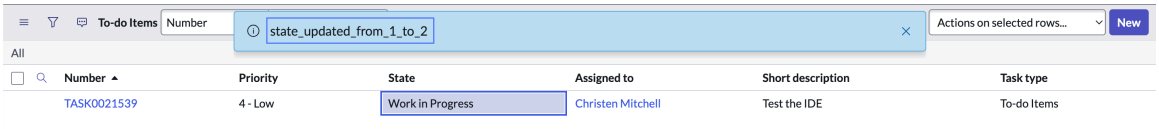
   e. Save your changes.

3. From the Status Bar, select **Build and Install**.

   If the installation completes successfully, the Lodash libraries are added to the EcmaScript Module [sys_module] table, and the `script.ts` module is updated in the EcmaScript Module [sys_module] table.

Result

After you update any field on a record in the To-do Items [x_snc_hello_world_to_do] table, the sample business rule runs and displays the message in snake case, with the words separated by underscores instead of spaces.



What to do next

Continue to Tutorial part 5: Clone the application on a different instance.

Tutorial part 5: Clone the application on a different instance

Clone the application from the remote repository to develop it on another instance.

Before you begin

Complete Tutorial part 4: Install and use a third-party library.

Role required: admin

About this task

If you have access to another instance, you can install the application from the remote repository onto the instance to support development across instances.

Note:
The instance and your user on the instance must meet the same requirements mentioned at the beginning of this tutorial.

Cloning is intended for developing an application on multiple non-production instances and managing it in a single repository. To publish an application and deploy it to a production instance, use the Application Repository. For more information, see ServiceNow application repository.

Procedure

1. Push your changes to the remote repository.

   a. From the Activity Bar, select the Source Control view ( ).

   b. From the Changes list, select the Stage All Tracked Changes icon ( ).

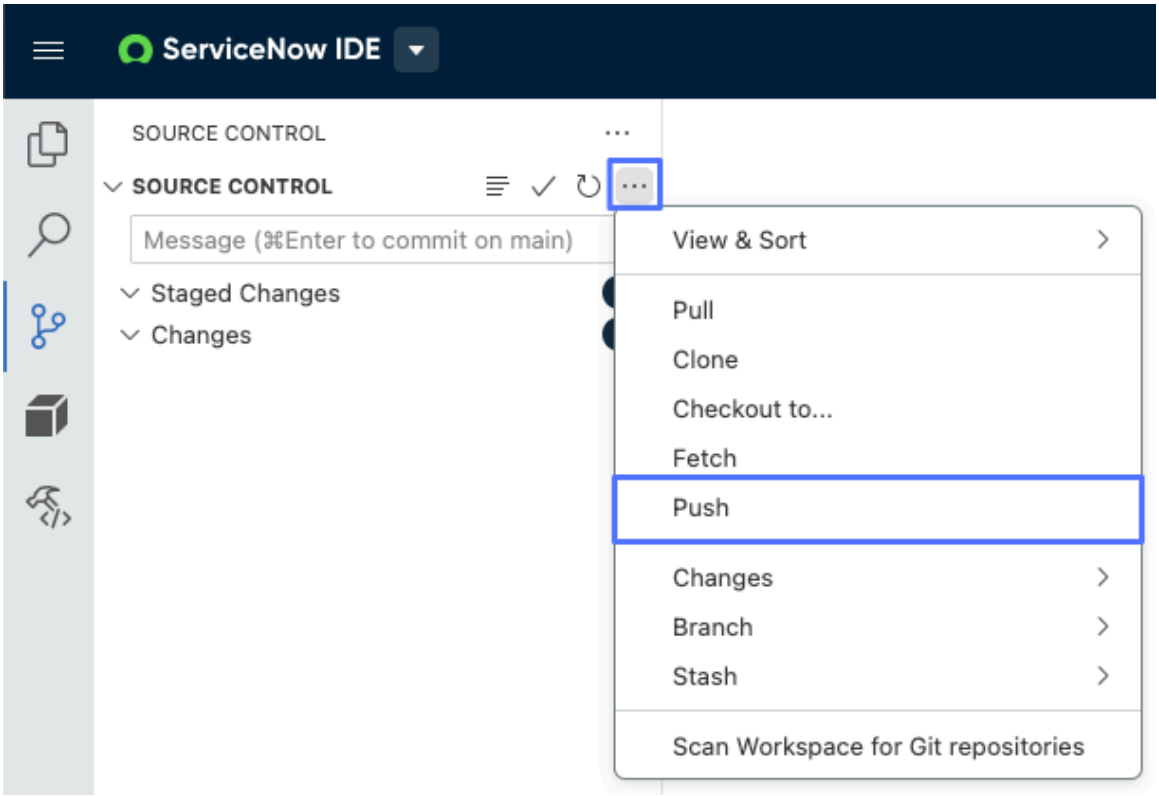
   c. From the Untracked Changes list, select the Stage All Untracked Changes icon ( ).
   All of your changes should be in the Staged Changes list.

   d. In the message box, enter a commit message.

   e. Select the Commit icon ( ).

f. Select the More actions menu icon (···) and select **Push**.

Example



All of your changes are available in the remote repository. You or other developers can clone the application onto another instance.

2. Log in to another ServiceNow instance.
3. Navigate to **All** > **App Development** > **ServiceNow IDE**.
4. Create a workspace or open an existing one.
5. Configure basic authentication in the ServiceNow IDE to connect to the remote repository.

   a. Use one of the following keyboard shortcuts to open the command palette:
   - Windows: Ctrl-Shift-P
   - Mac: Cmd-Shift-P

   b. Enter `Git: Set IDE Git credentials` and press Enter.

   c. From the New Git credential form, select **Basic auth**.

   d. On the form, fill in the fields.

New Git credential form

Field	Description
Git repository URL	The HTTPS URL to the Git repository you created in GitHub. For example: `https://github.com/<owner>/hello-world.git`.
Git username	Your GitHub user name.
Personal access token	The personal access token that you generated from GitHub.

e. Select **Submit**.

6. Clone the application.

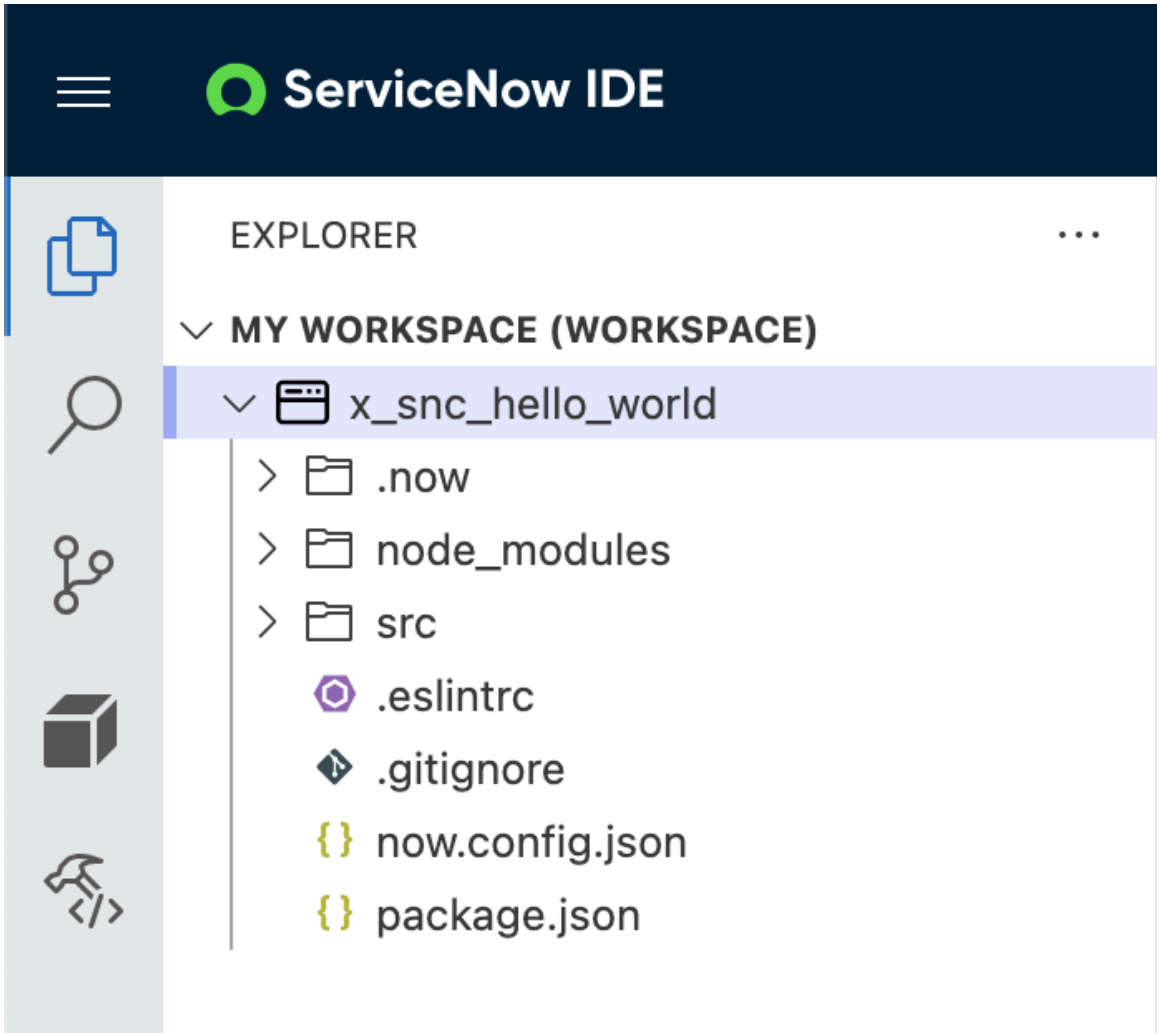
a. Use one of the following keyboard shortcuts to open the command palette:

- Windows: Ctrl-Shift-P
- Mac: Cmd-Shift-P

b. Enter `Git: Clone` and press Enter.

c. Enter the HTTPS URL to the remote Git repository and press Enter.

Result
The application is added to the instance with the files from the remote repository.



What to do next
Continue to Tutorial part 6: Learn more about the ServiceNow IDE.

Tutorial part 6: Learn more about the ServiceNow IDE

Learn more about the ServiceNow IDE to develop more complex applications.

Congratulations! You have created your first application in the ServiceNow IDE, learned how to write ServiceNow Fluent code to define application metadata, installed a third-party library and used its code in a JavaScript module, and managed all of these changes in source control with GitHub.

For more information about development in the ServiceNow IDE, refer to the following resources:

- ServiceNow IDE documentation
- ServiceNow Fluent API reference
- Introduction to the ServiceNow IDE on ServiceNow University
- ServiceNow IDE Demo video
- ServiceNow IDE and Fluent Creator Toolbox video
- ServiceNow SDK examples GitHub repository
- ServiceNow IDE, SDK, and Fluent forum in the ServiceNow Community
- ServiceNow IDE, SDK, and Fluent articles in the ServiceNow Community

- Search the Known Error Portal for known error articles
- Contact Customer Service and Support

Configuring the ServiceNow IDE

Install and set up the ServiceNow IDE for developers to use on a ServiceNow instance.

Install or update the ServiceNow IDE

Install or update the ServiceNow IDE application (sn_glider) from the ServiceNow® Store.

Before you begin

Review the ServiceNow IDE application listing in the ServiceNow Store for information on dependencies, licensing or subscription requirements, and release compatibility.

Role required: admin

About this task

ServiceNow IDE is active by default on instances on the Xanadu release. Update to the latest version of the ServiceNow IDE to use the latest features.

Procedure

1. Navigate to **Admin** > **Application Manager**.
2. Search for the ServiceNow IDE application (sn_glider).

   You can search for the application by its name or ID. If you can't find the application, you might have to request it from the ServiceNow Store.
3. Select the ServiceNow IDE application (sn_glider).
4. Select **Install** or **Proceed to Update**.

   In the Review Installation Details dialog box, you can select the version to install, review any dependencies that are installed along with your application, and select whether to install the application now or later.
5. In the dialog box, select **Install**.

What to do next

Create a workspace for your applications. For more information, see Create a workspace in the ServiceNow IDE.

ServiceNow IDE uses the public npm registry (`https://registry.npmjs.org`) as its default package source. If your network blocks access to this registry, you must have access to an alternate registry to download packages and build applications in the ServiceNow IDE. If access to the public npm registry is blocked on your system, you must configure a private npm registry in your Package Manager user settings in the ServiceNow IDE. For more information, see Install an npm package from a private registry with the ServiceNow IDE.

Update the ServiceNow SDK version for an application in the ServiceNow IDE

Configure which version of the ServiceNow SDK an application uses from the ServiceNow IDE.

Before you begin

Role required: admin

About this task

From the ServiceNow IDE, you can configure which version of the ServiceNow SDK, including the ServiceNow Fluent APIs, an application uses beginning with ServiceNow SDK version 3.0.

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace with an application.
3. From the Activity Bar, select the File Explorer view ( ).
4. Open the `package.json` file for the application.
5. In the `devDependencies` field, update the versions of the `@servicenow/sdk` and `@servicenow/eslint-plugin-sdk-app-plugin` packages to 3.0.0 or later.

   Example

   For example:

   ```
   "devDependencies": {
               "@servicenow/sdk": "3.0.0",
               "@servicenow/glide": "26.0.1",
               "eslint": "8.50.0",
               "@servicenow/eslint-plugin-sdk-app-plugin": "3.0.0"
   }
   ```

6. Save your changes.
7. Use one of the following keyboard shortcuts to open the command palette:
   - Windows: Ctrl-Shift-P
   - Mac: Cmd-Shift-P
8. Enter `Package Manager: Install Dependencies` and press Enter.
   The dependencies are updated in the `node_modules` directory.

Result

You can use the latest version of the ServiceNow SDK application packaging service and ServiceNow Fluent APIs in your application.

Adding applications in ServiceNow IDE

Add applications in the ServiceNow IDE to get started with development in source code.

1. Create a workspace in the ServiceNow IDE

   Create a workspace in which you can add applications in the ServiceNow IDE.

2. Get started developing a scoped application in source code by creating an application, converting an existing application, or cloning an existing application from a Git repository:

   - Create an application with the ServiceNow IDE

     Create a scoped application that supports development in source code.

   - Convert an application with the ServiceNow IDE

     Convert an existing scoped application to support development in source code.

- Clone a Git repository with the ServiceNow IDE

  Clone an existing scoped application that supports development in source code from a remote Git repository.

Create a workspace in the ServiceNow IDE

Create a workspace to view and organize the applications you're working on in the ServiceNow IDE.

Before you begin

Install the ServiceNow IDE. For more information, see Install or update the ServiceNow IDE.

Role required: admin

About this task

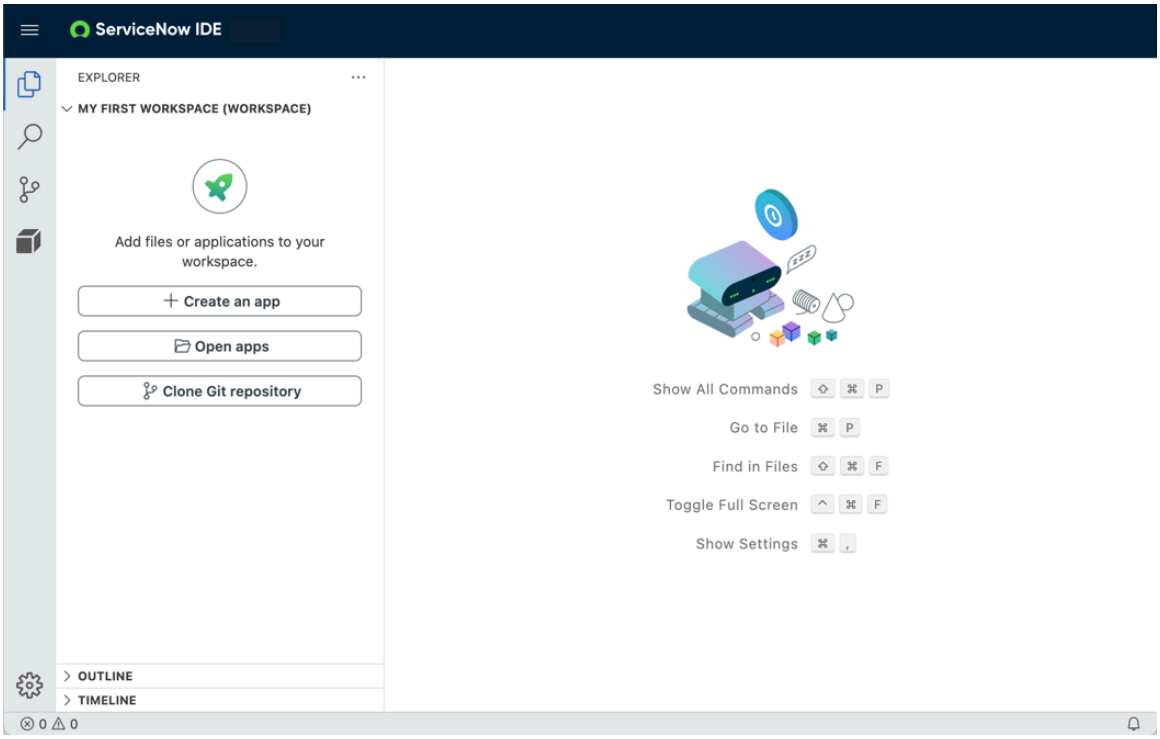
In a workspace in the ServiceNow IDE, you can add any applications that you're working on to navigate through multiple applications from one place. You can create multiple workspaces to group different sets of applications. Workspaces are specific to a user, and applications can be added or removed from a workspace at any time. When you open the ServiceNow IDE, the workspace in which you were most recently working opens. Workspaces in the ServiceNow IDE are based on workspaces in Visual Studio Code. For general information about workspaces, see the Visual Studio Code documentation website.

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. From the ServiceNow IDE home page, select **Create a workspace**.

   Tip:
   You can also use the `Workspaces: Create a Workspace` command from the command palette.

3. Enter a name for the workspace and press Enter.
4. Enter a description for the workspace and press Enter.
   The workspace becomes the active workspace.



5. **Optional:** Add existing applications to the workspace.

   a. Select **Open apps**.

   b. Select an application.
   Only applications created or converted with the ServiceNow IDE or ServiceNow SDK can be added. You can add additional applications to a workspace from the main menu or the command palette with the `Workspaces: Add Application to Workspace` command.

What to do next

Create, convert, or clone an application and add it to your workspace. For more information, see Adding applications in ServiceNow IDE.

To switch the active workspace, you can browse and select other workspaces from the ServiceNow IDE home page or from the command palette with the `Workspaces: Browse Workspaces` command.

Create an application with the ServiceNow IDE

Create a scoped application to develop in source code with the ServiceNow IDE.

Before you begin

Create a workspace for your applications. For more information, see Create a workspace in the ServiceNow IDE.

Role required: admin

Procedure

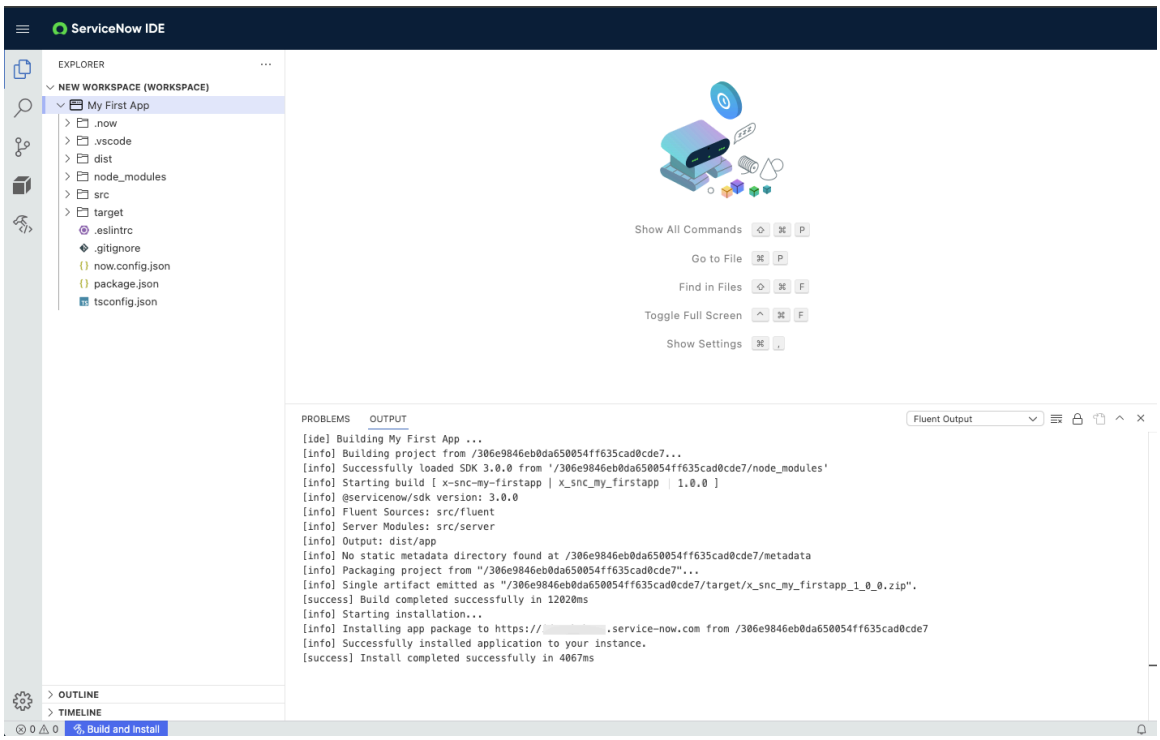
1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace.
3. Use one of the following keyboard shortcuts to open the command palette:

- Windows: Ctrl-Shift-P
- Mac: Cmd-Shift-P

4. Enter `Fluent: Create Fluent App` and press Enter.
5. Enter a name for the application and press Enter.
6. Enter a description for the application and press Enter.
7. Enter a scope for the application and press Enter.
   The scope name must be unique on the instance, begin with x_<prefix>, and be 18 characters or fewer. For more information, see Namespace identifier.
8. Enter a package name for the application and press Enter.
   The package name must adhere to Node Package Manager (npm) package naming standards.
9. Select a template that defines the default application structure.
10. **Optional:** Build and install your application to compile source code into application metadata and make your changes available across the instance. For more information, see Build and install an application in the ServiceNow IDE.

Result

A scoped application with the default application structure is added to the instance and open in your workspace. For information about the application structure, see the Application structure section of the Building applications in source code topic.



Trouble?

In the status bar, a message confirms whether the application was created. If the application creation fails, review the output logs in the panel.

> **Note:**
> For the ServiceNow IDE to install the required dependencies in an application, the public npm registry must respond with the HTTP `Access-Control-Allow-Origin` header.

What to do next

From your Git provider, create a dedicated Git repository for the application. Initialize a local Git repository for your application and push it to the remote repository. For more information, see Initialize a Git repository with the ServiceNow IDE.

In the ServiceNow IDE, start developing your application in source code with ServiceNow Fluent, writing custom JavaScript modules, or adding third-party libraries.

Convert an application with the ServiceNow IDE

Convert an existing scoped application to support development in source code with the ServiceNow IDE.

Before you begin

Create a workspace for your applications. For more information, see Create a workspace in the ServiceNow IDE.

Role required: admin

> **Note:**
> With ServiceNow IDE version 3.1.4 and earlier, the sn_glider.ide_fluent_admin role is also required to convert applications.

About this task

Existing scoped applications that weren't created with the ServiceNow IDE or ServiceNow SDK must be converted to support development in source code. Converting an application adds the necessary files and directories for developing it in source code. You can choose whether to convert existing application metadata into ServiceNow Fluent code.

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace.
3. Use one of the following keyboard shortcuts to open the command palette:
   - Windows: Ctrl-Shift-P
   - Mac: Cmd-Shift-P
4. Enter `Fluent: Convert a scoped app to Fluent` and press Enter.
5. Select a scoped application from the list.

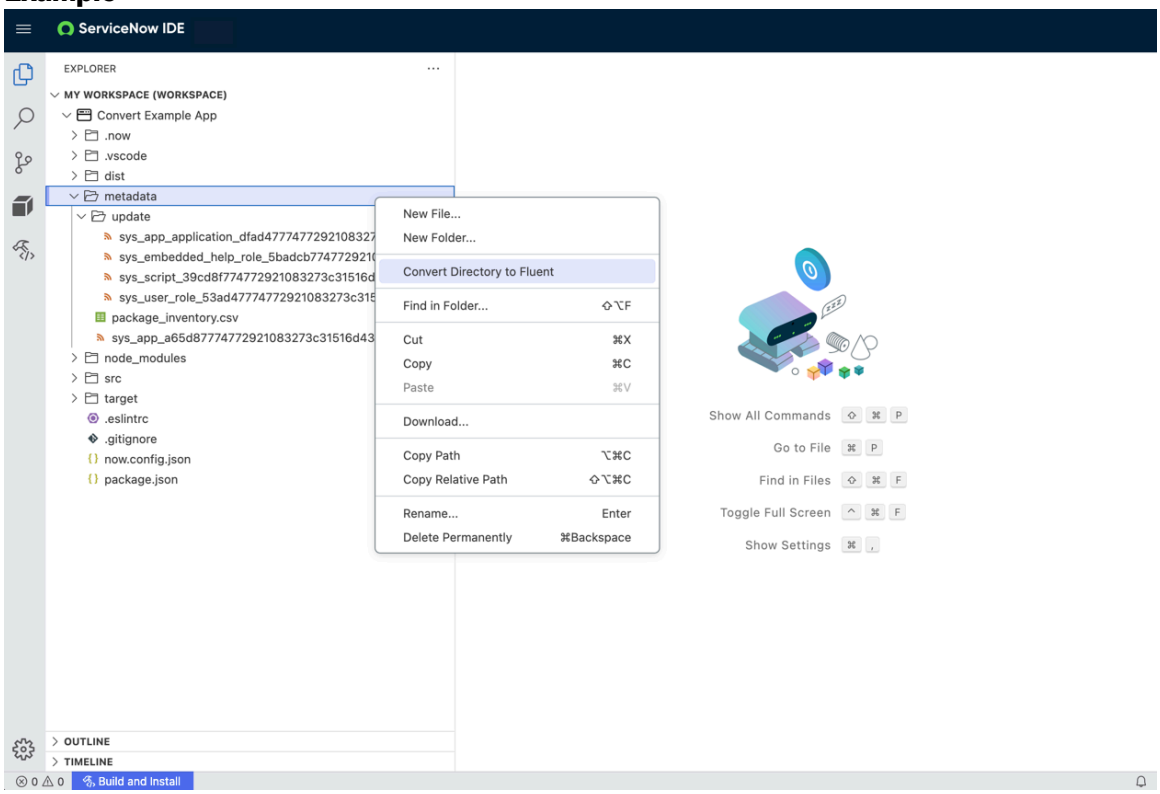
   Applications that haven't been converted are listed as `Is Fluent app: False`.

   The scoped application is added to your workspace with the default application structure but the application metadata isn't converted into ServiceNow Fluent code. For information about the application structure, see the Application structure section of the Building applications in source code topic.
6. **Optional:** To convert existing metadata into ServiceNow Fluent code, complete the following steps.

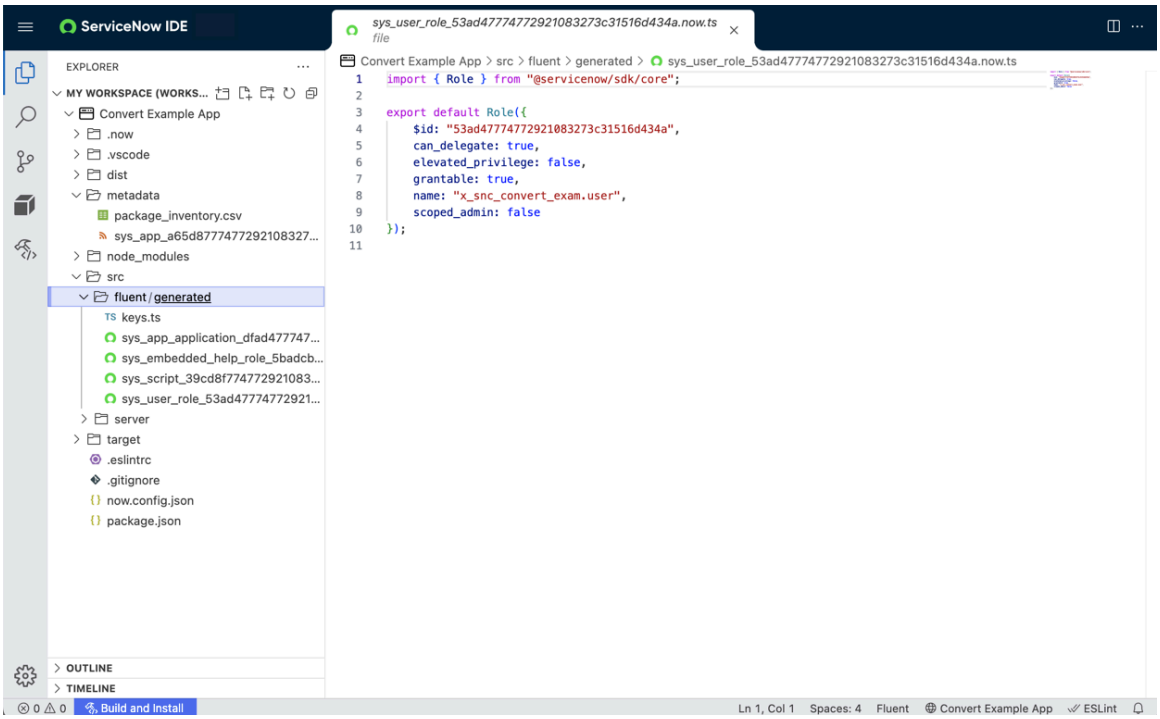
a. From the Activity Bar, select the File Explorer view ( ).

b. Right-click the `metadata` directory for the application and select **Convert Directory to Fluent**.

Example



Application metadata is defined in ServiceNow Fluent code in the `fluent/generated` directory and removed from the `metadata` directory and its sub-directories.



Note:
A limited number of metadata types, such as Metadata Snapshots [sys_metadata_link] and UX Assets [sys_ux_lib_asset], can't be represented as ServiceNow Fluent code and aren't transformed. These metadata types remain as metadata XML files in the `metadata` directory of your application.

7. **Optional:** Build and install your application to compile source code into application metadata and make your changes available across the instance. For more information, see Build and install an application in the ServiceNow IDE.

Result

The converted application is added to your workspace with the necessary files and directories to support development in source code. After installing a converted application, the **Package JSON** field of the custom application record [sys_app] contains the path to the `package.json` file for the application.

Trouble?

Note:
For the ServiceNow IDE to install the required dependencies in an application, the public npm registry must respond with the HTTP `Access-Control-Allow-Origin` header.

What to do next

From your Git provider, create a dedicated Git repository for the application. Initialize a local Git repository for your application and push it to the remote repository. For more information, see Initialize a Git repository with the ServiceNow IDE.

In the ServiceNow IDE, start developing your application in source code with ServiceNow Fluent, writing custom JavaScript modules, or adding third-party libraries.

Clone a Git repository with the ServiceNow IDE

Clone a remote Git repository to collaborate on applications in source control with the ServiceNow IDE.

Before you begin

- Create a workspace for your applications. For more information, see Create a workspace in the ServiceNow IDE.
- Set your basic or OAuth 2.0 credentials for the ServiceNow IDE to connect to your Git repository. For more information, see Connect to a Git provider using basic authentication with the ServiceNow IDE or Configure OAuth 2.0 credentials to connect to a Git provider with the ServiceNow IDE.

Role required: admin

About this task

You can clone a remote Git repository that contains applications created or converted with the ServiceNow IDE or ServiceNow SDK. The repository must contain one or more applications with `now.config.json` and `package.json` files.

Note:
ServiceNow IDE supports cloning from Git servers on Git version 2.3.2 or later.

Cloning is intended for developing an application on multiple non-production instances and managing it in a single repository. To publish an application and deploy it to a production

instance, use the Application Repository. For more information, see ServiceNow application repository.

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace to which you want to add the application.
3. Use one of the following keyboard shortcuts to open the command palette:
   - Windows: Ctrl-Shift-P
   - Mac: Cmd-Shift-P
4. Enter `Git: Clone` and press Enter.
5. Enter a remote Git repository URL and press Enter.

Result

The application is added to the instance and your workspace with the files from the remote repository. Only the default branch is cloned initially. To check out another branch, you must fetch the other branches from the remote repository using the `Git: Fetch` command from the command palette.

What to do next

You can check out or create branches in the repository and push changes to the remote repository. For more information, see Using source control in the ServiceNow IDE.

Integrating source control with the ServiceNow IDE

Integrate with remote Git repositories to manage applications in source control with the ServiceNow IDE.

You can connect to a Git provider using basic or OAuth 2.0 authentication. Then, initialize a repository for an application in the ServiceNow IDE and push it to a remote repository or clone a remote repository that contains an application. After setting up authentication and connecting to a repository, you can use common Git commands to manage applications in source control.

Learn how to get started using source control in the ServiceNow IDE in the following topics.

Instance requirements

If an instance includes modified configurations for saving attachments, the following requirements must be met to perform Git operations:

- If the *glide.attachment.extensions* system property is configured, it must contain `txt,gitdata`.
- If the *glide.security.attachment_type.use_blacklist* system property is set to true, the *glide.attachment.blacklisted.extensions* system property must not contain `txt,gitdata` and the *glide.attachment.blacklisted.types* system property must not contain `text/plain,application/octet-stream`.

If you want to use custom extensions for attachments, set the following properties to custom values: *sn_glider.git.attachment.extension.text* and *sn_glider.git.attachment.extension.binary*. For more information, see ServiceNow IDE properties.

Connect to a Git provider using basic authentication with the ServiceNow IDE

Connect to a Git domain using basic authentication credentials to manage applications in source control from the ServiceNow IDE.

Before you begin

- From your Git provider, generate a personal access token to use for basic authentication to the Git domain . You must provide your Git user name and personal access token when configuring your credentials for the ServiceNow IDE.
- Create a dedicated Git repository for an application in a Git provider such as GitHub, GitLab, Bitbucket, or Azure Repos.

Role required: admin

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Use one of the following keyboard shortcuts to open the command palette:
   - Windows: Ctrl-Shift-P
   - Mac: Cmd-Shift-P
3. Enter `Git: Set IDE Git credentials` and press Enter.
4. From the New Git credential form, select **Basic auth**.
5. On the form, fill in the fields.

New Git credential form

Field	Description
Git repository URL	The HTTPS URL of a Git repository associated with your Git credentials.
Git username	Your Git user name.
Personal access token	A personal access token that you generate from your Git provider.

6. Select **Submit**.

Result

Your Git credentials are associated with your user on the instance and used for all repositories in the domain from the Git repository URL. If you add different credentials for a repository in the same domain, the new credentials are used and the previous credentials are set to inactive.

What to do next

After initializing or cloning a repository, you can begin using source control. For more information, see Using source control in the ServiceNow IDE.

To manage existing Git credentials, use the `Git: Manage Git credentials` command from the command palette.

Connect to a Git provider using OAuth 2.0 with the ServiceNow IDE

Set up an OAuth 2.0 application registry and credentials to connect to your Git provider from the ServiceNow IDE.

Configure an OAuth 2.0 application registry for the ServiceNow IDE

Configure how the client ID and secret are sent to the OAuth 2.0 provider associated with your Git provider.

Before you begin

Create an OAuth application with your Git provider and configure it to redirect to your instance. In this OAuth application, use your instance URL as the homepage URL and `https://<instance>/oauth_redirect.do` for the authorization callback URL. GitHub, GitLab, Bitbucket, and Azure Repos are supported by default.

Important:
For Azure Repos, the maximum length of the **Client Secret** field must be updated to 2048 before you add the secret.

1. Navigate to **All** > **System Definition** > **Tables**.
2. Filter the table by entering `oauth_entity` for the **Name** field.
3. Select the Application Registries [oauth_entity] table.
4. In the Columns related list, locate the Client Secret column and enter `2048` as the value of its **Max length** attribute.
5. Select **Update**.

Role required: admin

About this task

To use OAuth 2.0 authentication with the ServiceNow IDE, you must register the OAuth application you created from your Git provider. Follow this procedure to configure an OAuth application registry [oauth_entity] on your instance.

Procedure

1. Navigate to **All** > **System OAuth** > **Application Registry** and then select **New**.
2. On the interceptor page, select **Connect to a third-party OAuth provider**.
3. On the form, fill in the fields.

   For additional information about fields on the form, see Connect to a third-party OAuth provider.

Application Registries form

Field	Description
Name	A unique name for the third-party OAuth connection.
Client ID	The client ID of the OAuth application in your Git provider.
Client Secret	The client secret of the OAuth application in your Git provider.
OAuth API Script	The script used to customize request and response to the external OAuth provider. Select one of the following depending on your Git provider: ○ GitHub: OauthAPIScriptForGitHub ○ GitLab: OauthAPIScriptForGitLab ○ Bitbucket: OauthAPIScriptForBitbucket ○ Azure Repos: OauthAPIScriptForAzureRepos

Field	Description
	Note: To use other Git providers, you can use these scripts as examples to create your own OAuth API script for your OAuth provider. The name of the script must begin with "Oauth".
Default Grant type	The default grant type used to establish the token. Select **Authorization code**. An authorization code is granted to the client to obtain an access token, which is then used to obtain access to the resource.
Refresh Token Lifespan	The time, in seconds, that the refresh token is valid.
Application	The application scope that contains this record.
Accessible from	An option to make the application registry accessible from all application scopes or from this scope only.
Active	An option for turning the OAuth application on or off.
Authorization URL	The OAuth authorization code endpoint for your Git domain. For example: ○ GitHub: `https://github.com/login/oauth/authorize` ○ GitLab: `https://gitlab.com/oauth/authorize` ○ Bitbucket: `https://bitbucket.org/site/oauth2/authorize` ○ Azure Repos: `https://app.vssps.visualstudio.com/oauth2/authorize`
Token URL	The OAuth server token endpoint for your Git domain. For example: ○ GitHub: `https://github.com/login/oauth/access_token` ○ GitLab: `https://gitlab.com/oauth/token` ○ Bitbucket: `https://bitbucket.org/site/oauth2/access_token` ○ Azure Repos: `https://app.vssps.visualstudio.com/oauth2/token`
Redirect URL	The OAuth callback endpoint. If empty, the instance auto-generates a value of `https://<instance>/oauth_redirect.do`.
Use mutual authentication	An option to use mutual authentication. Leave this option cleared to turn off using mutual authentication for token request and revocation.
Send Credentials	The way in which the OAuth client populates the client credentials in the request.

Field	Description
	○ For GitHub, GitLab, or Bitbucket, select **As Basic Authorization header**. ○ For Azure Repos, select **In Request Body (Form URL-Encoded)**.

4. Select **Submit**.

What to do next

Developers using the ServiceNow IDE must configure their own OAuth 2.0 credentials.

Configure OAuth 2.0 credentials to connect to a Git provider with the ServiceNow IDE

Connect to a Git domain using OAuth 2.0 credentials to manage applications in source control from the ServiceNow IDE.

Before you begin

- An administrator must configure how the client ID and secret are sent to the OAuth 2.0 provider associated with your Git provider. For more information, see Configure an OAuth 2.0 application registry for the ServiceNow IDE.
- Create a dedicated Git repository for an application in a Git provider such as GitHub, GitLab, Bitbucket, or Azure Repos.

Role required: admin

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Use one of the following keyboard shortcuts to open the command palette:
   - Windows: Ctrl-Shift-P
   - Mac: Cmd-Shift-P
3. Enter `Git: Set IDE Git credentials` and press Enter.
4. From the New Git credential form, select **OAuth**.
5. On the form, fill in the fields.

New Git credential form

Field	Description
Git repository URL	The HTTPS URL of a Git repository associated with your Git credentials.
Git username	Your Git user name.
Select an OAuth profile	The OAuth 2.0 credentials for your Git provider. The OAuth profile is created with the application registry, which must be configured by an administrator.

6. Select **Submit**.

   The first time you use a Git command, you're prompted to authorize your user from the Git provider.

Result
Your Git credentials are associated with your user on the instance and used for all repositories in the domain from the Git repository URL. If you add different credentials for a repository in the same domain, the new credentials are used and the previous credentials are set to inactive.

What to do next
After initializing or cloning a repository, you can begin using source control. For more information, see Using source control in the ServiceNow IDE.

To manage existing Git credentials, use the `Git: Manage Git credentials` command from the command palette.

Configure a MID Server to use source control with the ServiceNow IDE

Configure a MID Server to use source control with the ServiceNow IDE if your Git provider is behind a firewall.

Before you begin
Install a MID Server with a REST capability. For more information, see Installing the MID Server and Configure MID Server capabilities.

Role required: admin

Procedure
1. Change the application scope of the instance to ServiceNow IDE.
   a. In the Unified Navigation, select the globe icon ( ).
   b. Select **Application scope**.
   c. Select **ServiceNow IDE**.
2. Navigate to **All** > **MID Server** > **Applications**.
3. Select **New**.
4. On the form, fill in the fields.

MID Server Application form

Field	Description
Name	A name for the MID Server Application.
Default MID Server	The MID Server configured with a REST capability.
Application	The ServiceNow IDE.
Included in application ALL	An option to include this MID Server Application in the definition of ALL for a MID Server.

5. Select **Submit**.

What to do next
If you haven't already, configure basic or OAuth 2.0 authentication to connect to a Git domain or repository. For more information, see Connect to a Git provider using basic authentication with the ServiceNow IDE or Connect to a Git provider using OAuth 2.0 with the ServiceNow IDE.

Note:
The MID Server user must have the sn_glider.ide_git_user role or admin role to perform Git operations in the ServiceNow IDE. For more information, see Create the MID Server user and grant the role and ServiceNow IDE MID Server User [sn_glider.ide_git_user].

Initialize a Git repository with the ServiceNow IDE

Initialize a local Git repository for an application and push it to a remote Git repository to manage an application in source control.

Before you begin

- Create or convert an application with the ServiceNow IDE. For more information, see Create an application with the ServiceNow IDE or Convert an application with the ServiceNow IDE.
- Create a dedicated Git repository for the application from your Git provider.
- Set your basic or OAuth 2.0 credentials for the ServiceNow IDE to connect to your Git repository. For more information, see Connect to a Git provider using basic authentication with the ServiceNow IDE or Configure OAuth 2.0 credentials to connect to a Git provider with the ServiceNow IDE.

Role required: admin

About this task

An application on an instance can be connected to only one repository at a time. To clone an application that exists in a remote Git repository, see Clone a Git repository with the ServiceNow IDE.

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace with an application that isn't connected to a Git repository.
3. From the Activity Bar, select the Source Control view ( ).
4. Select **Initialize Repository** or use the `Git: Initialize Repository` command from the command palette.
5. Select the application for which you want to initialize a Git repository and press Enter.
6. Select **main** as the default branch name or enter another name and press Enter.
7. Select the Stage All Untracked Changes icon ( ).
8. Enter a commit message and select the Commit icon ( ).
9. Select the More actions menu icon ( ) and select **Push**.
10. Enter a remote repository URL and press Enter.

Result

The application is available in the remote repository.

Trouble?

If your Git credentials aren't configured or are inactive, the application isn't pushed to the remote repository. When prompted to configure your credentials, select **Configure** to configure your Git credentials and then try again.

What to do next

You can check out or create branches in the repository and push changes to the remote repository. For more information, see Using source control in the ServiceNow IDE.

Using source control in the ServiceNow IDE

Use Git commands and other source control features in the ServiceNow IDE to manage changes to an application across a development team.

Role required: admin

Git commands

After initializing a local Git repository in the ServiceNow IDE, you can perform several Git commands from the Source Control view ( ) or command palette, including but not limited to the following commands.

Git commands in the ServiceNow IDE

Command	Description
Checkout to (> **Checkout to...**) Command palette: **Git: Checkout to...**	Check out another branch from the repository. Select the branch from the list or create a branch and push it to the remote repository. Only one branch per repository can be checked out at a time on an instance (or developer sandbox).
Clone (> **Clone**) Command palette: **Git: Clone**	Clone a remote repository to add an application to your workspace. For more information, see Clone a Git repository with the ServiceNow IDE.
Commit ( ) Command palette: **Git: Commit**	Commit your staged changes to the local repository. Enter a commit message to describe your changes.
Create branch (> **Branch** > **Create branch...**) Command palette: **Git: Create branch...**	Add a branch to a repository and check it out.
Discard ( ) Command palette: **Git: Discard Changes**	Discard changes to undo modifications to an application.
Fetch (> **Fetch**) Command palette: **Git: Fetch**	Fetch to sync commits and branches from the remote repository into the local repository.
Pull (> **Pull**) Command palette: **Git: Pull**	Pull to merge the latest changes from the remote repository into the local repository.
Push (> **Push**)	Push your committed changes to the remote repository.

Git commands in the ServiceNow IDE (continued)

Command	Description
Command palette: **Git: Push**	
Stage (+) Command palette: **Git: Stage Changes**	Stage the changes in your working directory that you want to commit. When you stage changes, files move from the Changes list to the Staged Changes list.
Stash (··· > **Stash**) Command palette: **Git: Stash**, **Git: Pop**, **Git: Drop**, **Git: List**, **Git: Apply**, **Git: Clear**	Stash all uncommitted changes to save them in your working directory locally and come back to them later. The pop, drop, list, apply, and clear subcommands are supported when stashing. Select **Stash** > **Apply** to reapply your changes in your working directory.

Merge conflicts

If there's a conflict between local and remote changes in a file, the file is listed under Merge conflicts in the Source Control view ( ). You can review conflicts in the editor and resolve them by accepting the current or incoming change, both, or manually editing the file.

Commit history

The commit history for a branch is listed in the Commits section of the Source Control view ( ) and includes details about the commits. To see the commit history for a file, navigate to the File Explorer view ( ), select the file, and expand the Timeline section. When you select a commit, a Diff editor comparing the changes opens.

Repository changes

To update the remote repository an application is connected to, you can use the `Git: Update remote origin` command from the command palette and enter a different remote repository URL.

Developing applications with the ServiceNow IDE

Create and develop applications in source code with the ServiceNow IDE. Build applications to make your changes available across an instance and collaborate with users of any skill set.

In the ServiceNow IDE, you create scoped applications or convert existing applications and develop them in source code using ServiceNow Fluent to define application metadata [sys_metadata]. Optionally, you can create JavaScript modules and use third-party libraries to organize and reuse code within scoped applications.

When your changes are saved and ready, build an application to compile the source code to application metadata and make your changes available to users across the instance. As other users modify the application metadata, you can synchronize the changes into the source code.

Learn how to get started developing applications with the ServiceNow IDE in the following topics.

System requirements

ServiceNow IDE uses the public npm registry (`https://registry.npmjs.org`) as its default package source. If your network blocks access to this registry, you must have access to an alternate registry to download packages and build applications in the ServiceNow IDE. If access to the public npm registry is blocked on your system, you must configure a private npm registry in your Package Manager user settings in the ServiceNow IDE. For more information, see Install an npm package from a private registry with the ServiceNow IDE.

Synchronizing applications in the ServiceNow IDE

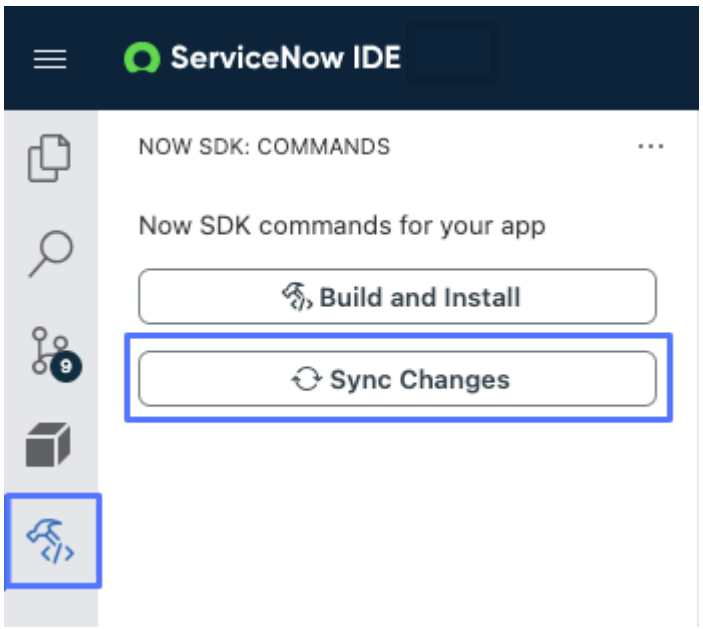
Synchronizing an application in the ServiceNow IDE downloads and transforms application metadata into ServiceNow Fluent code.

ServiceNow Fluent supports two-way synchronization, which allows changes to metadata to be synced from other ServiceNow AI Platform user interfaces into source code. When you build and install an application, changes to source code are compiled into metadata across the instance. This process enables collaborating with users of different skill sets because developers can modify the ServiceNow Fluent code while others modify the application metadata across the platform.

In the ServiceNow IDE, when metadata in an application is changed, you're prompted to sync the application to get the latest changes. If metadata changes are detected in application, syncing is required before you can install the application across the instance.

Note:
If you ignore the notification to sync an application, you aren't prompted to do so again for the remainder of the session. If you try to install the application or refresh the browser, you are prompted to sync again.

You can sync an application on demand from the Now SDK view ( ) or from the command palette with the `Fluent: Sync Fluent App with changed metadata` command.



Synchronization process in the ServiceNow IDE

The following list explains the stages of the synchronization process for applications in the ServiceNow IDE:

1. Before the first time an application is synced:
   - You should initialize a repository.
   - You should stage any changes to the application to retain them when the application is synced.
2. The first time that an application is synced:
   - New metadata that isn't defined in source code is transformed into source code in the `src/fluent/generated` directory.
   - Changes to metadata that is defined in source code are downloaded into source code in the `src/fluent` and `src/fluent/generated` directories.
   - Changes to existing metadata XML that hasn't been converted into source code are downloaded into the `metadata` directory.
3. Subsequent times that an application is synced:
   - Only the changes made since the last time the application was synced are downloaded and transformed.
   - Optionally, you can synchronize all metadata in the application with the `Fluent: Force Sync of Fluent App with all metadata` command from the command palette. Before running this command, you should stage any changes to retain them.

Related topics

ServiceNow Fluent

Define application metadata in code with ServiceNow Fluent in the ServiceNow IDE

Define application metadata in code with ServiceNow Fluent in the ServiceNow IDE.

Before you begin

Create, convert, or clone an application and add it to your workspace. For more information, see Adding applications in ServiceNow IDE.

Role required: admin

About this task

ServiceNow Fluent is a domain-specific language (DSL) based on TypeScript for defining the metadata files [sys_metadata] that make up applications and includes APIs for the different types of metadata, such as tables, roles, ACLs, business rules, and Automated Test Framework tests. For more information about ServiceNow Fluent APIs and examples, see ServiceNow Fluent API reference. The ServiceNow IDE has language processing and validation for ServiceNow Fluent APIs and applications by default.

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace with an application.
3. From the Activity Bar, select the File Explorer view ( ).
4. In the `src/fluent` directory, add a file with the `.now.ts` extension.
   You can define application metadata in a single file or as many `.now.ts` files as you want and organize files in directories within the `fluent` directory.

Tip:
In the `fluent` directory, you can refer to an example file named `index.now.ts`.

5. In the `.now.ts` file, use objects in the ServiceNow Fluent APIs to define metadata in the application.

   Example

   For example, to create a table [sys_db_object] in the application, use the Table API. The following example includes a simple table for to-do lists using a *`Table`* object with the necessary properties and values.

```
export const x_snc_example_to_do = Table({
    name: 'x_snc_example_to_do',
    schema: {
        deadline: DateColumn({ label: 'Deadline' }),
        state: StringColumn({
            label: 'State',
            choices: {
                ready: { label: 'Ready' },
                completed: { label: 'Completed' },
                inProgress: { label: 'In Progress' },
            },
        }),
        task: StringColumn({ label: 'Task', maxLength: 120 }),
    },
})
```

Note:
You can use the Record API to define application metadata that doesn't have a dedicated API.

6. Add the required imports for the APIs from `@servicenow/sdk/core`.

   Example

   For example, to define a table with a date column and string column, import the corresponding objects to use from the Table API:

```
import { Table, DateColumn, StringColumn }
 from '@servicenow/sdk/core'
```

7. **Optional:** For ServiceNow Fluent APIs that use server-side scripts, such as business rules, import code from JavaScript modules to call them from an object's *`script`* property.

   Example
   This example imports the `showStateUpdate` function, which can then be referenced from the *`script`* property.

```
import { showStateUpdate } from '../server/script.js'
```

8. Save your changes.
9. **Optional:** Build and install your application to compile source code into application metadata and make your changes available across the instance. For more information, see Build and install an application in the ServiceNow IDE.

Trouble?

Tip:
You can use the following directives in a code comment to help manage your code:

- `@fluent-ignore`: Suppresses ServiceNow Fluent diagnostic warnings and errors in the following line of code.
- `@fluent-disable-sync`: Turns off syncing changes to a ServiceNow Fluent object. Use before a call expression (for example, `Record({ ... })`) to turn off syncing for that object and its child objects. Only use this directive if you want to ignore changes made outside of the source code to the object and never update it when syncing.
- `@fluent-disable-sync-for-file`: Turns off syncing changes to a ServiceNow Fluent file (`.now.ts`). Use in the first line of the file to turn off syncing for all code in the file. Only use this directive if you want to ignore changes made outside of the source code to the file and never update it when syncing.

Example: Defining application metadata in source code with ServiceNow Fluent

In files with the `.now.ts` extension, use objects in the ServiceNow Fluent APIs to define metadata in the application. You must also include the required imports for the APIs from `@servicenow/sdk/core`. For objects with server-side scripts, such as the *`BusinessRule`* object, you can import and use code from JavaScript modules.

The following example includes the definitions of a table, client script, and business rule in the application. The client script uses a script from the `client-script.js` file. The business rule uses a function from the `script.js` JavaScript module.

```
import '@servicenow/sdk/global'
import { BusinessRule, ClientScript, DateColumn, StringColumn,
 Table } from '@servicenow/sdk/core'
import { showStateUpdate } from '../server/script.js'

//creates todo table, with three columns (deadline, status and task)
export const x_snc_example_to_do = Table({
    name: 'x_snc_example_to_do',
    schema: {
        deadline: DateColumn({ label: 'Deadline' }),
        state: StringColumn({
            label: 'State',
            choices: {
                ready: { label: 'Ready' },
                completed: { label: 'Completed' },
                inProgress: { label: 'In Progress' },
            },
        }),
        task: StringColumn({ label: 'Task', maxLength: 120 }),
    },
})

//creates a client script that pops up 'Table loaded successfully!!' message everytime todo
 record is loaded
ClientScript({
    $id: Now.ID['cs0'],
    name: 'my_client_script',
    table: 'x_snc_example_to_do',
    active: true,
```

```
    appliesExtended: false,
    global: true,
    uiType: 'all',
    description: 'Custom client script generated by Now SDK',
    isolateScript: false,
    type: 'onLoad',
    script: Now.include('../client/client-script.js'),
})

//creates a business rule that pops up state change message whenever a todo record is
 updated
BusinessRule({
    $id: Now.ID['br0'],
    action: ['update'],
    table: 'x_snc_example_to_do',
    script: showStateUpdate,
    name: 'LogStateChange',
    order: 100,
    when: 'after',
    active: true,
})
```

After building the application, this source code generates the following application metadata files on the instance.

Application metadata generated from ServiceNow Fluent code

ServiceNow Fluent

Create and use JavaScript modules in applications in the ServiceNow IDE

Optimize your codebase by defining reusable code blocks with JavaScript modules in the ServiceNow IDE.

Before you begin

Create, convert, or clone an application and add it to your workspace. For more information, see Adding applications in ServiceNow IDE.

Note:
To use TypeScript in modules, select TypeScript as the template type when creating an application.

Role required: admin

About this task

To learn about support for using JavaScript modules in scoped applications, including some limitations, see JavaScript modules and third-party libraries. For general information about the syntax used to create JavaScript modules, see the JavaScript modules page on the MDN Web Docs website.

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace with an application.
3. From the Activity Bar, select the File Explorer view ( ).
4. In the `src/server` directory of the application, create a JavaScript or TypeScript file to contain the module code you want to reuse.
5. **Optional:** Import server APIs or script includes to call them from your module.

   (Optional) Glide APIs can be imported from the `@servicenow/glide` package or their namespace in the package. Script includes can be imported from their application scope or the global scope in the `@servicenow/glide` package.

   For example:

   ```
   import { API } from "@servicenow/glide";
   import { API } from "@servicenow/glide/<namespace>";
   import { ScriptInclude } from "@servicenow/glide/<scope>";
   import { global } from "@servicenow/glide/global";
   ```

6. In the module, identify the code to export with *`export`* statements.

   You can use a named export or default export. Named exports can be variables, constants, functions, or classes whereas default exports can be functions or classes only.

   Example
   The following example is one way of adding a named export for multiple features (a function and a variable) in a module:

   ```
   export { myFunction, myVariable };
   ```

7. Use code from the exported module in other modules or server-side scripts.
8. Save your changes.

9. From the Status Bar, select **Build and Install**.

The active file that's open in the editor determines which application to build. If no files are open, select the application to build when prompted.

After building, the modules are added to the EcmaScript Module [sys_module] table.

What to do next

To use third-party libraries in a JavaScript module, see Use third-party libraries in applications in the ServiceNow IDE.

Related topics

JavaScript modules and third-party libraries

Use third-party libraries in applications in the ServiceNow IDE

Call third-party libraries in your application to use existing open-source functionality with the ServiceNow IDE.

Before you begin

Create a JavaScript module. For more information, see Create and use JavaScript modules in applications in the ServiceNow IDE.

To install and use packages from private registries, you must configure your Package Manager user settings in the ServiceNow IDE. For more information, see Install an npm package from a private registry with the ServiceNow IDE.

Role required: admin

About this task

Third-party libraries are added to applications as JavaScript modules. For general information about the syntax used to create JavaScript modules, see the JavaScript modules page on the MDN Web Docs website.

Important:
You can't use third-party libraries that rely on unsupported functionality, such as unsupported APIs or ECMAScript features. For more information about unsupported functionality, see JavaScript modules and third-party libraries.

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace with an application.
3. From the Activity Bar, select the File Explorer view ( ).
4. Open the `package.json` file for the application.
5. Add the `dependencies` field with the package name and version of any third-party libraries to use.

Example

```
"dependencies": {
      "<package name>": "<version>"
  }
```

6. Install the third-party library packages.

   a. Use one of the following keyboard shortcuts to open the command palette:

      - Windows: Ctrl-Shift-P
      - Mac: Cmd-Shift-P

   b. Enter `Package Manager: Install Dependencies` and press Enter.

   Packages are installed in the `node_modules` directory.

7. In a JavaScript module, import the library using an *`import`* statement.

   Example

   In this example, the module includes a namespace import for the lodash module.

   ```
   import * as lodash from "lodash"
   ```

   In this example, the module includes a named import for the camelCase function in the lodash module.

   ```
   import camelCase from 'lodash'
   ```

8. Call code imported from the library in your module to reuse it.
9. From the Status Bar, select **Build and Install**.

   The active file that's open in the editor determines which application to build. If no files are open, select the application to build when prompted.

   After building, the modules are added to the EcmaScript Module [sys_module] table.

Related topics

JavaScript modules and third-party libraries

Install an npm package from a private registry with the ServiceNow IDE

Install Node Package Manager (npm) packages from a private registry as dependencies in your application to use them as third-party libraries.

Before you begin

Role required: admin

About this task

To install packages from private registries, you must configure your Package Manager user settings in the ServiceNow IDE. Then you can choose in which applications to install packages.

ServiceNow IDE uses the public npm registry (`https://registry.npmjs.org`) as its default package source. If your network blocks access to this registry, you must have access to an alternate registry to download packages and build applications in the ServiceNow IDE. If access to the public npm registry is blocked on your system, you must configure a private npm registry in your Package Manager user settings in the ServiceNow IDE.

Note:
To install packages from a private registry, the registry must respond with the HTTP `Access-Control-Allow-Origin` header.

Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace.
3. Use one of the following keyboard shortcuts to open the command palette:
   - Windows: Ctrl-Shift-P
   - Mac: Cmd-Shift-P
4. Enter `Preferences: Open User Settings (JSON)` and press Enter.
5. Specify a private registry as the default registry or a scoped registry from which you can install packages.

   Note:
   To install packages from public registries, you can specify a public registry as the default registry or a scoped registry in addition to any private registries.

6. Provide your credentials for accessing the private registry.

Option	Description
Basic authentication	Provide a user name and password to access the default registry that you specified. `"package-manager.basicAuth": [ { "registry": "<private-registry-url>", "user": "<user-name>", "pass": "<password>" }, ... ]`
Legacy authentication	Provide a legacy token to access the default registry that you specified. Legacy tokens are basic authentication credentials encoded in Base64 format. `"package-manager.legacyAuth": [ { "registry": "<private-registry-url>", "token": "<legacy-token>" }, ... ]`
Token authentication	Provide a bearer token to access the default registry that you specified. `"package-manager.tokenAuth": [ { "registry": "<private-registry-url>", "token": "<token>" }, ... ]`

7. Save your changes to the `settings.json` file.
8. Install packages from the configured registries.

   a. Use one of the following keyboard shortcuts to open the command palette:
      - Windows: Ctrl-Shift-P
      - Mac: Cmd-Shift-P

   b. Enter `Package Manager: Install Dependencies` and press Enter.

   c. Select an application to install packages in as dependencies.

   Packages are installed in the `node_modules` directory.

Example: User settings for private registry access

In the following example, a user configured access to a private registry using basic authentication. The user also configured their settings to install packages from a public registry with the `@example` scope.

```
{
    "files.autoSave": "off",
    "package-manager.defaultRegistry": "<private-registry-url>",
    "package-manager.basicAuth": [
        {
        "registry": "<private-registry-url>",
            "user": "<user-name>",
            "pass": "<password>"
        }
    ],
    "package-manager.scopedRegistries": [
        {
            "scope": "@example",
            "registry": "<public-registry-url>"
        }
    ]
}
```

What to do next

Use the packages that you installed as third-party libraries in your application. For more information, see Use third-party libraries in applications in the ServiceNow IDE.

Create an application file from the Metadata Explorer

Create an application file in an embedded ServiceNow AI Platform user interface from the Metadata Explorer in the ServiceNow IDE.

Before you begin

Create, convert, or clone an application and add it to your workspace. For more information, see Adding applications in ServiceNow IDE.

Role required: admin

About this task

If you need to create some application metadata outside of source code, you can create application files from the Metadata Explorer within the ServiceNow IDE. To create an application

file from the ServiceNow IDE, an embedded ServiceNow AI Platform user interface opens in the editor.

Procedure

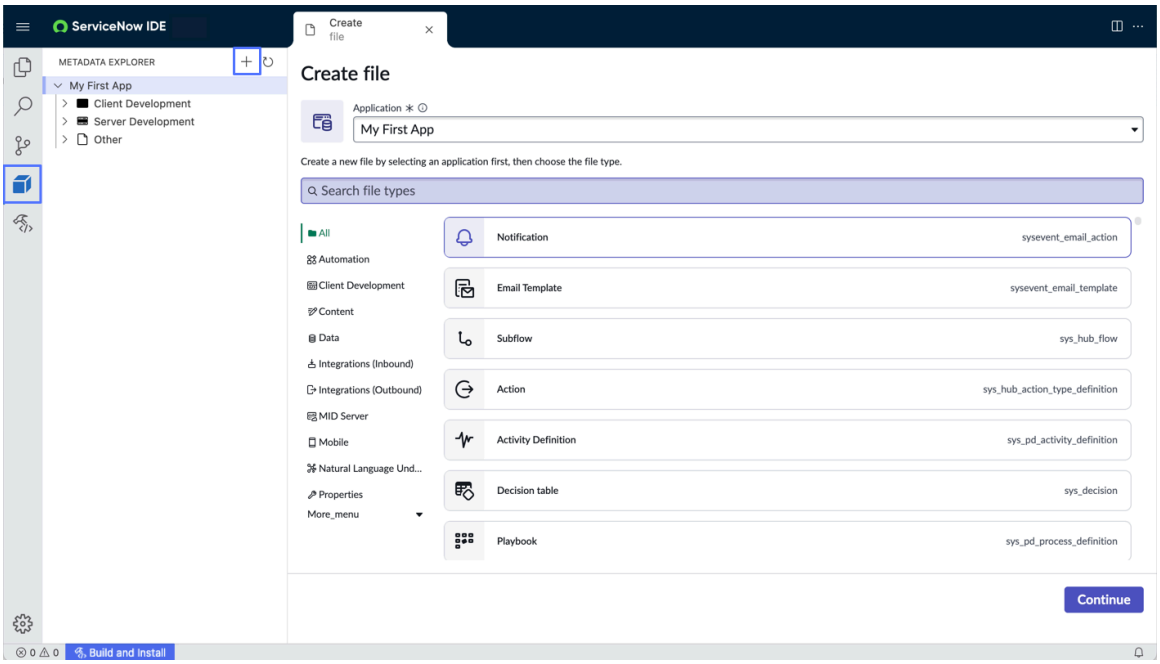
1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace with an application.
3. From the Activity Bar, select the Metadata Explorer view ( ).
4. Select the Create New File icon ( ).

> **Tip:**
> Alternatively, you can right-click an existing metadata category or file type in an application and select **Create New File** to create an application file of that category or type.

5. From the Application menu, select an application from your workspace.
6. From the list of file types, select the type of file to create.

> **Tip:**
> Search for a file type or select a category to find the file type you need.

Example



7. Select **Continue**.
8. In the embedded ServiceNow AI Platform user interface, fill in the fields to create the application file.
   The user interface and fields vary depending on the type of file that you created.
9. Select **Submit**.

Build and install an application in the ServiceNow IDE

Build an application to compile its source code and install application changes across an instance from the ServiceNow IDE.

Before you begin

Create, convert, or clone an application and add it to your workspace. For more information, see Adding applications in ServiceNow IDE.

Role required: admin

About this task

When you build an application, ServiceNow Fluent code is compiled into application metadata, and modules in the application are added to the EcmaScript Module [sys_module] table on the instance.

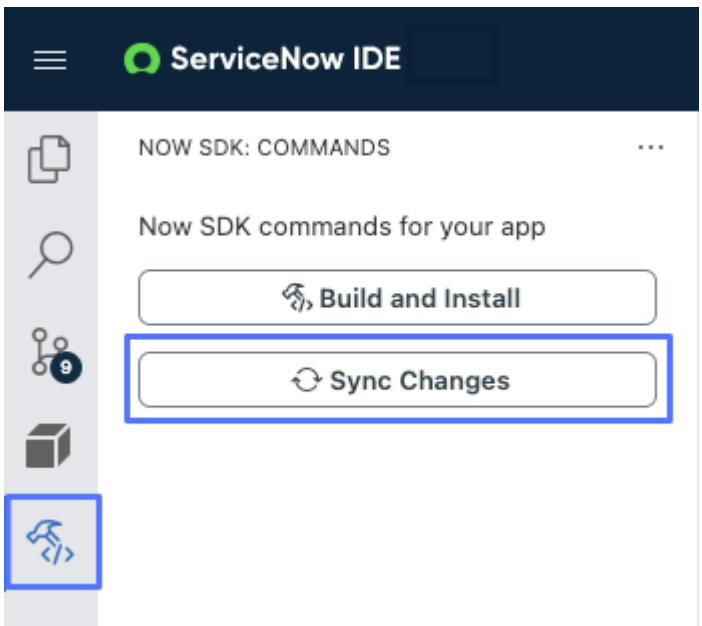
Procedure

1. Navigate to **All** > **App Development** > **ServiceNow IDE**.
2. Open a workspace with an application.
3. Synchronize changes made to the application metadata from across the instance.
   Syncing an application confirms you have the latest changes before making additional changes. Only the changes made since the last time the application was synced are downloaded and transformed. For more information, see Synchronizing applications in the ServiceNow IDE.

   a. From the Activity Bar, select the Now SDK view ( ).

   b. Select **Sync Changes**.
   The active file that's open in the editor determines which application to synchronize. If no files are open, select the application to synchronize when prompted.

   Example



4. From the Activity Bar, select the File Explorer view ( ).

5. Modify your application in one of the following ways and save your changes:
   - Define application metadata in code with ServiceNow Fluent in the ServiceNow IDE
   - Create and use JavaScript modules in applications in the ServiceNow IDE
   - Use third-party libraries in applications in the ServiceNow IDE
6. From the Status Bar, select **Build and Install**.

   The active file that's open in the editor determines which application to build. If no files are open, select the application to build when prompted.

   Trouble?
   In the status bar, you can see a message that confirms whether the build was successful or failed. If the build fails, review the output logs and any problems in your code from the panel.
7. **Optional:** Review your changes as application metadata.

   a. From the Activity Bar, select the Metadata Explorer view ( ).

   b. Open the metadata files that you changed and review your changes from the embedded ServiceNow AI Platform user interfaces.

   Tip:
   To see your changes in source code and metadata side by side, select the Split Editor icon ( ) or right-click a tab and select one of the **Split** options.

Result

The application is updated across the instance to reflect your changes. Other users can modify the application metadata simultaneous with modifications to the source code. Also, other developers can reuse module code in other modules or scripts within an application.

Trouble?

If you need to ensure that the metadata on the instance matches the metadata in the installation package, you can uninstall and reinstall the application on the instance using the `Fluent: Reinstall Fluent App` command from the command palette. For more information, see ServiceNow IDE commands.

Warning:
Changes to metadata on the instance that haven't been synced into your application in the ServiceNow IDE are removed.

What to do next

Use source control to stage, commit, and push your changes to a remote Git repository. For more information, see Using source control in the ServiceNow IDE.

ServiceNow IDE reference

Reference topics include information about ServiceNow Fluent APIs and ServiceNow IDE properties, roles, and more.

ServiceNow Fluent API reference

Use ServiceNow Fluent APIs to define the metadata that makes up scoped applications in source code with the ServiceNow IDE or ServiceNow SDK.

ServiceNow IDE commands

Use commands installed with ServiceNow IDE.

ServiceNow IDE properties

Use system properties installed with ServiceNow IDE.

ServiceNow IDE roles

Use roles installed with ServiceNow IDE.

ServiceNow IDE commands

Use commands from the command palette to perform many actions in the ServiceNow IDE.

The command palette includes commands unique to the ServiceNow IDE for creating and managing applications and commands from Visual Studio Code, such as Git commands for using source control. The following commands are unique to the ServiceNow IDE.

To open the command palette, use one of the following keyboard shortcuts:

- Windows: Ctrl-Shift-P
- Mac: Cmd-Shift-P

To close the command palette, press the Escape key.

ServiceNow IDE commands

Command	Description
Fluent: Apply Template for an existing Fluent App	Adds template files and directories for development in ServiceNow Fluent to an existing application.
Fluent: Build and Install	Build and install the application across the instance. Learn more: Build and install an application in the ServiceNow IDE
Fluent: Build with Now SDK	Build the application into an installable package.
Fluent: Convert a scoped app to Fluent	Convert an existing scoped application to support development in source code. **Note:** With ServiceNow IDE version 3.1.4 and earlier, the sn_glider.ide_fluent_admin role is required to use this command. Learn more: Convert an application with the ServiceNow IDE
Fluent: Create Fluent App	Create a scoped application to develop in source code. Learn more: Create an application with the ServiceNow IDE
Fluent: Download script dependencies	Download script dependencies in your application to get type-ahead support for Glide APIs and script includes. Type definitions are downloaded into the `@types/servicenow` directory based on the scripts in your application. After downloading script dependencies, you can create a `tsconfig.json` file in the `src/fluent` directory that includes the type definitions. For example:

ServiceNow IDE commands (continued)

Command	Description
	<pre>"include": ["./**/*.client.js", "./**/*.server.js", "../../@types/servicenow/*.client.d.ts", "../../@types/servicenow/*.server.d.ts",]</pre> Learn more: Downloading dependencies with the ServiceNow SDK
Fluent: Force Install Fluent App in Instance	Install an existing build artifact, which might overwrite recent changes.
Fluent: Force Sync of Fluent App with all metadata	Synchronize all metadata in the application rather than only the metadata that changed since the last time that the application was synchronized. **Warning:** Force synchronizing all metadata in the application might overwrite any changes in the application that haven't been built and installed on the instance. Learn more: Synchronizing applications in the ServiceNow IDE
Fluent: Install Fluent App in Instance	Install the application across the instance without building it again.
Fluent: Reinstall Fluent App	Uninstall and reinstall the application on the instance to verify that the metadata on the instance matches the metadata in the installation package. The source files in the application aren't changed. **Warning:** Changes to metadata on the instance that haven't been synced into your application in the ServiceNow IDE are removed. If you have previous versions of modules in the EcmaScript Module [sys_module] table that aren't needed, re-installing an application removes previous versions of the application's modules from the table. **Note:** With ServiceNow IDE version 3.1.4 and earlier, the sn_glider.ide_fluent_admin role is required to use this command.
Fluent: Restart Fluent Server	Restart the ServiceNow Fluent language server.
Fluent: Sync Fluent App with changed metadata	Synchronize changes made to the application metadata since the last time that the application was synchronized. Learn more: Synchronizing applications in the ServiceNow IDE

ServiceNow IDE commands (continued)

Command	Description
Git: Manage Git credentials	Manage existing Git credentials for a Git domain and your user on the instance.
Git: Set IDE Git credentials	Configure basic or OAuth 2.0 credentials that are associated with your user to authenticate with a Git provider. Learn more: • Connect to a Git provider using basic authentication with the ServiceNow IDE • Connect to a Git provider using OAuth 2.0 with the ServiceNow IDE
Metadata Explorer: Focus on Metadata Explorer View	Navigate to the Metadata Explorer view. Learn more: Create an application file from the Metadata Explorer
Metadata Explorer: Open in New Browser Tab	Open the Metadata Explorer in a new browser tab.
Metadata Explorer: Reload	Refresh the Metadata Explorer view.
Package Manager: Install Dependencies	Install third-party dependencies into the `node_modules` directory. Learn more: Use third-party libraries in applications in the ServiceNow IDE
Workspaces: Add Application to Workspace	Add an existing application to a workspace.
Workspaces: Add to Workspace	Create, open, or clone an application in a workspace.
Workspaces: Browse Workspaces	Browse through and open your ServiceNow IDE workspaces.
Workspaces: Create a Workspace	Create a ServiceNow IDE workspace. Learn more: Create a workspace in the ServiceNow IDE
Workspaces: Delete a Workspace	Delete a ServiceNow IDE workspace.
Workspaces: Rename a Workspace	Rename a ServiceNow IDE workspace.
Workspaces: Welcome	Navigate to the ServiceNow IDE home page, which lists all of your workspaces.

ServiceNow IDE properties

Manage how the ServiceNow IDE functions on an instance using the following system properties.

Note:
To open the System Properties [sys_properties] table, enter `sys_properties.list` in the navigation filter. To add properties to the table, see Add a system property.

Properties for ServiceNow IDE

Property	Description
sn_glider.default_to_bundled_sdk	Specifies whether to use the bundled version or the latest version of the ServiceNow SDK when creating or converting applications in the ServiceNow IDE. If true, the version of the ServiceNow SDK that's bundled with a version of the ServiceNow IDE is used. If false, the latest version of the ServiceNow SDK is used. • Type: true | false • Default value: false • Location: Add the property to the System Property [sys_properties] table
sn_glider.enable_ide	Enables access to the ServiceNow IDE. If false, access to the ServiceNow IDE is turned off across the instance. • Type: true | false • Default value: true • Location: Add the property to the System Property [sys_properties] table
sn_glider.fluent_convert_enabled	Enables converting existing scoped applications that weren't created with the ServiceNow IDE or ServiceNow SDK to support development in source code from the ServiceNow IDE. • Type: true | false • Default value: true • Location: Add the property to the System Property [sys_properties] table • Learn more: Convert an application with the ServiceNow IDE
sn_glider.git.attachment.extension.binary	Defines a custom extension for attachment files with binary content types (for example, `application/octet-stream`) to override the default `gitdata` extension. The custom extension that you specify with this property must also be specified with the *`glide.attachment.extensions`* system property. **Note:** If you reuse an existing extension, confirm that the value you set passes MIME type validations for binary types. • Type: string • Default value: gitdata

Properties for ServiceNow IDE (continued)

Property	Description
	• Location: Add the property to the System Property [sys_properties] table • Learn more: ServiceNow IDE MID Server User [sn_glider.ide_git_user]
sn_glider.git.attachment.extension.text	Defines a custom extension for attachment files with text content types (for example, `text/plain`) to override the default `txt` extension. The custom extension that you specify with this property must also be specified with the *`glide.attachment.extensions`* system property. **Note:** If you reuse an existing extension, confirm that the value you set passes MIME type validations for text types. • Type: string • Default value: txt • Location: Add the property to the System Property [sys_properties] table • Learn more: ServiceNow IDE MID Server User [sn_glider.ide_git_user]
sn_glider.pinnedSdkVersion	Specifies the version of the ServiceNow SDK to use when creating or converting applications in the ServiceNow IDE. • Type: string • Default value: The latest version of the ServiceNow SDK • Location: Add the property to the System Property [sys_properties] table

ServiceNow IDE roles

The following roles are installed for use with ServiceNow IDE.

Note:
Users with the Creator Studio Restricted User [sn_creatorstudio.restricted_user] role aren't able to access the ServiceNow IDE regardless of any other roles assigned.

ServiceNow IDE Administrator [sn_glider.admin]

Create and develop scoped applications in the ServiceNow IDE.

Contains Roles

List of roles contained within the role.

- sn_glider.create_app_admin
- sn_glider.read_admin
- sn_glider.write_admin

Groups

This role is assigned to no groups by default.

Special considerations

In addition to this role, the following roles are necessary for certain functionality in the ServiceNow IDE:

- credential_admin: Required to perform Git operations.
- sn_udc.admin: Required to modify application files from the Metadata Explorer.
- sn_udc.basic_read: Used for read-only access to application files in the Metadata Explorer.

ServiceNow IDE MID Server User [sn_glider.ide_git_user]

Assign administrator privileges to a MID server user to manage applications in source control from the ServiceNow IDE.

MID Server users must have the sn_glider.ide_git_user role or admin role to perform Git operations in the ServiceNow IDE. For more information, see Create the MID Server user and grant the role and Configure a MID Server to use source control with the ServiceNow IDE.

Contains Roles

List of roles contained within the role:

credential_admin

Groups

This role is assigned to no groups by default.

Special considerations

None.

ServiceNow SDK

Create and develop scoped applications in source code locally in Visual Studio Code Desktop and upload changes to an instance using the ServiceNow software development kit (SDK).

Note:
The ServiceNow SDK doesn't support the Global scope or global applications with instances on the Xanadu release.

Get started

Explore  Learn about developing applications with the ServiceNow SDK.	Configure  Install and configure the ServiceNow SDK locally.	Authenticate  Authenticate to ServiceNow instances.
Create  Create applications in source code.	Develop  Develop applications in source code.	Reference  Get details about the ServiceNow SDK CLI and ServiceNow Fluent APIs.

Which builder should I use to create an app?

Are you a developer who wants to use industry-standard development tools and processes?

The ServiceNow IDE and ServiceNow SDK support developing applications in source code with ServiceNow Fluent, creating JavaScript modules, and using third-party libraries. ServiceNow Fluent is a domain-specific programming language for creating application metadata in code.

The ServiceNow IDE is an implementation of Visual Studio Code for the Web on the ServiceNow AI Platform. The ServiceNow SDK uses Visual Studio Code Desktop locally. For more information, see Building applications in source code.

Are you a developer who wants more control in a centralized user interface?

Build apps smarter and deliver them faster with the new ServiceNow Studio. ServiceNow Studio empowers platform developers with a modern, unified environment for building on the ServiceNow AI Platform. ServiceNow Studio features streamlined navigation to applications and metadata, integrated low-code tools, efficient tracking and packaging of development work that accelerates development processes and enhances productivity. For more information, see Exploring ServiceNow Studio.

Need a more general app but still want low-code options?

App Engine Studio lets you build a broader range of apps than Creator Studio without being a programming pro. For more information, see Exploring App Engine Studio.

Want to build an app easily, without code?

Creator Studio specializes in helping you craft request-fulfillment applications without writing code. For example, an application to request office supplies by filling out a form, and someone approves or denies your request. For more information, see Exploring Creator Studio.

ServiceNow Fluent

JavaScript modules and third-party libraries

Exploring the ServiceNow SDK

Learn about developing scoped applications in source code locally and installing changes on an instance with the ServiceNow SDK.

ServiceNow SDK overview

With the ServiceNow SDK, you can create and modify scoped applications locally in Visual Studio Code Desktop and install those applications on a non-production instance beginning with the Washington DC release. By developing applications locally, you can work offline and use features that are available in Visual Studio Code but not in the ServiceNow IDE.

In Visual Studio Code, you can develop scoped applications in source code using ServiceNow Fluent to define application metadata [sys_metadata], write custom JavaScript modules, or add third-party libraries.

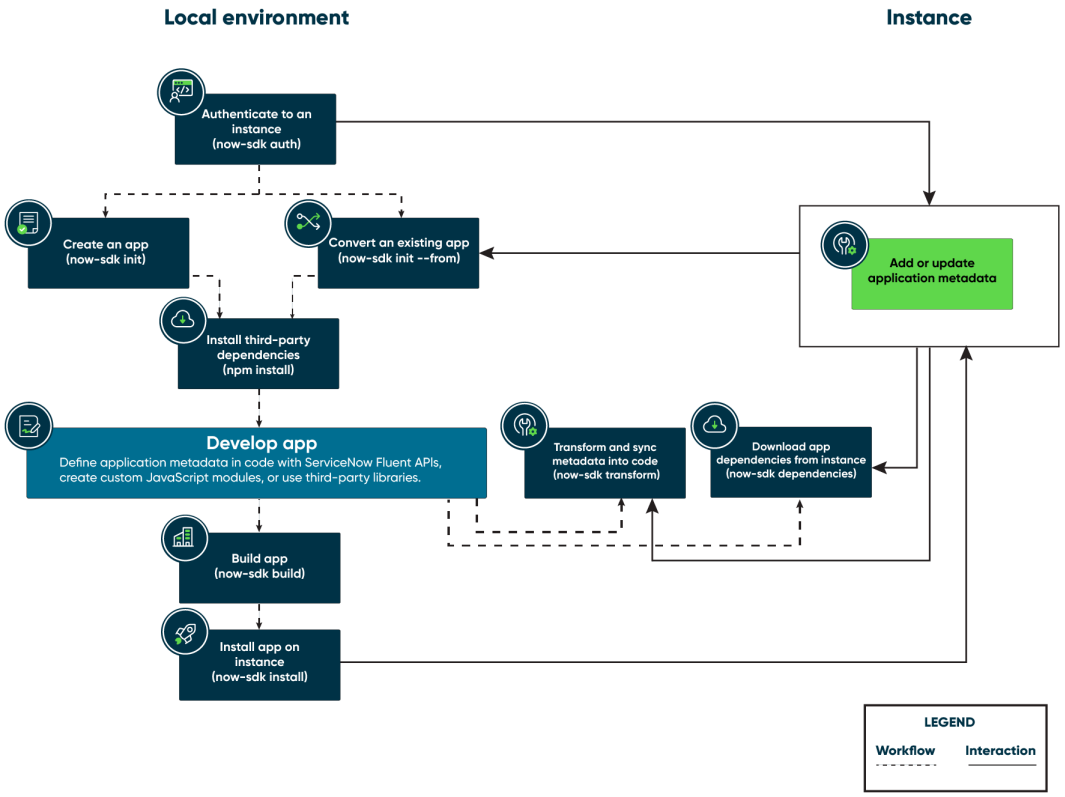
The ServiceNow SDK includes a command-line interface (CLI) for managing changes between an instance and a local application. Using simple CLI commands, you can authenticate to an instance, create or convert an application, transform application metadata (XML) into ServiceNow Fluent code, build and install the application on the instance, and more.

The ServiceNow SDK also serves as the application packaging service that builds applications in the ServiceNow IDE. For more information, see Exploring the ServiceNow IDE.

ServiceNow SDK workflow

The following infographic shows the workflow for developers to get started developing applications with the ServiceNow SDK.

Developing applications with the ServiceNow SDK



1. A developer installs the ServiceNow SDK locally. For more information, see Install the ServiceNow SDK in an application.
2. Using the CLI, the developer authenticates to a non-production instance to interface between their local environment and the instance with the `now-sdk auth` command. The developer must have the admin role on the instance.
3. The developer creates a scoped application (`now-sdk init`) or converts an existing scoped application from the instance (`now-sdk init --from`) for use with the ServiceNow SDK.
4. In Visual Studio Code, the developer can define application metadata in source code using ServiceNow Fluent, create custom JavaScript modules, or use third-party libraries.

   They can also download application and script dependencies from the instance to code against (`now-sdk dependencies`).
5. The developer builds the application, which compiles the source code and transforms it into application metadata for the instance (`now-sdk build`).
6. The developer installs the application on the instance (`now-sdk install`).
7. Other users can continue to modify the application metadata on the instance, and developers can reuse the code from modules in other modules or scripts within the application.
8. The developer downloads and transforms application metadata from the instance to get the latest updates to the application metadata locally (`now-sdk transform`), keeping it synchronized with the application on the instance.

You can manage applications in source control with your preferred Git provider. To develop a scoped application on another system with the ServiceNow SDK, other developers should clone

the application from a remote GIt repository rather than downloading and transforming it from the instance.

ServiceNow SDK benefits

Benefit	Feature	Users
Develop applications offline, outside of an instance in Visual Studio Code and manage them in source control with your preferred Git provider.	Developing applications with the ServiceNow SDK Visual Studio Code documentation	Developers
Write source code to define the metadata that makes up ServiceNow applications	ServiceNow Fluent	Developers
Organize and reuse code within scoped applications with custom JavaScript modules and third-party JavaScript utilities	JavaScript modules and third-party libraries	Developers

Configuring the ServiceNow SDK

Install or upgrade the ServiceNow SDK locally and get language processing and validation for ServiceNow Fluent in Visual Studio Code.

Install the ServiceNow SDK in an application

Install the ServiceNow software development kit (SDK) in a local application using Node Package Manager (npm).

Before you begin

Your system must meet the following minimum requirements to use the latest version of the ServiceNow SDK:

- Node.js v20.18.0
- npm v8.19.3

To install or upgrade Node.js or npm, see the installation instructions on the npm website.

Role required: admin

About this task

The ServiceNow SDK is available as an npm package from the public npm registry. The ServiceNow SDK supports integrating with ServiceNow instances beginning with the Washington DC release.

In the following procedure, you install the ServiceNow SDK within a new application using `npx` rather than globally. To install the ServiceNow SDK globally, use the `npm install --global @servicenow/sdk` command.

Note:
If you use `npx` to install the ServiceNow SDK in application rather than globally, you must use `npx @servicenow/sdk [command]` rather than `now-sdk [command]` with the ServiceNow SDK CLI.

Procedure

1. Open a command-line tool on your system.
2. Verify that your system meets the requirements.
   a. Enter `node -v` to check if you have Node.js installed and which version.
   b. Enter `npm -v` to check if you have npm installed and which version.
3. Create a local directory for your application.
4. Change directories into the directory for your application using the `cd` command.

   Example

   ```
   cd <path/to/directory>
   ```

5. Create an application with the ServiceNow SDK.

What to do next

Install the ServiceNow Fluent Language server to get language processing and validation for ServiceNow Fluent in Visual Studio Code. For more information, see Install the ServiceNow Fluent Language server in Visual Studio Code.

Upgrade the ServiceNow SDK

Upgrade to the latest version of the ServiceNow SDK for use with instances beginning with the Washington DC release.

Before you begin

Your system must meet the following minimum requirements to use the latest version of the ServiceNow SDK:

- Node.js v20.18.0
- npm v8.19.3

To install or upgrade Node.js or npm, see the installation instructions on the npm website.

Role required: admin

Procedure

Complete the following steps depending on whether you're updating a global installation of the ServiceNow SDK or the version used by an application.

What to do next

Install the ServiceNow Fluent Language server to get language processing and validation for ServiceNow Fluent in Visual Studio Code. For more information, see Install the ServiceNow Fluent Language server in Visual Studio Code.

Use the ServiceNow SDK to authenticate to a ServiceNow instance. For more information, see Authenticating to a ServiceNow instance with the ServiceNow SDK.

Install the ServiceNow Fluent Language server in Visual Studio Code

Get language processing and validation for ServiceNow Fluent in Visual Studio Code with the ServiceNow Fluent Language server.

Before you begin
Role required: admin

About this task
The ServiceNow Fluent Language server provides code completion features and validation for ServiceNow Fluent language files (`.now.ts`) and for ServiceNow SDK configuration files (`now.config.json`).

Procedure
1. In Visual Studio Code, select the Extensions view from the Activity Bar.
2. Search for `ServiceNow® Fluent Language`.
3. Select **Install**.

What to do next
To use ServiceNow Fluent in applications with the ServiceNow SDK, see Define application metadata in code with ServiceNow Fluent and the ServiceNow SDK.

Related topics
ServiceNow Fluent

Authenticating to a ServiceNow instance with the ServiceNow SDK
Authenticate to a ServiceNow instance and store user credentials for accessing the instance on your system with the ServiceNow SDK.

You can use basic or OAuth 2.0 credentials to authenticate to an instance. To use OAuth 2.0 authentication, your instance must have ServiceNow IDE (version 1.1 or later) installed or have the required XML configuration imported. By default, instances on the Xanadu release include ServiceNow IDE version 1.1.4 and support using OAuth 2.0 authentication with the ServiceNow SDK.

After authenticating to an instance with the ServiceNow SDK command-line interface (CLI), you can begin developing applications and installing them on your instance. A non-production instance should be used for application development.

Authenticate to a ServiceNow instance using basic authentication with the ServiceNow SDK
Use basic authentication to connect to a ServiceNow instance with the ServiceNow SDK.

Before you begin
Role required: admin

About this task
This procedure uses the ServiceNow SDK command-line interface (CLI). From a command-line tool, enter `now-sdk --help` to get information about the available commands and global options. To get additional information about a command and its parameters, enter the command and `--help` or `-h`. For example, `now-sdk auth --help`. For more information about the CLI, see ServiceNow SDK CLI.

Procedure
1. Create a local directory for your application.
2. In Visual Studio Code, open the directory.
3. From the application directory, open an integrated Terminal window.
4. Specify the instance to authenticate to with the `auth` command.

```
npx @servicenow/sdk auth --add <instance>
```

Example
For example:

```
npx @servicenow/sdk auth --add
 https://myinstance.service-now.com
```

Note:
Using the `npx` command installs the ServiceNow SDK in your application directory instead of globally.

5. Respond to the following series of prompts.

Prompt	Response
`Type of authentication to use`	Select `basic`.
`Alias for these credentials`	Enter an alias for your credentials and the instance. The alias can be used for authentication with the `init`, `transform`, `dependencies`, and `install` commands.
`The username to authenticate with the instance`	Enter your username for the instance. You must be assigned the admin role.
`The password to authenticate with the instance`	Enter your password.

Result
The alias and credentials are stored in the device keychain or credential manager on your system and are set as the default credentials.

What to do next
Add an application to your local system with the ServiceNow SDK. For more information, see Adding applications with the ServiceNow SDK.

Authenticate to a ServiceNow instance using OAuth 2.0 with the ServiceNow SDK

Use OAuth 2.0 authentication to connect to a ServiceNow instance with the ServiceNow SDK.

Before you begin
To use OAuth 2.0 authentication, your instance must have ServiceNow IDE (version 1.1 or later) installed or have the required XML configuration imported. By default, instances on the Xanadu release include ServiceNow IDE version 1.1.4 and support using OAuth 2.0 authentication with the ServiceNow SDK.

Role required: admin

About this task

This procedure uses the ServiceNow SDK command-line interface (CLI). From a command-line tool, enter `now-sdk --help` to get information about the available commands and global options. To get additional information about a command and its parameters, enter the command and `--help` or `-h`. For example, `now-sdk auth --help`. For more information about the CLI, see ServiceNow SDK CLI.

Procedure

1. Create a local directory for your application.
2. In Visual Studio Code, open the directory.
3. From the application directory, open an integrated Terminal window.
4. Specify the instance to authenticate to with the `auth` command.

```
npx @servicenow/sdk auth --add <instance>
```

Example

For example:

```
npx @servicenow/sdk auth --add
 https://myinstance.service-now.com
```

Note:
Using the `npx` command installs the ServiceNow SDK in your application directory instead of globally.

5. Respond to the following series of prompts.

Prompt	Response
`Type of authentication to use`	Select `oauth`.
`Alias for these credentials`	Enter an alias for your credentials and the instance. The alias can be used for authentication with the `init`, `transform`, `dependencies`, and `install` commands.

The ServiceNow SDK opens a web browser to authenticate with the instance.

6. Navigate to the web page that opens and log in to the instance if you aren't currently logged in.
7. Select **Accept** to allow the ServiceNow SDK to connect to the instance.
The page refreshes and includes an authentication code.
8. Select **Copy** to copy the authentication code provided.
9. In the command line, paste the authentication code.

Result

The alias and credentials are stored in the device keychain or credential manager on your system and are set as the default credentials.

What to do next

Add an application to your local system with the ServiceNow SDK. For more information, see Adding applications with the ServiceNow SDK.

Adding applications with the ServiceNow SDK

Add applications to your local system to get started with development in source code with the ServiceNow SDK.

- Create an application with the ServiceNow SDK

  Create a scoped application that supports development in source code.

- Convert an application with the ServiceNow SDK

  Convert an existing scoped application to support development in source code.

You can also clone an existing scoped application that has already been converted to support development in source code from a remote Git repository in Visual Studio Code Desktop. For more information, see Introduction to Git in VS Code in the Visual Studio Code documentation.

Create an application with the ServiceNow SDK

Create a scoped application to develop in source code with the ServiceNow SDK.

Before you begin

Use the ServiceNow SDK to authenticate to a ServiceNow instance. For more information, see Authenticating to a ServiceNow instance with the ServiceNow SDK.

Role required: admin

About this task

This procedure uses the ServiceNow SDK command-line interface (CLI). From a command-line tool, enter `now-sdk --help` to get information about the available commands and global options. To get additional information about a command and its parameters, enter the command and `--help` or `-h`. For example, `now-sdk auth --help`. For more information about the CLI, see ServiceNow SDK CLI.

Procedure

1. Create a local directory for your application.
2. In Visual Studio Code, open the directory.
3. From the application directory, open an integrated Terminal window.
4. Create an application following a guided set of prompts with the `init` command:

   ```
   npx @servicenow/sdk init
   ```

   Note:
   Using the `npx` command installs the ServiceNow SDK in your application directory instead of globally.

5. Respond to the following series of prompts.

Prompt	Response
`Select a template`	Select a template that determines the default application structure, such as whether to create a full-stack application that supports UI development ands whether to use JavaScript or TypeScript to create modules.

Prompt	Response
`Name of ServiceNow Application`	Enter a name for the application.
`NPM package name`	Enter a name for the application package used in the `package.json` file. The package name must adhere to Node Package Manager (npm) package naming standards.
`Create a Global/Scoped App?`	Select whether to create a scoped or global application. ○ Scoped: Create a scoped application that is protected by identifying and restricting access to application files and data. ○ Global: Create an application in the global scope to allow it to be accessible to other global applications. Global applications are supported only with instances beginning with the Australia release.
`Scope name`	For scoped applications, enter the scope of the application. The scope name must be unique on the instance, begin with x_<prefix>, and be 18 characters or fewer. For more information, see Namespace identifier.

Example
In the following example, a scoped application named Example App (x_snc_example_app) is created.

```
$ npx @servicenow/sdk init
[now-sdk] Bootstrapping a new ServiceNow application project...
? Select a template: now-sdk + basic
? Name of ServiceNow Application:  Example App
? NPM package name:  example-app
? Scope name:  x_snc_example_app
[now-sdk] Application created successfully.
          Install the required dependencies with your preferred
 package manager before running "$now-sdk build".
          Ex: Run "npm install" if using npm.
```

6. Install the required third-party dependencies using your preferred package manager.

Example
For example, if you use Node Package Manager (npm), run `npm install`.

7. Build the application with the `build` command:

```
now-sdk build
```

8. **Optional:** Install the application on an instance with the `install` command:

```
now-sdk install --auth <alias>
```

Result
A scoped application with the default application structure is available locally. For information about the application structure, see the Application structure section of the Building applications in source code topic.

If you installed the application successfully, it's available on the instance. For more information about installing applications, see Build and install an application with the ServiceNow SDK.

What to do next

In Visual Studio Code, start developing your application in source code with ServiceNow Fluent, writing custom JavaScript modules, or adding third-party libraries. For more information, see Developing applications with the ServiceNow SDK.

Convert an application with the ServiceNow SDK

Convert an existing scoped application to support development in source code with the ServiceNow SDK.

Before you begin

Use the ServiceNow SDK to authenticate to a ServiceNow instance. For more information, see Authenticating to a ServiceNow instance with the ServiceNow SDK.

Role required: admin

About this task

Existing scoped applications that weren't created with the ServiceNow IDE or ServiceNow SDK must be converted to support development in source code. Converting an application adds the necessary files and directories for developing it in source code. You can choose whether to convert existing application metadata into ServiceNow Fluent code. The application isn't changed on the instance until you build and install it on the instance.

This procedure uses the ServiceNow SDK command-line interface (CLI). From a command-line tool, enter `now-sdk --help` to get information about the available commands and global options. To get additional information about a command and its parameters, enter the command and `--help` or `-h`. For example, `now-sdk auth --help`. For more information about the CLI, see ServiceNow SDK CLI.

Procedure

1. Create a local directory for your application.
2. In Visual Studio Code, open the directory.
3. From the application directory, open an integrated Terminal window.
4. Convert an existing scoped application from an instance or a local directory using the `init` command.

   With the `--from` parameter, provide a sys_id of an application on the instance or a path to a local directory that contains an application to convert to support development in source code.

   ```
   npx @servicenow/sdk init --from <sys_id or path>
   ```

   Example

   For example:

   ```
   npx @servicenow/sdk init --from
    aadfdd904748a6500ff14ee4316d4369
   ```

   Note:
   Using the `npx` command installs the ServiceNow SDK in your application directory instead of globally.

5. At the prompt, enter a name for the application package used in the `package.json` file.

The package name must adhere to Node Package Manager (npm) package naming standards.

Example
In the following example, an application is downloaded from the instance and converted using its sys_id.

```
$ npx @servicenow/sdk init --from
 aadfdd904748a6500ff14ee4316d4369
[now-sdk] Bootstrapping a new ServiceNow application project...
[now-sdk] Please provide the missing required fields:
? NPM package name:  example-app
[now-sdk] Access Token has expired, refreshing token
[now-sdk] Downloading application package for
 aadfdd904748a6500ff14ee4316d4369 from
 https://myinstance.service-now.com
[now-sdk] Unzipping downloaded package...
[now-sdk] Successfully downloaded and unzipped application
 aadfdd904748a6500ff14ee4316d4369
[now-sdk] Summary of downloaded metadata files
Metadata: 13 (Total: 13)
  Copied To Metadata Directory::
    1. dictionary/x_snc_example_app_mytable.xml
    2. package_inventory.csv
    3. sys_app_aadfdd904748a6500ff14ee4316d4369.xml
    4. update/sys_db_object_7030a5d04748a6500ff14ee4316d4338.xml
    5. update/sys_dictionary_x_snc_example_app_mytable_null.xml
    6.
 update/sys_documentation_x_snc_example_app_mytable__en.xml
... and 7 more

[now-sdk] Successfully converted application.
[now-sdk] Install the required dependencies with your preferred
 package manager before running "$now-sdk build".
          Ex: Run "npm install" if using npm.
```

The application is available locally with the default application structure and supports development in source code. Existing application metadata is downloaded into in the `metadata` directory. For information about the application structure, see the Application structure section of the Building applications in source code topic.

6. Install the required third-party dependencies using your preferred package manager.

   Example
   For example, if you use Node Package Manager (npm), run `npm install`.

7. **Optional:** Transform existing application metadata (XML) into ServiceNow Fluent code using the `transform` command.

   (Optional) With the `--from` parameter, provide a path to a local directory or file that contains metadata XML to transform into ServiceNow Fluent code.

   ```
   now-sdk transform [--from <path>] [--directory <package path>]
    [--preview <flag>] [--auth <alias>]
   ```

   Tip:
   You can set the `--preview` parameter to true to preview the transformed ServiceNow Fluent code from the command line without saving the changes.

Example
For example:

```
now-sdk transform --from metadata/update --auth devuser1
```

Application metadata is defined in ServiceNow Fluent code in the `src/fluent/generated` directory and removed from the specified directory.

> **Note:**
> A limited number of metadata types, such as Metadata Snapshots [sys_metadata_link] and UX Assets [sys_ux_lib_asset], can't be represented as ServiceNow Fluent code and aren't transformed. These metadata types remain as metadata XML files in the `metadata` directory of your application.

8. Build the application with the `build` command.

```
now-sdk build
```

9. **Optional:** Update the application on the instance with the `install` command.

```
now-sdk install --auth <alias>
```

Result
The converted application is added to your local directory with the necessary files and directories to support development in source code. If you installed the application successfully, it's updated on the instance. For more information about installing applications, see Build and install an application with the ServiceNow SDK. After installing a converted application, the **Package JSON** field of the custom application record [sys_app] contains the path to the `package.json` file for the application.

New application metadata added after converting an application is automatically transformed into source code in the `src/fluent/generated` directory when you use the `transform` command. If metadata exists in the local application as both XML and source code, the XML version takes precedence when installed on the instance.

What to do next
In Visual Studio Code, start developing your application in source code with ServiceNow Fluent, writing custom JavaScript modules, or adding third-party libraries. For more information, see Developing applications with the ServiceNow SDK.

Developing applications with the ServiceNow SDK

Create and develop applications in source code locally in Visual Studio Code Desktop with the ServiceNow SDK. Build and install applications to make your changes available on an instance.

After installing the ServiceNow SDK, you can authenticate to an instance to create scoped applications or convert existing applications using the ServiceNow SDK command-line interface (CLI).

In Visual Studio Code, start developing your application in source code with ServiceNow Fluent, writing custom JavaScript modules, or adding third-party libraries.

When your changes are ready, build and install the local application on the instance with the ServiceNow SDK CLI. Download and transform changes to the application metadata from the instance to keep the application up to date locally before making additional changes.

Learn how to get started developing applications with the ServiceNow SDK in the following topics.

Using TypeScript in JavaScript modules with the ServiceNow SDK

ServiceNow SDK CLI

ServiceNow Fluent API reference

Define application metadata in code with ServiceNow Fluent and the ServiceNow SDK

Define application metadata in code with ServiceNow Fluent and the ServiceNow SDK.

Before you begin

- Install the ServiceNow Fluent Language server to get language processing and validation for ServiceNow Fluent in Visual Studio Code. For more information, see Install the ServiceNow Fluent Language server in Visual Studio Code.
- Add an application to your local system with the ServiceNow SDK. For more information, see Adding applications with the ServiceNow SDK.

Role required: admin

About this task

ServiceNow Fluent is a domain-specific language (DSL) based on TypeScript for defining the metadata files [sys_metadata] that make up applications and includes APIs for the different types of metadata, such as tables, roles, ACLs, business rules, and Automated Test Framework tests. For more information about ServiceNow Fluent APIs and examples, see ServiceNow Fluent API reference.

Procedure

1. In Visual Studio Code, open your scoped application directory.
2. In the `src/fluent` directory, add a file with the `.now.ts` extension.
   You can define application metadata in a single file or as many `.now.ts` files as you want and organize files in directories within the `fluent` directory.

   Tip:
   In the `fluent` directory, you can refer to an example file named `index.now.ts`.

3. In the `.now.ts` file, use objects in the ServiceNow Fluent APIs to define metadata in the application.

   Example

   For example, to create a table [sys_db_object] in the application, use the Table API. The following example includes a simple table for to-do lists using a *`Table`* object with the necessary properties and values.

```
export const x_snc_example_to_do = Table({
    name: 'x_snc_example_to_do',
    schema: {
        deadline: DateColumn({ label: 'Deadline' }),
        state: StringColumn({
            label: 'State',
            choices: {
                ready: { label: 'Ready' },
                completed: { label: 'Completed' },
                inProgress: { label: 'In Progress' },
            },
        }),
```

```
        task: StringColumn({ label: 'Task', maxLength: 120 }),
    },
})
```

Note:
You can use the Record API to define application metadata that doesn't have a dedicated API.

4. Add the required imports for the APIs from `@servicenow/sdk/core`.

   Example

   For example, to define a table with a date column and string column, import the corresponding objects to use from the Table API:

   ```
   import { Table, DateColumn, StringColumn }
    from '@servicenow/sdk/core'
   ```

5. **Optional:** For ServiceNow Fluent APIs that use server-side scripts, such as business rules, import code from JavaScript modules to call them from an object's *`script`* property.

   Example
   This example imports the `showStateUpdate` function, which can then be referenced from the *`script`* property.

   ```
   import { showStateUpdate } from '../server/script.js'
   ```

6. Save your changes.
7. **Optional:** Build and install your application to compile source code into application metadata and make your changes available on the instance. For more information, see Build and install an application with the ServiceNow SDK.

Trouble?

Tip:
You can use the following directives in a code comment to help manage your code:

- `@fluent-ignore`: Suppresses ServiceNow Fluent diagnostic warnings and errors in the following line of code.
- `@fluent-disable-sync`: Turns off syncing changes to a ServiceNow Fluent object. Use before a call expression (for example, `Record({ ... })`) to turn off syncing for that object and its child objects. Only use this directive if you want to ignore changes made outside of the source code to the object and never update it when syncing.
- `@fluent-disable-sync-for-file`: Turns off syncing changes to a ServiceNow Fluent file (`.now.ts`). Use in the first line of the file to turn off syncing for all code in the file. Only use this directive if you want to ignore changes made outside of the source code to the file and never update it when syncing.

Example: Defining application metadata in source code with ServiceNow Fluent

In files with the `.now.ts` extension, use objects in the ServiceNow Fluent APIs to define metadata in the application. You must also include the required imports for the APIs from `@servicenow/sdk/core`. For objects with server-side scripts, such as the *`BusinessRule`* object, you can import and use code from JavaScript modules.

Tip:
You can use content from another file in ServiceNow Fluent APIs by referring to the file from a property using the syntax `Now.include('path/to/file')`. Referring to content in a different file instead of including the content inline can be helpful for records with fields that support JavaScript, HTML, CSS, and so on to make developing different file types easier with the appropriate syntax highlighting. The `Now.include` utility supports two-way synchronization so changes to fields from other ServiceNow AI Platform user interfaces are synced into the referenced file's source code and changes to the code are synced back to metadata across the instance.

The following example includes the definitions of a table, client script, and business rule in the application. The client script uses a script from the `client-script.js` file. The business rule uses a function from the `script.js` JavaScript module.

```
import '@servicenow/sdk/global'
import { BusinessRule, ClientScript, DateColumn, StringColumn,
 Table } from '@servicenow/sdk/core'
import { showStateUpdate } from '../server/script.js'

//creates todo table, with three columns (deadline, status and task)
export const x_snc_example_to_do = Table({
    name: 'x_snc_example_to_do',
    schema: {
        deadline: DateColumn({ label: 'Deadline' }),
        state: StringColumn({
            label: 'State',
            choices: {
                ready: { label: 'Ready' },
                completed: { label: 'Completed' },
                inProgress: { label: 'In Progress' },
            },
        }),
        task: StringColumn({ label: 'Task', maxLength: 120 }),
    },
})

//creates a client script that pops up 'Table loaded successfully!!' message everytime todo
 record is loaded
ClientScript({
    $id: Now.ID['cs0'],
    name: 'my_client_script',
    table: 'x_snc_example_to_do',
    active: true,
    appliesExtended: false,
    global: true,
    uiType: 'all',
    description: 'Custom client script generated by Now SDK',
    isolateScript: false,
    type: 'onLoad',
    script: Now.include('../client/client-script.js'),
})

//creates a business rule that pops up state change message whenever a todo record is
 updated
BusinessRule({
    $id: Now.ID['br0'],
    action: ['update'],
```

```
    table: 'x_snc_example_to_do',
    script: showStateUpdate,
    name: 'LogStateChange',
    order: 100,
    when: 'after',
    active: true,
})
```

The client script referenced from the *ClientScript* object:

```
function onLoad() {
    g_form.addInfoMessage("Table loaded successfully!!")
}
```

The JavaScript module referenced from the *BusinessRule* object:

```
import { gs } from '@servicenow/glide'

export function showStateUpdate(current, previous) {
    const currentState = current.getValue('state')
    const previousState = previous.getValue('state')

    gs.addInfoMessage(`state updated from "${previousState}"
 to "${currentState}"`)
}
```

After building and installing the application, this source code generates the following application metadata files on the instance.

Application metadata generated from ServiceNow Fluent code

ServiceNow Fluent

Create and use JavaScript modules in applications with the ServiceNow SDK

Optimize your codebase by defining reusable code blocks with JavaScript modules and the ServiceNow SDK.

Before you begin

Add an application to your local system with the ServiceNow SDK. For more information, see Adding applications with the ServiceNow SDK.

Role required: admin

About this task

To learn about support for using JavaScript modules in scoped applications, including some limitations, see JavaScript modules and third-party libraries. For general information about the syntax used to create JavaScript modules, see the JavaScript modules page on the MDN Web Docs website.

Procedure

1. In Visual Studio Code, open your scoped application directory.
2. In the `src/server` directory of the application, create a JavaScript or TypeScript file to contain the module code you want to reuse.
3. **Optional:** Import server APIs or script includes to call them from your module.

   (Optional) Glide APIs can be imported from the `@servicenow/glide` package or their namespace in the package. Script includes can be imported from their application scope or the global scope in the `@servicenow/glide` package.

   For example:

   ```
   import { API } from "@servicenow/glide";
   import { API } from "@servicenow/glide/<namespace>";
   import { ScriptInclude } from "@servicenow/glide/<scope>";
   import { global } from "@servicenow/glide/global";
   ```

4. In the module, identify the code to export with *`export`* statements.

   You can use a named export or default export. Named exports can be variables, constants, functions, or classes whereas default exports can be functions or classes only.

   Example

   The following example is one way of adding a named export for multiple features (a function and a variable) in a module:

   ```
   export { myFunction, myVariable };
   ```

5. Use code from the exported module in other modules or server-side scripts.

6. Save your changes.

What to do next

To use third-party libraries in a JavaScript module, see Use third-party libraries in applications with the ServiceNow SDK.

To build your application and add the modules to the EcmaScript Module [sys_module] table, see Build and install an application with the ServiceNow SDK.

Related topics

JavaScript modules and third-party libraries

Using TypeScript in JavaScript modules with the ServiceNow SDK

Use TypeScript when creating JavaScript modules with the ServiceNow SDK.

TypeScript uses static typing and type annotations to support developers catching errors earlier while writing code in Visual Studio Code.

For general information about using TypeScript, see the TypeScript Documentation on the typescriptlang.org website.

Use TypeScript in JavaScript modules

Use TypeScript in JavaScript modules by adding support for TypeScript in your application.

Before you begin

Install TypeScript version 4.8.4 or later. For installation instructions, see Download TypeScript on the typescriptlang.org website.

Role required: admin

About this task

Follow this procedure to update existing applications that weren't created using a TypeScript template to use TypeScript in modules. Beginning with the ServiceNow SDK version 3.0, applications support using TypeScript in JavaScript modules by default using default compiler options. To use a `tsconfig.json` file with custom options for transpiling TypeScript into JavaScript during the build process, configure the `tsconfigPath` parameter in the `now.config.json` file. If you want to use a custom transpilation step before building the application, configure the `modulePaths` parameter in the `now.config.json` file.

Procedure

1. In Visual Studio Code, open your scoped application directory.
2. Open the application's `package.json` file and in the `devDependencies` object, add the TypeScript package and version.

   Example

   ```
   "devDependencies": {
         "typescript": "<version>",
         "@servicenow/sdk": "2.0.0",
         "@servicenow/glide": "26.0.1",
         "eslint": "8.50.0",
         "@servicenow/eslint-plugin-sdk-app-plugin": "2.0.0"
      }
   ```

3. In your application's `src/server` directory, add a `tsconfig.json` file that defines the options for compiling the application.

   Example

   ```
   {
         "compilerOptions": {
               "rootDir": "./",
               "outDir": "../../dist/server",
   ```

```
            "module": "es2022",
            "target": "es2022",
            "moduleResolution": "bundler",
            "allowJs": true,
            "declaration": false,
            "sourceMap": false,
            "skipLibCheck": true,
            "allowImportingTsExtensions": true,
            "noEmit": true
        },
        "include": [
            "./**/*.ts",
    "../../@types/**/*.modules.d.ts"
        ],
        "exclude": [
            "**/*.now.ts"
        ]
}
```

4. In the application's `now.config.json` file, set the `tsconfigPath` parameter to the location of the `tsconfig.json` for JavaScript modules. .

   Example

```
{
   "scope": "x_snc_example_app",
   "scopeId": "2f8400eb07426110f736e28f69d3017a",
   "name": "ExampleApp",
   "tsconfigPath": "./src/server/tsconfig.json"

}
```

5. In the `src/server` directory, add at least one `.ts` file to contain module code.
   For information about creating modules, see Create and use JavaScript modules in applications with the ServiceNow SDK.

What to do next

Build and install the application to compile the TypeScript files into JavaScript modules and add the modules to the EcmaScript Module [sys_module] table. For more information, see Build and install an application with the ServiceNow SDK.

Add type definitions for APIs

Get type-ahead support for APIs and scriptable objects outside of Glide APIs.

Before you begin

Role required: admin

About this task

Note:
You can download type definitions for most APIs, script includes, and other scriptable objects using the `now-sdk dependencies` command. For more information, see Download module and script dependencies.

Follow this procedure to manually add types definitions that the `now-sdk dependencies` doesn't download. You can declare modules directly in the ServiceNow SDK application to stub access to the APIs for type-ahead support. These modules aren't packaged in the application

package, but they can be tracked in a source control repository for the application and shared between developers.

Procedure

1. In Visual Studio Code, open your scoped application directory.
2. In your application, add a TypeScripe (`.ts`) file for type definitions.
3. In your TypeScript file, declare modules for APIs and scriptable objects.

Example

This example declares a module for an API using the API namespace (`sn_app_api`):

```
declare module '@servicenow/glide/sn_app_api' {
 class AppStoreAPI {
  static canUpgradeAnyStoreApp(): boolean
 }
}
```

This example declares a module to access objects defined in script includes using the scope of the script include (`x_1234_scope`):

```
declare module '@servicenow/glide/x_1234_scope' {
 class MyLogItemClass {
  myLogFunction()
 }
}
```

4. In JavaScript modules in your application, import the declared modules.

Example

This example imports the declared module for the AppStoreAPI.

```
import { gs } from '@servicenow/glide'
import { AppStoreAPI } from '@servicenow/glide/sn_app_api'

export const canUpgradeStoreApp = function () {
 var canUpgrade = AppStoreAPI.canUpgradeAnyStoreApp()
 if (canUpgrade) {
  gs.addInfoMessage(`You can upgrade store apps!`)
 } else {
  gs.addInfoMessage(`You cannot upgrade store apps!`)
 }
}
```

This example imports the declared module for the MyLogItemClass object.

```
import { MyLogItemClass } from '@servicenow/glide/x_1234_scope'

export const myLogFunction = function (status) {
 const myLogItem = new MyLogItemClass()
 myLogItem.myLogFunction(status)
}
```

Note:
Modules can access only global scriptable objects or scriptable objects in the same application scope.

Use third-party libraries in applications with the ServiceNow SDK

Call third-party libraries in your application to use existing open-source functionality with the ServiceNow SDK.

Before you begin

Create a JavaScript module. For more information, see Create and use JavaScript modules in applications with the ServiceNow SDK.

Role required: admin

About this task

Third-party libraries are added to applications as JavaScript modules. For general information about the syntax used to create JavaScript modules, see the JavaScript modules page on the MDN Web Docs website.

Important:
You can't use third-party libraries that rely on unsupported functionality, such as unsupported APIs or ECMAScript features. For more information about unsupported functionality, see JavaScript modules and third-party libraries.

Procedure

1. In Visual Studio Code, open your scoped application directory.
2. From the application directory, open an integrated Terminal window.
3. Install the npm package for the library.

   Example

   ```
   npm install <package name>
   ```

   The library's packages are added to your application in the `node_modules` directory, and the library is added as a dependency in the `package.json` file for the application.

   ```
   "dependencies": {
       "<package name>": "<version>"
     }
   ```

4. In a JavaScript module, import the library using an *`import`* statement.

   Example

   In this example, the module includes a namespace import for the lodash module.

   ```
   import * as lodash from "lodash"
   ```

   In this example, the module includes a named import for the camelCase function in the lodash module.

   ```
   import camelCase from 'lodash'
   ```

5. Call code imported from the library in your module to reuse it.

What to do next

Build and install your changes on an instance. For more information, see Build and install an application with the ServiceNow SDK.

Related topics

JavaScript modules and third-party libraries

Downloading dependencies with the ServiceNow SDK

Download application dependencies and TypeScript definitions from an instance for IntelliSense and validation of scripts and ServiceNow Fluent code.

Throughout the development process, you should download dependencies and TypeScript definitions from an instance to support coding against those dependencies in an application.

To download all script and ServiceNow Fluent dependencies for an application, you can use the `dependencies` command with no parameters. If needed, provide the application directory and authentication alias too.

```
now-sdk dependencies [--directory <package path>] [--auth
 <alias>]
```

Download ServiceNow Fluent application dependencies

Download TypeScript definitions for dependencies in other application scopes to get IntelliSense support and validation for ServiceNow Fluent code.

Before you begin

Add an application to your local system with the ServiceNow SDK. For more information, see Adding applications with the ServiceNow SDK.

Role required: admin

About this task

This procedure uses the ServiceNow SDK command-line interface (CLI). From a command-line tool, enter `now-sdk --help` to get information about the available commands and global options. To get additional information about a command and its parameters, enter the command and `--help` or `-h`. For example, `now-sdk auth --help`. For more information about the CLI, see ServiceNow SDK CLI.

Procedure

1. In Visual Studio Code, open your scoped application directory.
2. In the `now.config.json` file, add the items that your application depends on in the `dependencies` object.

   The `dependencies` object has the following structure. You must specify the application scope and the dependency type and names or sys_ids. Only tables and roles can be specified by name. You can use a wildcard (`*`) to add all items from a specified table and scope.

   ```
   "dependencies": {
        "<scope>": {
           "<type>": ["<sys_id or name>"],
           ...
        },
        ...
   }
   ```

   Example

   For example:

   ```
   {
     "dependencies": {
        "global": {
           "tables": ["incident", "problem"],
           "roles": ["admin"],
   ```

```
        "sys_script_client": ["fa776f6d97700100f309124eda2975bc"]
      },
      "x_custom": {
        "tables": ["custom_table"],
        "sys_security_acl": "*",
      }
    }
}
```

3. Save your changes.
4. From the application directory, open an integrated Terminal window.
5. Download dependencies of the application with the `dependencies` command.

Example

```
now-sdk dependencies --auth <alias> --fluent-only
```

Note:
If you want to download script dependencies too, exclude the `--fluent-only` parameter.

The `dependencies` command downloads the dependencies specified in the `now.config.json` file and generates TypeScript definitions for them in the `@types/servicenow/fluent` directory with the `.d.now.ts` file extension. When building the application, these files aren't compiled like source code files.

What to do next

You can reference dependencies in ServiceNow Fluent files using the `#now:{scope}/{category}` subpath import format. For example:

```
// Import roles from global scope
import { role as globalRole } from '#now:global/security'

// Import roles from custom app scope
import { role as xExampleAppRole } from '#now:x_example_app/security'

// Use in ACLs, flows, etc.
Acl({
    $id: Now.ID['my_acl'],
    type: 'record',
    table: 'incident',
    operation: 'read',
    roles: [globalRole.admin, xExampleAppRole.xExampleAppCool],
})
```

Your application's `package.json` file must include the following `imports` configuration to do so:

```
{
  "imports": {
    "#now:*": "./@types/servicenow/fluent/*/index.js"
  }
}
```

Download module and script dependencies

Download TypeScript definitions for module and script dependencies to get IntelliSense support and validation for Glide APIs and script includes.

Before you begin

Add an application to your local system with the ServiceNow SDK. For more information, see Adding applications with the ServiceNow SDK.

Role required: admin

About this task

This procedure uses the ServiceNow SDK command-line interface (CLI). From a command-line tool, enter `now-sdk --help` to get information about the available commands and global options. To get additional information about a command and its parameters, enter the command and `--help` or `-h`. For example, `now-sdk auth --help`. For more information about the CLI, see ServiceNow SDK CLI.

Procedure

1. In Visual Studio Code, open your scoped application directory.
2. From the application directory, open an integrated Terminal window.
3. Download dependencies for scripts in the application with the `dependencies` command.

   Example

   ```
   now-sdk dependencies --auth <alias> --type-defs-only
   ```

   Note:
   If you want to download application dependencies too, exclude the `--type-defs-only` parameter.

   The `dependencies` command downloads type definitions for all Glide APIs and scans the modules and scripts in your application and creates type definitions for the script includes that they use. Type definitions are added in the `@types/servicenow` directory. To add any other type definitions, you can create them manually. For more information, see Add type definitions for APIs.

4. In the `src/fluent` directory, create a `tsconfig.server.json` file for server-side scripts.
   In the `include` object, include the type definitions that you downloaded for server-side Glide APIs (`glide.server.d.ts`) and script includes (`script-includes.server.d.ts`).

   Example

   ```
   {
     "compilerOptions": {
       "lib": [
         "ES2021"
       ],
       "noEmit": true,
       "checkJs": false,
       "allowJs": true,
       "noEmitHelpers": true,
       "esModuleInterop": false,
       "module": "None",
       "types": []
     },
     "include": [
       "./**/*.server.js",
       "../../@types/servicenow/*.server.d.ts",
   ```

```
    ]
}
```

5. In the `src/fluent` directory, create a `tsconfig.client.json` file for client-side scripts. In the `include` object, include the type definitions that you downloaded for client-side Glide APIs (`glide.client.d.ts`).

Example

```
{
  "compilerOptions": {
    "target": "ES6",
    "lib": [
      "DOM",
      "ES6"
    ],
    "checkJs": false,
    "allowJs": true,
    "noEmit": true,
    "noEmitHelpers": true,
    "esModuleInterop": false,
    "module": "None",
    "types": []
  },
  "include": [
    "./**/*.client.js",
    "../../@types/servicenow/*.client.d.ts",
  ]
}
```

6. In the `src/fluent` directory, create a `tsconfig.json` file.

> **Note:**
> This `tsconfig.json` file is separate from a `tsconfig.json` file used for applications that use TypeScript to create JavaScript modules.

In the `references` object, add the paths to the `tsconfig.server.json` and `tsconfig.client.json` files.

Example

```
{
  "files": [],
  "references": [
    {
      "path": "./tsconfig.server.json"
    },
    {
      "path": "./tsconfig.client.json"
    }
  ]
}
```

7. Save your changes.

Result

With this configuration, you can use the `.server.js` file extension for server-side scripts and `.client.js` file extension for client-side scripts and get type-ahead support during development.

Build and install an application with the ServiceNow SDK

Build and install a local application developed with the ServiceNow SDK on a ServiceNow instance.

Before you begin

Add an application to your local system with the ServiceNow SDK. For more information, see Adding applications with the ServiceNow SDK.

Role required: admin

About this task

This procedure uses the ServiceNow SDK command-line interface (CLI). From a command-line tool, enter `now-sdk --help` to get information about the available commands and global options. To get additional information about a command and its parameters, enter the command and `--help` or `-h`. For example, `now-sdk auth --help`. For more information about the CLI, see ServiceNow SDK CLI.

Note:
To build global applications with the ServiceNow SDK, you should use Node Package Manager (npm) as your package manager, especially if your application has more complex dependencies.

Procedure

1. In Visual Studio Code, open your scoped application directory.
2. From the application directory, open an integrated Terminal window.
3. Download changes to the application from the instance with the `transform` command to stay up to date with changes locally.

   Example

   ```
   now-sdk transform --auth <alias>
   ```

   Changes to application metadata are downloaded and synchronized into source code. If metadata exists in the local application as both XML and source code, the XML version takes precedence when installed on the instance.

   Note:
   Updates to JavaScript modules aren't included when downloading application metadata from your instance.

4. Build your application using the `build` command.

   ```
   now-sdk build
   ```

   The build artifacts are output to the `dist/app` directory, including the metadata as XML files in the `dist/app/update` directory.
5. Install your application using the `install` command.

```
now-sdk install --auth <alias>
```

Warning:
If you set the `--reinstall` parameter to true with the `install` command, application metadata created by other developers on your instance can be removed. Any application metadata on your instance that is not present in the local installment package generated during the build process is removed during installment. Before building your application, use the `now-sdk transform` command to synchronize your local metadata with the metadata on your instance.

Result
The application is updated on your instance to reflect your local changes. ServiceNow Fluent code is compiled into application metadata, and modules in the application are added to the EcmaScript Module [sys_module] table on the instance.

Note:
If you have previous versions of modules in the EcmaScript Module [sys_module] table that aren't needed, re-installing an application removes previous versions of the application's modules from the table.

ServiceNow SDK reference

Reference topics provide additional information about ServiceNow SDK CLI commands and ServiceNow Fluent APIs.

ServiceNow SDK CLI

Use the ServiceNow SDK command-line interface (CLI) to manage changes between a local application and the application on an instance.

From the command-line tool on your system, enter `now-sdk` to start the CLI and return a list of available commands or `now-sdk [command]` to begin using the ServiceNow SDK.

Note:
If you use `npx` to install the ServiceNow SDK in application rather than globally, you must use `npx @servicenow/sdk [command]` rather than `now-sdk [command]` with the ServiceNow SDK CLI.

The CLI includes the following commands and global options:

Global options

Option	Description
--version, -v	Return the version of the CLI.
--help, -h	Return information about commands, sub-commands, and parameters.
--debug, -d	Return the debug logs generated with a command.

auth

Authenticate to an instance and store, update, or view user credentials for accessing an instance on your system.

The `auth` command has parameters for adding credentials, deleting credentials, listing credentials, and setting credentials to use by default.

For more information, see Authenticating to a ServiceNow instance with the ServiceNow SDK.

add

Store credentials in the device keychain or credential manager on your system.

The `auth` command has the following structure with the `--add` parameter:

```
npx @servicenow/sdk auth [--add <instance url>] [--type <auth
 method>] [--alias <alias>]
```

Note:
Using the `npx` command installs the ServiceNow SDK in your application directory instead of globally.

Required parameters

Parameter	Type	Description	Default value
--add	String	The URL of the target instance to access and to which you install applications. The instance must be on the Washington DC release or later.	—

Optional parameters

Parameter	Type	Description	Default value
--type	String	The method to use to authenticate with the target instance. Specify `basic` for basic authentication or `oauth` for OAuth 2.0 authentication.	basic
--alias	String	The alias for the instance and user credentials. The alias can be used for authentication with the `init`, `transform`, `dependencies`, and `install` commands.	—

For example:

```
npx @servicenow/sdk auth --add
 https://myinstance.service-now.com --type oauth --alias devuser1
```

delete

Remove credentials in the device keychain or credential manager on your system.

The `auth` command has the following structure with the `--delete` parameter:

```
now-sdk auth [--delete <alias or all>]
```

Required parameters

Parameter	Type	Description	Default value
--delete	String	The alias for the instance and user credentials. To delete all credentials, set this parameter to `--delete all`.	—

For example:

```
now-sdk auth --delete devuser1
```

list

View credentials saved in the device keychain or credential manager on your system. Passwords and authentication codes aren't returned.

The `auth` command has the following structure with the `--list` parameter:

```
now-sdk auth [--list]
```

Required parameters

Parameter	Type	Description	Default value
--list	String	Lists all available authentication credentials.	—

For example:

```
now-sdk auth --list
```

use

Set the credentials to be used by commands by default.

The `auth` command has the following structure with the `--use` parameter:

```
now-sdk auth [--use <alias>]
```

Required parameters

Parameter	Type	Description	Default value
--use	String	The alias for the instance and user credentials.	—

For example:

```
now-sdk auth --use devuser1
```

init

Create a custom scoped application or convert an existing scoped application to support development in source code. The application is added in the current directory.

To create an application with your default credentials, you can run the `init` command without any optional parameters. For example, `now-sdk init`. To convert an existing application, you must include the `--from` parameter to provide the sys_id of an application on an instance or a path to a local directory that contains an application.

After initializing an application, you must install the required third-party dependencies using your preferred package manager before building the application. For example, if you use Node Package Manager (npm), run `npm install`.

The `init` command has the following structure:

```
npx @servicenow/sdk init [--from <sys_id or path>] [--appName
 <name>] [--packageName <name>] [--scopeName <name>] [--auth
 <alias>] [--template <template>]
```

Note:
Using the `npx` command installs the ServiceNow SDK in your application directory instead of globally.

Optional parameters

Parameter	Type	Description	Default value
--from	String	A sys_id of an application on the instance or a path to a local directory that contains an application to convert to support development in source code. Converting an application adds the necessary files and directories for using the ServiceNow SDK locally and downloads the application metadata. The application isn't changed on the instance until you build and install it on the instance. After installing a converted application, the **Package JSON** field of the custom application record [sys_app] contains the path to the `package.json` file for the application.	—
--appName	String	A name for the application.	—
--packageName	String	A name for the application package used in the `package.json` file. The package name must adhere to Node Package Manager (npm) package naming standards.	—
--scopeName	String	The scope of the application. The scope name must be unique on the instance, begin with x_<prefix>, and be 18 characters	—

Optional parameters (continued)

Parameter	Type	Description	Default value
		or fewer. For more information, see Namespace identifier.	
--auth, -a	String	An alias for the credentials to use to authenticate to the instance.	If set, the default alias.
--template	String	A template for the default structure of the application. • base: An application with only the basic structure necessary for development in source code. • javascript.basic: An application configured for development in ServiceNow Fluent and JavaScript. • javascript.react: An application configured for development in ServiceNow Fluent, JavaScript, and React. • typescript.basic: An application configured for development in ServiceNow Fluent and TypeScript. TypeScript source files in the `src/server` directory are transpiled into JavaScript modules. • typescript.react: An application configured for development in ServiceNow Fluent, TypeScript, and React. TypeScript source files in the `src/server` directory are transpiled into JavaScript modules. • partial.javascript.react: Adds template files and directories to an existing application for development in ServiceNow Fluent, JavaScript, and React. • partial.typescript.react: Adds template files and directories to an existing application for development in ServiceNow Fluent, TypeScript, and React.	—

For example:

```
npx @servicenow/sdk init --from dbce0f6a3b3fda107b45b5d355e45af6
 --appName Example App --packageName example-app --scopeName
 x_snc_example --auth devuser1 --template base
```

For more information, see Create an application with the ServiceNow SDK or Convert an application with the ServiceNow SDK.

build

Compile source files and output build artifacts. Third-party library dependencies are converted into XML files that can be installed with the application.

The `build` command has the following structure:

```
now-sdk build <source> [--frozenKeys <flag>]
```

Optional parameters

Parameter	Type	Description	Default value
source	String	The path to the directory that contains the `package.json` file for your application. The `package.json` should be in the base directory of your application.	Current working directory
--frozenKeys	Boolean	An option to validate that the `keys.ts` file is up to date for continuous integration (CI) builds. If true and changes were made to the application's ServiceNow Fluent code, the `keys.ts` file isn't updated and the build fails. The `keys.ts` file is automatically generated in the `src/fluent/generated` directory.	false

For example:

```
now-sdk build /path/to/package --frozenKeys true
```

For more information, see Build and install an application with the ServiceNow SDK.

install

Package the build artifacts and install or update an application on an instance. Before using the `install` command, you must use the `build` command to generate an installable package.

The `install` command has the following structure:

```
now-sdk install [--source <package path>] [--reinstall <flag>]
 [--auth <alias>] [--open-browser <flag>] [--info <flag>]
```

Optional parameters

Parameter	Type	Description	Default value
--source	String	The path to the directory that contains the `package.json` file for your application.	Current working directory

Optional parameters (continued)

Parameter	Type	Description	Default value
		The `package.json` should be in the base directory of your application.	
--reinstall, -r	Boolean	An option to uninstall and reinstall the application on the instance to ensure that the metadata on the instance matches the metadata in the installation package. **Warning:** Metadata that is on the instance but not in your local application is removed. If you have previous versions of modules in the EcmaScript Module [sys_module] table that aren't needed, re-installing an application removes previous versions of the application's modules from the table.	false
--auth, -a	String	An alias for the credentials to use to authenticate to the instance. **Note:** For CI/CD pipelines, you can set the following environment variables to authenticate with an instance at runtime using basic authentication: • SN_SDK_INSTANCE_URL: The URL of the target instance to access and to which you install applications. • SN_SDK_USER: A username for the instance. • SN_SDK_USER_PWD: The password associated with the user. • SN_SDK_NODE_ENV: Set to SN_SDK_CI_INSTALL to enable CI server support.	If set, the default alias.
--open-browser, -b	Boolean	An option to open the application record in your default browser	false

Optional parameters (continued)

Parameter	Type	Description	Default value
		after successfully installing the application.	
--info, -i	Boolean	An option to return details about the most recent installation of this application, such as the status and records updated. When this parameter is used, the application isn't installed.	false

For example:

```
now-sdk install --source /path/to/package --reinstall false
 --auth devuser1 --open-browser true --info true
```

For more information, see Build and install an application with the ServiceNow SDK.

dependencies

Download application dependencies and TypeScript definitions from an instance to enable IntelliSense and code validation for an application.

The `dependencies` command downloads dependencies and TypeScript definitions for scripts and ServiceNow Fluent code:

- For scripts, this command downloads TypeScript definitions for all Glide APIs and scans the modules and scripts in your application and generates type definitions for the script includes that they use. Type definitions are added in the `@types/servicenow` directory. After downloading script dependencies, you must update your `tsconfig.json` file to include the type definitions.
- For ServiceNow Fluent, this command downloads the dependencies listed in an application's `now.config.json` file and generates TypeScript definitions for them in the `@types/servicenow/fluent` directory.

To download all script and ServiceNow Fluent dependencies for an application, you can use the `dependencies` command with no parameters. If needed, provide the application directory and authentication alias too.

The `dependencies` command has the following structure:

```
now-sdk dependencies [--directory <package path>] [--auth
 <alias>] [--type-defs-only <flag>] [--fluent-only <flag>] [--add <table> <sys_ids or names>]
[--scope <name>]
```

Optional parameters

Parameter	Type	Description	Default value
--directory	String	The path to the directory that contains the `package.json` file for your application.	Current working directory

Optional parameters (continued)

Parameter	Type	Description	Default value
		The `package.json` should be in the base directory of your application.	
--auth, -a	String	An alias for the credentials to use to authenticate to the instance.	If set, the default alias.
--type-defs-only	Boolean	An option to download TypeScript definitions for only script dependencies. Script types are downloaded in the `@types/servicenow` directory.	false
--fluent-only	Boolean	An option to download dependencies and TypeScript definitions for only ServiceNow Fluent dependencies from other application scopes. You must list an application's dependencies in its `now.config.json` file. ServiceNow Fluent types are generated in the `@types/servicenow/fluent` directory.	false
--add	String	Adds the dependencies that you want to download to the application's `now.config.json` file. You must specify the type of dependencies to add using the table name and then the names or sys_ids of each item to add, separated by spaces. `--add <table_name> <sys_id1> <sys_id2> <sys_id3>` • To add table dependencies, you can use the `table` alias and names of tables instead of the sys_ids. For example: `--add tables incident problem change_request` • To add role dependencies, you can use the `role` alias and	—

Optional parameters (continued)

Parameter	Type	Description	Default value
		names of roles instead of the sys_ids. For example: `--add roles admin user itil` Use a wildcard (`*`) to add all items from a specified table and scope. For example: `--add sys_security_acl "*"`	
sysIds	Array	A list of sys_ids of dependencies to download and generate TypeScript definitions from. This parameter only applies if you use the `--add` parameter.	—
--scope	String	The application scope from which to download dependencies. This parameter is required if you use the `--add` parameter.	—

For example:

```
now-sdk dependencies --directory /path/to/package --auth devuser1
 --add sys_ui_view fa776f6d97700100f309124eda2975bc --scope global
```

For more information, see Downloading dependencies with the ServiceNow SDK.

transform

Download application metadata (XML) from the instance and transform the metadata into ServiceNow Fluent source code to synchronize the application changes on the instance into your local application.

After initializing an application, you can run the `transform` command without any parameters to transform new application metadata from the instance into source code in the `src/fluent/generated` directory and synchronize changes to metadata into source code in the `src/fluent` directory. To transform metadata that existed when the application was initialized into source code, use the `--from` parameter to provide the path to a local directory or file that contains XML. If metadata exists in the local application as both XML and source code, the XML version takes precedence when installed on the instance.

The `transform` command has the following structure:

```
now-sdk transform [--from <path>] [--directory <package path>]
 [--preview <flag>] [--auth <alias>] [--format <flag>]
```

Optional parameters

Parameter	Type	Description	Default value
--from	String	A path to a local directory or file that contains metadata XML to	—

Optional parameters (continued)

Parameter	Type	Description	Default value
		transform into ServiceNow Fluent code.	
--directory	String	The path to the directory that contains the `package.json` file for your application. The `package.json` should be in the base directory of your application.	Current working directory
--preview	Boolean	An option to preview the transformed ServiceNow Fluent code from the command line without saving the changes.	false
--auth, -a	String	An alias for the credentials to use to authenticate to the instance.	If set, the default alias.
--format, -f	Boolean	An option to format new and updated ServiceNow Fluent source code when it's transformed.	true

For example:

```
now-sdk transform --from metadata/update
 --directory /path/to/package --preview true --auth devuser1
 --format true
```

For more information, see Convert an application with the ServiceNow SDK or Build and install an application with the ServiceNow SDK.

download

Download all application metadata (XML) from an application on an instance to compare with the metadata in your local application.

Updates to JavaScript modules aren't included when downloading application metadata from your instance.

The `download` command has the following structure:

```
now-sdk download <directory> [--source <package path>]
 [--incremental <flag>]
```

Required parameters

Parameter	Type	Description	Default value
directory	String	A path to any directory in which to download the metadata.	—

Required parameters (continued)

Parameter	Type	Description	Default value
		Note: This directory should be a different directory from the `metadata` directory in your application.	

Optional parameters

Parameter	Type	Description	Default value
--source	String	The path to the directory that contains the `package.json` file for your application. The `package.json` should be in the base directory of your application.	Current working directory
--incremental	Boolean	An option to download only changes to application metadata made on the instance and recorded in the Customer Updates [sys_update_xml] table.	false

For example:

```
now-sdk download /path/to/directory --source /path/to/package
 --incremental true
```

clean

Remove the build artifacts that were output with the previous build.

The `clean` command has the following structure:

```
now-sdk clean <source>
```

Optional parameters

Parameter	Type	Description	Default value
source	String	The path to the directory that contains the `package.json` file for your application. The `package.json` should be in the base directory of your application.	Current working directory

For example:

```
now-sdk clean /path/to/package
```

pack

Package the build artifacts that were output with the previous build into an installable ZIP file.

The `pack` command has the following structure:

```
now-sdk pack <source>
```

Optional parameters

Parameter	Type	Description	Default value
source	String	The path to the directory that contains the `package.json` file for your application. The `package.json` should be in the base directory of your application.	Current working directory

For example:

```
now-sdk pack /path/to/package
```

ServiceNow Fluent API reference

Use ServiceNow Fluent APIs to define the metadata that makes up scoped applications in source code with the ServiceNow IDE or ServiceNow SDK.

The ServiceNow Fluent API reference includes details about the APIs and examples. For additional examples of the ServiceNow Fluent APIs in use, see the ServiceNow SDK examples GitHub repository.

Related topics

ServiceNow Fluent

ServiceNow Fluent language constructs

ServiceNow Fluent language constructs provide additional functionality for development in source code with ServiceNow Fluent APIs.

Now.ID

The *`Now.ID`* construct is used to specify human-readable unique IDs for metadata defined in source code. *`Now.ID`* uses the format `Now.ID['String' or Number]` with the *`$id`* property in ServiceNow Fluent APIs. When you build an application, the ID is hashed into a unique sys_id.

You can use *`Now.ID`* only to define IDs for metadata and not to reference other metadata in an application. To reference other metadata within the same application, you can assign the object to a *`const`* variable and reference the variable identifier in other objects.

```
import { Role } from "@servicenow/sdk/core"

const managerRole = Role({
    $id: Now.ID['manager_role'],
    name: 'x_snc_example.manager'
})

Record({
```

```
  table: 'some_table',
  data: {
     role: managerRole //"role" is a reference field to sys_user_role
  }
})
```

Now.ref

The *Now.ref* construct is used to reference metadata in a different application that's not defined in source code. *Now.ref* uses the format Now.ref['table', 'sys_id' or {column: 'value'}, {column: 'value'}] with Reference properties in ServiceNow Fluent APIs.

```
import { Role } from "@servicenow/sdk/core"

Role({
    name: 'x_test.admin',
    contains_roles: [
        'x_test.manager',
        Now.ref('sys_user_role', { name: 'x_test.itil' }),              //
 Coalescing ID reference
        Now.ref('sys_user_role', '${itomId}'),                            //
 GUID-based reference
        Now.ref('sys_user_role', '3D82d1a88947942a90b6d8aa25126d439b',
 { name: 'x_test.csm' }),     // GUID with coalescing ID reference
    ],
})
```

Now.include

The *Now.include* construct is used to refer to text content in another file in the same application rather than including the content inline. *Now.include* uses relative file paths in the format Now.include('./path/to/file') with any property in ServiceNow Fluent APIs. Using *Now.include* allows you to code with the appropriate syntax highlighting for the file type and is especially helpful with properties that support other languages like JavaScript, HTML, CSS, and more.

Now.include supports two-way synchronization so that changes to fields from other ServiceNow AI Platform user interfaces are synced into the referenced file's source code and changes to the source code are synced back to metadata across the instance.

```
import { ScriptInclude } from '@servicenow/sdk/core'

ScriptInclude({
    $id: Now.ID['my-script-include'],
    name: 'MyScriptInclude',
    active: true,
    apiName: 'x_scriptincludes.MyScriptInclude',
    script: Now.include('./MyScriptInclude.server.js')  //The actual content of the
 "script" field is contained in the file specified
})
```

Now.attach

The *Now.attach* construct is used to refer to an image file in the same application and attach it to records associated with metadata defined in source code. *Now.attach* uses relative file paths in the format Now.attach('./path/to/file') with properties that support

user images (the user_image field type) in ServiceNow Fluent APIs. `Now.attach` supports the following file formats: `.jpg`, `.jpeg`, `.png`, `.gif`, `.bmp`, `.ico`, and `.svg`.

`Now.attach` supports two-way synchronization so that changes to image files from other ServiceNow AI Platform user interfaces are synced into the application in source code and changes to image files in source code are synced back to metadata across the instance.

```
import { Record } from '@servicenow/sdk/core'

Record({
    $id: Now.ID['sample-service-portal'],
    table: 'sp_portal',
    data: {
        title: 'Sample Portal',
        url_suffix: 'sample',
        icon: Now.attach('../../assets/servicenow.jpg')
    }
})
```

You can also reuse an image in an application by assigning the `Now.attach` construct to a `const` variable and referencing the variable identifier in other properties. For example:

```
import { Record } from '@servicenow/sdk/core'

const image = Now.attach('../../assets/servicenow.jpg')

Record({
    $id: Now.ID['test'],
    table: 'sp_portal',
    data: {
        title: 'Test Portal',
        url_suffix: 'test',
        icon: image,
        logo: image,
    }
})
```

Access Control List API - ServiceNow Fluent

The Access Control List API defines access control lists [sys_security_acl] that secure parts of an application.

For general information about access control lists (ACLs), see Access Control List Rules.

Related topics

ServiceNow Fluent

ACL object

Configure a custom ACL rule [sys_security_acl] to secure access to new objects or to change the default security behavior.

ACLs must include one or more roles, a security attribute, a condition, or a script.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
operation	String	Required. The operation that this ACL rule secures. An ACL rule can only secure one operation. To secure multiple operations, create a separate ACL rule for each. The operation must be `execute` if the *`type`* property is client_callable_flow_object, client_callable_script_include, graphql, processor, or rest_endpoint. Valid values: • execute: Allow users to execute scripts on a record or UI page. • create: Allow users to insert new records (rows) into a table. • read: Allow users to display records from a table. • write: Allow users to update records in a table. • delete: Allow users to remove records from a table or drop a table. • conditional_table_query_range: Enables users to give partial ACL-access based on read ACLs. Created for the tables that have the read ACLs without Data condition and script. • data_fabric: Enable users to allow Data Fabric connectors to access data on a particular table. • query_match: Enables users to submit match queries (such as "is", "is not", and "is empty"). • query_range: Enables users to submit range queries (such as "starts with", "ends with", and "contains") and sorting is unrestricted. • edit_task_relations: Allow users to extend the Task [task] table. • edit_ci_relations: Allow users to extend the Configuration Item [cmdb_ci] table. • save_as_template: Allow users to save a record as a template. • add_to_list: Allow users from viewing or personalizing specific columns in the list mechanic. Conditions and scripts aren't supported. • report_on: Allow users to report on tables.

Properties (continued)

Name	Type	Description
		• list_edit: Allow users to update records (rows) from a list. • report_view: Allow users to report on field ACLs. • personalize_choices: Allow users to configure the table or field.
type	String	Required. The type of object that this ACL rule secures. The type determines which operations are available. After creating an ACL rule, if you want to change the type, you must delete the ACL and create a new one with the correct type. Valid values: • record • rest_endpoint • ui_page • processor • graphql • pd_action • ux_data_broker • ux_page • ux_route • client_callable_flow_object • client_callable_script_include Default: record
active	Boolean	Flag that indicates whether the ACL rule is enforced. Valid values: • true: The ACL rule is enforced. • false: The ACL rule isn't enforced. Default: true
adminOverrides	Boolean	Flag that indicates whether users with the admin role automatically pass the permissions check for this ACL rule. Valid values: • true: Administrators automatically pass the permissions check. If true, admin users pass the permissions check regardless of what script or role restrictions apply.

Properties (continued)

Name	Type	Description
		However, the nobody role, which only ServiceNow personnel can assign, takes precedence over the admin override option. If an ACL is assigned the nobody role, admin users cannot access the resource even when *adminOverrides* is true. For more information, see Base system roles. • false: Administrators must meet the permissions defined in this ACL rule to gain access to the secured object. Use the *condition* or *script* properties to create a permissions check that administrators must pass. Default: true
script	Script	A custom script that defines the permissions required to access the object. This property supports a function from a JavaScript module, a reference to another file in the application that contains a script, or inline JavaScript. ACLs must include one or more roles, a security attribute, a condition, or a script. **Note:** If the *type* property is `graphql`, scripts aren't supported. The script can use the values of the `current` and `previous` global variables and system properties. The script must generate a true or false response in one of two ways: • return an `answer` variable set to a value of true or false • evaluate to true or false In either case, users only gain access to the object when the script evaluates to true and the user meets any conditions the ACL rule has. Both the conditions and the script must evaluate to true for a user to access the object. **Note:** If the evaluated item is in a related list, `current` points to the item the related list is on, not to the current item the ACL is for. However, If the item you are evaluating the ACL for is not in a related list, `current` points to the actual item. Format:

Properties (continued)

Name	Type	Description
		• For functions, use the name of a function, function expression, or default function exported from a JavaScript module and import it into the `.now.ts` file. For information about JavaScript modules, see JavaScript modules and third-party libraries. • To use text content from another file, refer to a file in the application using the following format: `Now.include('path/to/file')`. For more information, see ServiceNow Fluent language constructs. • To provide an inline script, use string literals or template literals for multiple lines of code: `'Script'` or `` `Script` ``.
description	String	A description of the object or permissions this ACL rule secures.
localOrExisting	String	The type of security attribute to apply. Valid values: • Local: A security attribute based on the *`condition`* property that is saved only for the ACL it is created in. • Existing: An existing security attribute to reference in the *`security_attribute`* property. Default: Local
decisionType	String	An option for whether the ACL should allow or deny access. Valid values: • allow: The ACL allows access. • deny: The ACL denies access. Default: allow
condition	String	A filter query that specifies the fields and values that must be true for users to access the object. For more information, see Operators available for filters and queries. ACLs must include one or more roles, a security attribute, a condition, or a script.
roles	Array	A list of variable identifiers of *`Role`* objects or sys_ids of roles that a user must have to access the object. For more information, see Role API - ServiceNow Fluent. ACLs must include one or more roles, a security attribute, a condition, or a script.

Properties (continued)

Name	Type	Description
		Note: Users with the admin role always pass this permissions check because the admin role automatically grants users all other roles.
securityAttribute	String	Pre-defined conditions for the ACL to use. For example, whether a user is impersonating another user. For more information about security attributes, see OOB (Out-of-Box) Security Attributes. ACLs must include one or more roles, a security attribute, a condition, or a script. **Note:** For security attributes with the *Is localized* field set to true, the *localOrExisting* property of the ACL should be set to Local. If the *Is localized* field is false, the *localOrExisting* property should be set to Existing.
table	String	The name of the table to which the ACL applies. This property only applies and is required if the *type* property is one of the following values: ux_data_broker, ux_page, ux_route, pd_action, or record.
field	String	The name of a field on the table to secure. You can use the wildcard character ("*") to select all fields.
name	String	The name of the ACL. This property only applies and is required if the *type* property is one of the following values: rest_endpoint, ui_page, processor, graphql, client_callable_flow_object, or client_callable_script_include.
protectionPolicy	String	A policy that determines whether someone can view or edit the script include after the application is installed on their instance. If undefined, other application developers can customize the script include. Valid values: • read: Allows anyone to read values from this downloaded or installed script include. No one can change script values on the instance on which they download or install the script include. • protected: Provides intellectual property protection for application developers. Customers who download the script include cannot see the contents of the script field. The script is encrypted in memory to prevent unauthorized users from seeing it in plain text.

Properties (continued)

Name	Type	Description
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { Acl } from "@servicenow/sdk/core";

export default Acl({
    $id: Now.ID['task_delete_acl'],
    active: true,
    adminOverrides: true,
    type: 'record',
    table: 'task',
    field: 'description',
    operation: 'delete',
    roles: [adminRole, managerRole],
})
```

The roles referenced are defined using the *Role* object:

```
import { Role } from "@servicenow/sdk/core";

const managerRole = Role({
   $id: Now.ID['manager_role'],
   name: 'x_snc_example.manager'
})

const adminRole = Role({
   $id: Now.ID['admin_role'],
   name: 'x_snc_example.admin',
   containsRoles: [managerRole]
})
```

Application Menu API - ServiceNow Fluent

The Application Menu API defines menus in the application navigator [sys_app_application].

For general information about application menus, see Create an application menu.

Related topics

ServiceNow Fluent

ApplicationMenu object

Create a menu for an application [sys_app_application].

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
title	String	Required. The label for the menu in the application navigator.
active	Boolean	Flag that indicates whether the menu appears in the application navigator. Valid values: • true: The menu appears. • false: The menu is hidden. Default: true
roles	Array	A list of variable identifiers of *`Role`* objects or names of roles that can access the menu. For more information, see Role API - ServiceNow Fluent.
category	Reference	The variable identifier of a menu category [sys_app_category] that defines the navigation menu style. To define a menu category, use the Record API - ServiceNow Fluent. For general information about menu categories, see Customize menu categories.
hint	String	A short description of the menu that displays as tooltip when hovering over it.
description	String	Additional information about what the application does.
name	String	An internal name to differentiate between applications with the same title.
order	Number	The relative position of the application menu in the application navigator. Default: 100
$meta	Object	Metadata for the application metadata.

Properties (continued)

Name	Type	Description
		With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances. `$meta: { installMethod: 'String' }` Valid values for *installMethod*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

```
import { ApplicationMenu } from "@servicenow/sdk/core";

ApplicationMenu({
   $id: Now.ID['my_app_menu'],
   title: 'My App Menu',
   hint: 'This is a hint',
   description: 'This is a description',
   category: appCategory,
   roles: ['admin'],
   active: true,
})
```

The category referenced is defined using the *Record* object:

```
import { Record } from "@servicenow/sdk/core";

export const appCategory = Record({
   table: 'sys_app_category',
   $id: Now.ID[9],
   data: {
      name: 'example',
      style: 'border-color: #a7cded; background-color: #e3f3ff;',
   },
})
```

Automated Test Framework Test API - ServiceNow Fluent

The Automated Test Framework Test API defines automated tests [sys_atf_test] that you can run to confirm that your instance works after making a change.

For general information about Automated Test Framework tests, see Test your apps with the ATF.

Related topics

ServiceNow Fluent

Test object

Create an automated test [sys_atf_test] containing a series of steps to execute.

Properties

Name	Type	Description
$id	String or Number	Required. A unique ID for the metadata object. When you build the application, this ID is hashed into a unique sys_id. For more information, see ServiceNow Fluent language constructs. Format: `Now.ID['String' or Number]`
name	String	A unique name for the test.
description	String	A description of what the test does.
active	Boolean	Flag that indicates whether the test is active. Valid values: • true: The test is active. • false: The test isn't active. Default: true
failOnServerError	Boolean	Flag that indicates whether to fail when a server error occurs during the test. Valid values: • true: The test fails when a server error occurs. • false: The test doesn't fail when a server error occurs. Default: true
configurationFunction	Function	The steps of the test. Test steps are passed as statements within the *atf* function. For example: `(atf) => { atf.form.openNewForm({ table: 'sn_example_table', formUI: 'standard_ui', view: '', }) }` For more information about test steps, see Supported test steps.
$meta	Object	Metadata for the application metadata. With the *installMethod* property, you can map the application metadata to an output directory that loads only in specific circumstances.

Properties (continued)

Name	Type	Description
		`$meta: { installMethod: 'String' }` Valid values for *`installMethod`*: • demo: Outputs the application metadata to the `metadata/unload.demo` directory to be installed with the application when the **Load demo data** option is selected. • first install: Outputs the application metadata to the `metadata/unload` directory to be installed only the first time an application is installed on an instance.

The output values of test steps with output variables can be saved as variables and used as inputs to other steps using the syntax `output.<output-variable>`. The output variables can be used both directly as inputs on appropriate fields or inside of a template string, such as with `atf.server.log` in the following example.

```
import { Test } from '@servicenow/sdk/core'

Test({
        active: true,
        failOnServerError: true,
        name: 'Simple example',
        description: 'An illustrative test written in fluent',
        $id: Now.ID[1],
    },
    (atf) => {
        atf.form.openNewForm({
            table: 'sn_table_app_reptile_table',
            formUI: 'standard_ui',
            view: '',
        })
        atf.form.setFieldValue({
            table: 'sn_table_app_reptile_table',
            formUI: 'standard_ui',
            fieldValues: {
                reptiles: 'lizard' as any,
            },
        })
        const output =
 atf.form.submitForm({ assertType: 'form_submitted_to_server',
 formUI: 'standard_ui' })
        atf.server.recordValidation({
            recordId: output.record_id,
            table: 'sn_table_app_reptile_table',
            assertType: 'record_validated',
            enforceSecurity: true,
            fieldValues: 'reptiles=lizard',
        })
        atf.server.log({
```

```
            log: `Submitted record with sys_id:
 ${output.record_id} to table ${output.table}`
        })
    }
)
```

Supported test steps

The following test steps are supported. For information about step properties, see the Test step categories documentation.

Note:
Some fields available for test steps on forms aren't available as properties in ServiceNow Fluent.

Test steps

Category	Steps
Application Navigator category	• atf.applicationNavigator.applicationMenuVisibility • atf.applicationNavigator.moduleVisibility • atf.applicationNavigator.navigateToModule
Email category	• atf.email.generateInboundEmail • atf.email.generateInboundReplyEmail • atf.email.generateRandomString • atf.email.validateOutboundEmail • atf.email.validateOutboundEmailGeneratedByFlow • atf.email.validateOutboundEmailGeneratedByNotification
Form category	• atf.form.addAttachmentsToForm • atf.form.clickDeclarativeAction • atf.form.clickModalButton • atf.form.clickUIAction • atf.form.declarativeActionVisibility • atf.form.fieldStateValidation • atf.form.fieldValueValidation • atf.form.openExistingRecord • atf.form.openNewForm • atf.form.setFieldValue • atf.form.submitForm • atf.form.uiActionVisibility

Test steps (continued)

Category	Steps
Forms in Service Portal category	• atf.form_SP.addAttachmentsToForm • atf.form_SP.clickUIAction_SP • atf.form_SP.fieldStateValidation_SP • atf.form_SP.fieldValueValidation_SP • atf.form_SP.openForm_SP • atf.form_SP.openServicePortalPage • atf.form_SP.setFieldValue_SP • atf.form_SP.submitForm_SP • atf.form_SP.uiActionVisibilityValidation_SP
Quick start tests for Dashboards	• atf.reporting.responsiveDashboard • atf.reporting.responsiveDashboardSharing
REST category	• atf.rest.assertJsonResponsePayloadElement • atf.rest.assertResponseHeader • atf.rest.assertResponseJSONPayloadIsValid • atf.rest.assertResponsePayload • atf.rest.assertResponseTime • atf.rest.assertResponseXMLPayloadIsWellFormed • atf.rest.assertStatusCode • atf.rest.assertStatusCodeName • atf.rest.assertXMLResponsePayloadElement • atf.rest.sendRestRequest
Server category	• atf.server.addAttachmentsToExistingRecord • atf.server.checkoutShoppingCart • atf.server.createUser • atf.server.impersonate • atf.server.log • atf.server.recordDelete • atf.server.recordInsert • atf.server.recordQuery • atf.server.recordUpdate • atf.server.recordValidation • atf.server.replayRequestItem

Test steps (continued)

Category	Steps
	• atf.server.runServerSideScript • atf.server.searchForCatalogItem • atf.server.setOutputVariables
